When you enable runtime auditing, applications generate audits when they use policy that is defined in the authorization store. You can configure auditing to log successes, failures, or both. Runtime auditing records client context and access checks. Access checks are based on the AccessCheck method described in the Authorization section of the Platform SDK. For more information about authorization-related application programming interfaces (APIs), see Authorization at the Microsoft Web site.

**Authorization store change auditing**
When you enable authorization store change auditing, audits are generated every time the authorization store is modified. The audit logs all events, successes and failures.

For authorization store change auditing, Authorization Manager supports the NTFS file system (for XML-based authorization stores) and Active Directory. The APIs upon which Authorization Manager is based are flexible enough to allow for the use of the Windows registry, Exchange Server, and SQL Server.

**Auditing availability**
The availability of auditing depends on the following:

- Whether the authorization store is based on Active Directory or XML.
- Whether auditing is applied at the authorization store level, the application level, or the scope level.

The following table describes the availability of the two auditing types.

| Level | Runtime auditing is available in | Authorization store change auditing is available in |
|---|---|---|
| Authorization store | • XML<br>• Active Directory | • XML<br>• Active Directory |
| Application | • XML<br>• Active Directory | • Active Directory |
| Scope | Not available | • Active Directory |

To use auditing, you have to select the appropriate check box on the **Auditing** tab. To enable runtime auditing, click the **Runtime application initialization auditing** check box. To enable authorization store change auditing, click the **Runtime client context and access check auditing** check box.

If the authorization store is based on XML, you also have to specify object access auditing. If the authorization store is based on Active Directory, you also have to specify directory service access auditing.

**Important**

- By default, object access auditing is turned off. Auditing for XML-based authorization stores only works if you turn on object access auditing. To do this, you need to use Group Policy at the domain, domain controller, or other applicable

organizational unit level in Active Directory, or through local security policy. If the XML-based authorization store is located on a domain controller, the **Default Domain Controllers Policy** Group Policy object (GPO) is the most appropriate place to turn on object access auditing. If the XML-based authorization store is located on a workstation or member server, edit the local Group Policy object for that computer to set local security policy, or edit another Group Policy object that applies to the computer through Active Directory. For more information about Active Directory, see Active Directory.

To enable object access auditing, double-click **Audit object access**.

**Where?**

- *Group Policy object name* (for example: Default Domain Controllers Policy)/Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy/Audit object access

Select the **Define these policy settings** check box, select the **Success** check box, and then select the **Failure** check box.

**Notes**

- If you are editing the local Group Policy object, the **Define these policy settings** check box does not appear in the Group Policy Object Editor. It only appears if you are editing Group Policy objects that are stored in Active Directory.

- If the **Success** and **Failure** auditing check boxes are unavailable, the **Define these policy settings** check box has probably been selected through security policy that is acting at a higher level in Active Directory. In this situation, you need to find out where the **Define these policy settings** check box is selected and clear the check box. To find this setting, look in the Group Policy objects (GPOs) that affect this computer.

**Important**

- By default, directory service access auditing is turned off. To use auditing for authorization stores that are stored in Active Directory, you must turn on directory service access auditing. You do this through Group Policy at the domain, domain controllers, or other applicable organizational unit level in Active Directory. The **Default Domain Controllers Policy** Group Policy object is usually the most appropriate place to turn on directory service-based access auditing. For more information about Group Policy, see Group Policy (pre-GPMC).

  To enable directory service access auditing, double-click **Audit directory service access** in Group Policy.

  **Where?**

  - *Group Policy object name* (for example: Default Domain Controllers Policy)/Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy/Audit directory service access

  **Notes**

  - If you are editing the local Group Policy object, the **Define these policy settings** check box does not appear in Group Policy. It only appears if you are editing Group Policy objects that are stored in Active Directory.

  - If the **Success** and **Failure** auditing check boxes are unavailable, the **Define these policy settings** check box has probably been selected through a security policy that is acting at a higher level in Active Directory. In this situation, you need to find out where the **Define these policy settings** check box is selected and clear the check box. To find this setting, look in the Group Policy objects (GPOs) that affect this computer.

After editing the Group Policy objects, run the **gpupdate** command to ensure that the changes take effect immediately. For more information, see Gpupdate.

**Auditing event logging**

All Authorization Manager audits are written to the **Security** section of the Event Viewer. For more information about Event

Viewer, see Event Viewer.

**Auditing that is enabled by inheritance**

Any auditing obtained through inheritance takes place regardless of the local setting. For example, in the case of an authorization store that is stored in Active Directory, auditing policy can be inherited from a parent organizational unit in Active Directory. In the case of an XML-based authorization store, audit policy on the folder containing the XML file is applicable.

For more information about auditing, see Auditing Security Events.

# Authorization Manager delegation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authorization Manager delegation**

Using delegation, you can assign responsibility to someone else. Delegation helps balance workloads, and it can help with security by assuring that individuals do not have more rights than they need.

Authorization stores that are stored in Active Directory support delegation.

XML-based authorization stores do not support delegation at any level. The XML file is secured as a whole by its NTFS file system access control entries (ACEs).

A scope within an authorization store that is stored in Active Directory cannot be delegated if the scope contains task definitions that include authorization rules, or role definitions that include authorization rules.

For more information about delegating authorization stores, see Delegate an authorization store. For more information about delegating applications, see Delegate an application. For more information about delegating a scope, see Delegate a scope.

For more information about delegation, see Delegating administration.

# Security Configuration Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security Configuration Manager**
The Security Configuration Manager tool set allows you to create, apply and edit the security for your local computer, organizational unit, or domain.

- Before configuring security, see Checklist: Securing computers using Security Configuration Manager.
- For tips about using Security Configuration Manager, see Best practices for Security Configuration and Analysis, Best practices for Security Templates, and Best practices for Security Settings.
- For help with specific tasks, see Security Configuration Manager How To....
- For general background information, see Security Configuration Manager Concepts.
- For problem-solving instructions, see Security Troubleshooting.

| Security Configuration Manager tool | Description |
|---|---|
| Security Templates | Defines a security policy in a template. These templates can be applied to Group Policy or to your local computer. |
| Security Settings extension to Group Policy | Edits individual security settings on a domain, site, or organizational unit. |
| Local Security Policy | Edits individual security settings on your local computer. |
| Secedit | Automates security configuration tasks at a command prompt. |

# Checklist: Securing computers using Security Configuration Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Securing computers using Security Configuration Manager**

| **Preparing to set up security** | |
|---|---|
| **Step** | **Reference** |
| Review security best practices. | Best practices for security |
| Review the descriptions of individual settings. | Security Setting Descriptions |
| Review default security settings. | Default security settings for groups, Default groups and Differences in default security settings |
| Have Users only use applications belonging to the Windows Logo Program for Software. | Applications that belong to the Windows Logo Program for Software are guaranteed to run for members of the Users group. For other applications to run, you might need to elevate the privileges of your users to Power Users or relax the User permissions security settings. Both are less secure configurations for your organization. For more information, see the Windows Logo Program for Software page at the Microsoft Web site. |
| **Analyze your current settings** | |
| **Step** | **Reference** |
| Review **Security Templates.** | Security Templates |
| Select a predefined security template or create a new security template to use for your computers. | Predefined security templates or Define a security template |
| Perform a security analysis on the computer. | Analyze system security |
| **Modify security settings** | |
| **Step** | **Reference** |
| Apply the appropriate template. | Apply a security template to local policy or Import a security template to a Group Policy object |
| (Optional) Modify security settings on your local computer | Edit local security settings |

| | |
|---|---|
| (Optional) Modify security settings for a domain or organizational unit. | Edit security settings on a Group Policy object |

# Security Configuration Manager Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- Best practices for Security Configuration and Analysis
- Best practices for Security Templates
- Best practices for Security Settings

# Best practices for Security Configuration and Analysis

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Security Configuration and Analysis**
Security Configuration and Analysis is a tool which can be used to analyze and configure computer security. For general security issues, see Best practices for security.

**If you require frequent analysis of a large number of computers, as with a domain-based infrastructure, use the Secedit.exe command line tool.**
For more information, see Automating security configuration tasks.

**Only use Security Configuration and Analysis to configure security areas not affected by Group Policy settings.**
This includes areas such as security on local files and folders, registry keys, and system services. Otherwise, Group Policy settings will override the local settings. For more information, see Group Policy.

**Do not use Security Configuration and Analysis when you are configuring security for a domain or an organizational unit.**
Otherwise, you must configure each client individually. In that case, you can:

- Use Security Templates to create a template and apply it to the appropriate Group Policy object. For more information, see Import a security template to a Group Policy object.

- Use the Security Settings extension to Group Policy to edit individual security settings on a Group Policy object. For more information, see Edit security settings on a Group Policy object.

# Best practices for Security Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Security Templates**

**Use templates properly**

- Do not apply predefined or newly-created security templates to your computer or network without testing to ensure that the right level of application functionality is maintained.

- Never edit the Setup security.inf template, since it gives you the option to reapply the default security settings. If you ever remove a security template from a Group Policy object, appropriately reapply the Setup security.inf to restore all default settings.

- Do not apply the Setup security.inf template through Group Policy. The Setup security.inf template should only be applied to the local computer through Secedit or Security Configuration and Analysis. It is preferable to apply it in parts using the Secedit command-line tool.

  For more information, see Automating security configuration tasks.

- Do not apply the Compatible template to domain controllers. For example, do not import the Compatible template to the Default Domain or Default Domain Controller Group Policy object.

**Use caution when modifying predefined templates**

- Instead of modifying a predefined template, customize the predefined template and then save the changes under a different template name. Since these templates were designed for specific needs, having the original template will always give you the option of using it.

  For more information, see Predefined security templates.

**Choose the appropriate default level of computer access**

- When deciding on the default level of computer access that end users will have, the determining factor is the installed base of applications that need to be supported. If users only use applications that belong to the Windows Logo Program for Software, then you can make all your end users members of the Users group. If not, you may have to make your end users part of the Power users group so that they have the appropriate privileges to use the application, which is less secure.

  For more information about the Windows Logo Program for Software, see the Windows Logo Program for Software page at the Microsoft Web site.

For more information, see Best practices for Security Configuration and Analysis and Best practices for Security Settings.

# Best practices for Security Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Be cautious when creating new policies**

- Always test a newly-created policy on a test computer before applying it to your network.

**Be aware that more than one policy can be applied to a computer**

- Because of this, there can be conflicts in security policy settings. The order of precedence from highest precedence to lowest precedence is:

  1. Organizational unit
  2. Domain
  3. Local computer

  For more information, see Applying security settings.

- You can use Resultant Set of Policy to find out what policies apply to a certain computer. For more information , see Resultant Set of Policy.

**Keep in mind that there can only be one account policy in a domain: the Default Domain Policy**
For more information, see Account and local policies.

**Apply templates appropriately**

- Do not apply the Compatible template to Domain Controller computers. For example, do not import the Compatible template to Default Domain Policy or Default Domain Controller Policy.

- Do not apply the Setup security template through Group Policy.

**Use the correct tools for configuring local policy**

- For local security policy, use the Local Security Policy shortcut for editing and fine-tuning security policy. Use Security Templates to create a local policy and then use Security Configuration and Analysis to apply the policy.

# Security Configuration Manager How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Analyze and configure security
- Modify local security policy
- Modify security settings

# Analyze and configure security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Analyze and configure security**

- Add Security Configuration and Analysis to an MMC console
- Add Security Templates to an MMC console
- Analyze system security
- Configure local computer security
- Import a security template to a Group Policy object
- Import a security template
- Export a security template
- Edit the analysis database
- Customize a predefined security template
- Define a security template
- Set a new security template path

# Add Security Configuration and Analysis to an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add Security Configuration and Analysis to an MMC console**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. Do one of the following:
   - To create a new console, on the **File** menu, click **New**.
   - To open an existing console, on the **File** menu, click **Open**, click the console that you want to open, and then click **Open**.
3. On the **File** menu, click **Add/Remove Snap-in**, and then, in **Add/Remove Snap-in**, click **Add**.
4. Click **Security Configuration and Analysis,** click **Add**, click **Close**, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- For more information, see Working with MMC console files.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add Security Templates to an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add Security Templates to an MMC console**

1. Click **Start**, click **Run**, then type **mmc**, then click **OK**.
2. (Optional) To open an existing console, on the **File** menu, click **Open**, click the console you want to open, and then click **Open**.
3. On the **File** menu, click **Add/Remove Snap-in**.
4. In **Add/Remove Snap-in**, click **Add**.
5. In **Available Standalone Snap-ins**, click **Security Templates**, click **Add**, click **Close**, and then click **OK**.
6. On the **File** menu, click **Save**.

**Note**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Analyze system security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To analyze system security**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Security Configuration and Analysis.
2. In the console tree, right-click **Security Configuration and Analysis**, and then click **Open Database**.

   **Where?**

   - *ConsoleRoot*/Security Configuration and Analysis

3. In **Open database**, do one of the following:

   - To create a new database, in **File name**, type a file name, and then click **Open**.
   - To open an existing database, click a database, and then click **Open**.

4. If you are creating a new database, in **Import Template**, click a template, and then click **Open**.
5. In the details pane, right-click **Security Configuration and Analysis**, and then click **Analyze Computer Now**.
6. Do one of the following:

   - To use the default log, in **Error log file path**, click **OK**.
   - To specify a different log, in **Error log file path**, type a valid path and file name, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Security Configuration and Analysis, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, click the console that you want to open, and then click **Open**. Then, in the console tree, click **Security Configuration and Analysis**.
- Security Configuration and Analysis displays the different security areas as they are analyzed. Once this is complete, you can check the log file or review the results. For more information on reviewing the analysis results, see Related Topics.
- To view the log file, in the console tree, right-click **Security Configuration and Analysis**, and then click **View Log File**.

- The default path for the log file is:

  *systemroot*\Documents and Settings*UserAccount*\My Documents\Security\Logs*DatabaseName*.log

#### Using a command line

1. Open Command Prompt.

2. Type:

   **secedit /analyze /db** *FileName*.sdb [**/cfg** *FileName*] [**/overwrite**] [**/log** *FileName*] [**/quiet**]

ArgumentDescription

**/db** *FileName*Specifies the database used to perform the analysis.

**/cfg** *FileName*Specifies a security template to import into the database prior to performing the analysis. Security templates are created using the Security Templates snap-in.

**/log** *FileName*Specifies a file in which to log the status of the configuration process. If not specified, configuration data is logged in Scesrv.log, which is located in the %windir%\Security\Logs folder.

**/quiet**Specifies that the analysis process should take place without further comments.

Example: secedit /analyze /db hisecws.sdb

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **secedit /?**

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure local computer security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure local computer security**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Security Configuration and Analysis.
2. In the console tree, right-click **Security Configuration and Analysis**, and then click **Open Database**.

   **Where?**

   - *ConsoleRoot*/Security Configuration and Analysis

3. In **Open database**, do one of the following:

   - To create a new database, in **File name**, type a file name, and then click **Open**.
   - To open an existing database, click a database, and then click **Open**.

4. If you are creating a new database, in **Import Template**, click a template, and then click **Open**.
5. In the console tree, right-click **Security Configuration and Analysis**, and then click **Configure Computer Now**.
6. Do one of the following:

   - To use the default log in **Error log file path**, click **OK**.
   - To specify a different log, in **Error log file path**, type a valid path and file name.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Security Configuration and Analysis, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, click the console that you want to open, and then click **Open**. In the console tree, click **Security Configuration and Analysis**.
- To check the log file, right-click **Security Configuration and Analysis**, and then click **View Log File**.
- The default path for the log file is:

  *systemroot*\Documents and Settings*UserAccount*\My Documents\Security\Logs\

**Using a command line**

1. Open Command Prompt.

2. Type:

   **secedit/configure/DB***FileName* [**/CFG** *FileName*][**/overwrite**][**/areas** *Area1 Area2*...] [**/log** *LogPath*] [**/quiet**]

| Argument | Description |
|---|---|
| **/DB** *FileName* | Specifies the database used to perform the security configuration. |
| **/CFG** *FileName* | Specifies a security template to import into the database prior to configuring the computer. Security templates are created using the Security Templates snap-in. |
| **/overwrite** | Specifies that the database should be emptied prior to importing the security template. If this parameter is not specified, the settings in the security template are accumulated in the database. If this parameter is not specified and there are conflicting settings in the database and the template that is being imported, the template settings take precedence. |
| **/areas** *Area1 Area2*... | Specifies the security areas to be applied to the system. If this parameter is not specified, all security settings that are defined in the database are applied to the system. To configure multiple areas, separate each area by a space. The following security areas are supported:<br><br>SECURITYPOLICY - Includes account policies, audit policies, event log settings, and security options.<br><br>GROUP_MGMT - Includes Restricted Group settings.<br><br>USER_RIGHTS - Includes user rights assignment.<br><br>REGKEYS - Includes registry permissions.<br><br>FILESTORE - Includes file system permissions.<br><br>SERVICES - Includes system service settings. |
| **/log** *LogPath* | Specifies a file in which to log the status of the configuration process. If not specified, configuration data is logged in the scesrv.log file, which is located in the %windir%\Security\Logs folder. |
| **/quiet** | Specifies that the configuration process should take place without prompting the user. |

Examples:

- secedit /configure /db hisecws.sdb /cfg

- hisecws.inf /overwrite /log hisecws.log

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- The default path for the log file is:

  %windir%\Security\Logs\Scesrv.log

- **Secedit /refreshpolicy** has been replaced with **gpupdate**. For information on how to refresh security settings, see Gpupdate.

- To view the complete syntax for this command, at a command prompt, type:

  **secedit /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import a security template to a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import a security template to a Group Policy object**

1. Perform one of these steps

| If | Do this |
|---|---|
| You are on a workstation or server which is joined to a domain and you would like to import a security template for a Group Policy object. | • Click **Start**, point to **Run**, type **mmc** and click **OK**.<br>• On the **File** menu, click **Add/Remove snap-in**.<br>• In **Add/Remove Snap-in**, click **Add**, in **Add Standalone Snap-in**, double-click **Group Policy Object Editor**.<br>• In **Select Group Policy Object**, click **Browse**, select the policy object you would like to modify, click **OK**, and then click **Finish**.<br>• Click **Close** and then click **OK**. |
| You are on a domain controller and you would like to import a security template for a domain or organizational unit. | • Open Active Directory Users and Computers.<br>• In the console tree, right-click the domain or organizational unit you want to set Group Policy for.<br>• Click **Properties**, and then click the **Group Policy** tab.<br>• Click **Edit** to open the Group Policy object you want to edit or click **New** to create a new Group Policy object, and then click **Edit**. |

2. In the Group Policy console tree, right-click **Security Settings.**

   **Where?**

   - *Group Policy Object* Policy/Computer Configuration/Windows Settings/Security Settings

3. Click **Import Policy**, click the security template you want to import, and then click **Open**.

4. (Optional) If you want to clear the database of any previously stored security templates, select the **Clear this database before importing** check box.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using

Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- Do not import Setup security.inf to a Group Policy object.

- The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Apply a security template to local policy

Security Setting Descriptions
Security Templates

# Import a security template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import a security template**

1. Open Security Configuration and Analysis.
2. In the console tree, right-click **Security Configuration and Analysis**, and then click **Import Template**.

   **Where?**

   - *ConsoleRoot*/Security Configuration and Analysis

3. (Optional) To clear the database of any template that has been previously stored, select the **Clear this database before importing** check box.
4. Click a template file, and then click **Open**.
5. Repeat these steps for each template that you want to merge into the database.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Security Configuration and Analysis, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, click the console that you want to open, and then click **Open**. In the console tree, click **Security Configuration and Analysis**. If Security Templates is not in the console, for instructions on installing it, see Related Topics.
- Importing templates to a personal database only affects the analysis database and does not affect your system settings.
- If you import more than one template, the database will merge the various templates to create one composite template, resolving conflicts in order of import. The last template that is imported takes precedence.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export a security template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export a security template**

1. Open Security Configuration and Analysis.
2. In the console tree, right-click **Security Configuration and Analysis**, and then click **Export Template**.

   **Where?**

   - *ConsoleRoot*/Security Configuration and Analysis

3. Type a valid file name and a path to the location where your template will be saved.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Security Configuration and Analysis, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, click the console that you want to open, and then click **Open**. In the console tree, click **Security Configuration and Analysis**. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit the analysis database

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit the analysis database**

1. Open Security Configuration and Analysis.
2. In the console tree, right-click **Security Configuration and Analysis**, click **Analyze Computer Now**, and then click **OK**.

   **Where?**

   - *ConsoleRoot*/Security Configuration and Analysis

3. After Security Configuration and Analysis has finished analyzing the computer, in the console tree, click the group of settings that contains the security attribute you want to edit.
4. In the details pane, double-click the security attribute that you want to edit.
5. Confirm that the **Define this policy in the database** check box is selected.
6. Configure the security attribute setting as you want it to be recorded in the database, and then click **OK**.
7. Repeat the last four steps for each security attribute that you want to edit.
8. When you are finished modifying the database settings, in the console tree, right-click **Security Configuration and Analysis**, and then click **Save**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Security Configuration and Analysis, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, click the console that you want to open, and then click **Open**. Then, in the console tree, click **Security Configuration and Analysis**.
- The changes that you make will not affect system security. They will only affect the analysis database.
- For more information, see Security Setting Descriptions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Customize a predefined security template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To customize a predefined security template**

1. Open **Security Templates**.
2. In the console tree, double-click the default path folder (*systemroot*\Security\Templates), and in the details pane, right-click the predefined template you want to modify.
3. Click **Save As**, type a new file name for the security template, and click **Save**.
4. In the console tree, double-click the new security template to display the security policies, and navigate until the security attribute you want to modify appears in the details pane.
5. In the details pane, right-click the security attribute and click **Properties**.
6. Select the **Define this policy setting in the template** check box, make your changes, then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Security Templates, click **Start**, and click **Run**, then type **mmc** and click **OK**. On the **File** menu, click **Open**, click the console that you want to open, then click **Open**. Then, in the console tree, click **Security Templates**.
- Only administrators have the permissions to make any changes to the default security template folder, which is:

  *systemroot*\Security\Templates

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define a security template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define a security template**

1. Open **Security Templates**.
2. Right-click the folder where you want to store the new template and click **New Template**.
3. In **Template name**, type the name for your new security template.
4. In **Description**, type a description of your new security template, and then click **OK**.
5. In the console tree, double-click the new security template to display the security areas and navigate until the security setting you want to configure is in the details pane.
6. In the details pane, right-click the security setting you want to configure and click **Properties**.
7. Select the **Define this policy setting in the template** check box, edit the settings, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Security Templates, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, click the console that you want to open, then click **Open**. In the console tree, click **Security Templates**.
- Only administrators have the permissions to make any changes to the default security template folder, which is:

  *systemroot*\Security\Templates

  If you would like to create a new folder for new security templates, see Set a new security template path.
- For more information on the different policy settings, see Security Setting Descriptions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set a new security template path

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set a new security template path**

1. Open **Security Templates**.
2. In the console tree, right-click **Security Templates**, click **New Template Search Path**, and select the new location.

   A folder with the path of the new location appears in the console tree.
3. (Optional) To add a description to the new template path (in addition to the name), in the console tree, right-click the new template folder, click **Set Description**, and then type the description you want to add.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Security Templates, click **Start**, and click **Run**, then type **mmc** and click **OK**. On the **File** menu, click **Open**, click the MMC console that you want to open, then click **Open**. Then, in the console tree, click **Security Templates**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify local security policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modify local security policy**

- Edit local security settings
- Apply a security template to local policy
- Assign user rights for your local computer
- Reapply default security settings

# Edit local security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit local security settings**

1. Open Local Security Settings.
2. Do one of the following:
   - To edit **Password Policy** or **Account Lockout Policy**, in the console tree, click **Account Policies**.
   - To edit an **Audit Policy**, **User Right Assignment**, or **Security Options**, in the console tree, click **Local Policies**.
3. In the console tree, click the folder that contains the policy you want to modify, and then, in the details pane, double-click the policy that you want to modify.
4. Make the changes you want and click **OK**.
5. To change other policies, repeat the three previous steps.

## Notes

- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.
- If you would like to edit the security settings for file system, registry, and system services on the local computer, you must first edit the changes in a security template and then configure the computer using Security Configuration and Analysis.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Apply a security template to local policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply a security template to local policy**

1. Open **Security Configuration and Analysis**.
2. In the console tree, right-click **Security Configuration and Analysis**, and then click **Open Database**.

   **Where?**

   - *ConsoleRoot*/**Security Configuration and Analysis**

3. In **File name**, type a file name and then click **Open**.
4. (Optional) If you are creating a new policy, in **Import Template**, do one of the following:

   - To clear the database of any previously imported templates, select the **Clear this database before importing** check box.
   - To append this template to any previously imported templates, confirm that the **Clear this database before importing** check box is cleared. (The last template that was imported has precedence over any conflicting values.)

5. In **Import Template**, click a template, and then click **Open**.
6. In the console tree, right-click **Security Configuration and Analysis**, and then click **Configure Computer Now**.
7. Do one of the following:

   - To use the default error log, in **Error log file path**, click **OK**.
   - To specify a different error log, in **Error log file path**, type a valid path and file name.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Security Configuration and Analysis, click **Start**, and click **Run**, then type **mmc** and click **OK**. On the **File** menu, click **Open**, click the console that you want to open, and then click **Open**. Then, in the console tree, click **Security Configuration and Analysis**.
- To check the log file, right click **Security Configuration and Analysis**, and then click **View Log File**.
- The default path for the log file is:

  *systemroot*\Documents and Settings*UserAccount*\My Documents\Security\Logs\

- The security settings on the local computer take effect immediately.

- To import more than one template to your computer policy, see Import a security template.

- If you import more than one template, the database will merge the various templates to create one composite template, resolving conflicts in order of import. The last template that is imported takes precedence over any conflicting settings.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign user rights for your local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign user rights for your local computer**

1. Open Local Security Settings.
2. In the console tree, click **User Rights Assignment**.

   **Where?**

   - Security Settings/Local Policies/User Rights Assignments

3. In the details pane, double-click the user right you want to change.
4. In ***UserRight* Properties**, click **Add User or Group**.
5. Add the user or group and click **OK**.

### Note

- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

# Reapply default security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reapply default security settings**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Security Configuration and Analysis.
2. In the console tree, right-click **Security Configuration and Analysis**, and then click **Open Database**.

   **Where?**

   - *ConsoleRoot*/Security Configuration and Analysis

3. In **File name**, type the file name, and then click **Open**.
4. Do one of the following:

   - For a domain controller, in the console tree, right-click **Security Configuration and Analysis**, click **Import Template**, and then click **DC security**.
   - For other computers, in the console tree, right-click **Security Configuration and Analysis**, click **Import Template**, and then click **setup security**.

5. Select the **Clear this database before importing** check box, and then click **Open**.
6. In the console tree, right-click **Security Configuration and Analysis**, and then click **Configure Computer Now**.
7. Do one of the following:

   - To use the default log specified in **Error log file path**, click **OK**.
   - To specify a different log, in **Error log file path**, type a valid path and file name, and then click **OK**.

8. When the configuration is done, right-click **Security Configuration and Analysis**, and then click **View Log File**.

**Important**

- Applying the entire setup security template is a drastic measure that should be avoided. Instead, use the **secedit** command-line tool to apply default settings for specific areas. See the **Using a command line** section of this procedure.

**Notes**

- Different permissions are required to perform this procedure, depending on the environment in which you reapply default security settings:

- If you reapply default security settings to your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- If you reapply default security settings to a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Security Configuration and Analysis, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, click the console that you want to open, and then click **Open**. In the console tree, click **Security Configuration and Analysis**.

- The default path for the log file is:

  *systemroot*\Documents and Settings*UserAccount*\My Documents\Security\Logs\

- When you reapply default security settings, all settings that are defined in Setup security.inf are set as the template specifies, but other settings that are not defined in the template may persist. For more information, see Applying security settings.

**Using a command line**

- Open Command Prompt.

- For a server or workstation, type:

  **secedit/configure/DB***FileName***/CFG "%windir%\Security\Templates\Setup security.inf"** [**/overwrite**][**/areas** *Area1 Area2*...] [**/log** *LogPath*] [**/quiet**]

  For a domain controller, type:

  **secedit/configure/DB***FileName***/CFG "%windir%\Security\Templates\DC security.inf"** [**/overwrite**][**/areas** *Area1 Area2*...] [**/log** *LogPath*] [**/quiet**]

| Argument | Description |
|---|---|
| **/DB** *FileName* | Required. Provides the path to a database that contains the security template that should be applied. To create a new database, type the database file name and path. |
| **/CFG "%windir%\Security\Templates\Setup security.inf"** | Specifies the Setup Security.inf template that contains the default security settings. |
| **/overwrite** | Specifies that the database should be emptied prior to importing the security template. If this parameter is not specified, the settings in the security template are accumulated into the database. If this parameter is not specified and there are conflicting settings in the database and the template being imported, the template settings win. |

| | |
|---|---|
| **/areas** *Area1 Area2* | Specifies the security areas to be applied to the system. If this parameter is not specified, all security settings defined in the database are applied to the system. To configure multiple areas, separate each area by a space. The following security areas are supported:<br><br>SECURITYPOLICY - Includes account policies, audit policies, event log settings, and security options.<br><br>GROUP_MGMT - Includes Restricted Group settings.<br><br>USER_RIGHTS - Includes user rights assignment.<br><br>REGKEYS - Includes registry permissions.<br><br>FILESTORE - Includes file system permissions.<br><br>SERVICES - Includes System Service settings. |
| **/log** *LogPath* | Specifies a file in which to log the status of the configuration process. If not specified, configuration data is logged in the Scesrv.log file, which is located in the %windir%\Security\Logs folder. |
| **/quiet** | Specifies that the configuration process should take place without prompting the user. |

**Important**

- It is advisable to apply **Setup security** in parts using the **Areas** parameter, so you can have control over which parts you are restoring.

**Notes**

- Different permissions are required to perform this procedure, depending on the environment in which you reapply default security settings:

    - If you reapply default security settings to your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

    - If you reapply default security settings to a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **secedit /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modify security settings**

- Edit security settings on a Group Policy object
- Permit users to log on locally to a domain controller

# Edit security settings on a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit a security setting on a Group Policy object**

Choose the appropriate environment for which you want to edit a security setting:

- For your local computer
- For a Group Policy object, when you are on a workstation or server that is joined to a domain.
- For a Group Policy object, when you are on a domain controller or on a workstation that has the Windows Server 2003Administration Tools Pack installed.
- For only domain controllers, when you are on a domain controller.

**For your local computer**

1. Open Local Security Settings.
2. In the console tree, click **Security Settings**.
3. Do one of the following:
   - To edit **Password Policy** or **Account Lockout Policy**, click **Account Policies**.
   - To edit an **Audit Policy**, a **User Right Assignment**, or **Security Options**, click **Local Policies**.
4. Double-click the security setting in the details pane that you want to modify.
5. Modify the security setting, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**For a Group Policy object, when you are on a workstation or server that is joined to a domain.**

1. On the taskbar, click **Start**, point to **Run**, type **mmc**, and then click **OK**.
2. In the console, on the **File** menu, click **Add/Remove snap-in**.
3. In **Add/Remove Snap-in**, click **Add**, and then, in **Add Standalone Snap-in**, double-click **Group Policy Object Editor**.
4. In **Select Group Policy Object**, click **Browse**, browse to the policy object you would like to modify, and then click **Finish**.
5. Click **Close**, and then click **OK**.

6. In the console tree, click **Security Settings**.

   **Where?**

   - GroupPolicyObject [ComputerName] Policy\Computer Configuration\Windows Settings\Security Settings

7. Do one of the following:

   - To edit **Password Policy**, **Account Lockout Policy**, or **Kerberos Policy**, in the details pane, double-click **Account Policies**.
   - To edit **Audit Policy**, **User Rights Assignment**, or **Security Options**, in the details pane, double-click **Local Policies**.
   - To edit event log settings, on the console tree, click **Event Log**.

8. In the details pane, double-click the security setting that you want to modify.
9. (Optional) If this security setting has not yet been defined, select the **Define these policy settings** check box.
10. Modify the security setting and then click **OK**.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

**For a Group Policy object, when you are on a domain controller or on a workstation that has the Windows Server 2003Administration Tools Pack installed.**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the Group Policy object for which you want to edit security settings.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Do one of the following:

   - To edit an existing Group Policy object, click **Edit**.
   - To create a new Group Policy object, click **New**, and then click **Edit**.

5. In the console tree, click **Security Settings**.

   **Where?**

   - GroupPolicyObject [ComputerName] Policy\Computer Configuration\Windows Settings\Security Settings

6. Do one of the following:

- To edit **Password Policy**, **Account Lockout Policy**, or **Kerberos Policy**, click **Account Policies**.
- To edit **Audit Policy**, **User Rights Assignment**, or **Security Options**, click **Local Policies**.
- To edit Event log settings, click **Event Log**.

7. Double-click the security setting in the details pane that you want to modify.
8. (Optional) If this security setting has not yet been defined, select the **Define these policy settings** check box.
9. Modify the security setting and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**For only domain controllers, when you are on a domain controller.**

1. Open Domain Controller Security Policy.
2. In the console tree, click **Security Settings**.

   **Where?**

   - GroupPolicyObject [ComputerName] Policy\Computer Configuration\Windows Settings\Security Settings

3. Do one of the following:

   - To edit **Password Policy**, **Account Lockout Policy**, or **Kerberos Policy**, in the console tree, double-click **Account Policies**.
   - To edit **Audit Policy**, **User Rights Assignment**, or **Security Options**, in the console tree, click **Local Policies**.
   - To edit event log settings, in the console tree, click **Event Log**.

4. In the details pane, double-click the security setting that you want to modify.
5. (Optional) If this security setting has not yet been defined, select the **Define these policy settings** check box.
6. Modify the security setting, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Domain Controller Security Policy, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and

then double-click **Domain Controller Security Policy**.

### Notes

- Always test a newly-created policy on a test organizational unit before applying it to your network.
- When you change a security setting and click **OK**, that setting will take effect in the next refresh of settings.
- The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Permit users to log on locally to a domain controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To permit users to log on locally to a domain controller**

1. Open Domain Controller Security Policy.
2. In the console tree, click **User Rights Assignment.**

   **Where?**

   - *GroupPolicyObjectName* [*DomainControllerName*] Policy/Computer Configuration/Windows Settings/Security Settings/Local Policies/User Rights Assignment

3. In the details pane, double-click **Allow log on locally**.
4. If this security setting has not yet been defined, select the **Define these policy settings** check box, and click **Add User or Group**.
5. In **Add user or group**, specify the user or group who will be granted permission to log on locally, and then click **OK** twice.

## Notes

- To open Domain Controller Security Policy, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.
- You can also explicitly deny users or groups the permission to log on locally by configuring the "Deny log on locally" user right. For more information, see Related Topics.
- Setting changes are applied every five minutes on a domain controller. Every 16 hours, there is a forced refresh on the settings, regardless of any changes.
- User Rights are defined by default in the Default Domain Controller Group Policy object, which is associated with the Domain Controllers organizational unit. As a result, all domain controllers have the same User Rights policy.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Security Configuration and Analysis overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security Configuration and Analysis overview**
Security Configuration and Analysis is a tool for analyzing and configuring local system security.

**Security analysis**
The state of the operating system and applications on a computer is dynamic. For example, you may need to temporarily change security levels so that you can immediately resolve an administration or network issue. However, this change can often go unreversed. This means that a computer may no longer meet the requirements for enterprise security.

Regular analysis enables an administrator to track and ensure an adequate level of security on each computer as part of an enterprise risk management program. An administrator can tune the security levels and, most importantly, detect any security flaws that may occur in the system over time.

Security Configuration and Analysis enables you to quickly review security analysis results. It presents recommendations alongside of current system settings and uses visual flags or remarks to highlight any areas where the current settings do not match the proposed level of security. Security Configuration and Analysis also offers the ability to resolve any discrepancies that analysis reveals.

**Security configuration**
Security Configuration and Analysis can also be used to directly configure local system security. Through its use of personal databases, you can import security templates that have been created with Security Templates and apply these templates to the local computer. This immediately configures the system security with the levels specified in the template.

For more information, see Security Configuration and Analysis.

# Security Templates overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security Templates overview**
With the Security Templates snap-in for Microsoft Management Console, you can create a security policy for your computer or for your network. It is a single point of entry where the full range of system security can be taken into account. The Security Templates snap-in does not introduce new security parameters, it simply organizes all existing security attributes into one place to ease security administration.

Importing a security template to a Group Policy object eases domain administration by configuring security for a domain or organizational unit at once. For more information, see Import a security template to a Group Policy object.

In order to apply a security template to your local computer, you can use Security configuration and analysis or the Secedit command-line tool. For more information, see Configure local computer security.

Security templates can be used to define:

- Account Policies
    - Password Policy
    - Account Lockout Policy
    - Kerberos Policy
- Local Policies
    - Audit Policy
    - User Rights Assignment
    - Security Options
- Event log: Application, system, and security Event Log settings
- Restricted Groups: Membership of security-sensitive groups
- System Services security settings: Startup and permissions for system services
- Registry security settings: Permissions for registry keys
- File System security settings: Permissions for folders and files

Each template is saved as a text-based .inf file. This enables you to copy, paste, import, or export some or all of the template attributes. With the exceptions of Internet Protocol security and public key policies, all security attributes can be contained in a security template.

**New and predefined templates**
With each member of the Microsoft® Windows Server 2003 family or with the Microsoft® Windows® XP operating system, there are a set of predefined templates created for different levels of security to suit your organization.

There are several predefined templates that can help you to secure your system based on your needs, these templates are for:

- Reapplying default settings.
- Implementing a highly secure environment.

- Implementing a less secure but more compatible environment.
- Securing the systemroot.

For more information, see Predefined security templates.

The **Setup security.inf** template allows you to reapply default security settings. This template is created during setup for each computer and must be applied locally.

You can create a new security template with your own preferences or use one of the predefined security templates. Before making any changes to your security settings you should understand what the default settings of your system are and what they mean.

For more information about Security Templates, see Security Templates.

# Local Security Policy overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local security policy overview**
A security policy is a combination of security settings that affect the security on a computer. You can use your local security policy to edit account policies and local policies on your local computer.

With the local security policy, you can control:

- Who accesses your computer.
- What resources users are authorized to use on your computer.
- Whether or not a user or group's actions are recorded in the event log.

**How policy is applied to a computer that is joined to a domain**
If your local computer is joined to a domain, you are subject to obtaining security policy from the domain's policy or from the policy of any organizational unit that you are a member of. If you are getting policy from more than one source, then any conflicts are resolved in this order of precedence, from highest to lowest:

- Organizational unit policy
- Domain policy
- Site policy
- Local computer policy

When you modify the security settings on your local computer using the local security policy, then you are directly modifying the settings on your computer. Therefore, the settings take effect immediately, but this may only be temporary. The settings will actually remain in effect on your local computer until the next refresh of Group Policy security settings, when the security settings that are received from Group Policy will override your local settings wherever there are conflicts. The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.

For more information, see Local Security Policy.

# Security settings overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security Settings overview**

Organizational units, domains, and sites are linked to Group Policy objects. The Security Settings tool allows you change the security configuration of the Group Policy object, in turn, affecting multiple computers. With Security Settings, you can modify the security settings of many computers, depending on the Group Policy object you modify, from just one computer joined to a domain.

Security settings or security policies are rules that are configured on a computer or multiple computers for protecting resources on a computer or network. Security settings can control:

- How users are authenticated to a network or computer.
- What resources users are authorized to use.
- Whether or not a user's or group's actions are recorded in the event log.
- Group membership.

For more information, see Security Setting Descriptions.

**Using Security Settings**

You can change the security configuration on multiple computers in two ways:

- Create a security policy using a security template with Security Templates and then import it through Security Settings to a Group Policy object. For more information, see Import a security template to a Group Policy object.
- Change a few select settings with Security Settings. For more information, see Edit security settings on a Group Policy object.

# Understanding Security Configuration Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Security Configuration Manager**
This section covers:

- Account and local policies
- Event log security settings
- Security settings for file system, registry, and system services
- Local computer security for file system, registry, system services

# Account and local policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Account and local policies**
All security policies are computer-based policies. This section explains account policies and local policies.

**Account policies**
Account policies are defined on computers, yet they affect how user accounts can interact with the computer or domain. Account policies contain three subsets:

- Password Policy. Used for domain or local user accounts. Determines settings for passwords, such as enforcement and lifetimes.
- Account Lockout Policy. Used for domain or local user accounts. Determines the circumstances and length of time that an account will be locked out of the system.
- Kerberos Policy. Used for domain user accounts. Determines Kerberos-related settings, such as ticket lifetimes and enforcement. Kerberos policies do not exist in Local Computer Policy.

For domain accounts, the account policy must be defined in the Default Domain Policy Group Policy object (GPO) or in a new GPO that is linked to the root of the domain and given precedence over the Default Domain Policy GPO, which is enforced by the domain controllers that make up the domain. If more than one GPO containing account policy settings is linked at the domain level, the domain's account policy consists of the cumulative policy settings from all the domain-linked GPOs.

A domain controller always obtains the account policy from a GPO linked to the domain, which by default is the Default Domain Policy GPO. This behavior occurs even if a different account policy is applied to the organizational unit (OU) that contains the domain controller. By default, workstations and servers joined to a domain (such as member computers) also receive the same account policy for their local accounts. However, local account policies for member computers can be differentiated from the domain account policy by defining an account policy for the OU that contains the member computers.

**Important**

- Modifying the Default Domain Policy is not recommended. If you need to set some account policy that differs from that in the Default Domain Policy GPO, you can create a new GPO and link to the root of domain, set the policy you want to use, and assign it higher precedence than Default Domain Policy GPO.

There are two policies in Security Options that also behave like account policies. These are:

- Network Access: Allow anonymous SID/NAME translation
- Network Security: Force Logoff when Logon Hours expire

**Local policies**
These policies apply to a computer and contain these subsets:

- Auditing Policy. Determines whether security events are logged into the Security log on the computer. Also determines whether to log successful attempts, failed attempts or both. (The Security log is part of Event Viewer.)
- User Rights Assignment. Determines which users or groups have logon rights or privileges on the computer.
- Security Options. Enables or disables security settings for the computer, such as digital signing of data, Administrator and Guest account names, floppy drive and CD-ROM access, driver installation, and logon prompts.

Because a computer can have more than one policy applied to it, there can be conflicts in security policy settings. The order of precedence from highest precedence to lowest precedence is organizational unit, domain, and local computer. For more

information, see Applying security settings.

# Event log security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Event log security settings**

This security area defines attributes that are related to the application, security, and system logs: maximum log size, access rights for each log, and retention settings and methods. The application log records events generated by programs; the security log records security events, including logon attempts, object access, and changes to security, depending on what is audited; and the system log records operating system events. For more information, see Event Viewer.

For more information on event log policies, see Settings for Event Logs.

# Security settings for file system, registry, and system services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security settings for file system, registry, and system services**

**File system and registry keys**
You can configure security attributes using Security Configuration Manager for all existing files, folders, and registry keys in the local file system:

- **Propagate inheritable permissions to all subfolders and files (or subkeys)**: Any child objects of this object inherit the parental object's security. provided the child object is not protected from inheritance. If there is a conflict, the explicit permissions on the child object will override the permissions inherited from the parent object.

- **Replace existing permissions on all subfolders and files (or subkeys) with inheritable permissions**: The parent object's permission entries will override any security settings on the child object, regardless of the child object's settings. The child object will have identical Access Control Entries as the parent object.

  **Caution**

  - If you select this option and then click **Apply**, you will override all child objects' security settings. You will not be able to reset the child objects' security settings by clearing the check box.

- **Do not allow permissions on this file or folder (or key) to be replaced**: Use this setting if you do not want to configure or analyze security for this object or any of its child objects.

**System services**
You can select this if the startup mode is:

- **Automatic**: Automatically starts when computer is restarted.

- **Manual**: Does not start unless someone starts it.

- **Disabled**: The service cannot be started.

### Notes

- You can also edit the security properties of the object: what user or group accounts have permission to read, write, delete, or execute inheritance settings or auditing and ownership permission by clicking **Edit Security**

- If you choose to set system service startup to **Automatic**, perform adequate testing to verify that the services can start without user intervention.

- You should track the system services used on a computer. For performance optimization, set unnecessary or unused services to Manual.

For more information on file and folder permissions, see Permissions for files and folders.

# Local computer security for file system, registry, system services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local computer security for file system, registry, system services**
In order to edit security settings on the file system, registry, or system services for the local computer, you must:

1. Create or edit a security template. For more information, see Define a security template.

2. Apply it to the local computer using Security Configuration and Analysis. For more information, see Configure local computer security

For more information, see Security settings for file system, registry, and system services.

# Using Security Configuration Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Security Configuration Manager**

This section covers:

- Applying security settings
- Predefined security templates
- Importing and exporting security templates
- Analyzing security and viewing results
- Resolving security discrepancies
- Automating security configuration tasks
- Security Setting Descriptions

# Applying security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Applying security settings through Group Policy**

**When policy is applied**
Once you have edited the security settings, the settings are refreshed on the computers in the organizational unit linked to your Group Policy object:

- When a computer is restarted the settings on that computer will be refreshed.
- The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.
- To force a computer to refresh its security settings as well as all Group Policy settings, see the Gpupdate command line tool.

**Precedence of policy when more than one policy is applied to a computer**
For security settings which are defined by more than one policy, the following order of precedence, from highest to lowest, is observed:

- Organizational Unit Policy
- Domain Policy
- Site Policy
- Local computer Policy

For example, a workstation that is joined to a domain will have its local security settings overridden by the domain policy wherever there is a conflict. Likewise, if the same workstation is a member of an Organizational Unit, the settings applied from the Organizational Unit's policy will override both the domain and local settings. If the workstation is a member of more than one Organizational Unit, then the Organizational Unit that immediately contains the workstation has the highest order of precedence.

**Notes**

- Use Resultant Set of Policies tool to find out what policies are applied and in what order to a computer. For more information , see Resultant Set of Policy.
- For domain accounts, there can be only one account policy which includes password policies, account lockout policies, and kerberos policies. For more information, see Account and local policies.

**Persistence in security settings**
Security settings may still persist even if a setting is no longer defined in the policy that originally applied it.

Persistence in security settings occurs when:

- The setting has not been previously defined for the computer.
- The setting is for a registry object.
- The settings is for a file system object.

All settings applied through local policy or a Group Policy object are stored in a local database on your computer. Whenever a security settings is modified, the computer saves the security setting value to the local database which retains a history of all the settings that have been applied to the computer. If a policy first defines a security setting and then no longer defines that setting, then the setting takes on the previous value in the database. If a previous value does not exist in the database then the setting does not revert to anything and remains defined as is. This behavior is sometimes called "tattooing."

Registry and file settings will maintain the values applied through policy until that setting is set to other values.

**Filtering security settings based on group membership**

You can also decide what users or groups will or will not have a Group Policy object applied to them regardless of what computer they have logged onto by denying them either the **Apply Group Policy** or **Read** permission on that Group Policy object. Both of these permissions are needed to apply Group Policy. For more information, see Group Policy (pre-GPMC).

# Predefined security templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Predefined security templates**

The predefined security templates are provided as a starting point for creating security policies that are customized to meet different organizational requirements. You can customize the templates with the Security Templates snap-in. Once you customize the predefined security templates, you can use them to configure security on an individual computer or thousands of computers. You can configure individual computers with the Security Configuration and Analysis snap-in, the Secedit command-line tool, or by importing the template into Local Security Policy. You can configure multiple machines by importing a template into Security Settings extension to Group Policy, which is an extension to Group Policy. You can also use a security template as a baseline for analyzing a system for potential security holes or policy violations by using the Security Configuration and Analysis snap-in. By default, the predefined security templates are stored in:

*systemroot*\Security\Templates

- **Default security (Setup security.inf)**

  The Setup security.inf template is created during installation for each computer. It can vary from computer to computer, based on whether the installation was a clean installation or an upgrade. Setup security.inf represents the default security settings that are applied during installation of the operating system, including the file permissions for the root of the system drive. It can be used on servers and client computers; it cannot be applied to domain controllers. You can apply portions of this template for disaster recovery purposes.

  Setup security.inf should never be applied using Group Policy. It contains a large amount of data and can seriously degrade performance if it is applied through Group Policy, because policy is periodically refreshed and a large amount of data would move through the domain.

  It is advisable to apply the Setup security.inf template in parts. Since the Secedit command-line tool gives you this option, it is advisable to use it.

  For more information, see Automating security configuration tasks.

- **Domain controller default security (DC security.inf)**

  This template is created when a server is promoted to a domain controller. It reflects file, registry, and system service default security settings. Reapplying it resets these areas to the default values, but it may overwrite permissions on new files, registry keys and system services created by other applications. It can be applied using the Security Configuration and Analysis snap-in or the Secedit command-line tool.

- **Compatible (Compatws.inf)**

  Default permissions for workstations and servers are primarily granted to three local groups: Administrators, Power Users, and Users. Administrators have the most privileges while Users have the least. Because of this, you can significantly improve the security, reliability, and total cost of system ownership by:

  - Making sure that end users are members of the Users group.
  - Deploying applications that can be run successfully by members of the Users group.

  People with User privileges can successfully run applications that take part in the Windows Logo program for Software. However, Users may not be able to run applications that do not meet the requirements of the program. If other applications must be supported, there are two options:

  - Allow members of the Users group to be members of the Power Users group.

- Relax the default permissions that are granted to the Users group.

Since Power Users have inherent capabilities, such as creating users, groups, printers, and shares, some administrators would rather relax the default User permissions than allow end users to be members of the Power Users group. This is precisely what the Compatible template is for. The Compatible template changes the default file and registry permissions that are granted to Users in a manner that is consistent with the requirements of most applications that do not belong to the Windows Logo program for Software. Additionally, since it is assumed that the administrator that is applying the Compatible template does not want end users to be Power Users, the Compatible template also removes all members of the Power Users group. For more information, see Default security settings for groups.

For more information on the Windows Logo program for Software, see the Microsoft Web site.

The Compatible template should not be applied to domain controllers. For example, do not import the Compatible template to the Default Domain policy or Default Domain Controller policy.

- **Secure (Secure*.inf)**

  The Secure templates define enhanced security settings that are least likely to impact application compatibility. For example, the Secure templates define stronger password, lockout, and audit settings.

  Additionally, the Secure templates limit the use of LAN Manager and NTLM authentication protocols by configuring clients to send only NTLMv2 responses and configuring servers to refuse LAN Manager responses.

  - In order to apply Securews.inf to a member computer, all of the domain controllers that contain the accounts of all users that log on to the client must run Windows NT 4.0Service Pack 4 or higher.

  - In order to apply Securews.inf to a member computer that is joined to a domain which contains domain controllers running Windows NT 4.0, the clocks between the domain controllers running Windows NT 4.0and the member computers must be within 30 minutes of each other.

  - If a client is configured with Securews.inf, it will not be able to connect to servers that only use the LAN Manager authentication protocol or that run Windows NT 4.0prior to Service Pack 4 using a local account defined on the target server.

  - If a client is configured with Securews.inf, it will not be able to connect to servers running Windows 2000or Windows NT 4.0using a local account defined on the target server unless the clock on the target server is within 30 minutes of the clock on the client.

  - If a client is configured with Securews.inf, it will not be able to connect to a computer running Windows XPor above using a local account defined on the target server unless the clock on the target server is within 20 hours of the clock on the client.

  - If a client is configured with Securews.inf, then it will not be able to connect to servers running LAN Manager that are running in share-level security mode.

  - If a server is configured with Securews.inf, then a user with a local account on that server will not be able to connect to it from a client computer running only LAN Manager that is using that local account.

  - If a server running Windows 2000is configured with securews.inf, then a client with a local account on that server that is also configured to use NTLMv2 authentication will not be able to connect unless the clocks on the two machines are within 30 minutes of each other.

  - If a server running Windows XPis configured with securews.inf, then a client with a local account on that server that is also configured to use NTLMv2 authentication will not be able to connect unless the clocks on the two machines are within 20 hours of each other.

  - If a domain controller is configured with Securedc.inf, then a user with an account in that domain will not be able

to connect to any member server from a client computer running only LAN Manager using that domain account.

- Computers that run LAN Manager include Windows for Workgroupsas well as Windows 95and Windows 98platforms that do not have the Active Directory Client Extensions Pack installed. If the Active Directory Client Extensions Pack is installed on Windows 95or Windows 98, then those clients will be able to use NTLMv2. Windows Millinnium Editionsupports NTLMv2 without additional modification.

- Computers that run Windows NTService Pack 4 or higher can be configured to send only NTLMv2 responses by setting **HKLM\System\CurrentControlSet\Control\LSA\LMCompatibilityLevel** to equal 3 or higher.

- Computers that run Windows NTService Pack 4 or higher can be configured to send only NTLMv2 responses by specifying this preference in the Network security: LAN Manager authentication level security option.

The Secure templates also provide further restrictions for anonymous users by preventing anonymous users (such as users from untrusted domains) from:

- Enumerating account names and shares.

- Performing SID-to-name or name-to-SID translations.

Finally, the Secure templates enable server-side Server Message Block (SMB) packet signing, which is disabled by default for servers. Since client-side SMB packet signing is enabled by default, SMB packet signing will always be negotiated when workstations and servers are operating at the Secure level.

- **Highly Secure (hisec*.inf)**

  The Highly Secure templates are supersets of the secure templates that impose further restrictions on the levels of encryption and signing that are required for authentication and for the data that flows over secure channels and between SMB clients and servers. For example, while the Secure templates cause servers to refuse LAN Manager responses, the Highly Secure templates cause servers to refuse both LAN Manager and NTLM responses. While the Secure template enables server-side SMB packet signing, the Highly Secure template requires it. Additionally, the Highly Secure templates require strong encryption and signing for the secure channel data that constitutes domain-to-member and domain-to-domain trust relationships. relationships. Thus, in order to apply hisecws.inf to a member machine:

  - All of the domain controllers that contain the accounts of all users that will logon to the client must be running Windows NT 4.0Service Pack 4 or higher.

  - All of the domain controllers for the domain that the client is joined to must run Windows 2000or later.

  - Clients that are configured with Hisecws.inf cannot connect to computers that only run LAN Manager or computers running Windows NT 4.0, Service Pack 3 or earlier using a local account defined on the target server.

  - Clients that are configured with Hisecws.inf cannot connect to servers running Windows 2000or Windows NT 4.0Service Pack 4 using a local account defined on the target server unless the clock on the target server is within 30 minutes of the clock on the client.

  - Clients that are configured with Hisecws.inf cannot connect to computers running Windows XPor above using a local account defined on the target computer unless the clock on the target computer is within 20 hours of the clock on the client.

  - Clients that are configured with Hisecws.inf cannot connect to LAN Manager servers operating in share-level security mode.

  - In order to apply Hisecdc.inf to a domain controller, all of the domain controllers in all trusted or trusting domains must run Windows 2000or Windows Server 2003 family operating systems.

  - If a server is configured with Hisecws.inf, then a user with a local account on that server will not be able to

connect to it from a client that does not support NTLMv2.

- If a server is configured with Hisecws.inf, then a client with a local account on that server will not be able to connect to the server unless the client's computer is configured to send NTLMv2 responses.

- If a server is configured with Hisecws.inf, then all clients that want to use SMB to connect to that server must enable client-side SMB packet signing. All computers running Windows 2000and Windows XPoperating systems enable client-side SMB packet signing by default.

- If a domain controller is configured with Hisecdc.inf, then a user with an account in that domain cannot connect to member servers using that domain user account if the connection is being attempted from a client that only uses the LAN Manager authentication protocol.

- If a domain controller is configured with Hisecdc.inf, then a user with an account in that domain will not be able to connect to member servers using that domain account unless:

Both the client and target server are running Windows 2000or above and can use Kerberos-based authentication rather than LAN Manager-based authentication.

The client is configured to send NTLMv2 responses.

- If a domain controller is configured with Hisecdc.inf, then Lightweight Directory Access protocol (LDAP) clients will not be able to bind with the Active Directory LDAP server unless data signing is negotiated. BIND requests using ldap_simple_bind or ldap_simple_bind_s are rejected. By default, all Microsoft LDAP clients that ship with Windows XPwill request data signing if Transport Layer Security/Secure Sockets Layer (TLS/SSL) is not already being used. If TLS/SSL is being used, then data signing is considered to be negotiated.

- Clients that do not support NTLMv2 include Windows for Workgroups, Windows NTclients prior to Service Pack 4, and Windows 95and Windows 98platforms that do not have the Active Directory Client Extensions Pack installed.

- Computers that run Windows NTService Pack 4 or higher can be configured to send only NTLMv2 responses by setting **HKLM\System\CurrentControlSet\Control\LSA\LMCompatibilityLevel**=3 or higher.

- Computers that run Windows 2000or higher can be configured to send only NTLMv2 responses by specifying this preference in the Network security: LAN Manager authentication level security option.

  In addition to further restrictions on the use of LAN Manager protocols and the requirements for encryption and signing of secure channel and SMB traffic, the Highly Secure templates also limit the use of cached logon data, such as data stored by Winlogon and Stored User Names and Passwords.

  Finally, Hisecws.inf uses restricted group settings to:

  - Remove all members of the Power Users group.

  - Ensure that only Domain Admins and the local Administrator account are members of the local Administrators group.

  Hisecws.inf defines these group restrictions under the assumption that users only use applications that belong to the Windows Logo program for Software. With those applications in place, neither the insecure Compatible template nor the insecure Power Users group is needed. Instead, users can run those applications successfully under the secure context of a normal member of the Users group, which is defined by the default security settings of the file system and registry. Members of the Administrators group can still use any application that they want.

  For information about the Windows Logo program for Software, see the Windows Logo program for Software page at the Microsoft Web site.

- **System root security (Rootsec.inf)**

Rootsec.inf specifies the root permissions. By default, Rootsec.inf defines these permissions for the root of the system drive. This template can be used to reapply the root directory permissions if they are inadvertently changed, or the template can be modified to apply the same root permissions to other volumes. As specified, the template does not overwrite explicit permissions that are defined on child objects; it propagates only the permissions that are inherited by child objects.

- **No Terminal Server user SID (Notssid.inf)**

  The default file system and registry access control lists that are on servers grant permissions to a Terminal Server security identifier (SID). The Terminal Server SID is used only when Terminal Server is running in application compatibility mode. If Terminal Server is not being used, this template can be applied to remove the unnecessary Terminal Server SIDs from the file system and registry locations. However, removing the access control entry for the Terminal Server SID from these default file system and registry locations does not increase the security of the system. Instead of removing the Terminal Server SID, simply run Terminal Server in Full Security mode. When running in Full Security mode, the Terminal Server SID is not used.

- **Internet Explorer (iesacls.inf)**

  The iesacls.inf template allows you to audit Internet Explorer use. This can be useful in conjunction with a plan to regularly review the event logs.

- **Optional Components (ocfiles*.inf)**

  These templates from previous Windows versions are no longer used or needed. Setup Security.inf replaces them.

**Caution**

- These security templates are constructed with the assumption that they will be applied to computers that use the default security settings. In other words, these templates incrementally modify the default security settings, if they are on the computer. They do *not* install the default security settings before performing the modifications.

- Predefined security templates should not be applied to production systems without testing to ensure that the right level of application functionality is maintained for your network and system architecture.

Security template settings can be viewed through Security Templates. The *.inf files can also be viewed as text files. These files are located in:

%windir%\Security\Templates

You cannot secure Windows XP Professionalsystems that are installed on file allocation table (FAT) file systems.

For more information, see Customize a predefined security template, Import a security template to a Group Policy object, Configure local computer security, and Reapply default security settings.

# Importing and exporting security templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Importing and exporting security templates**

Security Configuration and Analysis provides the ability to import and export security templates into or from a database.

If you have made any changes to the analysis database, you can save those settings by exporting them into a template. The export feature provides the ability to save the analysis database settings as a new template file. This template file can then be used to analyze or configure a system or it can be imported to a Group Policy object.

For more information, see Import a security template and Export a security template.

# Analyzing security and viewing results

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Analyzing security and viewing results**

Security Configuration and Analysis performs security analysis by comparing the current state of system security against an *analysis database*. During creation, the analysis database uses at least one security template. If you choose to import more than one security template, the database will merge the various templates and create one composite template. It resolves conflicts in order of import; the last template that is imported takes precedence.

**Viewing security analysis results**

Security Configuration and Analysis displays the analysis results by security area, using visual flags to indicate problems. It displays the current system and base configuration settings for each security attribute in the security areas. To change the analysis database settings, right-click the entry and click **Properties**.

| Visual flag | Meaning |
|---|---|
| Red X | The entry is defined in the analysis database and on the system, but the security setting values do not match. |
| Green check | The entry is defined in the analysis database and on the system and the setting values match. |
| Question mark | The entry is not defined in the analysis database and, therefore, was not analyzed.<br><br>If an entry is not analyzed, it may be that it was not defined in the analysis database or that the user who is running the analysis may not have sufficient permission to perform analysis on a specific object or area. |
| Exclamation point | This item is defined in the analysis database, but does not exist on the actual system. For example, there may be a restricted group that is defined in the analysis database but does not actually exist on the analyzed system. |
| No highlight | The item is not defined in the analysis database or on the system. |

If you choose to accept the current settings, the corresponding value in the base configuration is modified to match them. If you change the system setting to match the base configuration, the change will be reflected when you configure the system with Security Configuration and Analysis.

To avoid continued flagging of settings that you have investigated and determined to be reasonable, you can modify the base configuration. The changes are made to a copy of the template.

For more information, see Analyze system security, Resolving security discrepancies, and Security Setting Descriptions.

# Resolving security discrepancies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resolving security discrepancies**

You can resolve discrepancies between analysis database and system settings by:

- Accepting or changing some or all of the values that are flagged or not included in the configuration, if you determine that the local system security levels are valid due to the context (or role) of that computer. These attribute values are then updated in the base and applied to the system when you click **Configure Computer Now**. For more information, see Edit the analysis database.

- Configuring the system to the analysis database values, if you determine the system is not in compliance with valid security levels. For more information, see Configure local computer security.

- Importing a more appropriate template for the role of that computer into the database as the new base configuration and applying it to the system. For more information, see Import a security template.

Changes to the analysis database are made to the stored template in the database, not to the security template file. The security template file will only be modified if you either return to Security Templates and edit that template or export the stored configuration to the same template file.

You should use **Configure Computer Now** only to modify security areas *not* affected by Group Policy settings, such as security on local files and folders, registry keys, and system services. Otherwise, when the Group Policy settings are applied, it will take precedence over local settings—such as account policies. In general, do not use **Configure Computer Now** when you are analyzing security for domain-based clients, since you will have to configure each client individually. In this case, you should return to Security Templates, modify the template, and reapply it to the appropriate Group Policy object.

# Automating security configuration tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automating security configuration tasks**
By calling the Secedit.exe tool at a command prompt from a batch file or automatic task scheduler, you can use it to automatically create and apply templates, and analyze system security. You can also run it dynamically from a command prompt.

Secedit.exe is useful when you have multiple computers on which security must be analyzed or configured, and you need to perform these tasks during off-hours.

- For procedural information about using the Secedit.exe tool to perform security tasks, see Secedit.
- For information about defining Security Templates, see Security Templates.
- For more information about security configuration and analysis, see Security Configuration and Analysis.

**Note**

- The **secedit /refreshpolicy** command has been replaced with the **gpupdate** command. For information about how to refresh security settings, see Gpupdate.

# Security Setting Descriptions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security setting descriptions**

To locate this security setting in the console tree in Microsoft Management Console (MMC), see Computer Configuration\Windows Settings\Security Settings

| Security area | Description |
|---|---|
| Account Policies | Password Policy, Account Lockout Policy, and Kerberos Policy |
| Local Policies | Auditing Policy, User Rights Assignment, and Security Options |
| Event log | Application, system, and security Event Log settings |
| Restricted Groups | Membership of security-sensitive groups |
| System Services security settings | Startup and permissions for system services |
| Registry security settings | Permissions for registry keys |
| File System security settings | Permissions for folders and files |

You can configure the security settings that are described in this section on one computer, or on many computers, by using the Security Configuration Manager tools. The Security Configuration Manager tools consist of:

- Security Templates
- Security Configuration and Analysis
- The Secedit.exe command-prompt tool
- Local Security Policy
- The Security Settings Extension to Group Policy

To set or to modify individual security settings on individual computers, use Local Security Policy. To define security settings that are enforced on any number of computers, use the Security Settings Extension to Group Policy. To apply several settings in a batch, use Security Templates to define the settings, and then apply those settings by using Security Configuration and Analysis or Secedit.exe, or import the template that contains your settings into Local Policy or Group Policy.

# Account Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Account policies**
All security policies are computer-based policies. Account policies are defined on computers, yet they affect how user accounts can interact with the computer or domain. Account policies contain three subsets:

- Password Policy
- Account Lockout Policy
- Kerberos Policy

For domain accounts, the account policy must be defined in the Default Domain Policy Group Policy object (GPO) or in a new GPO that is linked to the root of the domain and given precedence over the Default Domain Policy GPO, which is enforced by the domain controllers that make up the domain. If more than one GPO containing account policy settings is linked at the domain level, the domain's account policy consists of the cumulative policy settings from all the domain-linked GPOs.

A domain controller always obtains the account policy from a GPO linked to the domain, which by default is the Default Domain Policy GPO. This behavior occurs even if a different account policy is applied to the organizational unit (OU) that contains the domain controller. By default, workstations and servers joined to a domain (such as member computers) also receive the same account policy for their local accounts. However, local account policies for member computers can be differentiated from the domain account policy by defining an account policy for the OU that contains the member computers.

**Important**

- Modifying the Default Domain Policy is not recommended. If you need to set some account policy that differs from that in the Default Domain Policy GPO, you can create a new GPO and link to the root of domain, set the policy you want to use, and assign it higher precedence than Default Domain Policy GPO.

For more information, see Account and local policies.

# Password Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Password policy**
Password policies are used for domain accounts or local user accounts. They determine settings for passwords, such as enforcement and lifetimes. This section covers:

- Enforce password history
- Maximum password age
- Minimum password age
- Minimum password length
- Passwords must meet complexity requirements
- Store passwords using reversible encryption

# Enforce password history

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enforce password history**

**Description**
This security setting determines the number of unique new passwords that have to be associated with a user account before an old password can be reused. The value must be between 0 and 24 passwords.

This policy enables administrators to enhance security by ensuring that old passwords are not reused continually.

**Default**:

- 24 on domain controllers.
- 0 on stand-alone servers.

**Note**

- By default, member computers follow the configuration of their domain controllers.

To maintain the effectiveness of the password history, do not allow passwords to be changed immediately after they were just changed by also enabling the Minimum password age security policy setting. For information about the minimum password age security policy setting, see Minimum password age.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\

For specific instructions about how to configure password policy settings, see Apply or modify password policy.

For more information, see:

- Password Best practices for passwords
- Password Policy
- Security Configuration Manager tools

# Maximum password age

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum password age**

**Description**
This security setting determines the period of time (in days) that a password can be used before the system requires the user to change it. You can set passwords to expire after a number of days between 1 and 999, or you can specify that passwords never expire by setting the number of days to 0. If the maximum password age is between 1 and 999 days, the Minimum password age must be less than the maximum password age. If the maximum password age is set to 0, the minimum password age can be any value between 0 and 998 days.

**Note**

- It is a security best practice to have passwords expire every 30 to 90 days, depending on your environment. This way, an attacker has a limited amount of time in which to crack a user's password and have access to your network resources.

**Default:** 42.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\

For specific instructions about how to configure password policy settings, see Apply or modify password policy.

For more information, see:

- Password Best practices for passwords
- Password Policy
- Security Configuration Manager tools

# Minimum password age

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Minimum password age**

**Description**
This security setting determines the period of time (in days) that a password must be used before the user can change it. You can set a value between 1 and 998 days, or you can allow changes immediately by setting the number of days to 0.

The minimum password age must be less than the Maximum password age, unless the maximum password age is set to 0, indicating that passwords will never expire. If the maximum password age is set to 0, the minimum password age can be set to any value between 0 and 998.

Configure the minimum password age to be more than 0 if you want Enforce password history to be effective. Without a minimum password age, users can cycle through passwords repeatedly until they get to an old favorite. The default setting does not follow this recommendation, so that an administrator can specify a password for a user and then require the user to change the administrator-defined password when the user logs on. If the password history is set to 0, the user does not have to choose a new password. For this reason, Enforce password history is set to 1 by default.

**Default**:

- 1 on domain controllers.
- 0 on stand-alone servers.

**Note**

- By default, member computers follow the configuration of their domain controllers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\

For specific instructions about how to configure password policy settings, see Apply or modify password policy.

For more information, see:

- Password Best practices for passwords
- Password Policy
- Security Configuration Manager tools

# Minimum password length

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Minimum password length**

**Description**
This security setting determines the least number of characters that a password for a user account may contain. You can set a value of between 1 and 14 characters, or you can establish that no password is required by setting the number of characters to 0.

**Default**:

- 7 on domain controllers.
- 0 on stand-alone servers.

**Note**

- By default, member computers follow the configuration of their domain controllers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\

For specific instructions about how to configure password policy settings, see Apply or modify password policy.

For more information, see:

- Password Best practices for passwords
- Password Policy
- Security Configuration Manager tools

# Passwords must meet complexity requirements

Updated: October 1, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

**Password must meet complexity requirements**

**Description**
This security setting determines whether passwords must meet complexity requirements. Complexity requirements are enforced when passwords are changed or created.

If this policy is enabled, passwords must meet the following minimum requirements when they are changed or created:

- Passwords must not contain the user's entire samAccountName (Account Name) value or entire displayName (Full Name) value. Both checks are not case sensitive:
    - The samAccountName is checked in its entirety only to determine whether it is part of the password. If the samAccountName is less than three characters long, this check is skipped.
    - The displayName is parsed for delimiters: commas, periods, dashes or hyphens, underscores, spaces, pound signs, and tabs. If any of these delimiters are found, the displayName is split and all parsed sections (tokens) are confirmed not to be included in the password. Tokens that are less than three characters in length are ignored, and substrings of the tokens are not checked. For example, the name "Erin M. Hagens" is split into three tokens: "Erin," "M," and "Hagens." Because the second token is only one character long, it is ignored. Therefore, this user could not have a password that included either "erin" or "hagens" as a substring anywhere in the password.
- Passwords must contain characters from three of the following five categories:
    - Uppercase characters of European languages (A through Z, with diacritic marks, Greek and Cyrillic characters)
    - Lowercase characters of European languages (a through z, sharp-s, with diacritic marks, Greek and Cyrillic characters)
    - Base 10 digits (0 through 9)
    - Nonalphanumeric characters: ~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/
    - Any Unicode character that is categorized as an alphabetic character but is not uppercase or lowercase. This includes Unicode characters from Asian languages.

| **Note** |
| --- |
| A given character can satisfy only one category. The GetStringTypeW API (http://go.microsoft.com/fwlink/?LinkId=205607) is used to test whether each character in the password is uppercase, lowercase, or alphanumeric. |

To create custom password filters, see Password Filters (http://go.microsoft.com/fwlink/?LinkId=205613).

**Default**:

- Enabled on domain controllers.
- Disabled on stand-alone servers.

| **Note** |
| --- |

| |
|---|
| By default, member computers inherit the password policy configuration from the domain. This password policy configuration is either defined at the domain-level or at any OU that has the member computer within its scope of management. If you define a password policy at an OU by using a GPO and that OU contains computer accounts, the computers that belong to those computer accounts inherit the password policy defined at the OU and apply it to the local users on the server. |

**Configuring this security setting**

You can configure this security setting by opening the appropriate policy and expanding the console tree: Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\

For specific instructions about how to configure password policy settings, see Apply or modify password policy.

For more information, see:

- Passwords Technical Overview
- Password policy
- Strong passwords
- Password Best practices
- Security Configuration Manager tools

**Change History**

| Date | Revision |
|---|---|
| November 15, 2010 | The description was revised to be more precise and accurate. The precise attribute names were added and the character categories were updated. |
| November 30, 2010 | The description "Far eastern" was changed to "Asian." |
| Oct 1, 2012 | The Note about how domain computers obtain password policy was revised. |

# Store passwords using reversible encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Store passwords using reversible encryption**

**Description**
This security setting determines whether the operating system stores passwords using reversible encryption.

This policy provides support for applications that use protocols that require knowledge of the user's password for authentication purposes. Storing passwords using reversible encryption is essentially the same as storing plaintext versions of the passwords. For this reason, this policy should never be enabled unless application requirements outweigh the need to protect password information.

This policy is required when using Challenge-Handshake Authentication Protocol (CHAP) authentication through remote access or Internet Authentication Services (IAS). It is also required when using Digest Authentication in Internet Information Services (IIS).

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\

For specific instructions about how to configure password policy settings, see Apply or modify password policy.

For more information, see:

- Password Best practices for passwords
- Password Policy
- Security Configuration Manager tools

# Account Lockout Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Account lockout policy**
Account lockout policies are used for domain accounts or local user accounts. They determine the circumstances and length of time that an account will be locked out of the system. This section covers:

- Account lockout duration
- Account lockout threshold
- Reset account lockout counter after

# Account lockout duration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Account lockout duration**

**Description**
This security setting determines the number of minutes a locked-out account remains locked out before automatically becoming unlocked. The available range is from 0 minutes through 99,999 minutes. If you set the account lockout duration to 0, the account will be locked out until an administrator explicitly unlocks it.

If an account lockout threshold is defined, the account lockout duration must be greater than or equal to the reset time.

**Default:** None, because this policy setting only has meaning when an Account lockout threshold is specified.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Account Lockout Policy\

For specific instructions about how to configure account lockout policy settings, see Apply or modify account lockout policy.

For more information, see:

- Password Best practices for account lockout policy
- Account Lockout Policy
- Security Configuration Manager tools

# Account lockout threshold

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Account lockout threshold**

**Description**
This security setting determines the number of failed logon attempts that causes a user account to be locked out. A locked-out account cannot be used until it is reset by an administrator or until the lockout duration for the account has expired. You can set a value between 0 and 999 failed logon attempts. If you set the value to 0, the account will never be locked out.

Failed password attempts against workstations or member servers that have been locked using either CTRL+ALT+DELETE or password-protected screen savers count as failed logon attempts.

**Default:** 0.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Account Lockout Policy\

For specific instructions about how to configure account lockout policy settings, see Apply or modify account lockout policy.

For more information, see:

- Password Best practices for account lockout policy
- Account Lockout Policy
- Security Configuration Manager tools

# Reset account lockout counter after

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Reset account lockout counter after**

**Description**
This security setting determines the number of minutes that must elapse after a failed logon attempt before the failed logon attempt counter is reset to 0 bad logon attempts. The available range is 1 minute to 99,999 minutes.

If an account lockout threshold is defined, this reset time must be less than or equal to the Account lockout duration.

**Default:** None, because this policy setting only has meaning when an Account lockout threshold is specified.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Account Lockout Policy\

For specific instructions about how to configure account lockout policy settings, see Apply or modify account lockout policy.

For more information, see:

- Password Best practices for account lockout policy
- Account Lockout Policy
- Security Configuration Manager tools

# Kerberos Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Kerberos policy**
Kerberos policies are used for domain user accounts. They determine Kerberos-related settings, such as ticket lifetimes and enforcement. Kerberos policies do not exist in Local Computer Policy. This section covers:

- Enforce user logon restrictions
- Maximum lifetime for service ticket
- Maximum lifetime for user ticket
- Maximum lifetime for user ticket renewal
- Maximum tolerance for computer clock synchronization

# Enforce user logon restrictions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enforce user logon restrictions**

**Description**
This security setting determines whether the Kerberos V5 Key Distribution Center (KDC) validates every request for a session ticket against the user rights policy of the user account. Validation of each request for a session ticket is optional, because the extra step takes time and it may slow network access to services.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Kerberos Policy\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Kerberos Policy
- Configure Kerberos policy
- Security Configuration Manager tools

# Maximum lifetime for service ticket

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum lifetime for service ticket**

**Description**
This security setting determines the maximum amount of time (in minutes) that a granted session ticket can be used to access a particular service. The setting must be greater than 10 minutes and less than or equal to the setting for Maximum lifetime for user ticket.

If a client presents an expired session ticket when it requests a connection to a server, the server returns an error message. The client must request a new session ticket from the Kerberos V5 Key Distribution Center (KDC). Once a connection is authenticated, however, it no longer matters whether the session ticket remains valid. Session tickets are used only to authenticate new connections with servers. Ongoing operations are not interrupted if the session ticket that is used to authenticate the connection expires during the connection.

**Default:** 600 minutes (10 hours).

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Kerberos Policy\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Kerberos Policy
- Configure Kerberos policy
- Security Configuration Manager tools

# Maximum lifetime for user ticket

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum lifetime for user ticket**

**Description**
This security setting determines the maximum amount of time (in hours) that a user's ticket-granting ticket (TGT) may be used. When a user's TGT expires, a new one must be requested or the existing one must be "renewed."

**Default:** 10 hours.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Kerberos Policy\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Kerberos Policy
- Configure Kerberos policy
- Security Configuration Manager tools

# Maximum lifetime for user ticket renewal

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum lifetime for user ticket renewal**

**Description**
This security setting determines the period of time (in days) during which a user's ticket-granting ticket (TGT) may be renewed.

**Default:** 7 days.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Kerberos Policy\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Kerberos Policy
- Configure Kerberos policy
- Security Configuration Manager tools

# Maximum tolerance for computer clock synchronization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum tolerance for computer clock synchronization**

**Description**
This security setting determines the maximum time difference (in minutes) that Kerberos V5 tolerates between the time on the client clock and the time on the domain controller running Windows Server 2003 that provides Kerberos authentication.

To prevent "replay attacks," Kerberos V5 uses time stamps as part of its protocol definition. For time stamps to work properly, the clocks of the client and the domain controller need to be in sync as much as possible. In other words, both computers must be set to the same time and date. Because the clocks of two computers are often out of sync, administrators can use this policy to establish the maximum acceptable difference to Kerberos V5 between a client clock and domain controller clock. If the difference between a client clock and the domain controller clock is less than the maximum time difference that is specified in this policy, any time stamp that is used in a session between the two computers is considered to be authentic.

**Important**

- This setting is not persistent. If you configure this setting and then restart the computer, this setting reverts to the default value. For more information, see the Microsoft Knowledge Base.

**Default:** 5 minutes.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Account Policies\Kerberos Policy\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Kerberos Policy
- Configure Kerberos policy
- Security Configuration Manager tools

# Local Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local policies**

These policies apply to computers, and they contain these subsets:

- Auditing Policy. Determines whether security events are logged into the Security log on the computer. Also determines whether to log successful attempts, failed attempts or both. (The Security log is part of Event Viewer.)
- User Rights Assignment. Determines which users or groups have logon rights or privileges on the computer.
- Security Options. Enables or disables security settings for the computer, such as digital signing of data, Administrator and Guest account names, floppy drive and CD-ROM access, driver installation, and logon prompts.

# Auditing Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Auditing policy**
Before you implement auditing policy, you must decide which event categories you want to audit. The auditing settings that you choose for the event categories define your auditing policy. On member servers and workstations that are joined to a domain, auditing settings for the event categories are undefined by default. On domain controllers, auditing is turned on by default. By defining auditing settings for specific event categories, you can create an auditing policy that suits the security needs of your organization.

The event categories that you can choose to audit are:

- Audit account logon events
- Audit account management
- Audit directory service access
- Audit logon events
- Audit object access
- Audit policy change
- Audit privilege use
- Audit process tracking
- Audit system events

For more information about auditing, see Auditing Security Events.

# Audit account logon events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit account logon events**

**Description**
This security setting determines whether to audit each instance of a user logging on to or logging off from another computer in which this computer is used to validate the account. Account logon events are generated when a domain user account is authenticated on a domain controller. The event is logged in the domain controller's security log. Logon events are generated when a local user is authenticated on a local computer. The event is logged in the local security log. Account logoff events are not generated.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when an account logon attempt succeeds. Failure audits generate an audit entry when an account logon attempt fails.

To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

If success auditing for account logon events is enabled on a domain controller, an entry is logged for each user who is validated against that domain controller, even though the user is actually logging on to a workstation that is joined to the domain.

**Default**: Success.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| Account Logon Events | Description |
|---|---|
| 672 | An authentication service (AS) ticket was successfully issued and validated. |
| 673 | A ticket granting service (TGS) ticket was granted. |
| 674 | A security principal renewed an AS ticket or TGS ticket. |
| 675 | Preauthentication failed. This event is generated on a Key Distribution Center (KDC) when a user types in an incorrect password. |
| 676 | Authentication ticket request failed. This event is not generated in Windows XP or in the Windows Server 2003 family. |
| 677 | A TGS ticket was not granted. This event is not generated in Windows XP or in the Windows Server 2003 family. |
| 678 | An account was successfully mapped to a domain account. |
| 681 | Logon failure. A domain account logon was attempted. This event is not generated in Windows XP or in the Windows Server 2003 family. |
| 682 | A user has reconnected to a disconnected terminal server session. |
| 683 | A user disconnected a terminal server session without logging off. |

For more information about security events, see Security Events on the Microsoft Windows Resource Kits Web site.

# Audit account management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit account management**

**Description**
This security setting determines whether to audit each event of account management on a computer. Examples of account management events include:

- A user account or group is created, changed, or deleted.
- A user account is renamed, disabled, or enabled.
- A password is set or changed.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when any account management event succeeds. Failure audits generate an audit entry when any account management event fails. To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

**Default**:

- Success on domain controllers.
- No auditing on member servers

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| Account Management Events | Description |
|---|---|
| 624 | A user account was created. |
| 627 | A user password was changed. |
| 628 | A user password was set. |
| 630 | A user account was deleted. |
| 631 | A global group was created. |
| 632 | A member was added to a global group. |
| 633 | A member was removed from a global group. |
| 634 | A global group was deleted. |
| 635 | A new local group was created. |
| 636 | A member was added to a local group. |

| | |
|---|---|
| 637 | A member was removed from a local group. |
| 638 | A local group was deleted. |
| 639 | A local group account was changed. |
| 641 | A global group account was changed. |
| 642 | A user account was changed. |
| 643 | A domain policy was modified. |
| 644 | A user account was auto locked. |
| 645 | A computer account was created. |
| 646 | A computer account was changed. |
| 647 | A computer account was deleted. |
| 648 | A local security group with security disabled was created.<br>**Note**<br>• SECURITY_DISABLED in the formal name means that this group cannot be used to grant permissions in access checks. |
| 649 | A local security group with security disabled was changed. |
| 650 | A member was added to a security-disabled local security group. |
| 651 | A member was removed from a security-disabled local security group. |
| 652 | A security-disabled local group was deleted. |
| 653 | A security-disabled global group was created. |
| 654 | A security-disabled global group was changed. |
| 655 | A member was added to a security-disabled global group. |
| 656 | A member was removed from a security-disabled global group. |
| 657 | A security-disabled global group was deleted. |
| 658 | A security-enabled universal group was created. |
| 659 | A security-enabled universal group was changed. |
| 660 | A member was added to a security-enabled universal group. |
| 661 | A member was removed from a security-enabled universal group. |
| 662 | A security-enabled universal group was deleted. |
| 663 | A security-disabled universal group was created. |
| 664 | A security-disabled universal group was changed. |
| 665 | A member was added to a security-disabled universal group. |
| 666 | A member was removed from a security-disabled universal group. |
| 667 | A security-disabled universal group was deleted. |

| | |
|---|---|
| 668 | A group type was changed. |
| 684 | Set the security descriptor of members of administrative groups.<br>**Note**<br>• Every 60 minutes on a domain controller a background thread searches all members of administrative groups (such as domain, enterprise, and schema administrators) and applies a fixed security descriptor on them. This event is logged. |
| 685 | Name of an account was changed. |

# Audit directory service access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit directory service access**

**Description**
This security setting determines whether to audit the event of a user accessing an Active Directory object that has its own system access control list (SACL) specified.

By default, this value is set to no auditing in the Default Domain Controller Group Policy object (GPO), and it remains undefined for workstations and servers where it has no meaning.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when a user successfully accesses an Active Directory object that has a SACL specified. Failure audits generate an audit entry when a user unsuccessfully attempts to access an Active Directory object that has a SACL specified. To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

Note that you can set a SACL on an Active Directory object by using the **Security** tab in that object's **Properties** dialog box. This is the same as Audit object access, except that it applies only to Active Directory objects and not to file system and registry objects.

**Default**:

- Success on domain controllers.
- Undefined for a member computer.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

There is only one directory service access event, which is identical to the Object Access security event message 566.

| Directory service access events | Description |
|---|---|
| 566 | A generic object operation took place. |

For more information about security events, see Security Events on the Microsoft Windows Resource Kits Web site.

For more information, see:

- Auditing Policy
- Auditing Security Events Best practices for auditing
- Security Configuration Manager tools

# Audit logon events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit logon events**

**Description**
This security setting determines whether to audit each instance of a user logging on to or logging off from a computer.

Account logon events are generated on domain controllers for domain account activity and on local computers for local account activity. If both account logon and logon audit policy categories are enabled, logons that use a domain account generate a logon or logoff event on the workstation or server, and they generate an account logon event on the domain controller. Additionally, interactive logons to a member server or workstation that use a domain account generate a logon event on the domain controller as the logon scripts and policies are retrieved when a user logs on. For more information about account logon events, see Audit account logon events.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when a logon attempt succeeds. Failure audits generate an audit entry when a logon attempt fails.

To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

**Default**: Success.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| Logon Events | Description |
|---|---|
| 528 | A user successfully logged on to a computer. For information about the type of logon, see the Logon Types table below. |
| 529 | Logon failure. A logon attempt was made with an unknown user name or a known user name with a bad password. |
| 530 | Logon failure. A logon attempt was made user account tried to log on outside of the allowed time. |
| 531 | Logon failure. A logon attempt was made using a disabled account. |
| 532 | Logon failure. A logon attempt was made using an expired account. |
| 533 | Logon failure. A logon attempt was made by a user who is not allowed to log on at this computer. |
| 534 | Logon failure. The user attempted to log on with a type that is not allowed. |
| 535 | Logon failure. The password for the specified account has expired. |
| 536 | Logon failure. The Net Logon service is not active. |
| 537 | Logon failure. The logon attempt failed for other reasons.<br>**Note**<br>• In some cases, the reason for the logon failure may not be known. |

| | |
|---|---|
| 538 | The logoff process was completed for a user. |
| 539 | Logon failure. The account was locked out at the time the logon attempt was made. |
| 540 | A user successfully logged on to a network. |
| 541 | Main mode Internet Key Exchange (IKE) authentication was completed between the local computer and the listed peer identity (establishing a security association), or quick mode has established a data channel. |
| 542 | A data channel was terminated. |
| 543 | Main mode was terminated.<br>**Note**<br>• This might occur as a result of the time limit on the security association expiring (the default is eight hours), policy changes, or peer termination. |
| 544 | Main mode authentication failed because the peer did not provide a valid certificate or the signature was not validated. |
| 545 | Main mode authentication failed because of a Kerberos failure or a password that is not valid. |
| 546 | IKE security association establishment failed because the peer sent a proposal that is not valid. A packet was received that contained data that is not valid. |
| 547 | A failure occurred during an IKE handshake. |
| 548 | Logon failure. The security ID (SID) from a trusted domain does not match the account domain SID of the client. |
| 549 | Logon failure. All SIDs corresponding to untrusted namespaces were filtered out during an authentication across forests. |
| 550 | Notification message that could indicate a possible denial-of-service attack. |
| 551 | A user initiated the logoff process. |
| 552 | A user successfully logged on to a computer using explicit credentials while already logged on as a different user. |
| 682 | A user has reconnected to a disconnected terminal server session. |
| 683 | A user disconnected a terminal server session without logging off.<br>**Note**<br>• This event is generated when a user is connected to a terminal server session over the network. It appears on the terminal server. |

When event 528 is logged, a logon type is also listed in the event log. The following table describes each logon type.

| **Logon type** | **Logon title** | **Description** |
|---|---|---|
| 2 | Interactive | A user logged on to this computer. |
| 3 | Network | A user or computer logged on to this computer from the network. |
| 4 | Batch | Batch logon type is used by batch servers, where processes may be executing on behalf of a user without their direct intervention. |
| 5 | Service | A service was started by the Service Control Manager. |
| 7 | Unlock | This workstation was unlocked. |

| | | |
|---|---|---|
| 8 | NetworkCleartext | A user logged on to this computer from the network. The user's password was passed to the authentication package in its unhashed form. The built-in authentication packages all hash credentials before sending them across the network. The credentials do not traverse the network in plaintext (also called cleartext). |
| 9 | NewCredentials | A caller cloned its current token and specified new credentials for outbound connections. The new logon session has the same local identity, but uses different credentials for other network connections. |
| 10 | RemoteInteractive | A user logged on to this computer remotely using Terminal Services or Remote Desktop. |
| 11 | CachedInteractive | A user logged on to this computer with network credentials that were stored locally on the computer. The domain controller was not contacted to verify the credentials. |

For more information about security events, see Security Events on the Microsoft Windows Resource Kits Web site.

# Audit object access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit object access**

**Description**
This security setting determines whether to audit the event of a user accessing an object--for example, a file, folder, registry key, printer, and so forth--that has its own system access control list (SACL) specified.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when a user successfully accesses an object that has an appropriate SACL specified. Failure audits generate an audit entry when a user unsuccessfully attempts to access an object that has a SACL specified.

To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

Note that you can set a SACL on a file system object using the **Security** tab in that object's **Properties** dialog box.

**Default**: No auditing.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| Object Access Events | | Description |
|---|---|---|
| 560 | Access was granted to an already existing object. | |
| 562 | A handle to an object was closed. | |
| 563 | An attempt was made to open an object with the intent to delete it.<br>**Note**<br>• This is used by file systems when the FILE_DELETE_ON_CLOSE flag is specified in Createfile(). | |
| 564 | A protected object was deleted. | |
| 565 | Access was granted to an already existing object type. | |
| 567 | A permission associated with a handle was used.<br>**Note**<br>• A handle is created with certain granted permissions (Read, Write, and so on). When the handle is used, up to one audit is generated for each of the permissions that was used. | |
| 568 | An attempt was made to create a hard link to a file that is being audited. | |
| 569 | The resource manager in Authorization Manager attempted to create a client context. | |

| | |
|---|---|
| 570 | A client attempted to access an object.<br>**Note**<br>• An event will be generated for every attempted operation on the object. |
| 571 | The client context was deleted by the Authorization Manager application. |
| 572 | The administrator manager initialized the application. |
| 772 | The certificate manager denied a pending certificate request. |
| 773 | Certificate Services received a resubmitted certificate request. |
| 774 | Certificate Services revoked a certificate. |
| 775 | Certificate Services received a request to publish the certificate revocation list (CRL). |
| 776 | Certificate Services published the certificate revocation list (CRL). |
| 777 | A certificate request extension was made. |
| 778 | One or more certificate request attributes changed. |
| 779 | Certificate Services received a request to shutdown. |
| 780 | Certificate Services backup started. |
| 781 | Certificate Services backup completed. |
| 782 | Certificate Services restore started. |
| 783 | Certificate Services restore completed. |
| 784 | Certificate Services started. |
| 785 | Certificate Services stopped. |
| 786 | The security permissions for Certificate Services changed. |
| 787 | Certificate Services retrieved an archived key. |
| 788 | Certificate Services imported a certificate into its database. |
| 789 | The audit filter for Certificate Services changed. |
| 790 | Certificate Services received a certificate request. |
| 791 | Certificate Services approved a certificate request and issued a certificate. |
| 792 | Certificate Services denied a certificate request. |
| 793 | Certificate Services set the status of a certificate request to pending. |
| 794 | The certificate manager settings for Certificate Services changed. |
| 795 | A configuration entry changed in Certificate Services. |
| 796 | A property of Certificate Services changed. |
| 797 | Certificate Services archived a key. |
| 798 | Certificate Services imported and archived a key. |

| | |
|---|---|
| 799 | Certificate Services published the CA certificate to Active Directory. |
| 800 | One or more rows have been deleted from the certificate database. |
| 801 | Role separation enabled. |

# Audit policy change

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit policy change**

**Description**
This security setting determines whether to audit every incident of a change to user rights assignment policies, audit policies, or trust policies.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when a change to user rights assignment policies, audit policies, or trust policies is successful. Failure audits generate an audit entry when a change to user rights assignment policies, audit policies, or trust policies fails.

To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

**Default**:

- Success on domain controllers.
- No auditing on member servers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| Policy Change Events | Description |
|---|---|
| 608 | A user right was assigned. |
| 609 | A user right was removed. |
| 610 | A trust relationship with another domain was created. |
| 611 | A trust relationship with another domain was removed. |
| 612 | An audit policy was changed. |
| 613 | An Internet Protocol security (IPSec) policy agent started. |
| 614 | An IPSec policy agent was disabled. |
| 615 | An IPSec policy agent changed. |
| 616 | An IPSec policy agent encountered a potentially serious failure. |
| 617 | A Kerberos policy changed. |
| 618 | Encrypted Data Recovery policy changed. |
| 620 | A trust relationship with another domain was modified. |
| 621 | System access was granted to an account. |

| | |
|---|---|
| 622 | System access was removed from an account. |
| 623 | Per user auditing policy was set for a user.<br><br>For information about per user selective auditing, see Per-user selective auditing. |
| 625 | Per user audit policy was refreshed. |
| 768 | A collision was detected between a namespace element in one forest and a namespace element in another forest.<br><br>**Note**<br><br>• When a namespace element in one forest overlaps a namespace element in another forest, it can lead to ambiguity in resolving a name belonging to one of the namespace elements. This overlap is also called a collision. Not all parameters are valid for each entry type. For example, fields such as DNS name, NetBIOS name, and SID are not valid for an entry of type 'TopLevelName'. |
| 769 | Trusted forest information was added.<br><br>**Note**<br><br>• This event message is generated when forest trust information is updated and one or more entries are added. One event message is generated per added, deleted, or modified entry. If multiple entries are added, deleted, or modified in a single update of the forest trust information, all the generated event messages have a single unique identifier called an operation ID. This allows you to determine that the multiple generated event messages are the result of a single operation. Not all parameters are valid for each entry type. For example, parameters such as DNS name, NetBIOS name and SID are not valid for an entry of type "TopLevelName". |
| 770 | Trusted forest information was deleted.<br><br>**Note**<br><br>• See note for event 769. |
| 771 | Trusted forest information was modified.<br><br>**Note**<br><br>• See note for event 769. |
| 805 | The event log service read the security log configuration for a session. |

For more information about security events, see Security Events in the Microsoft Windows Resource Kits on the Microsoft Web site.

- Security Configuration Manager tools

# Audit privilege use

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit privilege use**

**Description**
This security setting determines whether to audit each instance of a user exercising a user right.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit this type of event at all. Success audits generate an audit entry when the exercise of a user right succeeds. Failure audits generate an audit entry when the exercise of a user right fails.

To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

**Default**: No auditing.

Audits are not generated for use of the following user rights, even if success audits or failure audits are specified for **Audit privilege use**. Enabling auditing of these user rights tend to generate many events in the security log which may impede your computer's performance. To audit the following user rights, enable the **FullPrivilegeAuditing** registry key.

- Bypass traverse checking
- Debug programs
- Create a token object
- Replace process level token
- Generate security audits
- Back up files and directories
- Restore files and directories

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| Privilege use events | Description |
|---|---|
| 576 | Specified privileges were added to a user's access token.<br>**Note**<br>• This event is generated when the user logs on. |

| | |
|---|---|
| 577 | A user attempted to perform a privileged system service operation. |
| 578 | Privileges were used on an already open handle to a protected object. |

For more information about security events, see Security Events on the Microsoft Windows Resource Kits Web site.

For more information, see:

- Auditing Policy
- Auditing Security Events Best practices for auditing
- Security Configuration Manager tools

# Audit process tracking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit process tracking**

**Description**
This security setting determines whether to audit detailed tracking information for events such as program activation, process exit, handle duplication, and indirect object access.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when the process being tracked succeeds. Failure audits generate an audit entry when the process being tracked fails.

To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

**Default**: No auditing

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| Event | Event Description |
|---|---|
| 592 | A new process was created. |
| 593 | A process exited. |
| 594 | A handle to an object was duplicated. |
| 595 | Indirect access to an object was obtained. |
| 596 | A data protection master key was backed up.<br>**Note**<br>• The master key is used by the CryptProtectData and CryptUnprotectData routines, and Encrypting File System (EFS). The master key is backed up each time a new one is created. (The default setting is 90 days.) The key is usually backed up to a domain controller. |
| 597 | A data protection master key was recovered from a recovery server. |
| 598 | Auditable data was protected. |
| 599 | Auditable data was unprotected. |
| 600 | A process was assigned a primary token. |
| 601 | A user attempted to install a service. |
| 602 | A scheduler job was created. |

# Audit system events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Vista

**Audit system events**

**Description**
This security setting determines whether to audit when a user restarts or shuts down the computer or when an event occurs that affects either the system security or the security log.

If you define this policy setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when a system event is executed successfully. Failure audits generate an audit entry when a system event is attempted unsuccessfully.

To set this value to **No auditing**, in the **Properties** dialog box for this policy setting, select the **Define these policy settings** check box and clear the **Success** and **Failure** check boxes.

**Default**:

- Success on domain controllers.
- No auditing on member servers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy\

For specific instructions about how to configure auditing policy settings, see Define or modify auditing policy settings for an event category.

| System Event Messages | Description |
|---|---|
| 512 | Windows is starting up. |
| 513 | Windows is shutting down. |
| 514 | An authentication package was loaded by the Local Security Authority. |
| 515 | A trusted logon process has registered with the Local Security Authority. |
| 516 | Internal resources allocated for the queuing of security event messages have been exhausted, leading to the loss of some security event messages. |
| 517 | The audit log was cleared. |
| 518 | A notification package was loaded by the Security Accounts Manager. |
| 519 | A process is using an invalid local procedure call (LPC) port in an attempt to impersonate a client and reply or read from or write to a client address space. |
| 520 | The system time was changed.<br>**Note**<br>• This audit normally appears twice. |

For more information about security events, see Security Events on the Microsoft Windows Resource Kits Web site.

For more information, see:

- Auditing Policy
- Auditing Security Events Best practices
- Security Configuration Manager tools

# User Rights Assignment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User rights assignment**
This section covers:

- Access this computer from the network
- Act as part of the operating system
- Add workstations to domain
- Adjust memory quotas for a process
- Allow log on locally
- Allow log on through Terminal Services
- Back up files and directories
- Bypass traverse checking
- Change the system time
- Create a pagefile
- Create a token object
- Create global objects
- Create permanent shared objects
- Debug programs
- Deny access to this computer from the network
- Deny log on as a batch job
- Deny log on as a service
- Deny log on locally
- Deny log on through Terminal Services
- Enable computer and user accounts to be trusted for delegation
- Force shutdown from a remote system
- Generate security audits
- Impersonate a client after authentication
- Increase scheduling priority

- Load and unload device drivers
- Lock pages in memory
- Log on as a batch job
- Log on as a service
- Manage auditing and security log
- Modify firmware environment values
- Perform volume maintenance tasks
- Profile single process
- Profile system performance
- Remove computer from docking station
- Replace a process level token
- Restore files and directories
- Shut down the system
- Synchronize directory service data
- Take ownership of files or other objects

# Access this computer from the network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Access this computer from the network**

**Description**
This user right determines which users and groups are allowed to connect to the computer over the network. Terminal Services are not affected by this user right.

**Default:**

- On workstations and servers:
    - Administrators
    - Backup Operators
    - Power Users
    - Users
    - Everyone
- On domain controllers:
    - Administrators
    - Authenticated Users
    - Everyone

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Act as part of the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Act as part of the operating system**

**Description**
This user right allows a process to impersonate any user without authentication. The process can therefore gain access to the same local resources as that user.

Processes that require this privilege should use the *LocalSystem* account, which already includes this privilege, rather than using a separate user account with this privilege specially assigned. If your organization only uses servers that are members of the Windows Server 2003 family, you do not need to assign this privilege to your users. However, if your organization uses servers running Windows 2000 or Windows NT 4.0, you might need to assign this privilege to use applications that exchange passwords in plaintext.

**Caution**

- Assigning this user right can be a security risk. Only assign this user right to trusted users.

**Default:** Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and opening the following folder in the console tree: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Add workstations to domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Add workstations to domain**

**Description**
This security setting determines which groups or users can add workstations to a domain.

This security setting is valid only on domain controllers. By default, any authenticated user has this right and can create up to 10 computer accounts in the domain.

Adding a computer account to the domain allows the computer to participate in Active Directory-based networking. For example, adding a workstation to a domain enables that workstation to recognize accounts and groups that exist in Active Directory.

**Default:** Authenticated Users on domain controllers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Note**

- Users who have the Create Computer Objects permission on the Active Directory computers container can also create computer accounts in the domain. The distinction is that users with permissions on the container are not restricted to the creation of only 10 computer accounts. In addition, computer accounts that are created by means of **Add workstations to domain** have Domain Administrators as the owner of the computer account, while computer accounts that are created by means of permissions on the computers container have the creator as the owner of the computer account. If a user has permissions on the container and also has the **Add workstations to domain** user right, the computer is added, based on the computer container permissions rather than on the user right.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Adjust memory quotas for a process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adjust memory quotas for a process**

**Description**
This privilege determines who can change the maximum memory that can be consumed by a process.

This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.

**Note**

- This privilege is useful for system tuning, but it can be misused, for example, in a denial-of-service attack.

**Default:** Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Allow log on locally

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Allow log on locally**

**Description**
This logon right determines which users can interactively log on to this computer. Logons initiated by pressing CTRL+ALT+DEL sequence on the attached keyboard requires the user to have this logon right. Additionally this logon right may be required by some service or administrative applications that can log on users. If you define this policy for a user or group, you must also give the **Administrators** group this right.

**Default:**

- On workstations and servers: Administrators, Backup Operators, Power Users, Users, and Guest.
- On domain controllers: Account Operators, Administrators, Backup Operators, Print Operators, and Server Operators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Deny log on locally
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Allow log on through Terminal Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Allow log on through Terminal Services**

**Description**
This security setting determines which users or groups have permission to log on as a Terminal Services client.

**Default:**

- On workstation and servers: Administrators, Remote Desktop Users.
- On domain controllers: Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This setting does not have any effect on Windows 2000 computers that have not been updated to Service Pack 2.

For more information, see:

- Deny log on through Terminal Services
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Back up files and directories

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Back up files and directories**

**Description**
This user right determines which users can bypass file and directory, registry, and other persistent object permissions for the purposes of backing up the system.

Specifically, this user right is similar to granting the following permissions to the user or group in question on all files and folders on the system:

- Traverse Folder/Execute File
- List Folder/Read Data
- Read Attributes
- Read Extended Attributes
- Read Permissions

**Caution**

- Assigning this user right can be a security risk. Since there is no way to be sure that a user is backing up data, stealing data, or copying data to be distributed, only assign this user right to trusted users.

**Default:** Administrators and Backup Operators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Restore files and directories
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Bypass traverse checking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Bypass traverse checking**

**Description**
This user right determines which users can traverse directory trees even though the user may not have permissions on the traversed directory. This privilege does not allow the user to list the contents of a directory, only to traverse directories.

This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.

**Default:**

- On workstations and servers:
    - Administrators
    - Backup Operators
    - Power Users
    - Users
    - Everyone
- On domain controllers:
    - Administrators
    - Authenticated Users

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Change the system time

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Change the system time**

**Description**
This user right determines which users and groups can change the time and date on the internal clock of the computer. Users that are assigned this user right can affect the appearance of event logs. If the system time is changed, events that are logged will reflect this new time, not the actual time that the events occurred.

This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.

**Default:**

- On workstations and servers:
    - Administrators
    - Power Users
- On domain controllers:
    - Administrators
    - Server Operators

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Create a pagefile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create a pagefile**

**Description**
This user right determines which users and groups can call an internal application programming interface (API) to create a page file. This user right is used internally by the operating system and usually does not need to be assigned to any users.

For information about how to specify a paging file size for a given drive, see Change the size of the virtual memory paging file.

**Default:** Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Create a token object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create a token object**

**Description**
This security setting determines which accounts can be used by processes to create a token that can then be used to get access to any local resources when the process uses an internal application programming interface (API) to create an access token.

This user right is used internally by the operating system. Unless it is necessary, do not assign this user right to a user, group, or process other than *Local System*.

**Caution**

- Assigning this user right can be a security risk. Do not assign this user right to any user, group, or process that you do not want to take over the system.

**Default:** Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Create global objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create global objects**

**Description**
This user right is required for a user account to create global objects during Terminal Services sessions. Users can still create session-specific objects without being assigned this user right.

**Caution**

- Assigning this user right can be a security risk. Assign this user right only to trusted users.

**Default:**

- Administrators
- Local System
- Services

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Create permanent shared objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create permanent shared objects**

**Description**
This user right determines which accounts can be used by processes to create a directory object in the Windows 2000 Server, Windows 2000 Professional, Windows XP Professional, and Windows Server 2003 family object manager.

This user right is used internally by the operating system and is useful to kernel-mode components that extend the Windows 2000 Server, Windows 2000 Professional, Windows XP Professional, and Windows Server 2003 family object namespace. Because components that are running in kernel mode already have this user right assigned to them, it is not necessary to specifically assign it.

**Default:** Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Debug programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Debug programs**

**Description**
This user right determines which users can attach a debugger to any process or to the kernel. Developers who are debugging their own applications to not need to be assigned this user right. Developers who are debugging new system components will need this user right to be able to do so. This user right provides complete access to sensitive and critical operating system components.

### Caution

- Assigning this user right can be a security risk. Only assign this user right to trusted users.

### Default:

- Administrators
- Local System

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Deny access to this computer from the network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deny access to this computer from the network**

**Description**
This security setting determines which users are prevented from accessing a computer over the network. This policy setting supersedes the Access this computer from the network policy setting if a user account is subject to both policies.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Deny log on as a batch job

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deny log on as a batch job**

**Description**
This security setting determines which accounts are prevented from being able to log on as a batch job. This policy setting supersedes the Log on as a batch job policy setting if a user account is subject to both policies.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Deny log on as a service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deny log on as a service**

**Description**
This security setting determines which service accounts are prevented from registering a process as a service. This policy setting supersedes the Log on as a service policy setting if an account is subject to both policies.

**Note**

- This security setting does not apply to the System, Local Service, or Network Service accounts.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Deny log on locally

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deny log on locally**

**Description**
This security setting determines which users are prevented from logging on at the computer. This policy setting supersedes the Allow log on locally policy setting if an account is subject to both policies.

**Important**

- If you apply this security policy to the Everyone group, no one will be able to log on locally.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Deny log on through Terminal Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deny log on through Terminal Services**

**Description**
This security setting determines which users and groups are prohibited from logging on as a Terminal Services client.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This setting does not have any effect on Windows 2000 computers that have not been updated to Service Pack 2.

For more information, see:

- Allow log on through Terminal Services
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Enable computer and user accounts to be trusted for delegation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enable computer and user accounts to be trusted for delegation**

**Description**
This security setting determines which users can set the **Trusted for Delegation** setting on a user or computer object.

The user or object that is granted this privilege must have write access to the account control flags on the user or computer object. A server process running on a computer (or under a user context) that is trusted for delegation can access resources on another computer using delegated credentials of a client, as long as the client account does not have the **Account cannot be delegated** account control flag set.

This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.

**Caution**

- Misuse of this user right, or of the **Trusted for Delegation** setting, could make the network vulnerable to sophisticated attacks using Trojan horse programs that impersonate incoming clients and use their credentials to gain access to network resources.

**Default:** Administrators on domain controllers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Allow a computer to be trusted for delegation
- Allow a user to be trusted for delegation
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Force shutdown from a remote system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Force shutdown from a remote system**

**Description**
This security setting determines which users are allowed to shut down a computer from a remote location on the network. Misuse of this user right can result in a denial of service.

This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.

**Default:**

- On workstations and servers: Administrators.
- On domain controllers: Administrators, Server Operators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Shut down the system
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Generate security audits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Generate security audits**

**Description**
This security setting determines which accounts can be used by a process to add entries to the security log. The security log is used to trace unauthorized system access. Misuse of this user right can result in the generation of many auditing events, potentially hiding evidence of an attack or causing a denial of service if the **Audit: Shut down system immediately if unable to log security audits** security policy setting is enabled. For more information about the Audit: Shut down system immediately if unable to log security audits security policy setting, see Audit: Shut down system immediately if unable to log security audits

**Default:** Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Manage auditing and security log
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Impersonate a client after authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Impersonate a client after authentication**

**Description**
Assigning this privilege to a user allows programs running on behalf of that user to impersonate a client. Requiring this user right for this kind of impersonation prevents an unauthorized user from convincing a client to connect (for example, by remote procedure call (RPC) or named pipes) to a service that they have created and then impersonating that client, which can elevate the unauthorized user's permissions to administrative or system levels.

### Caution

- Assigning this user right can be a security risk. Only assign this user right to trusted users.

### Default:

- Administrators
- Service

### Note

- By default, services that are started by the Service Control Manager have the built-in Service group added to their access tokens. Component Object Model (COM) servers that are started by the COM infrastructure and that are configured to run under a specific account also have the Service group added to their access tokens. As a result, these services get this user right when they are started.

  In addition, a user can also impersonate an access token if any of the following conditions exist.

  - The access token that is being impersonated is for this user.
  - The user, in this logon session, created the access token by logging on to the network with explicit credentials.
  - The requested level is less than Impersonate, such as Anonymous or Identify.

  Because of these factors, users do not usually need this user right.

  For more information, search for "SeImpersonatePrivilege" in the Microsoft Platform SDK.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Increase scheduling priority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Increase scheduling priority**

**Description**
This security setting determines which accounts can use a process with Write Property access to another process to increase the execution priority assigned to the other process. A user with this privilege can change the scheduling priority of a process through the Task Manager user interface.

**Default:** Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Load and unload device drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Load and unload device drivers**

**Description**
This user right determines which users can dynamically load and unload device drivers or other code in to kernel mode. This user right does not apply to Plug and Play device drivers. It is recommended that you do not assign this privilege to other users. Instead, use the `StartService()` API.

### Caution

- Assigning this user right can be a security risk. Do not assign this user right to any user, group, or process that you do not want to take over the system.

**Default:** Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Lock pages in memory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Lock pages in memory**

**Description**
This security setting determines which accounts can use a process to keep data in physical memory, which prevents the system from paging the data to virtual memory on disk. Exercising this privilege could significantly affect system performance by decreasing the amount of available random access memory (RAM).

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Log on as a batch job

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Log on as a batch job**

**Description**
This security setting allows a user to be logged on by means of a batch-queue facility.

For example, when a user submits a job by means of the task scheduler, the task scheduler logs that user on as a batch user rather than as an interactive user.

**Note**

- In Windows 2000 Server, Windows 2000 Professional, Windows XP Professional, and Windows Server 2003, the Task Scheduler automatically grants this right as necessary. The Task Scheduler injects this right for the user into the computer's effective policy immediately after the task is scheduled. If there is a contradictory group policy defining the **Logon as a batch job** user right, the effective policy settings will be overwritten by the group policy only upon policy refresh.

**Default:** Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Deny log on as a batch job
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Log on as a service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Log on as a service**

**Description**
This security setting determines which service accounts can register a process as a service.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Deny log on as a service
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Manage auditing and security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage auditing and security log**

**Description**
This security setting determines which users can specify object access auditing options for individual resources, such as files, Active Directory objects, and registry keys.

This security setting does not allow a user to enable file and object access auditing in general. For such auditing to be enabled, the Audit object access setting in Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policies must be configured.

You can view audited events in the security log of the Event Viewer. A user with this privilege can also view and clear the security log.

**Default:** Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Modify firmware environment values

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modify firmware environment values**

**Description**
This security setting determines who can modify firmware environment values. Firmware environment variables are settings stored in the nonvolatile RAM of non-x86-based computers. The effect of the setting depends on the processor.

- On x86-based computers, the only firmware environment value that can be modified by assigning this user right is the Last Known Good Configuration setting, which should only be modified by the system.
- On x64-based computers, boot information is stored in nonvolatile RAM. Users must be assigned this user right to run **bootcfg.exe** and to change the Default Operating System setting on **Startup and Recovery** in **System Properties**.
- On all computers, this user right is required to install or upgrade Windows.

**Note**

- This security setting does not affect who can modify the system environment variables and user environment variables that are displayed on the **Advanced** tab of **System Properties**. For information about how to modify these variables, see Add or change the values of environment variables.

**Default:** Administrators, Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Bootcfg
- Assign user rights for your local computer
- Security Configuration Manager tools

# Perform volume maintenance tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Perform volume maintenance tasks**

**Description**

This security setting determines which users and groups can run maintenance tasks on a volume, such as remote defragmentation.

Use caution when assigning this user right. Users with this user right can explore disks and extend files in to memory that contains other data. When the extended files are opened, the user might be able to read and modify the acquired data.

**Default:** Administrators

**Configuring this security setting**

You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignments\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Profile single process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Profile single process**

**Description**
This security setting determines which users can use performance monitoring tools to monitor the performance of nonsystem processes.

**Default:** Administrators, Power users, Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Profile system performance
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Profile system performance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Profile system performance**

**Description**
This security setting determines which users can use performance monitoring tools to monitor the performance of system processes.

**Default:** Administrators, Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Profile single process
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Remove computer from docking station

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remove computer from docking station**

**Description**
This security setting determines whether a user can undock a portable computer from its docking station without logging on.

If this policy is enabled, the user must log on before removing the portable computer from its docking station. If this policy is disabled, the user may remove the portable computer from its docking station without logging on.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Replace a process level token

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Replace a process level token**

**Description**
This security setting determines which user accounts can call the `CreateProcessAsUser()` application programming interface (API) so that one service can start another. An example of a process that uses this user right is Task Scheduler. For information about Task Scheduler, see Task Scheduler overview.

**Default:** Network Service, Local System.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Restore files and directories

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restore files and directories**

**Description**
This security setting determines which users can bypass file, directory, registry, and other persistent objects permissions when restoring backed up files and directories, and determines which users can set any valid security principal as the owner of an object.

Specifically, this user right is similar to granting the following permissions to the user or group in question on all files and folders on the system:

- Traverse Folder/Execute File
- Write

### Caution

- Assigning this user right can be a security risk. Since users with this user right can overwrite registry settings, hide data, and gain ownership of system objects, only assign this user right to trusted users.

### Default:

- Workstations and servers: Administrators, Backup Operators.
- Domain controllers: Administrators, Backup Operators, Server Operators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Back up files and directories
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Shut down the system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shut down the system**

**Description**
This security setting determines which users who are logged on locally to the computer can shut down the operating system using the **Shut Down** command. Misuse of this user right can result in a denial of service.

**Default:**

- Workstations: Administrators, Backup Operators, Power Users, Users.
- Servers: Administrators, Backup Operators, Power Users.
- Domain controllers: Administrators, Backup Operators, Server Operators, Print Operators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Force shutdown from a remote system
- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Synchronize directory service data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Synchronize directory service data**

**Description**
This security setting determines which users and groups have the authority to synchronize all directory service data. This is also known as Active Directory synchronization.

**Defaults:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Take ownership of files or other objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Take ownership of files or other objects**

**Description**
This security setting determines which users can take ownership of any securable object in the system, including Active Directory objects, files and folders, printers, registry keys, processes, and threads.

**Caution**

- Assigning this user right can be a security risk. Since owners of objects have full control of them, only assign this user right to trusted users.

**Default:** Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- User Rights Assignment
- Assign user rights for your local computer
- Security Configuration Manager tools

# Security Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security options**
This section covers:

- Accounts: Administrator account status
- Accounts: Guest account status
- Accounts: Limit local account use of blank passwords to console logon only
- Accounts: Rename administrator account
- Accounts: Rename guest account
- Audit: Audit the access of global system objects
- Audit: Audit the use of Backup and Restore privilege
- Audit: Shut down system immediately if unable to log security audits
- Devices: Allow undock without having to log on
- Devices: Allowed to format and eject removable media
- Devices: Prevent users from installing printer drivers
- Devices: Restrict CD-ROM access to locally logged-on user only
- Devices: Restrict floppy access to locally logged-on user only
- Devices: Unsigned driver installation behavior
- Domain controller: Allow server operators to schedule tasks
- Domain controller: LDAP server signing requirements
- Domain controller: Refuse machine account password changes
- Domain member: Digitally encrypt or sign secure channel data (always)
- Domain member: Digitally encrypt secure channel data (when possible)
- Domain member: Digitally sign secure channel data (when possible)
- Domain member: Maximum machine account password age
- Domain member: Require strong (Windows 2000 or later) session key
- Domain member: Disable machine account password changes
- Interactive logon: Do not display last user name

- Interactive logon: Do not require CTRL+ALT+DEL
- Interactive logon: Message text for users attempting to log on
- Interactive logon: Message title for users attempting to log on
- Interactive logon: Number of previous logons to cache (in case domain controller is not available)
- Interactive logon: Prompt user to change password before expiration
- Interactive logon: Require Domain Controller authentication to unlock
- Interactive logon: Require smart card
- Interactive logon: Smart card removal behavior
- Microsoft network client: Digitally sign communications (always)
- Microsoft network client: Digitally sign communications (if server agrees)
- Microsoft network client: Send unencrypted password to connect to third-party SMB servers
- Microsoft network server: Amount of idle time required before suspending session
- Microsoft network server: Digitally sign communications (always)
- Microsoft network server: Digitally sign communications (if client agrees)
- Microsoft network server: Disconnect clients when logon hours expire
- Network access: Allow anonymous SID/Name translation
- Network access: Do not allow anonymous enumeration of SAM accounts
- Network access: Do not allow anonymous enumeration of SAM accounts and shares
- Network access: Do not allow storage of credentials or .NET Passports for network authentication
- Network access: Let Everyone permissions apply to anonymous users
- Network access: Named pipes that can be accessed anonymously
- Network access: Remotely accessible registry paths
- Network access: Remotely accessible registry paths and subpaths
- Network access: Restrict anonymous access to Named Pipes and Shares
- Network access: Shares that can be accessed anonymously
- Network access: Sharing and security model for local accounts
- Network security: Do not store LAN Manager hash value on next password change

- Network security: Force logoff when logon hours expire
- Network security: LAN Manager authentication level
- Network security: LDAP client signing requirements
- Network security: Minimum session security for NTLM SSP based (including secure RPC) clients
- Network security: Minimum session security for NTLM SSP based (including secure RPC) servers
- Recovery console: Allow automatic administrative logon
- Recovery console: Allow floppy copy and access to all drives and all folders
- Shutdown: Allow system to be shut down without having to log on
- Shutdown: Clear virtual memory pagefile
- System cryptography: Force strong key protection for user keys stored on the computer
- System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing
- System objects: Default owner for objects created by members of the Administrators group
- System objects: Require case insensitivity for non-Windows subsystems
- System objects: Strengthen default permissions of internal system objects (e.g., Symbolic Links)
- System settings: Optional subsystems
- System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies

# Accounts: Administrator account status

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accounts: Administrator account status**

**Description**
This security setting determines whether the local Administrator account is enabled or disabled.

### Notes

- If you try to reenable the Administrator account after it has been disabled, and if the current Administrator password does not meet the password requirements, you cannot reenable the account. In this case, an alternative member of the Administrators group must reset the password on the Administrator account. For information about how to reset a password, see Reset a password.

- Disabling the Administrator account can become a maintenance issue under certain circumstances. For example, in a domain environment, if the secure channel that constitutes your join fails for any reason, and there is no other local Administrator account, you must restart in Safe Mode to fix the problem that is causing your join status to be broken.

- Under Safe Mode boot, the Administrator account is always enabled, regardless of this setting.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Options

- Security Configuration Manager tools

# Accounts: Guest account status

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accounts: Guest account status**

**Description**
This security setting determines if the Guest account is enabled or disabled.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Note**

- If the Guest account is disabled and the security option **Network Access: Sharing and Security Model for local accounts** is set to **Guest Only**, network logons, such as those performed by the Microsoft Network Server (SMB Service), will fail.

For more information, see:

- Network access: Sharing and security model for local accounts
- Security Configuration Manager tools

# Accounts: Limit local account use of blank passwords to console logon only

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accounts: Limit local account use of blank passwords to console logon only**

**Description**
This security setting determines whether local accounts that are not password protected can be used to logon from locations other than the physical computer console. If enabled, then local accounts that are not password protected will only be able to log on at the computer's keyboard. This security setting does not apply to guest accounts.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

### Caution

- Computers that are not in physically secure locations should always enforce strong password policies for all local user accounts. Otherwise, anyone with physical access to the computer can log on using a user account that does not have a password. This is especially important for portable computers.
- If you apply this security policy to the Everyone group, no one will be able to log on through terminal services.

### Notes

- This setting does not affect logons that use domain accounts.
- It is possible for applications that use remote interactive logons to bypass this setting.

For more information, see:

- Security Configuration Manager tools

# Accounts: Rename administrator account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accounts: Rename administrator account**

**Description**
This security setting determines whether a different account name is associated with the security identifier (SID) for the account **Administrator**. Because the Administrator account is known to exist on all computers running Windows 2000 Server, Windows 2000 Professional, Windows XP Professional, and the Windows Server 2003 family, renaming the account makes it slightly more difficult for unauthorized persons to guess this privileged user name and password combination.

**Default:** Administrator.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Accounts: Rename guest account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accounts: Rename guest account**

**Description**
This security setting determines whether a different account name is associated with the security identifier (SID) for the account "Guest." Because the Guest account is known to exist on all computers running Windows 2000 Server, Windows 2000 Professional, Windows XP Professional, and the Windows Server 2003 family, renaming the account makes it slightly more difficult for unauthorized persons to guess this user name and password combination.

**Default:** Guest.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Audit: Audit the access of global system objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Audit: Audit the access of global system objects**

**Description**
This security setting determines whether to audit the access of global system objects.

If this policy is enabled, it causes system objects, such as mutexes (mutual exclusive), events, semaphores (locking mechanisms used inside resource managers or resource dispensers), and DOS devices, to be created with a default system access control list (SACL). If the Audit object access audit policy is also enabled, access to these system objects is audited.

**Note**

- When configuring this security setting, changes will not take effect until you restart Windows.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Audit: Audit the use of Backup and Restore privilege

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Audit: Audit the use of Backup and Restore privilege**

**Description**
This security setting determines whether to audit the use of all user privileges, including Backup and Restore, when the Audit privilege use policy is in effect. Enabling this option when the **Audit privilege use** policy is also enabled generates an audit event for every file that is backed up or restored.

If you disable this policy, then use of the Backup or Restore privilege is not audited even when **Audit privilege use** is enabled.

**Note**

- When configuring this security setting, changes will not take effect until you restart Windows.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Audit: Shut down system immediately if unable to log security audits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Audit: Shut down system immediately if unable to log security audits**

**Description**
This security setting determines whether the system shuts down if it is unable to log security events.

If this security setting is enabled, it causes the system to stop if a security audit cannot be logged for any reason. Typically, an event fails to be logged when the security audit log is full and the retention method that is specified for the security log is either **Do Not Overwrite Events** or **Overwrite Events by Days**.

If the security log is full and an existing entry cannot be overwritten, and this security option is enabled, the following Stop error appears:

**STOP: C0000244 {Audit Failed}**

**An attempt to generate a security audit failed.**

To recover, an administrator must log on, archive the log (optional), clear the log, and reset this option as desired. Until this security setting is reset, no users, other than a member of the Administrators group will be able to log on to the system, even if the security log is not full.

**Note**

- When configuring this security setting, changes will not take effect until you restart Windows.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Auditing Security Events
- Security Configuration Manager tools

# Devices: Allow undock without having to log on

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Devices: Allow undock without having to log on**

**Description**
This security setting determines whether a portable computer can be undocked without having to log on. If this policy is enabled, logon is not required and an external hardware eject button can be used to undock the computer. If disabled, a user must log on and have the **Remove computer from docking station** privilege to undock the computer.

**Default**: Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Caution**

- Disabling this policy may tempt users to try and physically remove the laptop from its docking station using methods other than the external hardware eject button. Since this may cause damage to the hardware, this setting, in general, should only be disabled on laptop configurations that are physically securable.

For more information, see:

- Security Configuration Manager tools
- Remove computer from docking station

# Devices: Allowed to format and eject removable media

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Devices: Allowed to format and eject removable media**

**Description**
This security setting determines who is allowed to format and eject removable NTFS media. This capability can be given to:

- Administrators
- Administrators and Power Users
- Administrators and Interactive Users

**Default**: Administrators.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Devices: Prevent users from installing printer drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Devices: Prevent users from installing printer drivers**

**Description**
For a computer to print to a network printer, the driver for that network printer must be installed on the local computer. This security setting determines who is allowed to install a printer driver as part of adding a network printer. If this setting is enabled, only Administrators and Power Users can install a printer driver as part of adding a network printer. If this setting is disabled, any user can install a printer driver as part of adding a network printer.

### Default:

- Enabled on servers.
- Disabled on workstations.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

### Notes

- This setting does not affect the ability to add a local printer.
- This setting does not affect Power Users or Administrators.

For more information, see:

- Security Configuration Manager tools

# Devices: Restrict CD-ROM access to locally logged-on user only

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Devices: Restrict CD-ROM access to locally logged-on user only**

**Description**
This security setting determines whether a CD-ROM is accessible to both local and remote users simultaneously.

If this policy is enabled, it allows only the interactively logged-on user to access removable CD-ROM media. If this policy is enabled and no one is logged on interactively, the CD-ROM can be accessed over the network.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Devices: Restrict floppy access to locally logged-on user only

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Devices: Restrict floppy access to locally logged-on user only**

**Description**
This security setting determines whether removable floppy media are accessible to both local and remote users simultaneously.

If this policy is enabled, it allows only the interactively logged-on user to access removable floppy media. If this policy is enabled and no one is logged on interactively, the floppy can be accessed over the network.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Devices: Unsigned driver installation behavior

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Devices: Unsigned driver installation behavior**

**Description**
This security setting determines what happens when an attempt is made to install a device driver (by means of Setup API) that has not been tested by the Windows Hardware Quality Lab (WHQL).

The options are:

- **Silently succeed**
- **Warn but allow installation**
- **Do not allow installation**

**Default: Warn but allow installation**.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Domain controller: Allow server operators to schedule tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain controller: Allow server operators to schedule tasks**

**Description**
This security setting determines if Server Operators are allowed to submit jobs by means of the AT schedule facility.

### Note

- This security setting only affects the AT schedule facility; it does not affect the Task Scheduler facility.

**Default:** This policy is not defined, which means that the system treats it as disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Domain controller: LDAP server signing requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain controller: LDAP server signing requirements**

**Description**
This security setting determines whether the LDAP server requires signing to be negotiated with LDAP clients, as follows:

- **None:** Data signing is not required in order to bind with the server. If the client requests data signing, the server supports it.

- **Require signature:** Unless TLS\SSL is being used, the LDAP data signing option must be negotiated.

**Default:** Not defined, which has the same effect as **None**.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Caution**

- If you set the server to **Require Signature,** you must also set the client. Not setting the client results in loss of connection with the server.

**Notes**

- This setting does not have any impact on ldap_simple_bind or ldap_simple_bind_s. No Microsoft LDAP clients that are shipped with Windows XP Professional use ldap_simple_bind or ldap_simple_bind_s to talk to a domain controller.

- If signing is required, then ldap_simple_bind and ldap_simple_bind_s requests are rejected. No Microsoft LDAP clients running Windows XP Professional or the Windows Server 2003 family use ldap_simple_bind or ldap_simple_bind_s to bind to directory service.

For more information, see:

- Security Configuration Manager tools

# Domain controller: Refuse machine account password changes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain controller: Refuse machine account password changes**

## Description

This security setting determines whether domain controllers will refuse requests from member computers to change computer account passwords. By default, member computers change their computer account passwords every 30 days. If enabled, the domain controller will refuse computer account password change requests.

If it is enabled, this setting does not allow a domain controller to accept *any* changes to a computer account's password.

**Default:** Disabled.

**Configuring this security setting**

You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Domain member: Maximum machine account password age
- Domain member: Disable machine account password changes
- Security Configuration Manager tools

# Domain member: Digitally encrypt or sign secure channel data (always)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain member: Digitally encrypt or sign secure channel data (always)**

**Description**
This security setting determines whether all secure channel traffic initiated by the domain member must be signed or encrypted.

When a computer joins a domain, a computer account is created. After that, when the system starts, it uses the computer account password to create a secure channel with a domain controller for its domain. This secure channel is used to perform operations such as NTLM pass through authentication, LSA SID\Name Lookup etc.

This setting determines whether or not all secure channel traffic initiated by the domain member meets minimum security requirements. Specifically it determines whether all secure channel traffic initiated by the domain member must be signed or encrypted. If this policy is enabled, then the secure channel will not be established unless either signing or encryption of all secure channel traffic is negotiated. If this policy is disabled, then encryption and signing of all secure channel traffic is negotiated with the Domain Controller in which case the level of signing and encryption depends on the version of the Domain Controller and the settings of the following two policies:

- Domain member: Digitally encrypt secure channel data (when possible)
- Domain member: Digitally sign secure channel data (when possible)

**Default**: Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- In order to take advantage of this policy on member workstations and servers, all domain controllers that constitute the member's domain must be running Windows NT 4.0 Service Pack 6 or higher.
- In order to take advantage of this policy on domain controllers, *All* domain controllers in the same domain, as well as all trusted domains, must be running Windows NT 4.0 Service Pack 6 or higher.

**Notes**

- If this policy is enabled, the policy **Domain member: Digitally sign secure channel data (when possible)** is assumed to be enabled regardless of its current setting. This ensures that the domain member attempts to negotiate at least signing of the secure channel traffic.
- If this policy is enabled, the policy **Domain member: Digitally sign secure channel data (when possible)** is assumed to be enabled regardless of its current setting. This ensures that the domain member attempts to negotiate at least signing of the secure channel traffic.
- Logon information transmitted over the secure channel is always encrypted regardless of whether encryption of ALL other secure channel traffic is negotiated or not.

For more information, see:

- Domain member: Digitally encrypt secure channel data (when possible)
- Domain member: Digitally sign secure channel data (when possible)
- Domain member: Require strong (Windows 2000 or later) session key
- Security Configuration Manager tools

# Domain member: Digitally encrypt secure channel data (when possible)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain member: Digitally encrypt secure channel data (when possible)**

**Description**
This security setting determines whether a domain member attempts to negotiate encryption for all secure channel traffic that it initiates.

When a computer joins a domain, a computer account is created. After that, when the system starts, it uses the computer account password to create a secure channel with a domain controller for its domain. This secure channel is used to perform operations such as NTLM passthrough authentication, LSA SID\Name Lookup etc.

This setting determines whether or not the domain member attempts to negotiate encryption for all secure channel traffic that it initiates. If enabled, the domain member will request encryption of all secure channel traffic. If the domain controller supports encryption of all secure channel traffic (Windows NT 4.0 Service Pack 6 or higher), then all secure channel traffic will be encrypted. Otherwise only logon information transmitted over the secure channel will be encrypted. If this setting is disabled, then the domain member will not attempt to negotiate secure channel encryption.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- There is no known reason for disabling this setting. Besides unnecessarily reducing the potential confidentiality level of the secure channel, disabling this setting may unnecessarily reduce secure channel throughput, because concurrent API calls that use the secure channel are only possible when the secure channel is signed or encrypted.

**Note**

- Domain controllers are also domain members and establish secure channels with other domain controllers in the same domain as well as domain controllers in trusted domains.

For more information, see:

- Domain member: Digitally encrypt or sign secure channel data (always)
- Domain member: Digitally sign secure channel data (when possible)
- Domain member: Require strong (Windows 2000 or later) session key
- Security Configuration Manager tools

# Domain member: Digitally sign secure channel data (when possible)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain member: Digitally sign secure channel data (when possible)**

**Description**
This security setting determines whether a domain member attempts to negotiate signing for all secure channel traffic that it initiates.

When a computer joins a domain, a computer account is created. After that, when the system starts, it uses the computer account password to create a secure channel with a domain controller for its domain. This secure channel is used to perform operations such as NTLM pass through authentication, LSA SID\Name Lookup etc.

This setting determines whether or not the domain member attempts to negotiate signing for all secure channel traffic that it initiates. If enabled, the domain member will request signing of all secure channel traffic. If the Domain Controller supports signing of all secure channel traffic (Windows NT 4.0 Service Pack 6 or higher), then all secure channel traffic will be signed which ensures that it cannot be tampered with in transit.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Notes**

- If the policy **Domain member: Digitally encrypt or sign secure channel data (always) is enabled**, then this policy is assumed to be enabled regardless of its current setting.
- Domain controllers are also domain members and establish secure channels with other domain controllers in the same domain as well as domain controllers in trusted domains.

For more information, see:

- Domain member: Digitally encrypt or sign secure channel data (always)
- Domain member: Digitally encrypt secure channel data (when possible)
- Domain member: Require strong (Windows 2000 or later) session key
- Security Configuration Manager tools

# Domain member: Maximum machine account password age

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain member: Maximum machine account password age**

**Description**
This security setting determines how often a domain member will attempt to change its computer account password.

**Default:** 30 days.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This setting applies to Windows 2000 computers, but it is not available through the Security Configuration Manager tools on these computers.

For more information, see:

- Domain controller: Refuse machine account password changes
- Domain member: Disable machine account password changes
- Security Configuration Manager tools

# Domain member: Require strong (Windows 2000 or later) session key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain member: Require strong (Windows 2000 or later) session key**

**Description**
This security setting determines whether 128-bit key strength is required for encrypted secure channel data.

When a computer joins a domain, a computer account is created. After that, when the system starts, it uses the computer account password to create a secure channel with a domain controller within the domain. This secure channel is used to perform operations such as NTLM passthrough authentication, LSA SID\Name Lookup, and so on.

Based on what version of Windows is running on the domain controller that the domain member is communicating with and the settings of the following parameters:

- Domain member: Digitally encrypt or sign secure channel data (always)
- Domain member: Digitally encrypt secure channel data (when possible)

some or all of the information that is transmitted over the secure channel will be encrypted. This policy setting determines whether or not 128-bit key strength is required for the secure channel information that is encrypted.

If this setting is enabled, then the secure channel will not be established unless 128-bit encryption can be performed. If this setting is disabled, then the key strength is negotiated with the domain controller.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- In order to take advantage of this policy on member workstations and servers, all domain controllers that constitute the member's domain must be running Windows 2000 or later.
- In order to take advantage of this policy on domain controllers, all domain controllers in the same domain as well as all trusted domains must run Windows 2000 or later.

For more information, see:

- Domain member: Digitally encrypt or sign secure channel data (always)
- Domain member: Digitally encrypt secure channel data (when possible)
- Domain member: Digitally sign secure channel data (when possible)
- Security Configuration Manager tools

# Domain member: Disable machine account password changes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain member: Disable machine account password changes**

**Description**
Determines whether a domain member periodically changes its computer account password. If this setting is enabled, the domain member does not attempt to change its computer account password. If this setting is disabled, the domain member attempts to change its computer account password as specified by the setting for **Domain Member: Maximum age for machine account password**, which by default is every 30 days.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

### Notes

- This security setting should not be enabled. Computer account passwords are used to establish secure channel communications between members and domain controllers and, within the domain, between the domain controllers themselves. Once it is established, the secure channel is used to transmit sensitive information that is necessary for making authentication and authorization decisions.

- This setting should not be used in an attempt to support dual-boot scenarios that use the same computer account. If you want to dual-boot two installations that are joined to the same domain, give the two installations different computer names.

For more information, see:

- Domain controller: Refuse machine account password changes

- Domain member: Maximum machine account password age

- Security Configuration Manager tools

# Interactive logon: Do not display last user name

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Do not display last user name**

**Description**
This security setting determines whether the name of the last user to log on to the computer is displayed in the Windows logon screen.

If this policy is enabled, the name of the last user to successfully log on is not displayed in the **Log On to Windows** dialog box.

If this policy is disabled, the name of the last user to log on is displayed.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Interactive logon: Do not require CTRL+ALT+DEL

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Do not require CTRL+ALT+DEL**

**Description**
This security setting determines whether pressing CTRL+ALT+DEL is required before a user can log on.

If this policy is enabled on a computer, a user is not required to press CTRL+ALT+DEL to log on. Not having to press CTRL+ALT+DEL leaves users susceptible to attacks that attempt to intercept the users' passwords. Requiring CTRL+ALT+DEL before users log on ensures that users are communicating by means of a trusted path when entering their passwords.

If this policy is disabled, any user is required to press CTRL+ALT+DEL before logging on to Windows (unless they are using a smart card for Windows logon).

**Default:**

- Disabled on workstations and servers that are joined to a domain.
- Enabled on stand-alone workstations.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Interactive logon: Message text for users attempting to log on

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Message text for users attempting to log on**

**Description**
This security setting specifies a text message that is displayed to users when they log on.

This text is often used for legal reasons, for example, to warn users about the ramifications of misusing company information or to warn them that their actions may be audited.

**Default**: No message.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree to: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\.

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Caution**

- Windows XP and Windows Server 2003 add support for configuring logon text that can exceed 512 characters in length and that can also contain carriage return/line feed (CR/LF) sequences. If you do not use CR/LF sequences in your logon text, the maximum number of characters that you can add is 512. If you use CR/LF sequences, you can use a maximum of four lines of 512 characters each for a total of 2,048 characters. However, Windows 2000–based client computers cannot interpret and display logon text that is created by computers running Windows XP or Windows Server 2003. You must use a Windows 2000–based computer to create a logon text policy that applies to Windows 2000–based computers. If you inadvertently create a logon text policy by using a computer running Windows XP Professional or Windows Server 2003, and you discover that it does not display properly on Windows 2000–based computers, do the following:

    - Undefine the setting.

    - Redefine the setting by using a Windows 2000–based computer.

      You cannot simply change a Windows XP Professional or a Windows Server 2003–defined logon message policy by using a Windows 2000–based computer. The setting must be undefined first.

For more information, see:

- Interactive logon: Message title for users attempting to log on

- Security Configuration Manager tools

# Interactive logon: Message title for users attempting to log on

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Message title for users attempting to log on**

**Description**
This security setting allows the specification of a title to appear in the title bar of the window that contains the Interactive logon: Message text for users attempting to log on.

**Default**: No message.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Interactive logon: Number of previous logons to cache (in case domain controller is not available)

Updated: June 17, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Number of previous logons to cache (in case domain controller is not available)**

**Description**
Determines the number of users who can have cached credentials on the computer.

All previous users' logon information is cached locally so that, in the event that a domain controller is unavailable during subsequent logon attempts, they are able to log on . If a domain controller is unavailable and a user's logon information is cached, the user is prompted with a message that reads as follows:

*Windows cannot connect to a server to confirm your logon settings. You have been logged on using previously stored account information. If you changed your account information since you last logged on to this computer, those changes will not be reflected in this session.*

If a domain controller is unavailable and a user's logon information is not cached, the user is prompted with this message:

*The system cannot log you on now because the domain <DOMAIN_NAME> is not available.*

In this policy setting, a value of 0 disables logon caching. Any value above 50 only caches 50 logon attempts.

**Default:** 10

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Interactive logon: Prompt user to change password before expiration

Updated: June 29, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Prompt user to change password before expiration**

**Description**
Determines how far in advance (in days) users are warned that their password is about to expire. With this advance warning, the user has time to construct a password that is sufficiently strong.

**Default:** 14 days.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Interactive logon: Require Domain Controller authentication to unlock

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Require Domain Controller authentication to unlock**

**Description**
Logon information must be provided to unlock a locked computer. For domain accounts, this security setting determines whether a domain controller must be contacted to unlock a computer. If this setting is disabled, a user can unlock the computer using cached credentials. If this setting is enabled, a domain controller must authenticate the domain account that is being used to unlock the computer.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This setting applies to Windows 2000 computers, but it is not available through the Security Configuration Manager tools on these computers.

For more information, see:

- Security Configuration Manager tools

# Interactive logon: Require smart card

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Require smart card**

**Description**
This security setting requires users to log on to a computer using a smart card.

The options are:

- **Enabled**. Users can only log on to the computer using a smart card.
- **Disabled**. Users can log on to the computer using any method.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This setting will apply to any computers running Windows 2000 through changes in the registry, but the security setting is not viewable through the Security Configuration Manager tool set.

For more information, see:

- Security Configuration Manager tools
- Smart Cards

# Interactive logon: Smart card removal behavior

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interactive logon: Smart card removal behavior**

**Description**
This security setting determines what happens when the smart card for a logged-on user is removed from the smart card reader.

The options are:

- **No Action**
- **Lock Workstation**
- **Force Logoff**
- **Disconnect if a remote Terminal Services session**

If you click **Lock Workstation** in the **Properties** dialog box for this policy, the workstation is locked when the smart card is removed, allowing users to leave the area, take their smart card with them, and still maintain a protected session.

If you click **Force Logoff** in the **Properties** dialog box for this policy, the user is automatically logged off when the smart card is removed.

If you click **Disconnect if a remote Terminal Services session**, removal of the smart card disconnects the session without logging the user off. This allows the user to insert the smart card and resume the session later, or at another smart card reader-equipped terminal, without having to log on again.

**Default:** No action specified.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

- Security Configuration Manager tools

# Microsoft network client: Digitally sign communications (always)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft network client: Digitally sign communications (always)**

**Description**
This security setting determines whether packet signing is required by the SMB client component.

The server message block (SMB) protocol provides the basis for Microsoft file and print sharing and many other networking operations, such as remote Windows administration. To prevent man-in-the-middle attacks that modify SMB packets in transit, the SMB protocol supports the digital signing of SMB packets. This policy setting determines whether SMB packet signing must be negotiated before further communication with an SMB server is permitted.

If this setting is enabled, the Microsoft network client will not communicate with a Microsoft network server unless that server agrees to perform SMB packet signing. If this policy is disabled, SMB packet signing is negotiated between the client and server.

**Default**: Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- For this policy to take effect on computers running Windows 2000, client-side packet signing must also be enabled. To enable client-side SMB packet signing, set **Microsoft network client: Digitally sign communications (if server agrees)**.
- Computers that have this policy set will not be able to communicate with computers that do not have server-side packet signing enabled. By default, server-side packet signing is enabled only on domain controllers running Windows 2000 and later.
- Server-side packet signing can be enabled on computers running Windows 2000 and later by setting **Microsoft network server: Digitally sign communications (if client agrees)**
- Server-side packet signing can be enabled on computers running Windows NT 4.0 Service Pack 3 and later by setting the following registry value to 1:

  **HKLM\System\CurrentControlSet\Services\LanManServer\Parameters\EnableSecuritySignature**

- Server-side packet signing cannot be enabled on computers running Windows 95 or Windows 98.

**Notes**

- All Windows operating systems support both a client-side SMB component and a server-side SMB component. To take advantage of SMB packet signing, both the client-side SMB component and server-side SMB component that are involved in a communication must have SMB packet signing either enabled or required. On Windows 2000 and later operating systems, enabling or requiring packet signing for client and server-side SMB components is controlled by the following four policy settings:
  - **Microsoft network client: Digitally sign communications (always)** - Controls whether or not the client-side SMB component requires packet signing.

    - **Microsoft network client: Digitally sign communications (if server agrees)** - Controls whether or not the client-side SMB component has packet signing enabled.

    - **Microsoft network server: Digitally sign communications (always)** - Controls whether or not the server-side SMB component requires packet signing.

    - **Microsoft network server: Digitally sign communications (if client agrees)** - Controls whether or not the server-side SMB component has packet signing enabled.

- If server-side SMB signing is required, a client will not be able to establish a session with that server, unless it has client-side SMB signing enabled. By default, client-side SMB signing is enabled on workstations, servers, and domain controllers. Similarly, if client-side SMB signing is required, that client will not be able to establish a session with servers that do not have packet signing enabled. By default, server-side SMB signing is enabled only on domain controllers.

- If server-side SMB signing is enabled, SMB packet signing will be negotiated with clients that have client-side SMB signing enabled.

- Using SMB packet signing can impose up to a 15 percent performance hit on file service transactions.

For more information, see:

- Microsoft network client: Digitally sign communications (if server agrees)

- Microsoft network server: Digitally sign communications (if client agrees)

- Microsoft network server: Digitally sign communications (always)

- Security Configuration Manager tools

# Microsoft network client: Digitally sign communications (if server agrees)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft network client: Digitally sign communications (if server agrees)**

**Description**
This security setting determines whether the SMB client attempts to negotiate SMB packet signing.

The server message block (SMB) protocol provides the basis for Microsoft file and print sharing and many other networking operations, such as remote Windows administration. To prevent man-in-the-middle attacks that modify SMB packets in transit, the SMB protocol supports the digital signing of SMB packets. This policy setting determines whether the SMB client component attempts to negotiate SMB packet signing when it connects to an SMB server.

If this setting is enabled, the Microsoft network client will ask the server to perform SMB packet signing upon session setup. If packet signing has been enabled on the server, packet signing will be negotiated. If this policy is disabled, the SMB client will never negotiate SMB packet signing.

**Default**: Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

### Notes

- All Windows operating systems support both a client-side SMB component and a server-side SMB component. To take advantage of SMB packet signing, both the client-side SMB component and server-side SMB component that are involved in a communication must have SMB packet signing either enabled or required. On Windows 2000 and later, enabling or requiring packet signing for client and server-side SMB components is controlled by the following four policy settings:

    - **Microsoft network client: Digitally sign communications (always)** - Controls whether or not the client-side SMB component requires packet signing.

    - **Microsoft network client: Digitally sign communications (if server agrees)** - Controls whether or not the client-side SMB component has packet signing enabled.

    - **Microsoft network server: Digitally sign communications (always)** - Controls whether or not the server-side SMB component requires packet signing.

    - **Microsoft network server: Digitally sign communications (if client agrees)** - Controls whether or not the server-side SMB component has packet signing enabled.

- If server-side SMB signing is required, a client will not be able to establish a session with that server unless it has client-side SMB signing enabled. By default, client-side SMB signing is enabled on workstations, servers, and domain controllers.

- Similarly, if client-side SMB signing is required, that client will not be able to establish a session with servers that do not have packet signing enabled. By default, server-side SMB signing is enabled only on domain controllers.

- If server-side SMB signing is enabled, SMB packet signing will be negotiated with clients that have client-side SMB signing enabled.

- Using SMB packet signing can degrade performance up to 15 percent on file service transactions.

For more information, see:

- Microsoft network client: Digitally sign communications (always)
- Microsoft network server: Digitally sign communications (if client agrees)
- Microsoft network server: Digitally sign communications (always)
- Security Configuration Manager tools

# Microsoft network client: Send unencrypted password to connect to third-party SMB servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft network client: Send unencrypted password to connect to third-party SMB servers**

**Description**
If this security setting is enabled, the Server Message Block (SMB) redirector is allowed to send plaintext passwords to non-Microsoft SMB servers that do not support password encryption during authentication.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Microsoft network server: Amount of idle time required before suspending session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft network server: Amount of idle time required before suspending a session**

**Description**
This security setting determines the amount of continuous idle time that must pass in a Server Message Block (SMB) session before the session is suspended due to inactivity.

Administrators can use this policy to control when a computer suspends an inactive SMB session. If client activity resumes, the session is automatically reestablished.

For this policy setting, a value of 0 means to disconnect an idle session as quickly as is reasonably possible. The maximum value is 99999, which is 208 days; in effect, this value disables the policy.

**Default:**

- 15 minutes for servers.
- Undefined for workstations.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Microsoft network server: Digitally sign communications (always)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft network server: Digitally sign communications (always)**

**Description**
This security setting determines whether packet signing is required by the SMB server component.

The server message block (SMB) protocol provides the basis for Microsoft file and print sharing and many other networking operations, such as remote Windows administration. To prevent "man-in-the-middle" attacks that modify SMB packets in transit, the SMB protocol supports the digital signing of SMB packets. This policy setting determines whether SMB packet signing must be negotiated before further communication with an SMB client is permitted.

If this setting is enabled, the Microsoft network server will not communicate with a Microsoft network client unless that client agrees to perform SMB packet signing. If this setting is disabled, SMB packet signing is negotiated between the client and server.

**Default**:

- Disabled for member servers.
- Enabled for domain controllers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Notes**

- All Windows operating systems support both a client-side SMB component and a server-side SMB component. To take advantage of SMB packet signing, both the client-side SMB component and server-side SMB component that are involved in a communication must have SMB packet signing either enabled or required. On Windows 2000 and later, enabling or requiring packet signing for client and server-side SMB components is controlled by the following four policy settings:
    - Microsoft network client: Digitally sign communications (always) - Controls whether or not the client-side SMB component requires packet signing.
    - Microsoft network client: Digitally sign communications (if server agrees) - Controls whether or not the client-side SMB component has packet signing enabled.
    - Microsoft network server: Digitally sign communications (always) - Controls whether or not the server-side SMB component requires packet signing.
    - Microsoft network server: Digitally sign communications (if client agrees) - Controls whether or not the server-side SMB component has packet signing enabled.
- If server-side SMB signing is required, a client will not be able to establish a session with that server unless it has client-side SMB signing enabled. By default, client-side SMB signing is enabled on workstations, servers, and domain controllers.
- Similarly, if client-side SMB signing is required, that client will not be able to establish a session with servers that do not have packet signing enabled. By default, server-side SMB signing is enabled only on domain controllers.

- If server-side SMB signing is enabled, SMB packet signing will be negotiated with clients that have client-side SMB signing enabled.

- Using SMB packet signing can degrade performance up to 15 percent on file service transactions.

**Important**

- For this policy to take effect on computers running Windows 2000, server-side packet signing must also be enabled. To enable server-side SMB packet signing, set the following policy:

  Microsoft network server: Digitally sign communications (if server agrees)

- For servers running Windows 2000 Server or Windows Server 2003 to negotiate signing with client computers running Windows NT 4.0 or Windows 98, the following registry value must be set to 1 on the server:

  HKLM\System\CurrentControlSet\Services\lanmanserver\parameters\enableW9xsecuritysignature

- Computers that have this policy set will not communicate with computers that do not have client-side packet signing enabled. Client-side packet signing can be enabled on computers running Windows 2000 and later by setting the following policy:

For more information, see:

- Microsoft network client: Digitally sign communications (always)

- Microsoft network client: Digitally sign communications (if server agrees)

- Microsoft network server: Digitally sign communications (if client agrees)

- Security Configuration Manager tools

# Microsoft network server: Digitally sign communications (if client agrees)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft network server: Digitally sign communications (if client agrees)**

**Description**
This security setting determines whether the SMB server will negotiate SMB packet signing with clients that request it.

The server message block (SMB) protocol provides the basis for Microsoft file and print sharing and many other networking operations, such as remote Windows administration. To prevent man-in-the-middle attacks that modify SMB packets in transit, the SMB protocol supports the digital signing of SMB packets. This policy setting determines whether the SMB server will negotiate SMB packet signing when an SMB client requests it.

If this setting is enabled, the Microsoft network server will negotiate SMB packet signing as requested by the client. That is, if packet signing has been enabled on the client, packet signing will be negotiated. If this policy is disabled, the SMB client will never negotiate SMB packet signing.

**Default**: Enabled on domain controllers only.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

### Important

- Tor Windows 2000 servers to negotiate signing with Windows NT 4.0 clients, the following registry value must be set to 1 on the server running Windows 2000:
  HKLM\System\CurrentControlSet\Services\lanmanserver\parameters\enableW9xsecuritysignature

### Notes

- All Windows operating systems support both a client-side SMB component and a server-side SMB component. To take advantage of SMB packet signing, both the client-side SMB component and server-side SMB component that are involved in a communication must have SMB packet signing either enabled or required. For Windows 2000 and above, enabling or requiring packet signing for client and server-side SMB components is controlled by the following four policy settings:

    - Microsoft network client: Digitally sign communications (always) - Controls whether or not the client-side SMB component requires packet signing.

    - Microsoft network client: Digitally sign communications (if server agrees) - Controls whether or not the client-side SMB component has packet signing enabled.

    - Microsoft network server: Digitally sign communications (always) - Controls whether or not the server-side SMB component requires packet signing.

    - Microsoft network server: Digitally sign communications (if client agrees) - Controls whether or not the server-side SMB component has packet signing enabled.

- If server-side SMB signing is required, a client will not be able to establish a session with that server unless it has client-side SMB signing enabled. By default, client-side SMB signing is enabled on workstations, servers, and domain controllers.

- Similarly, if client-side SMB signing is required, that client will not be able to establish a session with servers that do not have packet signing enabled. By default, server-side SMB signing is enabled only on domain controllers.

- If server-side SMB signing is enabled, SMB packet signing will be negotiated with clients that have client-side SMB signing enabled.

- Using SMB packet signing can impose up to a 15 percent performance hit on file service transactions.

For more information, see:

- Microsoft network client: Digitally sign communications (always)

- Microsoft network client: Digitally sign communications (if server agrees)

- Microsoft network server: Digitally sign communications (always)

- Security Configuration Manager tools

# Microsoft network server: Disconnect clients when logon hours expire

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft network server: Disconnect clients when logon hours expire**

**Description**
This security setting determines whether to disconnect users who are connected to the local computer outside their user account's valid logon hours. This setting affects the Server Message Block (SMB) component.

When this policy is enabled, it causes client sessions with the SMB Service to be forcibly disconnected when the client's logon hours expire.

If this policy is disabled, an established client session is allowed to be maintained after the client's logon hours have expired.

**Default:** Undefined.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Set logon hours
- Security Configuration Manager tools

# Network access: Allow anonymous SID/Name translation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Allow anonymous SID/name translation**

**Description**
This security setting determines if an anonymous user can request security identifier (SID) attributes for another user.

If this policy is enabled, a user with knowledge of an administrator's SID could contact a computer that has this policy enabled and use the SID to get the administrator's name.

**Default**:

- Disabled on workstations and member servers.
- Enabled on domain controllers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Account and local policies
- Security Configuration Manager tools

# Network access: Do not allow anonymous enumeration of SAM accounts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Do not allow anonymous enumeration of SAM accounts**

**Description**
This security setting determines what additional permissions will be granted for anonymous connections to the computer.

Windows allows anonymous users to perform certain activities, such as enumerating the names of domain accounts and network shares. This is convenient, for example, when an administrator wants to grant access to users in a trusted domain that does not maintain a reciprocal trust.

This security option allows additional restrictions to be placed on anonymous connections as follows:

- **None. Rely on default permissions.**
- **Do not allow enumeration of SAM accounts.** This option replaces Everyone with Authenticated Users in the security permissions for resources.

**Default:**

- Enabled on workstation.
- Disabled on server.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This policy has no impact on domain controllers.

For more information, see:

- Network access: Let Everyone permissions apply to anonymous users
- Security Configuration Manager tools

# Network access: Do not allow anonymous enumeration of SAM accounts and shares

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Do not allow anonymous enumeration of SAM accounts and shares**

**Description**
This security setting determines whether anonymous enumeration of SAM accounts and shares is allowed.

Windows allows anonymous users to perform certain activities, such as enumerating the names of domain accounts and network shares. This is convenient, for example, when an administrator wants to grant access to users in a trusted domain that does not maintain a reciprocal trust. If you do not want to allow anonymous enumeration of SAM accounts and shares, then enable this policy.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Network access: Let Everyone permissions apply to anonymous users
- Security Configuration Manager tools

# Network access: Do not allow storage of credentials or .NET Passports for network authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Do not allow storage of credentials or .NET Passports for network authentication**

**Description**
This security setting determines whether Stored User Names and Passwords saves passwords, credentials, or .NET Passports for later use when it gains domain authentication.

If it is enabled, this setting prevents the Stored User Names and Passwords from storing passwords and credentials.

**Note**

- When configuring this security setting, changes will not take effect until you restart Windows.

For more information about Stored User Names and Passwords, see Stored User Names and Passwords.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools
- Stored User Names and Passwords

# Network access: Let Everyone permissions apply to anonymous users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Let Everyone permissions apply to anonymous users**

**Description**
This security setting determines what additional permissions are granted for anonymous connections to the computer.

Windows allows anonymous users to perform certain activities, such as enumerating the names of domain accounts and network shares. This is convenient, for example, when an administrator wants to grant access to users in a trusted domain that does not maintain a reciprocal trust. By Default, the Everyone security identifier (SID) is removed from the token created for anonymous connections. Therefore, permissions granted to the Everyone group do not apply to anonymous users. If this option is set, anonymous users can only access those resources for which the anonymous user has been explicitly given permission.

If this policy is enabled, the Everyone SID is added to the token that is created for anonymous connections. In this case, anonymous users are able to access any resource for which the Everyone group has been given permissions.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Network access: Do not allow anonymous enumeration of SAM accounts and shares
- Security Configuration Manager tools

# Network access: Named pipes that can be accessed anonymously

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Named pipes that can be accessed anonymously**

**Description**
This security setting determines which communication sessions (pipes) will have attributes and permissions that allow anonymous access.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Network access: Remotely accessible registry paths

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Remotely accessible registry paths**

**Description**
This security setting determines which registry paths can be accessed over the network, regardless of the users or groups listed in the access control list (ACL) of the **winreg** registry key. For information about the **winreg** registry key, see article Q153183, "How to Restrict Access to the Registry from a Remote Computer," in the Microsoft Knowledge Base.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

### Note

- This security setting is not available on earlier versions of Windows. The security setting that appears on computers running Windows XP, "Network access: Remotely accessible registry paths" corresponds to the "Network access: Remotely accessible registry paths and subpaths" security option on members of the Windows Server 2003 family. For more information, see Network access: Remotely accessible registry paths and subpaths.

### Default:

- **System\CurrentControlSet\Control\ProductOptions**
- **System\CurrentControlSet\Control\Server Applications**
- **Software\Microsoft\Windows NT\CurrentVersion**

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Network access: Remotely accessible registry paths and subpaths

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Remotely accessible registry paths and subpaths**

**Description**
This security setting determines which registry paths and subpaths can be accessed over the network, regardless of the users or groups listed in the access control list (ACL) of the **winreg** registry key. For information about the **winreg** registry key, see article Q153183, "How to Restrict Access to the Registry from a Remote Computer," in the Microsoft Knowledge Base.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Note**

- On Windows XP, this security setting was called "Network access: Remotely accessible registry paths." If you configure this setting on a member of the Windows Server 2003 family that is joined to a domain, this setting is inherited by computers running Windows XP, but will appear as the "Network access: Remotely accessible registry paths" security option. For more information, see Network access: Remotely accessible registry paths.

**Default:**

- **System\CurrentControlSet\Control\Print\Printers**
- **System\CurrentControlSet\Services\Eventlog**
- **Software\Microsoft\OLAP Server**
- **Software\Microsoft\Windows NT\CurrentVersion\Print**
- **Software\Microsoft\Windows NT\CurrentVersion\Windows**
- **System\CurrentControlSet\Control\ContentIndex**
- **System\CurrentControlSet\Control\Terminal Server**
- **System\CurrentControlSet\Control\Terminal Server\UserConfig**
- **System\CurrentControlSet\Control\Terminal Server\DefaultUserConfiguration**
- **Software\Microsoft\Windows NT\CurrentVersion\Perflib**
- **System\CurrentControlSet\Services\SysmonLog**
- **System\CurrentControlSet\Services\CertSvc**
- **System\CurrentControlSet\Services\Wins**

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer

Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Network access: Restrict anonymous access to Named Pipes and Shares

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Restrict anonymous access to Named Pipes and Shares**

**Description**
When enabled, this security setting restricts anonymous access to shares and pipes to the settings for:

- Network access: Named pipes that can be accessed anonymously
- Network access: Shares that can be accessed anonymously

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For information on implementing this policy, see:

- Security Configuration Manager tools

# Network access: Shares that can be accessed anonymously

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Shares that can be accessed anonymously**

**Description**
This security setting determines which network shares can accessed by anonymous users.

**Default:** None specified.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Network access: Sharing and security model for local accounts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access: Sharing and security model for local accounts**

**Description**
This security setting determines how network logons using local accounts are authenticated. If this setting is set to **Classic**, network logons that use local account credentials authenticate by using those credentials. If this setting is set to **Guest only**, network logons that use local accounts are automatically mapped to the Guest account. The Classic model allows fine control over access to resources. By using the Classic model, you can grant different types of access to different users for the same resource. By using the Guest only model, you can have all users treated equally. All users authenticate as Guest, and they all receive the same level of access to a given resource, which can be either Read Only or Modify.

There are two models available:

- Classic: Local users authenticate as themselves.
- Guest only: Local users authenticate as Guest.

**Default:** Guest only on Windows XP Professional. Classic on the Windows Server 2003 family and Windows XP Professional computers joined to a domain.

**Important**

- With the Guest only model, any user who can access your computer over the network (including anonymous Internet users) can access your shared resources. You must use the Internet Connection Firewall (ICF), Windows Firewall, or other similar device to protect your computer from unauthorized access. Similarly, with the Classic model, local accounts must be password protected; otherwise, those user accounts can be used by anyone to access shared system resources.
- This setting only affects computers running Windows XP Professional which are not joined to a domain.
- This policy will have no impact on computers running Windows 2000.
- Windows Firewall is not included in the original release of Windows Server 2003. Internet Connection Firewall is included only in the original release of Windows Server 2003, Standard Edition and the original release of the 32-bit version of Windows Server 2003, Enterprise Edition.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Notes**

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- This setting does not affect interactive logons that are performed remotely by using such services as Telnet or Terminal Services.
- When the computer is not joined to a domain, this setting also modifies the **Sharing** and **Security** tabs in the Windows Explorer to correspond to the sharing and security model that is being used.

For more information, see:

- Security Configuration Manager tools

# Network security: Do not store LAN Manager hash value on next password change

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network security: Do not store LAN Manager hash value on next password change**

**Description**
This security setting determines if, at the next password change, the LAN Manager (LM) hash value for the new password is stored. The LM hash is relatively weak and prone to attack, as compared with the cryptographically stronger Windows NT hash. Since the LM hash is stored on the local computer in the security database the passwords can be compromised if the security database is attacked. For more information on cryptographic hashes of passwords, see Microsoft NTLM .

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- Windows 2000 Service Pack 2 (SP2) and above offer compatibility with authentication to previous versions of Windows, such as Microsoft Windows NT 4.0.

- This setting can affect the ability of computers running Windows 2000 Server, Windows 2000 Professional, Windows XP, and the Windows Server 2003 family to communicate with computers running Windows 95 and Windows 98.

For more information, see:

- Security Configuration Manager tools

# Network security: Force logoff when logon hours expire

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network security: Force logoff when logon hours expire**

**Description**
This security setting determines whether to disconnect users who are connected to the local computer outside their user account's valid logon hours. This setting affects the Server Message Block (SMB) component.

When this policy is enabled, it causes client sessions with the SMB server to be forcibly disconnected when the client's logon hours expire.

If this policy is disabled, an established client session is allowed to be maintained after the client's logon hours have expired.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Note**

- This security setting behaves as an account policy. For domain accounts, there can be only one account policy. The account policy must be defined in the Default Domain Policy, and it is enforced by the domain controllers that make up the domain. A domain controller always pulls the account policy from the Default Domain Policy Group Policy object (GPO), even if there is a different account policy applied to the organizational unit that contains the domain controller. By default, workstations and servers that are joined to a domain (for example, member computers) also receive the same account policy for their local accounts. However, local account policies for member computers can be different from the domain account policy by defining an account policy for the organizational unit that contains the member computers. Kerberos settings are not applied to member computers.

For more information, see:

- Account and local policies
- Set logon hours
- Security Configuration Manager tools

# Network security: LAN Manager authentication level

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network security: LAN Manager authentication level**

**Description**
This security setting determines which challenge/response authentication protocol is used for network logons. This choice affects the level of authentication protocol used by clients, the level of session security negotiated, and the level of authentication accepted by servers as follows:

- **Send LM & NTLM responses:** Clients use LM and NTLM authentication and never use NTLMv2 session security; domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send LM & NTLM - use NTLMv2 session security if negotiated:** Clients use LM and NTLM authentication and use NTLMv2 session security if the server supports it; domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send NTLM response only:** Clients use NTLM authentication only and use NTLMv2 session security if the server supports it; domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send NTLMv2 response only:** Clients use NTLMv2 authentication only and use NTLMv2 session security if the server supports it; domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send NTLMv2 response only\refuse LM:** Clients use NTLMv2 authentication only and use NTLMv2 session security if the server supports it; domain controllers refuse LM (accept only NTLM and NTLMv2 authentication).
- **Send NTLMv2 response only\refuse LM & NTLM:** Clients use NTLMv2 authentication only and use NTLMv2 session security if the server supports it; domain controllers refuse LM and NTLM (accept only NTLMv2 authentication).

**Important**

- This setting can affect the ability of computers running Windows 2000 Server, Windows 2000 Professional, Windows XP Professional, and the Windows Server 2003 family to communicate with computers running Windows NT 4.0 and earlier over the network. For example, at the time of this writing, computers running Windows NT 4.0 SP4 and earlier did not support NTLMv2. Computers running Windows 95 and Windows 98 did not support NTLM. For more information about how these settings apply to previous versions of Windows, see Knowledge Base Search

**Default:**

- **Send NTLM response only.**

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Network security: LDAP client signing requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network security: LDAP client signing requirements**

**Description**
This security setting determines the level of data signing that is requested on behalf of clients issuing LDAP BIND requests, as follows:

- **None:** The LDAP BIND request is issued with the options that are specified by the caller.
- **Negotiate signing:** If Transport Layer Security/Secure Sockets Layer (TLS\SSL) has not been started, the LDAP BIND request is initiated with the LDAP data signing option set in addition to the options specified by the caller. If TLS\SSL has been started, the LDAP BIND request is initiated with the options that are specified by the caller.
- **Require signature:** This is the same as **Negotiate signing**. However, if the LDAP server's intermediate saslBindInprogress response does not indicate that LDAP traffic signing is required, the caller is told that the LDAP BIND command request failed.

**Caution**

- If you set the server to **Require signature,** you must also set the client. Not setting the client results in a loss of connection with the server.

**Note**

- This setting does not have any impact on ldap_simple_bind or ldap_simple_bind_s. No Microsoft LDAP clients that are shipped with Windows XP Professional use ldap_simple_bind or ldap_simple_bind_s to talk to a domain controller.

**Default:** Negotiate signing.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Network security: Minimum session security for NTLM SSP based (including secure RPC) clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network security: Minimum session security for NTLM SSP based (including secure RPC) clients**

**Description**
This security setting allows a client to require the negotiation of message confidentiality (encryption), message integrity, 128-bit encryption, or NTLMv2 session security. These values are dependent on the LAN Manager Authentication Level security setting value.

- **Require message integrity**. The connection will fail if message integrity is not negotiated. The integrity of a message can be assessed through message signing. Message signing proves that the message has not been tampered with by attaching a cryptographic signature which identifies the sender and is a numeric representation of the contents of the message. This signature ensures that the message has not been tampered with.

- **Require message confidentiality**. The connection will fail if encryption is not negotiated. Encryption converts data into a form that is not readable by anyone until decrypted.

- **Require NTLMv2 session security**. The connection will fail if the NTLMv2 protocol is not negotiated. For more information about NTLM and NTLMv2, see Logon and Authentication; at the Microsoft Windows Resource Kits Web site.

- **Require 128-bit encryption**. The connection will fail if strong encryption (128-bit) is not negotiated.

**Default:** No requirements.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This setting will apply to any computers running Windows 2000 through changes in the registry but the security setting will not be viewable through the Security Configuration Manager tool set.

For more information, see:

- Security Configuration Manager tools

- Network security: LAN Manager authentication level

# Network security: Minimum session security for NTLM SSP based (including secure RPC) servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network security: Minimum session security for NTLM SSP based (including secure RPC) servers**

**Description**
This security setting allows a server to require the negotiation of message confidentiality (encryption), message integrity, 128-bit encryption, or NTLMv2 session security. These values are dependent on the LAN Manager Authentication Level security setting value.

- **Require message integrity**. The connection will fail if message integrity is not negotiated. The integrity of a message can be assessed through message signing. Message signing proves that the message has not been tampered with by attaching a cryptographic signature which identifies the sender and is a numeric representation of the contents of the message. This signature ensures that the message has not been tampered with.

- **Require message confidentiality**. The connection will fail if encryption is not negotiated. Encryption converts data into a form that is not readable by anyone until decrypted.

- **Require NTLMv2 session security**. The connection will fail if the NTLMv2 protocol is not negotiated. For more information about NTLM and NTLMv2, see Logon and Authentication; at the Microsoft Windows Resource Kits Web site.

- **Require 128-bit encryption**. The connection will fail if strong encryption (128-bit) is not negotiated.

**Default:** No requirements.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Important**

- This setting will apply to any computers running Windows 2000 through changes in the registry but the security setting will not be viewable through the Security Configuration Manager tool set.

For more information, see:

- Security Configuration Manager tools

- Network security: LAN Manager authentication level

# Recovery console: Allow automatic administrative logon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovery console: Allow automatic administrative logon**

**Description**
This security setting determines if the password for the Administrator account must be given before access to the system is granted. If this option is enabled, the Recovery Console does not require you to provide a password, and it automatically logs on to the system.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Recovery console: Allow floppy copy and access to all drives and all folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovery console: Allow floppy copy and access to all drives and all folders**

**Description**
Enabling this security option makes the Recovery Console SET command available, which allows you to set the following Recovery Console environment variables:

- **AllowWildCards:** Enable wildcard support for some commands (such as the DEL command).
- **AllowAllPaths:** Allow access to all files and folders on the computer.
- **AllowRemovableMedia:** Allow files to be copied to removable media, such as a floppy disk.
- **NoCopyPrompt:** Do not prompt when overwriting an existing file.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Shutdown: Allow system to be shut down without having to log on

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shutdown: Allow system to be shut down without having to log on**

**Description**
This security setting determines whether a computer can be shut down without having to log on to Windows.

When this policy is enabled, the **Shut Down** command is available on the Windows logon screen.

When this policy is disabled, the option to shut down the computer does not appear on the Windows logon screen. In this case, users must be able to log on to the computer successfully and have the Shut down the system user right before they can perform a system shutdown.

**Default**

- Enabled on workstations.
- Disabled on servers.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# Shutdown: Clear virtual memory pagefile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shutdown: Clear virtual memory pagefile**

**Description**
This security setting determines whether the virtual memory pagefile is cleared when the system is shut down.

Virtual memory support uses a system pagefile to swap pages of memory to disk when they are not used. On a running system, this pagefile is opened exclusively by the operating system, and it is well protected. However, systems that are configured to allow booting to other operating systems might have to make sure that the system pagefile is wiped clean when this system shuts down. This ensures that sensitive information from process memory that might go into the pagefile is not available to an unauthorized user who manages to directly access the pagefile.

When this policy is enabled, it causes the system pagefile to be cleared upon clean shutdown. If you enable this security option, the hibernation file (hiberfil.sys) is also zeroed out when hibernation is disabled on a portable computer system.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# System cryptography: Force strong key protection for user keys stored on the computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Cryptography: Force strong key protection for user keys stored on the computer**

**Description**
This security setting determines if users' private keys require a password to be used.

The options are:

- **User input is not required when new keys are stored and used**
- **User is prompted when the key is first used**
- **User must enter a password each time they use a key**

  For more information, see Public Key Infrastructure.

**Default:** Not defined.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System cryptography: Use FIPS compliant algorithms for encryption, hashing and signing**

**Description**
This security setting determines if the Transport Layer Security/Secure Sockets Layer (TL/SS) Security Provider supports only the TLS_RSA_WITH_3DES_EDE_CBC_SHA cipher suite. In effect, this means that the provider only supports the Transport Layer Security (TLS) protocol as a client and as a server (if applicable). It uses only the Triple DES encryption algorithm for the TLS traffic encryption, only the Rivest, Shamir, and Adleman (RSA) public key algorithm for the TLS key exchange and authentication, and only the Secure Hashing Algorithm 1 (SHA-1) for the TLS hashing requirements.

For Encrypting File System Service (EFS), it supports only the Triple Data Encryption Standard (DES) encryption algorithm for encrypting file data supported by the NTFS file system. By default, EFS uses the Advanced Encryption Standard (AES) algorithm with a 256-bit key in the Windows Server 2003 family and DESX algorithm in Windows XP for encrypting file data. For information about EFS, see Encrypting File System.

For Terminal Services, it supports only the Triple DES encryption algorithm for encrypting terminal services network communication. For information about Terminal Services, see Terminal Services.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

**Note**

- The Federal Information Processing Standard (FIPS) 140-1 is a security implementation designed for certifying cryptographic software. FIPS 140-1 validated software is required by the U.S. Government and requested by other prominent institutions.

For more information, see:

- Encrypting File System
- Security Configuration Manager tools

# System objects: Default owner for objects created by members of the Administrators group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System objects: Default owner for objects created by members of the Administrators group**

## Description

This security setting determines which users and groups have the authority to run volume maintenance tasks, such as Disk Cleanup and Disk Defragmenter.

**Default:** Administrators group (on servers).

**Configuring this security setting**

You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# System objects: Require case insensitivity for non-Windows subsystems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System objects: Require case insensitivity for non-Windows subsystems**

**Description**
This security setting determines whether case insensitivity is enforced for all subsystems. The Win32 subsystem is case insensitive. However, the kernel supports case sensitivity for other subsystems, such as POSIX.

If this setting is enabled, case insensitivity is enforced for all directory objects, symbolic links, and IO objects, including file objects. Disabling this setting does not allow the Win32 subsystem to become case sensitive.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# System objects: Strengthen default permissions of internal system objects (e.g., Symbolic Links)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System objects: Strengthen default permissions of internal system objects (e.g., Symbolic Links)**

**Description**
This security setting determines the strength of the default discretionary access control list (DACL) for objects.

Active Directory maintains a global list of shared system resources, such as DOS device names, mutexes, and semaphores. In this way, objects can be located and shared among processes. Each type of object is created with a default DACL that specifies who can access the objects and what permissions are granted.

If this policy is enabled, the default DACL is stronger, allowing users who are not administrators to read shared objects but not allowing these users to modify shared objects that they did not create.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# System settings: Optional subsystems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System settings: Optional subsystems**

**Description**
This security setting determines which subsystems are used to support your applications. With this security setting, you can specify as many subsytems to support as your environment demands.

**Default:** POSIX.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Security Configuration Manager tools

# System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies**

**Description**
This security setting determines if digital certificates are processed when a user or process attempts to run software with an .exe file name extension. This security settings is used to enable or disable certificate rules, a type of software restriction policies rule. With software restriction policies, you can create a certificate rule that will allow or disallow software that is signed by Authenticode to run, based on the digital certificate that is associated with the software. In order for certificate rules to take effect, you must enable this security setting.

When certificate rules are enabled, software restriction policies will check a certificate revocation list (CRL) to make sure the software's certificate and signature are valid. This may decrease performance when start signed programs. You can disable this feature. On **Trusted Publishers Properties**, clear the **Publisher** and **Timestamp** check boxes. For more information, see Set trusted publisher options.

**Default:** Disabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options\

For specific instructions about how to configure this security setting, see Enable certificate rules.

For more information, see:

- Software Restriction Policies
- Create a certificate rule
- Security levels and additional rules
- Best practices for security
- Security Options

# Settings for Event Logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Settings for event logs**
This section covers:

- Maximum application log size
- Maximum security log size
- Maximum system log size
- Prevent local guests group from accessing application log
- Prevent local guests group from accessing security log
- Prevent local guests group from accessing system log
- Retain application log
- Retain security log
- Retain system log
- Retention method for application log
- Retention method for security log
- Retention method for system log

# Maximum application log size

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum application log size**

**Description**
This security setting specifies the maximum size of the application event log, which has a maximum of 4 GB.

### Notes

- Log file sizes must be a multiple of 64 KB. If you enter a value that is not a multiple of 64 KB, Event Viewer will set the log file size to a multiple of 64 KB.
- This setting does not appear in the Local Computer Policy object.
- Event Log size and log wrapping should be defined to match the business and security requirements you determined when designing your enterprise security plan. Consider implementing these Event Log settings at the site, domain, or organizational unit level, to take advantage of Group Policy settings.

**Default:** For the Windows Server 2003 family, 16 MB; for Windows XP Professional Service Pack 1, 8 MB; for Windows XP Professional, 512 KB.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Maximum security log size

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum security log size**

**Description**
This security setting specifies the maximum size of the security event log, which has a maximum size of 4 GB.

### Notes

- Log file sizes must be a multiple of 64 KB. If you enter a value that is not a multiple of 64 KB, Event Viewer will set the log file size to a multiple of 64 KB.
- This setting does not appear in the Local Computer Policy object.
- Event Log size and log wrapping should be defined to match the business and security requirements you determined when designing your enterprise security plan. Consider implementing these Event Log settings at the site, domain, or organizational unit level, to take advantage of Group Policy settings.

**Default:** For the Windows Server 2003 family, 16 MB; for Windows XP Professional Service Pack 1, 8 MB; for Windows XP Professional, 512 KB.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Maximum system log size

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximum system log size**

**Description**
This security setting specifies the maximum size of the system event log, which has a maximum size of 4 GB.

### Notes

- Log file sizes must be a multiple of 64 KB. If you enter a value that is not a multiple of 64 KB, Event Viewer will set the log file size to a multiple of 64 KB.
- This setting does not appear in the Local Computer Policy object.
- Event Log size and log wrapping should be defined to match the business and security requirements you determined when designing your Enterprise Security Plan. Consider implementing these Event Log settings at the site, domain, or organizational unit level, to take advantage of Group Policy settings.

**Default:** For the Windows Server 2003 family, 16 MB; for Windows XP Professional Service Pack 1, 8 MB; for Windows XP Professional, 512 KB.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Prevent local guests group from accessing application log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Prevent local guests group from accessing application log**

**Description**
This security setting determines if guests are prevented from accessing the application event log.

### Notes

- This setting does not appear in the Local Computer Policy object.
- This security setting affects only computers running Windows 2000, Windows XP and Windows Server 2003.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

# Prevent local guests group from accessing security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Prevent local guests group from accessing security log**

**Description**
This security setting determines if guests are prevented from accessing the security event log.

### Notes

- This setting does not appear in the Local Computer Policy object.
- This security setting affects only computers running Windows 2000, Windows XP and Windows Server 2003.
- A user must possess the Manage auditing and security log user right to access the security log.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Prevent local guests group from accessing system log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Prevent local guests group from accessing system log**

**Description**
This security setting determines if guests are prevented from accessing the system event log.

### Notes

- This setting does not appear in the Local Computer Policy object.
- This security setting affects only computers running Windows 2000, Windows XP and Windows Server 2003.

**Default:** Enabled.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Retain application log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Retain application log**

**Description**
This security setting determines the number of days' worth of events to be retained for the application log if the retention method for the application log is **By Days**.

Set this value only if you archive the log at scheduled intervals and you make sure that the Maximum application log size is large enough to accommodate the interval.

### Notes

- This setting does not appear in the Local Computer Policy object.
- A user must possess the Manage auditing and security log user right to access the security log.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Retain security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Retain security log**

**Description**
This security setting determines the number of days' worth of events to be retained for the security log if the retention method for the security log is **By Days**.

Set this value only if you archive the log at scheduled intervals and you make sure that the Maximum security log size is large enough to accommodate the interval.

### Note

- This setting does not appear in the Local Computer Policy object.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Retain system log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Retain system log**

**Description**
This security setting determines the number of days' worth of events to be retained for the system log if the retention method for the system log is **By Days**.

Set this value only if you archive the log at scheduled intervals and you make sure that the Maximum system log size is large enough to accommodate the interval.

### Note

- This setting does not appear in the Local Computer Policy object.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Retention method for application log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Retention method for application log**

**Description**
This security setting determines the "wrapping" method for the application log.

If you do not archive the application log, in the **Properties** dialog box for this policy, select the **Define this policy setting** check box, and then click **Overwrite events as needed**.

If you archive the log at scheduled intervals, in the **Properties** dialog box for this policy, select the **Define this policy setting** check box, and then click **Overwrite events by days** and specify the appropriate number of days in the **Retain application log** setting. Make sure that the Maximum application log size is large enough to accommodate the interval.

If you must retain all the events in the log, in the **Properties** dialog box for this policy, select the **Define this policy setting** check box, and then click **Do not overwrite events (clear log manually)**. This option requires that the log be cleared manually. In this case, when the maximum log size is reached, new events are discarded.

**Note**

- This setting does not appear in the Local Computer Policy object.

**Default:** None.

**Configuring this security setting**
You can configure this security setting by opening the appropriate policy and expanding the console tree as such: Computer Configuration\Windows Settings\Security Settings\Event Log\

For specific instructions about how to configure security policy settings, see Edit security settings on a Group Policy object.

For more information, see:

- Event Viewer
- Security Configuration Manager tools

# Retention method for security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Retention method for security log**

**Description**
This security setting determines the "wrapping" method for the security log.

If you do not archive the security log, in the **Properties** dialog box for this policy, select the **Define this policy setting** check box, and then click **Overwrite events as needed**.

If you archive the log at scheduled intervals, in the **Properties** dialog box for this policy, select the **Define this policy setting** check box, and then click **Overwrite events by days** and specify the appropriate number of days in the retain security log setting. # Restricted Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restricted Groups**
To locate this security setting in the console tree in Microsoft Management Console (MMC), see Computer Configuration\Windows Settings\Security Settings\Restricted Groups

**Description**
This security setting allows an administrator to define two properties for security-sensitive groups ("restricted" groups).

The two properties are **Members** and **Member Of**. The **Members** list defines who belongs and who does not belong to the restricted group. A group can be a member of groups other than those listed in the **Member Of** section. The **Member Of** section simply ensures that the restricted group is added to the groups listed in **Member Of**. It does not remove the group from other groups of which it is a member.

When a Restricted Groups Policy is enforced, any current member of a restricted group that is not on the **Members** list is removed. Any user on the **Members** list who is not currently a member of the restricted group is added.

You can use Restricted Groups policy to control group membership. Using the policy, you can specify what members are part of a group. Any members that are not specified in the policy are removed during configuration or refresh. In addition, the reverse membership configuration option ensures that each Restricted Group is a member of only those groups that are specified in the **Member Of** column.

For example, you can create a Restricted Groups policy to only allow specified users (for example, Alice and John) to be members of the Administrators group. When policy is refreshed, only Alice and John will remain as members of the Administrators group.

There are two ways to apply Restricted Groups policy:

- Define the policy in a security template, which will be applied during configuration on your local computer.
- Define the setting on a Group Policy object (GPO) directly, which means that the policy goes into effect with every refresh of policy. The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.

**Default:** None specified.

**Caution**

- If a Restricted Groups policy is defined and Group Policy is refreshed, any current member not on the Restricted Groups policy members list is removed. This can include default members, such as administrators.

**Notes**

- Restricted Groups should be used primarily to configure membership of local groups on workstation or member servers.
- An empty **Members** list means that the restricted group has no members; an empty **Member Of** list means that the groups to which the restricted group belongs are not specified.

For more information, see:

- Security Configuration Manager tools
- To Create a Restricted Groups policy in a security template

# System Services security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Services security settings**
To locate this security setting in the console tree in Microsoft Management Console (MMC), see Computer Configuration\Windows Settings\Security Settings\System Services

**Description**
Allows an administrator to define the startup mode (manual, automatic, or disabled) as well as the access permissions (Start, Stop, or Pause) for all system services.

**Default:** Undefined.

### Notes

- This setting does not appear in the Local Computer Policy object.
- If you choose to set system service startup to Automatic, perform adequate testing to verify that the services can start without user intervention.
- For performance optimization, set unnecessary or unused services to Manual.

For more information, see:

- Security Configuration Manager tools
- Services Snap-in

# Registry security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Registry security settings**
To locate this security setting in the console tree in Microsoft Management Console (MMC), see Computer Configuration\Windows Settings\Security Settings\Registry

**Description**
Allows an administrator to define access permissions (on discretionary access control lists (DACLs)) and audit settings (on system access control lists (SACLs)) for registry keys using Security Configuration Manager.

**Default:** Undefined.

**Note**

- This setting does not appear in the Local Computer Policy object.

For more information, see:

- Security Configuration Manager tools
- The Registry
- Access Control
- Auditing Security Events

# File System security settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File System security settings**
To locate this security setting in the console tree in Microsoft Management Console (MMC), see Computer Configuration\Windows Settings\Security Settings\File System

**Description**
Allows an administrator to define access permissions (on discretionary access control lists (DACLs)) and audit settings (on system access control lists (SACLs)) for file system objects using Security Configuration Manager.

**Default:** Undefined.

**Note**

- This setting does not appear in the Local Computer Policy object.

For more information, see:

- Security Configuration Manager tools
- Access Control
- Auditing Security Events

# Public Key Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Public key policies**
Using public key policies in a Windows Server 2003 domain, an administrator can automatically issue certificates to computers, manage encrypted data recovery agents, create certificate trust lists, or automatically establish trust of certification authorities.

- For help with specific tasks, see Public Key Policies How To ...
- For general background information, see Public Key Policies Concepts

# Public Key Policies How To ...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Add a trusted root certification authority to a Group Policy object
- Delete a trusted root certification authority from a Group Policy object
- Prevent users from selecting new root certification authorities with a Group Policy
- Prevent users from trusting third-party root certification authorities with a Group Policy
- Create an automatic certificate request for computers in a Group Policy object
- Delete an automatic certificate request for computers in a Group Policy object
- Create a certificate trust list for a Group Policy object
- Edit a certificate trust list for a Group Policy object
- Delete a certificate trust list for a Group Policy object
- Add a recovery agent for the local computer
- Add a recovery agent for a domain
- Change the recovery policy for the local computer
- Create a recovery policy for a domain
- Not require a recovery agent for a domain
- Disable Encrypting File System for a domain

# Add a trusted root certification authority to a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a trusted root certification authority to a Group Policy object**

1. Open the Group Policy object (GPO) that you want to edit.

2. In the console tree, click **Trusted Root Certification Authorities**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Trusted Root Certification Authorities

3. On the **Action** menu, point to **All Tasks**, and then click **Import**.

   This starts the Certificate Import Wizard, which guides you through the process of importing a root certificate and installing it as a trusted root certification authority (CA) for this GPO.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a GPO, see Group Policy (pre-GPMC).

- This procedure does not apply to Local Policy objects.

- You can import a trusted root certificate from a PKCS #12 file (.pfx, .p12), a PKCS #7 file (.spc, .p7b), a certificate file (.cer, .crt), or a Microsoft serialized certificate store file (.sst).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a trusted root certification authority from a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a trusted root certification authority from a Group Policy object**

1. Open the Group Policy object (GPO) that you want to edit.
2. In the console tree, click **Trusted Root Certification Authorities**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Trusted Root Certification Authorities

3. In the details pane, click the root certificate that you want to delete.
4. On the **Action** menu, click **Delete**.
5. If you are sure that you want to delete this certificate, click **Yes**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a GPO, see Group Policy (pre-GPMC).
- This procedure does not apply to Local Policy objects.

# Prevent users from selecting new root certification authorities with a Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prevent users from selecting new root certification authorities with a Group Policy**

1. Open the Group Policy object (GPO) that you want to edit.

2. In the console tree, right-click **Trusted Root Certification Authorities**, and then click **Properties**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Trusted Root Certification Authorities

3. Clear the **Allow users to select new root certification authorities (CAs) to trust** check box.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a GPO, see Group Policy (pre-GPMC).

- This procedure does not apply to Local Policy objects.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Prevent users from trusting third-party root certification authorities with a Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prevent users from trusting third-party root certification authorities with a Group Policy**

1. Open the Group Policy object (GPO) that you want to edit.
2. In the console tree, right-click **Trusted Root Certification Authorities**, and click **Properties**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Trusted Root Certification Authorities

3. In **Client computers can trust the following certificate stores**, click **Enterprise Root Certification Authorities**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a GPO, see Group Policy (pre-GPMC).
- This procedure does not apply to Local Policy objects.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create an automatic certificate request for computers in a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an automatic certificate request for computers in a Group Policy object**

1. Open the Group Policy object (GPO) that you want to edit.

2. In the console tree, click **Automatic Certificate Request Settings**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies

   - Automatic Certificate Request Settings

3. On the **Action** menu, point to **New**, and then click **Automatic Certificate Request**.

   This starts the Automatic Certificate Request Setup Wizard. Follow the steps in the wizard to create an automatic certificate request for computers that have this GPO applied to them.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a GPO, see Group Policy (pre-GPMC).

- This procedure does not apply to Local Policy objects.

- To use the Automatic Certificate Request Setup Wizard, you must know the certificate template that you want to use. A certificate based on the selected template will be requested automatically at the first occurrence of any of the following: a user logs on, Group Policy is refreshed, or a computer joins the domain and is subject to a Group Policy setting.

- The Automatic Certificate Request Setup Wizard asks which certification authority (CA) it should query when the wizard runs on Windows 2000. The wizard will not prompt you when it runs on Windows XP or the Windows Server 2003 family.

- There can only be one certificate request for each certificate type per GPO.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete an automatic certificate request for computers in a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete an automatic certificate request for computers in a Group Policy object**

1. Open the Group Policy object (GPO) that you want to edit.
2. In the console tree, click **Automatic Certificate Request Settings**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Automatic Certificate Request Settings

3. In the details pane, click the automatic certificate request that you want to delete.
4. On the **Action** menu, click **Delete**.
5. If you are sure that you want to delete this automatic certificate request, click **Yes**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a GPO, see Group Policy (pre-GPMC).
- This procedure does not apply to Local Policy objects.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a certificate trust list for a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a certificate trust list for a Group Policy object**

1. Open the Group Policy object (GPO) that you want to edit.

2. In the console tree, click **Enterprise Trust**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Enterprise Trust

3. On the **Action** menu, point to **New**, and then click **Certificate Trust List**.

   This starts the Certificate Trust List Wizard. Follow the steps in the wizard to create a certificate trust list (CTL) for the GPO.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a GPO, see Group Policy (pre-GPMC).

- This procedure does not apply to Local Policy objects.

- To use the Certificate Trust List Wizard, you need the following information:

  - The certificate purposes for this CTL. For more information about CTL purposes, see Using enterprise trust policy.

  - The certificates that you want to add to the CTL. You can add certificates from the certificate store on the local computer or from a file. Acceptable file formats from which you can import a certificate are an X.509 v3 certificate file (.cer, .crt), a PKCS #7 file (.spc, .p7b), or a Microsoft serialized certificate store (.sst).

  - A certificate that has the Trust List Signing purpose and its associated private key in your personal certificate store. For general instructions on how to request a certificate, see Request a certificate.

  - As an option, you can enter a time stamp service URL to time-stamp the CTL.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit a certificate trust list for a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit a certificate trust list for a Group Policy object**

1. Open the Group Policy object (GPO) that you want to edit.
2. In the console tree, click **Enterprise Trust**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Enterprise Trust

3. In the details pane, click the certificate trust list (CTL) that you want to edit.
4. On the **Action** menu, point to **All Tasks**, and then click **Edit**.

   This starts the Certificate Trust List Wizard. Follow the steps in the wizard to edit the CTL for the GPO.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a GPO, see Group Policy (pre-GPMC).
- This procedure does not apply to Local Policy objects.
- To use the Certificate Trust List Wizard, you need the following information:
  - The certificate purposes for this CTL. For more information about CTL purposes, see Using enterprise trust policy.
  - The certificates that you want to add to the CTL. You can add certificates from the certificate store on the local computer or from a file. Acceptable file formats from which you can import a certificate are an X.509 v3 certificate file (.cer, .crt), a PKCS #7 file (.spc, .p7b) or a Microsoft serialized certificate store (.sst).
  - A certificate that has the Trust List Signing purpose and its associated private key in your personal certificate store. For general instructions on how to request a certificate, see Request a certificate.
  - As an option, you can enter a time stamp service URL to time-stamp the CTL.

# Delete a certificate trust list for a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a certificate trust list for a Group Policy object**

1. Open the Group Policy object (GPO) that you want to edit.
2. In the console tree, click **Enterprise Trust**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Enterprise Trust

3. In the details pane, right-click the certificate trust list (CTL) that you want to delete.
4. On the **Action** menu, click **Delete**.
5. Click **Yes** if you are sure that you want to delete this CTL.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a GPO, see Group Policy (pre-GPMC).
- This procedure does not apply to Local Policy objects.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a recovery agent for the local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a recovery agent for the local computer**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Add Standalone Snap-in**, click **Group Policy Object Editor**, and then click **Add**.
4. Under **Group Policy Object**, make sure that Local Computer is displayed, and then click **Finish**.
5. Click **Close**, and then click **OK**.
6. In **Local Computer Policy**, click **Public Key Policies**.

   **Where?**

   - Local Computer Policy/Computer Configuration/Windows Settings/Security Settings/Public Key Policies

7. In the details pane, right-click **Encrypting File System**.
8. Click **Add Data Recovery Agent**, and then follow the instructions in the Add Recovery Agent Wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- Be prepared to provide the wizard with the user name for a user with a published recovery certificate. Alternatively, you can use the wizard to browse for .cer files that contain information about the recovery agent you are adding.
- Adding a recovery agent from a file identifies the user as USER_UNKNOWN. This is because the name is not stored in the file.
- Before you can add or create a recovery agent, you must configure Group Policy on your computer. For more information about using Group Policy, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a recovery agent for a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a recovery agent for a domain**

1. Open Active Directory Users and Computers.
2. Right-click the domain whose recovery policy you want to change, and then click **Properties**.
3. Click the **Group Policy** tab.
4. Right-click the recovery policy you want to change, and then click **Edit**.
5. In the console tree, click **Encrypting File System**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Encrypting File System

6. In the details pane, right-click, then click **Add Data Recovery Agent**.
7. Follow the instructions of the wizard to complete this procedure.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- This operation can be performed on any sites, domains or organizational units within an Active Directory forest.
- Adding a recovery agent from a file identifies the user as USER_UNKNOWN. This is because the name is not stored in the file.
- Adding a recovery agent from Active Directory requires that File Recovery certificates are published in Active Directory. However, the default EFS File Recovery certificate template does not publish these certificates. This can be changed by copying the default EFS File Recovery certificate template to create a new template and configuring it to **Publish certificate in Active Directory**. For more information on modifying certificate templates, see Related Topics.
- Before you can add or create a recovery agent, you must configure Group Policy on your computer. For more information about using Group Policy, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the recovery policy for the local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the recovery policy for the local computer**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Add Standalone Snap-in**, click **Group Policy Object Editor**, and then click **Add**.
4. Under **Group Policy Object**, make sure that **Local Computer** is displayed, click **Finish**.
5. Click **Close**, and then click **OK**.
6. In **Local Computer Policy**, click **Public Key Policies**.

   **Where?**

   - Local Computer Policy/Computer Configuration/Windows Settings/Security Settings/Public Key Policies

7. Right-click **Encrypting File System**, and then do one of the following:

   - To designate a user as an additional recovery agent using the Add Recovery Agent Wizard, click **Add Data Recovery Agent**.
   - To allow EFS to work without recovery agents, point to **All Tasks** and then click **Do Not Require Data Recovery Agents**.
   - To delete this EFS policy and every recovery agent, point to **All Tasks** and then click **Delete Policy**. If you select this option, users can still encrypt files on this computer. Note that this option will not appear unless there is an EFS policy on the computer.

### Important

- Before changing the recovery policy in any way, you should first back up the recovery keys to a floppy disk.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- There is no default recovery agent on a standalone computer. A file recovery certificate can be created by running cipher.exe /r, and the **Add Data Recovery Agent** option can be used to import this certificate into the EFS policy. Fore more information on cipher.exe, see Related Topics.
- You can make changes to the File Recovery certificate by right-clicking the certificate and then clicking **Properties**. For example, you can give the certificate a friendly name and enter a text description.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a recovery policy for a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a recovery policy for a domain**

1. Open Active Directory Users and Computers.
2. Right-click the domain whose recovery policy you want to change, and then click **Properties**.
3. Click the **Group Policy** tab.
4. Right-click the recovery policy you want to change, and then click **Edit**.
5. In the console tree, click **Encrypting File System**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Encrypting File System

6. Do one of the following:

   - If you need to create a certificate to use as the Encrypting File System (EFS) recovery certificate, right-click **Encrypting File System** and click **Create Data Recovery Agent**.
   - If you want to use an existing certificate, click **Add Data Recovery Agent** and follow the instructions that are given by the wizard to complete this procedure.

**Important**

- Before changing the recovery policy in any way, you should first back up the recovery keys to a floppy disk.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- In a domain, a default recovery policy is implemented for the domain when the first domain controller is set up. The first domain administrator is issued the self-signed certificate, which designates the domain administrator as the recovery agent. To change the default recovery policy for a domain, log on to the first domain controller as an administrator.
- If you choose **Create Data Recovery Agent** during this procedure, the domain controller will contact a Windows Server 2003 family certification authority (CA) to request a certificate based on the EFS Recovery Agent certificate template. If this template is unavailable or does not allow you to obtain a certificate, Windows displays the following message: "Windows cannot create a data recovery agent."

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Not require a recovery agent for a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To not require a recovery agent for a domain**

1. Open Active Directory Users and Computers.
2. Right-click the domain whose recovery policy you want to change, and then click **Properties**.
3. Click the **Group Policy** tab.
4. Right-click the recovery policy you want to change, and then click **Edit**.
5. In the console tree, click **Encrypting File System**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Encrypting File System

6. Right-click **Encrypting File System**, point to **All Tasks**, then click **Do Not Require Data Recovery Agents**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- This operation can be performed on any sites, domains or organizational units within an Active Directory forest.
- If EFS policy is currently defined, you must select **Delete Policy** before you are able to follow this procedure.
- This procedure allows EFS to continue working without using recovery agents. To disable EFS, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable Encrypting File System for a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable Encrypting File System for a domain**

1. Open Active Directory Users and Computers.
2. Right-click the domain whose recovery policy you want to change, and then click **Properties**.
3. Click the **Group Policy** tab.
4. Right-click the recovery policy you want to change, and then click **Edit**.
5. In the console tree, click **Encrypting File System**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Encrypting File System

6. Right-click **Encrypting File System**, then click **Properties**.
7. Clear the **Allow users to encrypt files using Encrypting File System (EFS)** check box.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- This operation can be performed on any sites, domains or organizational units within an Active Directory forest.
- This procedure completely disables EFS. To allow EFS to continue working without using recovery agents, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Public Key Policies Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section covers:

- Public Key Policies overview
- Understanding Public Key Policies
- Using Public Key Policies

# Public Key Policies overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Public key policies overview**

You can use the public key policy settings in Group Policy to:

- Have computers automatically submit a certificate request to an enterprise certification authority and install the issued certificate. This is useful for ensuring that computers have the certificates that they need to perform public key cryptographic operations in your organization, for example, for Internet Protocol security (IPSec) or for client authentication. For more information about certificate autoenrollment for computers, see Automatic certificate request settings.

- Create and distribute a certificate trust list (CTL). A certificate trust list is a signed list of root certification authority certificates that an administrator considers reputable for designated purposes such as client authentication or secure e-mail. For example, if you want to trust a certification authority's certificates for IPSec, but not for client authentication, you can implement that trust relationship with a certificate trust list. For more information about certificate trust lists, see Enterprise trust policy.

- Establish common trusted root certification authorities. You can use this policy setting to make computers and users subject to common root certification authorities (in addition to the ones that they already trust individually). It is not necessary to use this policy setting for certification authorities in a domain, because they are already trusted by all users and computers in the domain. This policy is primarily for establishing trust in a root certification authority that is not a part of your organization. For more information about root certification authorities, see Policies to establish trust of root certification authorities.

- Add encrypted data recovery agents, and change the encrypted data recovery policy settings. For more information about this policy setting, see Recovering data. For a general overview of Encrypting File System (EFS), see Encrypting File System overview.

It is not necessary for you to use these public key policy settings in Group Policy to deploy a public key infrastructure in your organization. However, these settings give you additional flexibility and control when you establish trust in certification authorities, issue certificates to computers, and deploy EFS across a domain.

# Understanding Public Key Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding public key policies**

You can create public key policies for distribution to computers or users within a site, domain, or organizational unit. To do this, use Group Policy, with the Security Settings extension enabled. This section covers:

- Automatic certificate request settings
- Policies to establish trust of root certification authorities
- Enterprise trust policy
- Recovering data

# Automatic certificate request settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automatic certificate request settings**

Certificate enrollment is the process of requesting, receiving, and installing a certificate. By using automatic certificate settings in public key policies, you can have computers that are associated with a Group Policy object (GPO) automatically enroll for certificates. This can save you the step of explicitly enrolling for computer-related certificates for each computer.

After you establish an automatic certificate request, the actual certificate requests occur the next time the computers associated with the GPO log on to the network.

For more information, see Automatic certificate request policy and Public Key Policies overview.

# Policies to establish trust of root certification authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policies to establish trust of root certification authorities**

When a client presents a certificate to a host, the host has to trust the certificate of the root certification authority (CA) in the certification path to accept the certificate as a valid credential. You might want to establish trust automatically in specific root CAs for groups of users or computers.

You can use the public key policy in Group Policy to establish common trusted root CAs for the users and computers associated with a Group Policy object (GPO). When you apply the GPO to a site, domain, or organizational unit, the corresponding computers inherit the policy. These computers then trust the root CAs whose certificates you imported into the trusted root certification authority policy.

You have the option of designating trusted CAs by using either the trusted root certification authority policy or the enterprise trust policy. Use the following guidelines in determining which policy to use:

- If your organization has its own Windows 2000 root CAs and uses Active Directory, you do not need to use the Group Policy mechanism to distribute the root certificates.
- If your organization has its own root CAs that are installed on servers not running Windows 2000, use the trusted root certification authority policy to distribute your organization's root certificates. For more information, see Trusted root certification authority policy.
- If your organization does not have its own CAs, use the enterprise trust policy to create certificate trust lists (CTLs) to establish your organization's trust of external root CAs. For more information, see Enterprise trust policy.

For more information, see Public Key Policies overview.

# Enterprise trust policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enterprise trust policy**
A certificate trust list (CTL) enables you to control trust of the purpose and of the validity period of certificates issued by external certification authorities (CAs).

Typically, a certification authority can issue certificates for a wide variety of purposes, such as secure e-mail or client authentication. But there might be situations in which you want to limit the trust of certificates issued by a particular certification authority, especially if the CA is outside your organization. In these situations, creating a CTL and using it through Group Policy can be useful.

Suppose, for example, a certification authority named "My CA" is capable of issuing certificates for server authentication, client authentication, code signing, and secure e-mail. However, you only want to trust certificates issued by My CA for the purpose of client authentication. You can create a CTL and limit the purpose for which you trust certificates issued by My CA so that they are only valid for client authentication. Any certificates issued for another purpose by My CA are not accepted for use by any computer or user in the scope of the Group Policy object (GPO) to which the CTL is applied.

There can be multiple CTLs in an organization. Because the uses and trusts of certificates for particular domains or organizational units might be different, you can create separate CTLs to reflect these uses and assign particular CTLs to particular GPOs.

Through the use of Group Policy in your organization, you have the option of designating trust in CAs by using either the trusted root certification authority policy or the enterprise trust policy (CTLs). Use the following guidelines in determining which policy to use:

- If your organization has its own root CAs and uses Active Directory, you do not need to use the Group Policy mechanism to distribute those root certificates.

- If your organization has its own root CAs that are not installed on servers, you should use the trusted root certification authority policy to distribute your organization's root certificates. For more information, see Trusted root certification authority policy.

- If your organization does not have its own CAs, use the enterprise trust policy to create CTLs to establish your organization's trust of external root CAs. For more information, see Using enterprise trust policy.

For more information, see Public Key Policies overview.

# Recovering data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovering data**

Data recovery is important when you need to be able to recover data encrypted by an employee after the employee leaves, or when the user loses the private key. Data recovery is available through the Encrypting File System (EFS) as a part of the overall security policy for the system. For example, if you should ever lose your file encryption certificate and associated private key through disk failure, arson, or any other reason, the person who is the designated recovery agent can recover the data. In a business environment, an organization can recover data encrypted by an employee after the employee leaves.

**Recovery policy**

EFS uses recovery policies to provide built-in data recovery. A *recovery policy* is a type of public key policy that provides for one or more user accounts to be designated as recovery agents.

A recovery policy is configured locally for stand-alone computers. For computers that are part of a network, a recovery policy is configured at the domain, organizational unit, or individual computer level, and applies to all Windows XP and Windows Server 2003 family-based computers that the policy applies to. A certification authority (CA) issues recovery certificates, and you use Certificates in Microsoft Management Console (MMC) to manage them.

In a domain, the Windows Server 2003 family implements a default recovery policy for the domain when the first domain controller is set up. The self-signed certificate is issued to the domain administrator. That certificate designates the domain administrator as the recovery agent. To change the default recovery policy for a domain, log on to the first domain controller as an administrator. Additional recovery agents can be added to this policy and the original recovery agent can be removed at any time.

Because the Windows XP and Windows Server 2003 family security subsystems handle enforcing, replicating, and caching of the recovery policy, users can implement file encryption on a system that is temporarily offline, such as a portable computer. This process is similar to logging on to their domain account using cached credentials. For more information, see Change the recovery policy for the local computer and Create a recovery policy for a domain.

**Recovery agents**

A recovery agent is an individual authorized to decrypt data that was encrypted by another user. Recovery agents do not need any other permissions to function in this role. Recovery agents are useful, for example, when employees leave the company and their remaining data needs to be decrypted. Before you can add a recovery agent for a domain, you must ensure that each recovery agent has been issued an X.509v3 certificate.

Each recovery agent has a special certificate and associated private key that allows data recovery wherever the recovery policy applies. If you are the recovery agent, you should be sure to use the **Export** command in Certificates in MMC to back up the recovery certificate and the associated private key to a secure location. After backing them up, you should use Certificates in MMC to delete the recovery certificate. Then, when you need to perform a recovery operation for a user, you should first restore the recovery certificate and associated private key using the **Import** command from Certificates in MMC. After recovering the data, you should again delete the recovery certificate. You do not have to repeat the export process.

To add recovery agents for a domain, you add their certificates to the existing recovery policy. For steps on how to add recovery agents to a domain, see Add a recovery agent for a domain.

### Note

- Recovery agent information that has been added and removed is not automatically updated on existing EFS files. The information in these files is updated the next time the file is accessed. New files always use the current recovery agent information.

# Using Public Key Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using public key policies**

This section covers:

- Automatic certificate request policy
- Trusted root certification authority policy
- Using enterprise trust policy
- Encrypted data recovery agents policy

# Automatic certificate request policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automatic certificate request policy**

To create an automatic certificate request, you need the following information:

- The certificate type that you want computers that are associated with the Group Policy object (GPO) to automatically enroll for. Computers can automatically request only certificate types that have a purpose associated with computers, not with users. Examples of computer-related certificates include:
    - Computer certificates
    - Internet Protocol security (IPSec) certificates
    - Web Server certificates
- The certification authority (CA) that can issue the certificate.

  You can select from a predefined list of CAs. The CA that you select must be capable of issuing a certificate of the type and purpose that you have specified.

For more information, see Automatic certificate request settings, Create an automatic certificate request for computers in a Group Policy object, and Delete an automatic certificate request for computers in a Group Policy object.

# Trusted root certification authority policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Trusted root certification authority policy**

To establish a trusted root certification authority using Group Policy, the Group Policy object (GPO) that you create must have access to the root certificate. This requires that you import a copy of the root certification authority certificate.

You can do this by using the procedure in Add a trusted root certification authority to a Group Policy object.

For a root certification authority certificate to be imported, the root certificate must be in a PKCS #12 file, in a PKCS #7 file, or in binary-encoded X.509 v3 certificate files. For more information about these file formats, see Importing and exporting certificates.

For more information on trusted root certification authority policies, see Policies to establish trust of root certification authorities and Delete a trusted root certification authority from a Group Policy object.

# Using enterprise trust policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using enterprise trust policy**

You can assign a certificate trust list (CTL) to a Group Policy object (GPO) either by creating a new CTL or by importing an existing one. If you are creating a new CTL, you must sign the CTL with a certificate issued for this purpose by a certification authority (CA).

Creating a CTL also requires:

- The root certificates that you want to include in the CTL.
- The purposes for which you want to trust the root certificates in the CTL.

For more information, see Enterprise trust policy, Create a certificate trust list for a Group Policy object, Edit a certificate trust list for a Group Policy object, and Delete a certificate trust list for a Group Policy object.

# Encrypted data recovery agents policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encrypted data recovery agents policy**

You can manage encrypted data recovery policy for computers in a domain by using the following procedures:

- Add a recovery agent for a domain
- Create a recovery policy for a domain

You can manage encrypted data recovery policy for a local computer by using the following procedures:

- Add a recovery agent for the local computer
- Change the recovery policy for the local computer

For more information, see Encrypting File System overview and Recovering data.

# Software Restriction Policies

Updated: November 22, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This product help topic links to checklists, best practices, procedures, and troubleshooting for Windows Server 2003.

**Software restriction policies**

| **Tip** |
| --- |
| For updated information about Software Restriction Policies, including how it works and troubleshooting for Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, and Windows Server 2003, see Software Restriction Policies. |

You can use software restriction policies to identify software and to control its ability to run on your local computer, organizational unit, domain, or site.

- Before implementing software restriction policies to prevent an e-mail virus from running on your computer, see Checklist: Using software restriction policies to help protect your computer against an e-mail virus.
- For tips about using software restriction policies, see Software Restriction Policies Best Practices.
- For help with specific tasks, see Software Restriction Policies How To....
- For general background information, see Software Restriction Policies Concepts.
- For problem-solving instructions, see Software Restriction Policies Troubleshooting.

# Checklist: Using software restriction policies to help protect your computer against an e-mail virus

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Using software restriction policies to help protect your computer against an e-mail virus**

| Step | Reference |
|---|---|

| Open Software Restriction Policies. | Open Software Restriction Policies |
| If you have not previously defined software restriction policies, create new software restriction policies. | Create new software restriction policies |
| Create a path rule for the folder that your e-mail program uses to run e-mail attachments, and then set the security level to **Disallowed**. | Create a path rule |
| Specify the file types to which the rule applies. | Add or delete a designated file type |
| Modify policy settings so that they apply to the users and groups that you want:<br>• Specify users or groups to which you do not want the Group Policy object's (GPO) policy settings to apply.<br>• Exclude local administrators from the software restriction policies of a specific policy setting in Group Policy and still have the rest of Group Policy apply to the administrators. | Group Policy (pre-GPMC); Prevent software restriction policies from applying to local administrators |

# Software Restriction Policies Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Do not modify the default domain policy.**

- If you do not edit the default domain policy, you always have the option of reapplying the default domain policy if something goes wrong with your customized domain policy.

**Create a separate Group Policy object for software restriction policies.**

- If you create a separate Group Policy object (GPO) for software restriction policies, you can disable software restriction policies in an emergency without disabling the rest of your domain policy.

  For more information, see Group Policy (pre-GPMC).

**If you experience problems with applied policy settings, restart Windows in Safe Mode.**

- Software restriction policies do not apply when Windows is started in Safe Mode. If you accidentally lock down a workstation with software restriction policies, restart the computer in Safe Mode, log on as a local administrator, modify the policy, run **gpupdate**, restart the computer, and then log on normally.

  For more information about restarting the computer in Safe Mode, see Start the computer in Safe Mode. For more information about **gpupdate**, see Gpupdate.

**Use caution when defining a default setting of Disallowed.**

- When you define a default setting of **Disallowed**, all software is disallowed except for software that has been explicitly allowed. Any file that you want to open has to have a software restriction policies rule that allows it to open.

- To protect administrators from locking themselves out of the system, when the default security level is set to **Disallowed**, four registry path rules are automatically created. You can delete or modify these registry path rules; however, this is not recommended.

  For more information, see Setting the default security level to Disallowed.

**For best security, use access control lists in conjunction with software restriction policies.**

- Users might try to circumvent software restriction policies by renaming or moving disallowed files or by overwriting unrestricted files. As a result, it is recommended that you use access control lists (ACLs) to deny users the access necessary to perform these tasks. For information about access control, see Access Control.

**Test new policy settings thoroughly in test environments before applying the policy settings to your domain.**

- New policy settings might act differently than originally expected. Testing diminishes the chance of encountering a problem when you deploy policy settings across your network.

- You can set up a test domain, separate from your organization's domain, in which to test new policy settings. You can also test the policy settings by creating a test GPO and linking it to a test organizational unit. When you have thoroughly tested the policy settings with test users, you can link the test GPO to your domain.

- Do not set programs or files to **Disallowed** without testing to see what the effect may be. Restrictions on certain files can seriously affect the operation of your computer or network.

- Information that is entered incorrectly or typing mistakes can result in a policy setting that does not perform as expected. Testing new policy settings before applying them can prevent unexpected behavior.

**Filter user policy settings based on membership in security groups.**

- You can specify users or groups for which you do not want a policy setting to apply by clearing the **Apply Group Policy** and **Read** check boxes, which are located on the **Security** tab of the properties dialog box for the GPO.

- When the Read permission is denied, the policy setting is not downloaded by the computer. As a result, less bandwidth is consumed by downloading unnecessary policy settings, which enables the network to function more quickly. To deny the Read permission, select **Deny** for the **Read** check box, which is located on the **Security** tab of the properties dialog box for the GPO.

  For more information, see Group Policy (pre-GPMC).

**Do not link to a GPO in another domain or site.**

- Linking to a GPO in another domain or site can result in poor performance.

# Software Restriction Policies How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Create new software restriction policies
- Open Software Restriction Policies
- Apply software restriction policies to DLLs
- Prevent software restriction policies from applying to local administrators
- Enable certificate rules
- Create a certificate rule
- Create a hash rule
- Create an Internet zone rule
- Create a path rule
- Create a registry path rule
- Add or delete a designated file type
- Change the default security level of software restriction policies
- Set trusted publisher options

# Create new software restriction policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create new software restriction policies**

1. Open Software Restriction Policies.

2. On the **Action** menu, click **New Software Restriction Policies**.

## Notes

- Different administrative credentials are required to perform this procedure, depending on your environment:

    - If you create new software restriction policies for your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

    - If you create new software restriction policies for a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.

- If software restriction policies have already been created for a Group Policy object (GPO), the **New Software Restriction Policies** command does not appear on the **Action** menu. To delete the software restriction policies that are applied to a GPO, in the console tree, right-click **Software Restriction Policies**, and then click **Delete Software Restriction Policies**. When you delete software restriction policies for a GPO, you also delete all software restriction policies rules for that GPO. After you delete software restriction policies, you can create new software restriction policies for that GPO.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Open Software Restriction Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open Software Restriction Policies**

- For your local computer
- For a domain, site, or organizational unit, and you are on a member server or on a workstation that is joined to a domain
- For a domain or organizational unit, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed
- For a site, and you are on a domain controller or on a workstation that has the Administration Tools Pack installed

**For your local computer**

1. Open Local Security Settings.
2. In the console tree, click **Software Restriction Policies**.

   **Where?**

   - Security Settings/Software Restriction Policies

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**For a domain, site, or organizational unit, and you are on a member server or on a workstation that is joined to a domain**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. In **Select Group Policy Object**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit--or create a new one, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, click **Software Restriction Policies**.

   **Where?**

- *Group Policy Object* [*ComputerName*] Policy/Computer Configuration or

  User Configuration/Windows Settings/Security Settings/Software Restriction Policies

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.

**For a domain or organizational unit, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the Group Policy object (GPO) that you want to open software restriction policies for.

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click **Edit** to open the GPO that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.

5. In the console tree, click **Software Restriction Policies**.

   **Where?**

   - *Group Policy Object* [*ComputerName*] Policy/Computer Configuration or

     User Configuration/Windows Settings/Security Settings/Software Restriction Policies

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**For a site, and you are on a domain controller or on a workstation that has the Administration Tools Pack installed**

1. Open Active Directory Sites and Services.

2. In the console tree, right-click the site that you want to set Group Policy for.

   **Where?**

   - Active Directory Sites and Services [*Domain_Controller_Name.Domain_Name*]/Sites/Site

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click an entry in **Group Policy Object Links** to select an existing Group Policy object (GPO), and then click **Edit**. You can also click **New** to create a new GPO, and then click **Edit**.

5. In the console tree, click **Software Restriction Policies**.

   **Where**

   - *Group Policy Object* [*ComputerName*] Policy/Computer Configuration or

     User Configuration/Windows Settings/Security Settings/Software Restriction Policies

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.

## Notes

- To set policy settings that will be applied to computers, regardless of which users log on to them, click **Computer Configuration**.

- To set policy settings that will be applied to users, regardless of which computer they log on to, click **User Configuration**.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Apply software restriction policies to DLLs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply software restriction policies to DLLs**

1. Open Software Restriction Policies.
2. In the details pane, double-click **Enforcement**.
3. Under **Apply software restriction policies to the following**, click **All software files**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- By default, software restriction policies do not check dynamic-link libraries (DLLs). Checking DLLs can decrease system performance, because software restriction policies must be evaluated every time a DLL is loaded. However, you may decide to check DLLs if you are concerned about receiving a virus that targets DLLs. If the default security level is set to **Disallowed**, and you enable DLL checking, you must create software restriction policies rules that allow each DLL to run. For more information about rules, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Prevent software restriction policies from applying to local administrators

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prevent software restriction policies from applying to local administrators**

1. Open Software Restriction Policies.
2. In the details pane, double-click **Enforcement**.
3. Under **Apply software restriction policies to the following users**, click **All users except local administrators**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create a new software restriction policy setting for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- If it is common for users to be members of the local Administrators group on their computers in your organization, you may not want to enable this option.
- If you are defining a software restriction policy setting for your local computer, use this procedure to prevent local administrators from having software restriction policies applied to them. If you are defining a software restriction policy setting for your network, filter user policy settings based on membership in security groups through Group Policy. For more information about Group Policy, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable certificate rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable certificate rules**

- For your local computer
- For a Group Policy object, and you are on a server that is joined to a domain
- For a Group Policy object, and you are on a domain controller or a on workstation that has the Windows Server 2003 Administration Tools Pack installed
- For only domain controllers, and you are on a domain controller or on a workstation that has the Administration Tools Pack installed

**For your local computer**

1. Open Local Security Settings.
2. In the console tree, click **Security Options**.

   **Where?**

   - Security Settings/Local Policies/Security Options
3. In the details pane, double-click **System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies**.
4. Do one of the following, and then click **OK**:

   - To enable certificate rules, click **Enabled**.
   - To disable certificate rules, click **Disabled**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**For a Group Policy object, and you are on a server that is joined to a domain**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.

4. In **Select Group Policy Object**, click **Browse**.

5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit--or create a new one, and then click **Finish**.

6. Click **Close**, and then click **OK**.

7. In the console tree, click **Security Options**.

   **Where?**

   - *GroupPolicyObject* [*ComputerName*] Policy/Computer Configuration/Windows Settings/Security Settings/Local Policies/Security Options

8. In the details pane, double-click **System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies**.

9. If this policy setting has not yet been defined, select the **Define these policy settings** check box.

10. Do one of the following, and then click **OK**:

    - To enable certificate rules, click **Enabled**.

    - To disable certificate rules, click **Disabled**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.

**For a Group Policy object, and you are on a domain controller or a on workstation that has the Windows Server 2003 Administration Tools Pack installed**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the Group Policy object (GPO) for which you want to enable certificate rules.

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click **Edit** to open the GPO that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.

5. In the console tree, click **Security Options**.

   **Where?**

   - *GroupPolicyObject* [*ComputerName*] Policy/Computer Configuration/Windows Settings/Security Settings/Local Policies/Security Options

6. In the details pane, double-click **System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies**.

7. If this policy setting has not yet been defined, select the **Define these policy settings** check box.

8. Do one of the following, and then click **OK**:

    - To enable certificate rules, click **Enabled**.

    - To disable certificate rules, click **Disabled**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**For only domain controllers, and you are on a domain controller or on a workstation that has the Administration Tools Pack installed**

1. Open Domain Controller Security Settings.

2. In the console tree, click **Security Options**.

    **Where?**

    - *GroupPolicyObject* [*ComputerName*] Policy/Computer Configuration/Windows Settings/Security Settings/Local Policies/Security Options

3. In the details pane, double-click **System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies**.

4. If this policy setting has not yet been defined, select the **Define these policy settings** check box.

5. Do one of the following, and then click **OK**:

    - To enable certificate rules, click **Enabled**.

    - To disable certificate rules, click **Disabled**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Domain Controller Security Policy, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.

**Note**

- You must perform this procedure before certificate rules can take effect.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a certificate rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a certificate rule**

1. Open Software Restriction Policies.
2. In either the console tree or the details pane, right-click **Additional Rules**, and then click **New Certificate Rule**.
3. Click **Browse**, and then select a certificate or signed file.
4. In **Security level**, click either **Disallowed** or **Unrestricted**.
5. In **Description**, type a description for this rule, and then click **OK**.

## Notes

- Different administrative credentials are required to perform this procedure, depending on your environment:
    - If you create a certificate rule for your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
    - If you create a certificate rule for a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It might be necessary to create a new software restriction policy setting for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- Certificate rules are not enabled by default. For information about how to enable certificate rules, see "Enable certificate rules" in Related Topics.
- The only file types that are affected by certificate rules are those that are listed in **Designated file types** in the details pane for Software Restriction Policies. There is one list of designated file types that is shared by all rules. For more information, see "Add or delete a designated file type" in Related Topics.
- For software restriction policies to take effect, users must update policy settings by logging off from and logging on to their computers.
- When more than one software restriction policies rule is applied to policy settings, there is a precedence of rules for handling conflicts. For more information, see "Precedence of software restriction policies" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a hash rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a hash rule**

1. Open Software Restriction Policies.
2. In either the console tree or the details pane, right-click **Additional Rules**, and then click **New Hash Rule**.
3. Click **Browse** to find a file, or paste a precalculated hash in **File hash**.
4. In **Security level**, click either **Disallowed** or **Unrestricted**.
5. In **Description**, type a description for this rule, and then click **OK**.

**Notes**

- Different administrative credentials are required to perform this procedure, depending on your environment:
    - If you create a hash rule on your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
    - If you create a hash rule on a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create a new software restriction policy setting for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- A hash rule can be created for a virus or a Trojan horse to prevent them from running.
- If you want other people to use a hash rule so that a virus cannot run, calculate the hash of the virus by using software restriction policies, and then e-mail the hash value to the other people. Never e-mail the virus itself.
- If a virus has been sent through e-mail, you can also create a path rule to prevent execution of e-mail attachments. For more information, see "Create a path rule" in Related Topics.
- A file that is renamed or moved to another folder results in the same hash. Any change to the file itself results in a different hash.
- The only file types that are affected by hash rules are those that are listed in **Designated File Types** in the details pane for Software Restriction Policies. There is one list of designated file types that is shared by all rules. For more information, see "Add or delete a designated file type" in Related Topics.
- For software restriction policies to take effect, users must update policy settings by logging off from and logging on to their computers.
- When more than one software restriction policies rule is applied to policy settings, there is a precedence of rules for

handling conflicts. For more information see, "Precedence of software restriction policies" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create an Internet zone rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an Internet zone rule**

1. Open Software Restriction Policies.
2. In either the console tree or the details pane, right-click **Additional Rules**, and then click **New Internet Zone Rule**.
3. In **Internet zone**, click an Internet zone.
4. In **Security level**, click either **Disallowed** or **Unrestricted**, and then click **OK**.

## Notes

- Different administrative credentials are required to perform this procedure, depending on your environment:
  - If you create an Internet zone rule for your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
  - If you create an Internet zone rule for a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create a new software restriction policy setting for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- Zone rules only apply to files with an .msi file type, which are Windows Installer packages.
- For software restriction policies to take effect, users must update policy settings by logging off from and logging on to their computers.
- When more than one software restriction policies rule is applied to policy settings, there is a precedence of rules for handling conflicts. For more information see, "Precedence of software restriction policies" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a path rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a path rule**

1. Open Software Restriction Policies.
2. In either the console tree or the details pane, right-click **Additional Rules**, and then click **New Path Rule**.
3. In **Path**, type a path, or click **Browse** to find a file or folder.
4. In **Security level**, click either **Disallowed** or **Unrestricted**.
5. In **Description**, type a description for this rule, and then click **OK**.

**Caution**

- On certain folders, such as the Windows folder, setting the security level to **Disallowed** can adversely affect the operation of your operating system. Make sure that you do not disallow a crucial component of the operating system or one of its dependent programs.

**Notes**

- Different administrative credentials are required to perform this procedure, depending on your environment:
    - If you create a path rule for your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
    - If you create a path rule for a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create new software restriction policies for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- If you create a path rule for software with a security level of **Disallowed**, users can still run the software by copying it to another location.
- The wildcard characters that are supported by the path rule are * and ?.
- You can use environment variables, such as %programfiles% or %systemroot%, in the path rule.
- If you want to create a path rule for software when you do not know where it is stored on a computer but you have its registry key, you can create a registry path rule. For more information about how to create a registry path rule, see Related Topics.
- To prevent users from executing e-mail attachments, you can create a path rule for your e-mail program's attachment directory that prevents users from running e-mail attachments.

- The only file types that are affected by path rules are those that are listed in **Designated File Types** in the details pane for Software Restriction Policies. There is one list of designated file types that is shared by all rules. For more information, see "Add or delete a designated file type" in Related Topics.

- For software restriction policies to take effect, users must update policy settings by logging off from and logging on to their computers.

- When more than one software restriction policies rule is applied to policy settings, there is a precedence of rules for handling conflicts. For more information, see "Precedence of software restriction policies" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a registry path rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a registry path rule**

1. Click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. In the console tree, right-click the registry key that you want to create a rule for, and then click **Copy Key Name**. Note the value name in the details pane.
3. Open Software Restriction Policies.
4. In either the console tree or the details pane, right-click **Additional Rules**, and then click **New Path Rule**.
5. In **Path**, paste the registry key name, followed by the value name.
6. Enclose the registry path in percent signs (%), for example, **%HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\PlatformSDK\Directories\InstallDir%**.
7. In **Security level**, click either **Disallowed** or **Unrestricted**.
8. In **Description**, type a description for this rule, and then click **OK**.

## Notes

- Different administrative credentials are required to perform this procedure, depending on your environment:
  - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
  - If you create a registry path rule for a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create a new software restriction policy setting for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- Format the registry path as follows: **%[Registry Hive]\[Registry Key Name]\[Value Name]%**
- The name of the registry hive has to be written out; abbreviations do not work. For example, **HKCU** cannot be substituted for **HKEY_CURRENT_USER**.
- The registry path rule can contain a suffix after the closing percent sign. Do not use a backslash (\) in the suffix. For example, **%HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders\Cache%OLK*** is valid.
- The only file types that are affected by path rules are those that are listed in **Designated File Types** in the details pane for Software Restriction Policies. There is one list of designated file types that is shared by all rules. For more information,

see "Add or delete a designated file type" in Related Topics.

- To refresh software restriction policies, you must log off from and then log on to your computer.
- When more than one software restriction policies rule is applied to policy settings, there is a precedence of rules for handling conflicts. For more information, see "Precedence of software restriction policies" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add or delete a designated file type

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add or delete a designated file type**

1. Open Software Restriction Policies.
2. In the details pane, double-click **Designated File Types**.
3. Do one of the following:
   - To add a file type, in **File extension**, type the file name extension, and then click **Add**.
   - To delete a file type, in **Designated file types**, click the file type, and then click **Remove**.

## Notes

- Different administrative credentials are required to perform this procedure, depending on the environment in which you add or delete a designated file type:
  - If you add or delete a designated file type for your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
  - If you add or delete a designated file type for a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create a new software restriction policy setting for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- The list of designated file types is shared by all rules for both Computer Configuration and User Configuration for a GPO.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the default security level of software restriction policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the default security level of software restriction policies**

1. Open Software Restriction Policies.
2. In the details pane, double-click **Security Levels**.
3. Right-click the security level that you want to set as the default, and then click **Set as default**.

### Caution

- In certain directories, setting the default security level to **Disallowed** can adversely affect your operating system. For more information about setting your default security setting to **Disallowed**, see Related Topics.

### Notes

- Different administrative credentials are required to perform this procedure, depending on the environment for which you change the default security level of software restriction policies:
- If you change the default security level of software restriction policies on your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- If you change the default security level of software restriction policies on a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create a new software restriction policy setting for this Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- In the details pane, the current default security level is indicated by a black circle with a check mark in it. If you right-click the current default security level, the **Set as default** command does not appear in the menu.
- Software restriction policies rules are created to specify exceptions to the default security level. When the default security level is set to **Unrestricted**, rules can specify software that is not allowed to run. When the default security level is set to **Disallowed**, rules can specify software that is allowed to run.
- At installation, the default security level of software restriction policies on all files on your system is set to **Unrestricted**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set trusted publisher options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set trusted publisher options**

1. Open Software Restriction Policies.
2. Double-click **Trusted Publishers**.
3. Click the users that you want to decide which certificates will be trusted, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Software Restriction Policies, see "Open Software Restriction Policies" in Related Topics.
- It may be necessary to create a new software restriction policy setting for the Group Policy object (GPO) if you have not already done so. For information about how to create new software restriction policies, see Related Topics.
- You can use this procedure to determine whether users, local administrators, or enterprise administrators can add trusted publishers. For example, you can use this tool to prevent users from making trust decisions about publishers of ActiveX controls.
- Local computer administrators have the right to specify trusted publishers on the local computer, while enterprise administrators have the right to specify trusted publishers on an organizational-unit level.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Software Restriction Policies Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section covers:

- Software restriction policies overview
- Applying software restriction policies
- Security levels and additional rules
- Precedence of software restriction policies rules
- Setting the default security level to Disallowed
- System events for software restriction policies

# Software restriction policies overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Software restriction policies overview**

Software restriction policies address the need to regulate unknown or untrusted software. With the rise in the use of networks, the Internet, and e-mail for business computing, users find themselves exposed to new software in a variety of ways. Users must constantly make decisions about running unknown software. Viruses and Trojan horses often intentionally misrepresent themselves to trick users into running them. It is difficult for users to make safe choices about what software they should run.

With software restriction policies, you can protect your computing environment from untrusted software by identifying and specifying what software is allowed to run. You can define a default security level of **Unrestricted** or **Disallowed** for a Group Policy object (GPO) so that software is either allowed or not allowed to run by default. You can make exceptions to this default security level by creating software restriction policies rules for specific software. For example, if the default security level is set to **Disallowed**, you can create rules that allow specific software to run. The types of rules are as follows:

- Hash rules
- Certificate rules
- Path rules (including registry path rules)
- Internet zone rules

For more information about each of these rules, see Security levels and additional rules.

Software restriction policies consist of the default security level and all the rules that apply to a GPO. Software restriction policies can be applied across a domain, to local computers, or to individual users. Software restriction policies provide a number of ways to identify software, and they provide a policy-based infrastructure to enforce decisions about whether the identified software can run. With software restriction policies, when users execute software programs, they must adhere to the guidelines that are set up by administrators.

With software restriction policies, you can:

- Control the ability of software to run on your system. For example, if you are concerned about users receiving viruses through e-mail, you can apply a policy setting that does not allow certain file types to run in the e-mail attachment directory of your e-mail program.
- Permit users to run only specific files on multiuser computers. For example, if you have multiple users on your computers, you can set up software restriction policies in such a way that users do not have access to any software except the specific files that are necessary for their work.
- Decide who can add trusted publishers to your computer.
- Control whether software restriction policies affect all users or just certain users on a computer.
- Prevent any files from running on your local computer, organizational unit, site, or domain. For example, if your system has a known virus, you can use software restriction policies to stop a computer from opening the file that contains the virus.

**Important**

- Software restriction policies should not be used as a replacement for antivirus software.

For more information, see:

- Software Restriction Policies
- Create a certificate rule
- Create a hash rule
- Create an Internet zone rule
- Create a path rule
- Create a registry path rule

# Applying software restriction policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Applying software restriction policies**

Software restriction policies use rules to identify and control how software runs. You can identify a software program by its hash, certificate, or path or by the Internet zone where it resides. After the software is identified, you can decide whether or not to allow it to run. For more information, see Security levels and additional rules.

Software restriction policies can apply to computers or users, depending on whether you choose to modify settings in Computer Configuration or in User Configuration. For more information, see Open Software Restriction Policies

You apply software restriction policies through Group Policy. You apply the policy settings to a Group Policy object (GPO), which is linked to your local computer, site, domain, or organizational unit. If more than one policy setting applies, the policy settings are in the following order of precedence, from lowest to highest:

- Local computer policy
- Site policy
- Domain policy
- Organizational-unit policy

For example, for a workstation that is joined to a domain, the domain policy settings override the local security policy settings for the workstation's software restriction policies wherever there is a conflict. Likewise, if the same workstation is a member of an organizational unit, the policy settings that are applied from the organizational unit policy override both the domain policy settings and the local policy settings wherever there is a conflict. If the workstation is a member of more than one organizational unit, the organizational unit that immediately contains the workstation has the highest precedence. For more information, see Group Policy (pre-GPMC).

To check the precedence of policy when more than one GPO is applied, you can use Resultant Set of Policy (RSoP). For more information, see Resultant Set of Policy.

Each policy setting is refreshed when you restart the computer. When you modify the policy settings, they are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The policy settings are also refreshed every 16 hours, whether or not there are any changes. You can refresh policy settings by running the command-line utility **gpupdate** and then logging off from and logging on to your computer. For more information, see Gpupdate.

# Security levels and additional rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security levels and additional rules**

For software restriction policies, the security level options are:

- **Unrestricted**, which allows software to run with the full rights of the user who is logged on to the computer.
- **Disallowed**, which does not allow the software to run.

You can use the following rules to make exceptions to the default security level for software restriction policies. For example, if the default security level is **Disallowed**, you can create a path rule that makes an exception to the default security level and allows a software program to run.

More than one rule can be applied to software. When this happens, the rule with the highest precedence determines if the software will run or not run. For information about the precedence of these rules, see Precedence of software restriction policies rules.

**Hash rule**

A hash is a series of bytes with a fixed length that uniquely identifies a software program or file. The hash is computed by a hash algorithm. When a hash rule is created for a software program, software restriction policies calculate a hash of the program. When a user tries to open a software program, a hash of the program is compared to existing hash rules for software restriction policies. The hash of a software program is always the same, regardless of where the program is located on the computer. However, if a software program is altered in any way, its hash also changes, and it no longer matches the hash in the hash rule for software restriction policies.

For example, you can create a hash rule and set the security level to **Disallowed** to prevent users from running a certain file. A file can be renamed or moved to another folder and still result in the same hash. However, any changes to the file itself also change its hash value and allow the file to bypass restrictions.

For more information, see Create a hash rule.

**Certificate rule**

Software restriction policies can also identify software by its signing certificate. You can create a certificate rule that identifies software and then allows or does not allow the software to run, depending on the security level. For example, you can use certificate rules to automatically trust software from a trusted source in a domain without prompting the user. You can also use certificate rules to run files in disallowed areas of your operating system.

Certificate rules are not enabled by default. For information about how to enable certificate rules, see Enable certificate rules.

For information on how to create a certificate rule, see Create a certificate rule. For more information about certificates, see Certificates.

**Path rule**

A path rule identifies software by its file path. For example, if you have a computer that has a default security level of **Disallowed**, you can still grant unrestricted access to a specific folder for each user. You can create a path rule by using the file path and setting the security level of the path rule to **Unrestricted**. Some common paths for this type of rule are %userprofile%, %windir%, %appdata%, %programfiles%, and %temp%. You can also create registry path rules that use the registry key of the software as its path.

Because these rules are specified by the path, if a software program is moved, the path rule no longer applies.

For more information about how to create a path rule, see Create a path rule. For more information on how to create a registry path rule, see Create a registry path rule.

For information about the precedence of path rules when more than one path rule is applied to a file or folder, see Precedence of software restriction policies rules.

**Internet zone rule**

Zone rules apply only to Windows Installer packages. For more information, see Windows Installer overview.

A zone rule can identify software from a zone that is specified through Internet Explorer. These zones are Internet, Intranet, Restricted sites, Trusted sites, and My Computer.

For more information, see Create an Internet zone rule.

# Precedence of software restriction policies rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Precedence of software restriction policies rules**

You can apply several software restriction policies rules to the same software. The rules are applied in the following order of precedence, from highest to lowest:

- Hash rule
- Certificate rule
- Path rule
- Internet zone rule

For example, if you create a hash rule with a security level of **Unrestricted** for a software program that resides in a folder that has a path rule assigned to it with a security level of **Disallowed**, the program will run. The hash rule takes precedence over the path rule.

If two path rules are assigned to the same object, the more specific rule takes precedence. For example, if there is a path rule for C:\Windows\ with a security level of **Disallowed**, but there is also a path rule for C:\Windows\System32\ with a security level of **Unrestricted**, the more specific path rule takes precedence. Software programs in C:\Windows\ will not run, but programs in C:\Windows\System32\ will run.

If two identical rules with differing security levels are applied to software, the more conservative rule takes precedence. For example, if two hash rules--one with a security level of **Disallowed** and one with a security level of **Unrestricted**--are applied to the same software program, the rule with a security level of **Disallowed** takes precedence, and the program will not run.

For more information, see:

- Software Restriction Policies
- Create a hash rule
- Create a certificate rule
- Create a path rule
- Create an Internet zone rule

# Setting the default security level to Disallowed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting the default security level to Disallowed**

You can set software restriction policies so that the operating system has one of two default security levels: **Unrestricted** and **Disallowed**. When you first create software restriction policies, a default setting of **Unrestricted** is automatically defined. You can then apply rules that restrict the execution of specified software programs. When you set the default security level to **Disallowed**, most software is restricted. There are four registry path rules that are automatically created to prevent you from completely locking down your system, including locking yourself out of it. You must then apply rules for all other software that you want to run.

Software restriction policies are applied through the operating system. Certain software programs must be set to **Unrestricted** for the operating system to function at all. The following tips can help you decide which programs to set to **Unrestricted** if you decide to use a default security level of **Disallowed**:

- When the default security level is set to **Disallowed**, four registry path rules are created automatically. They are as follows:

  - **%HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SystemRoot%**
  - **%HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SystemRoot%*.exe**
  - **%HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SystemRoot%\System32*.exe**
  - **%HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\ProgramFilesDir%**

  These registry path rules are created as a safeguard against locking yourself and all users out of the system. Only advanced users should consider modifying or deleting these rules.

- Startup items are put in **HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Run** in the registry. If you want them to run, make sure that you create a registry path rule for them. For information about creating a registry path rule, see Create a registry path rule.

- If a computer must run logon scripts, create a path rule that allows them. For information about creating a path rule, see Create a path rule.

- Explore your software programs when you create rules for them. Many programs start other programs to perform certain tasks. For example, Microsoft Word starts Microsoft Clip Organizer to manage clip art. For optimal performance, it is essential that all supporting programs be allowed to run.

For more information about software restriction policies, see Software Restriction Policies.

# System events for software restriction policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System events for software restriction policies**

When users try to run software that has been disallowed by software restriction policies or by software restriction policies rules, events are generated and stored in the application log, as indicated in the following table. You can view these events with the Event Viewer. For more information about Event Viewer, see Event Viewer.

| Event ID | What it means |
|---|---|
| 865 | A user attempted to run software that is disallowed by the default security level. |
| 866 | A user attempted to run software that is disallowed by a path rule. |
| 867 | A user attempted to run software that is disallowed by a certificate rule. |
| 868 | A user attempted to run software that is disallowed by an Internet zone rule or a hash rule. |

For more information about the event log, see Settings for Event Logs. For more information about software restriction policies, see Software Restriction Policies.

# Software Restriction Policies Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Users receive a message that says "Windows cannot open this program because it has been prevented by a software restriction policy. For more information, open Event Viewer or contact your system administrator." Or, on the command line, a message says "The system cannot execute the specified program."
- Modified software restriction policies are not taking effect.
- You have added a rule to software restriction policies, and you cannot log on to your computer.
- A new policy setting is not applying to a specific file name extension.

**Users receive a message that says "Windows cannot open this program because it has been prevented by a software restriction policy. For more information, open Event Viewer or contact your system administrator." Or, on the command line, a message says "The system cannot execute the specified program."**
**Cause:** The default security level (or a rule) was created so that the software program is set as **Disallowed**, and as a result it will not start.

**Solution:** Look in the event log for an in-depth description of the message. The event log message indicates what software program is set as **Disallowed** and what rule is applied to the program.

**See also:** Software Restriction Policies

**Modified software restriction policies are not taking effect.**
**Cause:** Software restriction policies that are specified in a domain through Group Policy override any policy settings that are configured locally. This may imply that there is a policy setting from the domain that is overriding your policy setting. For more information, see Group Policy (pre-GPMC).

**Cause:** Group Policy may not have refreshed its policy settings. Group Policy applies changes to policy settings periodically; therefore, it is likely that the policy changes that were made in the directory have not yet been refreshed.

**Solution:** You can refresh policy settings with the command-line utility **gpupdate** or by logging off from and then logging back on to your computer. For best results, run **gpupdate**, and then log off from and log back on to your computer. For more information, see Gpupdate.

The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.

**Cause:** The local computer on which you changed software restriction policies for the network cannot contact a domain controller.

**Solution:** To successfully modify policy for a network, the computer on which you modify software restriction policies must be able to contact a domain controller to update policy for the network. If the computer on which you are working cannot contact the domain controller, software restriction policies are not applied. If your computer is a member of a domain, local software restriction policies are not applied unless the computer can contact the domain controller to ensure that network policy does not override local policy.

**You have added a rule to software restriction policies, and you cannot log on to your computer.**
**Cause:** Your computer accesses many software programs and files when it starts. It is possible to inadvertently set one of these programs or files to **Disallowed**. Because the computer cannot access the program or file, it cannot start properly.

**Solution:** Start the computer in Safe Mode, log on as a local administrator, and then change software restriction policies to allow the program or file to run.

**A new policy setting is not applying to a specific file name extension.**
**Cause:** The file name extension is not in the list of designated file types for software restriction policies.

**Solution:** Add the file name extension to the list of supported file types.

For more information, see Add or delete a designated file type.

# Auditing Security Events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Auditing security events**
You can set up audit policy so that user or system activity in specified event categories is recorded. You can monitor security-related activity, such as who accesses an object, if a user logs on to or logs off from a computer, or if changes are made to an auditing policy setting.

- Before defining auditing policy settings in the object access event category, see Checklist: Setting up object access auditing.
- For tips about auditing, see Auditing Security Events Best practices.
- For help with specific tasks, see Auditing Security Events How To....
- For general background information, see Auditing Security Events Concepts.

# Checklist: Setting up object access auditing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Setting up object access auditing**

| Step | Reference |
| --- | --- |
| Read the auditing overview. | Auditing overview |
| Enable auditing of the object access event category. | Define or modify auditing policy settings for an event category |
| Apply auditing policy to a specified object. | Apply or modify auditing policy settings for a local file or folder; Apply or modify auditing policy settings for an object using Group Policy |

# Auditing Security Events Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Create an audit plan before implementing audit policy.**

- Decide what type of information you want to gain by collecting audit events:

  - If you are interested in intrusion detection--tracking the attempts of users to gain access to areas for which they are not authorized--you can collect failure audits. But enabling failure audits can be a risk to your organization. If users attempt to access a resource for which they are not authorized, they can create so many failure audits that the security log becomes full, and the computer cannot collect any more audits. If you have the **Audit: Shut down system immediately if unable to log security audits** policy setting enabled, users can start a denial-of-service attack through your audit policy.

  - If you are interested in forensics--using the audit log to determine exactly what happens in your organization--you can collect a combination of success and failure audits.

- Consider the resources that you have available for collecting and reviewing an audit log. Audit events take up space on your computers, and they take up your time and the time of people in your organization. Do not audit events that do not really interest you.

**Collect and archive security logs across your organization.**

- If an intrusion occurs, isolate and preserve the security log entries. These entries can be valuable during an investigation of the intrusion.

- An audit trail can contain information about changes that are made to your computer or to other computers on the network. If intruders gain administrator rights and permissions, or if administrators abuse their rights and permissions, they can clear the security log, leaving you without a trail of their actions. If you use a tool that regularly collects and saves security log entries across your organization, even if intruders or administrators clear the local security log, you are more likely to be able to trace the actions of intruders or administrators. Microsoft Operations Manager is an example of such a tool. For the most recent tools available, see Search Microsoft.com at the Microsoft Web site.

**Audit success and failure events in the system event category.**

- By auditing success and failure events in the system event category, you can notice unusual activity that may indicate that an intruder is attempting to gain access to your computer or your network.

- The number of audits that are generated when this setting is enabled tends to be relatively low, and the quality of information that is gained from the events tends to be relatively high.

  For information about the system event category, see Audit system events.

  For information about how to enable auditing in the system event category, see Define or modify auditing policy settings for an event category.

**Audit success events in the policy change event category on domain controllers.**

- If an event is logged in the policy change event category, someone has changed the Local Security Authority (LSA) security policy configuration.

- If you use Group Policy to edit your auditing policy settings, it is not necessary to audit events in the policy change event

category on member servers.

- If you decide to audit failure events in the policy change event category, you can see if unauthorized users or attackers are trying to change policy settings, including security policy settings. Although this can be helpful for intrusion detection, the increase in resources that is required and the possibility of a denial-of-service attack usually outweigh the benefits.

  For information about the policy change event category, see Audit policy change.

  For information about how to enable auditing in the policy change event category, see Define or modify auditing policy settings for an event category.

**Audit success events in the account management event category.**

- By auditing success events in the account management event category, you can verify changes that are made to account properties and group properties.

- If you decide to audit failure events in the account management event category, you can see if unauthorized users or attackers are trying to change account properties or group properties. Although this can be helpful for intrusion detection, the increase in resources that is required and the possibility of a denial-of-service attack usually outweigh the benefits.

  For information about the account management event category, see Audit account management.

  For information about how to enable auditing in the account management event category, see Define or modify auditing policy settings for an event category.

**Audit success events in the logon event category.**

- By auditing success events in the logon event category, you have a record of when each user logs on to or logs off from a computer. If an unauthorized person steals a user's password and logs on to a computer, you can determine when the breach of security occurred.

- If you decide to audit failure events in the logon event category, you can see if unauthorized users or attackers are trying to log on to a computer. Although this can be helpful for intrusion detection, the possibility of a denial-of-service attack increases with the auditing of failure events in the logon event category. If you have failure auditing enabled in these event categories, users from outside of your organization can fill the security log or cause events to be overwritten by continuously attempting to log on to your network with incorrect usernames or passwords. If you also have the **Audit: Shut down system immediately if unable to log security audits** policy setting enabled, the consequences of logging failure events in these categories can be more severe - the user could cause a denial of service if the security log is filled.

  For information about how to enable auditing in the logon event category, see Define or modify auditing policy settings for an event category.

**Audit success events in the account logon event category on domain controllers.**

- By auditing success events in the account logon event category, you can see when users log on to or log off from the domain.

- It is not necessary to audit events in the account logon event category on member servers.

- If you decide to audit failure events in the account logon event category, you can see if unauthorized users or attackers are trying to log on to your network. Although this can be helpful for intrusion detection, the possibility of a denial-of-service attack increases with the auditing of failure events in the account logon event category. If you have failure auditing enabled in these event categories, users from outside of your organization can fill the security log or cause events to be overwritten by continuously attempting to log on to your network with incorrect usernames or passwords. If you also have the **Audit: Shut down system immediately if unable to log security audits** policy setting enabled, the consequences of logging failure events in these categories can be more severe - the user could cause a denial of service

if the security log is filled.

For information about the account logon event category, see Audit account logon events.

For information about how to enable auditing in the account logon event category, see Define or modify auditing policy settings for an event category.

**Be specific when setting up auditing on an object.**

- To audit object access, you must enable the **Audit object access** policy setting and then edit the system access control list (SACL) that is associated with the object. For more information, see Checklist: Setting up object access auditing.

- For best system performance, minimize the number of entries in the SACL for an object. One entry in a SACL that contains 1000 users does not degrade system performance as much as 1000 separate entries.

- To reduce the volume of events that is generated and to maximize the effectiveness of each event, only audit the actions that really interest you. For example, if you are interested in users reading a file, do not audit Full Control.

  For information about the object access event category, see Audit object access.

  For information about operation-based auditing, see Operation-based auditing on files or folders.

  For information about how to enable auditing in the object access event category, see Define or modify auditing policy settings for an event category.

**Set an appropriate size for the security log.**

- It is important that the size of the security log be configured appropriately, based on the number of events that your auditing policy settings generate.

  For information about managing event logs, see Event Viewer.

  For information about settings for the event logs, see Settings for Event Logs.

# Auditing Security Events How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Define or modify auditing policy settings for an event category
- Apply or modify auditing policy settings for a local file or folder
- Apply or modify auditing policy settings for an object using Group Policy
- View the security log

# Define or modify auditing policy settings for an event category

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define or modify auditing policy settings for an event category**

- For your local computer
- For only domain controllers, when you are on a domain controller or on a workstation that hasWindows Server 2003Administration Tools Pack installed
- For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed
- For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

**For your local computer**

1. Open Local Security Settings.
2. In the console tree, click **Audit Policy**.

   **Where?**

   - Security Settings/Local Policies/Audit Policy

3. In the details pane, double-click an event category that you want to change the auditing policy settings for.
4. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.
   - To audit unsuccessful attempts, select the **Failure** check box.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**For only domain controllers, when you are on a domain controller or on a workstation that has Windows Server 2003 Administration Tools Pack installed**

1. Open Domain Controller Security Policy.
2. In the console tree, click **Audit Policy**.

   **Where?**

- Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy

3. In the details pane, double-click an event category that you want to change the auditing policy settings for.

4. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

5. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.

   - To audit unsuccessful attempts, select the **Failure** check box.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Domain Controller Security Policy, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click **Edit** to open the Group Policy object (GPO) that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.

5. In the console tree, click **Audit Policy**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy

6. In the details pane, double-click an event category that you want to change the auditing policy settings for.

7. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

8. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.

   - To audit unsuccessful attempts, select the **Failure** check box.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain**

1. Open Microsoft Management Console (MMC).

2. In the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.

3. Click **Group Policy Object Editor**, and then click **Add**.

4. On the **Select Group Policy Object** page in the Group Policy Wizard, click **Browse**.

5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit--or create a new one, click **OK**, and then click **Finish**.

6. Click **Close**, and then click **OK**.

7. In the console tree, click **Audit Policy**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy

8. In the details pane, double-click an event category that you want to change the auditing policy settings for.

9. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

10. Do one or both of the following, and then click **OK**.

    - To audit successful attempts, select the **Success** check box.

    - To audit unsuccessful attempts, select the **Failure** check box.

    **Notes**

    - To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

    - To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.

**Notes**

- To audit object accesses, enable auditing of the object access event category by following the steps above. Then, enable auditing on the specific object. For information about how to enable auditing on an object, see "Apply or modify auditing

policy settings for a local file or folder" or "Apply or modify auditing policy settings for an object using Group Policy" in Related Topics.

- After your audit policy is configured, events will be recorded in the security log. Open the security log to view these events. For information about the security log, see "Use the security log" in Related Topics.

- The default auditing policy setting for domain controllers is **No Auditing**. This means that even if auditing is enabled in the domain, the domain controllers do not inherit auditing policy locally. If you want domain auditing policy to apply to domain controllers, you must modify this policy setting.

# Apply or modify auditing policy settings for a local file or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply or modify auditing policy settings for a local file or folder**

1. Open Windows Explorer.
2. Right-click the file or folder that you want to audit, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, and then click the **Auditing** tab.
4. Do one of the following:
   - To set up auditing for a new user or group, click **Add**. In **Enter the object name to select**, type the name of the user or group that you want, and then click **OK**.
   - To remove auditing for an existing group or user, click the group or user name, click **Remove**, click **OK**, and then skip the rest of this procedure.
   - To view or change auditing for an existing group or user, click its name, and then click **Edit**.
5. In the **Apply onto** box, click the location where you want auditing to take place.
6. In the **Access** box, indicate what actions you want to audit by selecting the appropriate check boxes:
   - To audit successful events, select the **Successful** check box.
   - To stop auditing successful events, clear the **Successful** check box.
   - To audit unsuccessful events, select the **Failed** check box.
   - To stop auditing unsuccessful events, clear the **Failed** check box.
   - To stop auditing all events, click **Clear All**.
7. If you want to prevent subsequent files and subfolders of the original object from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.

**Important**

- Before setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files or folders will be audited. For more information about how to enable object access auditing, see "Define or modify auditing policy settings for an event category" in Related Topics.

**Notes**

- You must be logged on as a member of the Administrators group or you must have been granted the **Manage auditing**

**and security log** right in Group Policy to perform this procedure.

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- For information about how to audit local registry keys, see "Audit activity on a registry key" in Related Topics.
- After object access auditing is enabled, view the security log in Event Viewer to review the results of your changes.
- You can set up file and folder auditing only on NTFS drives.
- If you see the following:
    - In the **Auditing Entry for *File or Folder*** dialog box, in the **Access** box, the check boxes are unavailable ...
    - In the **Advanced Security Settings for *File or Folder*** dialog box, the **Remove** button is unavailable ...

  auditing has been inherited from the parent folder.
- Because the security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the security log. The maximum size for the security log is defined in Event Viewer.

# Apply or modify auditing policy settings for an object using Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply or modify auditing policy settings for an object using Group Policy**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the Group Policy Wizard, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit--or create a new one, click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. Do one or more of the following:

| To audit | Do this |
|---|---|
| System services | In the console tree, click **System Services**.<br>Where?<br>• Computer Configuration/Windows Settings/Security Settings/System Services<br>In the details pane, right-click the service that you want to apply or modify auditing policy settings for, and then click **Properties**.<br>If it is not already selected, select the **Define this policy setting** check box, and then select the appropriate setting.<br>Click **Edit security**. |
| Registry keys | In the console tree, click **Registry**.<br>Where?<br>• Computer Configuration/Windows Settings/Security Settings/Registry<br>If you want to add a registry key to this GPO to audit, right-click **Registry**, and then click **Add Key**. Browse to the key that you want, and then click **OK**.<br>If you want to apply or modify auditing settings on a registry key that has already been added to this GPO, in the details pane, right-click the registry key, click **Properties**, and then click **Edit Security**. |

| | |
|---|---|
| Files or folders | In the console tree, click **File System**.<br><br>Where?<br><br>• Computer Configuration/Windows Settings/Security Settings/File System<br><br>If you want to add a file or folder to this GPO to audit, right-click **File System**, and then click **Add File**. Browse to the file that you want, or make a new folder, and then click **OK**.<br><br>If you want to apply or modify auditing settings on a file or folder that has already been added to this GPO, in the details pane, right-click the file or folder, click **Properties**, and then click **Edit Security**. |

8. Click **Advanced**, and then click the **Auditing** tab.

9. Do one of the following:

   - To set up auditing for a new user or group, click **Add**. In **Name**, type the name of the user or group that you want, and then click **OK**.
   - To view or change auditing for an existing group or user, click the name that you want, and then click **Edit**.
   - To remove auditing for an existing group or user, click the name that you want, click **Remove**, click **OK**, and then skip the rest of this procedure.

10. Select the appropriate entry in the **Apply onto** list.

11. In the **Access** box, indicate what actions you want to audit by selecting the appropriate check boxes:

    - To audit successful events, select the **Successful** check box.
    - To stop auditing successful events, clear the **Successful** check box.
    - To audit unsuccessful events, select the **Failed** check box.
    - To stop auditing unsuccessful events, clear the **Failed** check box.
    - To stop auditing all events, click **Clear All**.

12. If you want to prevent files and subfolders in the tree from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.

**Important**

- Before setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files or folders will be audited. For more information about how to enable object access auditing, see "Define or modify auditing policy settings for an event category" in Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- For more information on selecting where to apply auditing entries, see Related Topics.
- You can set up file and folder auditing only on NTFS drives.
- If you see the following:
    - In the **Auditing Entry for *File or Folder*** dialog box, in the **Access** box, the check boxes are unavailable ...
    - In the **Advanced Security Settings for *File or Folder*** dialog box, the **Remove** button is unavailable ...

  auditing is inherited from the parent folder.
- After object access auditing is enabled, view the security log in Event Viewer to review the results of your changes.
- Because the security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the security log. The maximum size for the security log is defined in Event Viewer.

# Auditing Security Events Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about auditing:

- Auditing overview
- Viewing security logs
- Operation-based auditing on files or folders
- Auditing settings on objects
- How inheritance affects file and folder auditing
- Selecting where to apply auditing entries
- Per-user selective auditing

# Auditing overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Auditing overview**
Establishing audit policy is an important facet of security. Monitoring the creation or modification of objects gives you a way to track potential security problems, helps to ensure user accountability, and provides evidence in the event of a security breach.

The most common types of events to be audited are:

- Access to objects, such as files and folders.
- Management of user accounts and group accounts.
- Users logging on to and logging off from the system.

When you implement audit policy:

- Specify the categories of events that you want to audit. Examples of event categories are user logon, user logoff, and account management. The event categories that you select constitute your audit policy. For more information about each event category, see Auditing Policy.
- Set the size and behavior of the security log. You can view the security log with Event Viewer. For more information about the security log, see Viewing security logs.
- If you want to audit directory service access or object access, determine which objects you want to monitor access of and what type of access you want to monitor. For example, if you want to audit any attempts by users to open a particular file, you can configure auditing policy settings in the object access event category so that both successful and failed attempts to read a file are recorded.

  For more information about how to set up object access auditing, see:

  - Apply or modify auditing policy settings for a local file or folder
  - Apply or modify auditing policy settings for an object using Group Policy

For more information about auditing, see Auditing Security Events.

# Viewing security logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing security logs**

Auditing a local object creates an entry in the security log. The security entries that appear in the security log depend on the auditing categories that you select for your audit policy. For events that are related to object access, the entries in the security log also depend on the auditing policy settings that are defined for each object. For more information about auditing, see Auditing Security Events.

For example, if your audit policy specifies the auditing of files and folders, and a file's properties specify that failed deletions of that file are to be audited, each failed attempt by a user to delete the file appears in the security log.

You can view the security log by using Event Viewer.

**Size of the security log**

It is important that you set the size of the security log appropriately. Because the security log is limited in size, choose which events you audit carefully. Also, consider the amount of disk space that you are willing to devote to the security log. The maximum amount is defined in Event Viewer.

For information on what to do when the security log is full, see Audit: Shut down system immediately if unable to log security audits.

For more information about security events, see "Security Events" at the Microsoft Windows Resource Kits Web site.

# Operation-based auditing on files or folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Operation-based auditing on files or folders**

Operation-based auditing is a new feature in the Windows Server 2003 family. In earlier versions of Windows, information that was gained from object access auditing was not as detailed as it is with operation-based auditing. While you could determine that a user attempted to access an object, there was no way to be sure that the object was accessed in every way that was documented in the audit event. With operation-based auditing, you can audit operations on files and folders. This means that you can audit certain operations, such as Write, as well as the accessing of objects. Operation-based auditing is enabled when object access auditing is enabled on a file or folder. Object access events are recorded, along with operations such as Write, in the security log.

To enable operation-based auditing, you must:

- Enable the **Audit object access** policy setting. For more information, see Define or modify auditing policy settings for an event category.
- Apply audit policy to a specific folder. For more information, see:
  - Apply or modify auditing policy settings for a local file or folder
  - Apply or modify auditing policy settings for an object using Group Policy

Operation-based audits are categorized as object audits, and they are logged as event number 567 in the security log. They are generated the first time an operation is performed. Only files and folders can be set up to generate operation-based audits.

# Auditing settings on objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Auditing settings on objects**

Each object has a set of security information, or security descriptor, attached to it. Part of the security descriptor specifies the groups or users that can access an object and the types of access (permissions) that are granted to those groups or users. This part of the security descriptor is known as a discretionary access control list (DACL).

A security descriptor for an object also contains auditing information. This auditing information is known as a system access control list (SACL). More specifically, a SACL specifies the following:

- The group or user accounts to audit when they access the object.
- The operations to be audited for each group or user, for example, modifying a file.
- A Success or Failure attribute for each access event, based on the permissions that are granted to each group and user in the object's DACL.

You can apply auditing to an object, and, through inheritance, the auditing can apply to any child objects. For example, if you want to audit failed access to a folder, this auditing event can be inherited by all files within the folder. For more information, see How inheritance affects file and folder auditing.

To audit files and folders, you must be logged on as a member of the Administrators group.

For more information about auditing, see Auditing Security Events.

# How inheritance affects file and folder auditing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How inheritance affects file and folder auditing**

After you set up auditing on a parent folder, new files and subfolders that are created in that folder inherit auditing. If you do not want them to inherit auditing, in the **Apply onto** box in the **Auditing Entry for *File or Folder*** dialog box, click **This folder only** when you set up auditing for the parent folder. In cases where you want to prevent only certain files or subfolders from inheriting auditing, right-click the file or subfolder that you want to prevent from inheriting auditing, click **Properties**, click the **Security** tab, click **Advanced**, click the **Auditing** tab, and then clear the check box that is labeled **Inherit from parent the auditing entries that apply to child objects. Include these with entries explicitly defined here**.

If the check boxes in **Auditing Entry for *File or Folder*** are unavailable or if, in **Access Control Settings**, the **Remove** button is unavailable, auditing has been inherited from the parent folder.

To make changes to inherited auditing:

- Make the changes to the parent folder, and then the file or folder will inherit auditing.
- On the **Auditing** tab in the **Advanced Security Settings for *File or Folder*** dialog box, clear the check box that is labeled **Inherit from parent the auditing entries that apply to child objects. Include these with entries explicitly defined here**. You can then click **Edit** or **Remove** to make changes or remove auditing. However, the file or folder will no longer inherit auditing changes from the parent folder.

For more information, see Auditing Security Events.

# Selecting where to apply auditing entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Selecting where to apply auditing entries**

The **Auditing Entry** dialog box appears when you audit files or folders. In this dialog box, the **Apply onto** list displays the locations where you can apply auditing entries. How these auditing entries are applied depends on whether the **Apply these auditing entries to objects and/or containers within this container only** check box is selected. By default, this check box is cleared.

Click either **Cleared** or **Selected** below to see how auditing entries are applied, depending on whether this check box is cleared or selected. When this check box is:

- Cleared ...
- Selected ...

**Cleared ...**

| Apply onto | Audits the current folder | Audits subfolders in the current folder | Audits files in the current folder | Audits all subsequent subfolders | Audits files in all subsequent subfolders |
|---|---|---|---|---|---|
| This folder only | x | | | | |
| This folder, subfolders, and files | x | x | x | x | x |
| This folder and subfolders | x | x | | x | |
| This folder and files | x | | x | | x |
| Subfolders and files only | | x | x | x | x |
| Subfolders only | | x | | x | |
| Files only | | | x | | x |

**Selected ...**

| Apply onto | Audits the current folder | Audits subfolders in the current folder | Audits files in the current folder | Audits all subsequent subfolders | Audits files in all subsequent subfolders |
|---|---|---|---|---|---|
| This folder only | x | | | | |
| This folder, subfolders, and files | x | x | x | | |
| This folder and subfolders | x | x | | | |
| This folder and files | x | | x | | |

| | | | | | |
|---|---|---|---|---|---|
| Subfolders and files only | | **x** | **x** | | |
| Subfolders only | | **x** | | | |
| Files only | | | **x** | | |

For information about how to set up auditing on objects, see Checklist: Setting up object access auditing.

For more information about auditing, see Auditing Security Events.

# Per-user selective auditing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Per-user selective auditing**

For information about per-user selective auditing, see "Security Auditing" at the Microsoft Windows Resource Kits Web site.

For information about auditing, see Auditing Security Events.

# Encrypting File System

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encrypting File System**

With Encrypting File System (EFS), you can encrypt files and directories that are stored on a disk.

- Before using EFS with a server cluster, see Checklist: Configuring Encrypting File System in a server cluster.
- For tips about using EFS, see Encrypting File System best practices.
- For help with specific tasks, see Encrypting File System How To ....
- For general background information, see Encrypting File System Concepts.
- For problem-solving instructions, see Encrypting File System Troubleshooting.

# Checklist: Configuring Encrypting File System in a server cluster

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring Encrypting File System in a server cluster**
Using Encrypting File System (EFS) on a server cluster requires several tasks to be performed before EFS files can be safely encrypted and decrypted on the server cluster.

| | Step | Reference |
|---|---|---|
| | Create a server cluster | Checklist: Planning and creating a server cluster |
| | Configure the computer accounts for the server cluster to be trusted for delegation<br><br>**Important**<br><br>• All cluster node computer accounts, as well as the virtual server computer account, must be trusted for delegation. | Allow a computer to be trusted for delegation |
| | Configure users of this cluster for roaming user profiles to ensure the private keys of the users are available to each node of the server cluster | Create a roaming user profile |
| | Create a file share for storage of encrypted files | Create a cluster-managed file share |
| | Configure the cluster to support Kerberos authentication | Enable Kerberos authentication for virtual servers |
| | Create or copy files on the cluster server file share | |
| | Encrypt files on the cluster server file share | Encrypt a file or folder |

# Encrypting File System best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### Encrypting File System best practices

#### Ensure files intended for encryption are created and remain encrypted

- Encrypt folders before creating sensitive files in them for maximum security. Doing this causes the files to be created as encrypted and their data is never written to the disk as plaintext.
- Encrypt the My Documents folder if you save most of your documents to the My Documents folder. This ensures that your personal documents are encrypted by default. For Roaming User Profiles, this should only be done when the My Documents folder is redirected to a network location.
- Encrypt folders instead of individual files so that, if a program creates temporary files during editing, these are encrypted as well.

#### Manage private keys to ensure file security

- The designated recovery agent should export the data recovery certificate and private key to disk, secure them in a safe place, and delete the data recovery private key from the system. In this way, the only person who can recover data for the system is the person who has physical access to the data recovery private key.
- The number of designated recovery agents should be kept to a minimum. This exposes fewer keys to cryptographic attack and provides a higher level of assurance that encrypted data will not be decrypted inappropriately.
- Use Microsoft Certificate Services to manage Encrypting File System (EFS) and Data Recovery Agent (DRA) certificates and private keys.

### Caution

- When configuring Certificate Services and using a custom certificate template to issue EFS certificates, do not select the **Prompt the user during enrollment and require user input when the private key is used** option. This option prevents EFS from using the private key for encryption or decryption.

#### Provide security and reliability of data at all times

- Encrypt sensitive data on computers that are members of a domain. This protects against compromise of data though offline cryptographic attacks.
- Use Internet Protocol security (IPSec) to ensure that data remains encrypted as it is transmitted over the network. EFS can be used in conjunction with Web Distributed Authoring and Versioning (WebDAV) to store encrypted data on the Internet. In addition, EFS can be used with Server Message Block (SMB) signing to ensure that the transmission and reception of EFS files across a network is not altered in any way.
- Back up the entire server that stores server-based encrypted data regularly. This ensures that, in case of data recovery, the profiles that include decryption keys can be restored.

# Encrypting File System How To ...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Encrypt or Decrypt Files
- Copy or Move Encrypted Files or Folders
- Recover Files or Folders
- Add users to or remove users from a file
- Back up an EFS certificate with the private key

# Encrypt or Decrypt Files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encrypt or decrypt files**

- Encrypt a file or folder
- Decrypt a file or folder
- Enable a remote server for file encryption
- Encrypt a file or folder on a remote computer

# Encrypt a file or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To encrypt a file or folder**

1. Open Windows Explorer.
2. Right-click the file or folder that you want to encrypt, and then click **Properties**.
3. On the **General** tab, click **Advanced**.
4. Select the **Encrypt contents to secure data** check box, and then click **OK**.
5. In the **Properties** dialog box, click **OK**, and then do one of the following:
   - To encrypt a file and the parent folder, in the **Encryption Warning** dialog box, click **Encrypt the file and the parent folder**.
   - To encrypt a file only, in the **Encryption Warning** dialog box, click **Encrypt the file only**.
   - To encrypt a folder only, in the **Confirm Attribute Changes** dialog box, click **Apply changes to this folder only**.
   - To encrypt a folder and its subfolders and files, in the **Confirm Attribute Changes** dialog box, click **Apply changes to this folder, subfolders and files**.

**Notes**

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- You can only encrypt files and folders on NTFS file system volumes.
- Files or folders that are compressed cannot also be encrypted. If you encrypt a compressed file or folder, that file or folder will be uncompressed.
- Files marked with the System attribute cannot be encrypted, nor can files in the systemroot folder.
- If you choose to encrypt the parent folder when you encrypt a single file, all files and subfolders that are added to the folder in the future will be encrypted when they are added.
- If you choose to encrypt all files and subfolders when you encrypt a folder, all files and subfolders currently in the folder are encrypted, as well as any files and subfolders that are added to the folder in the future. If you choose to encrypt the folder only, all files and subfolders currently in the folder are not encrypted. However, any files and subfolders that are added to the folder in the future are encrypted when they are added.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**
Decrypt a file or folder

# Decrypt a file or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To decrypt a file or folder**

1. Open Windows Explorer.
2. Right-click the encrypted file or folder, and then click **Properties**.
3. On the **General** tab, click **Advanced**.
4. Clear the **Encrypt contents to secure data** check box.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- When you decrypt a folder, you are asked if you want all files and subfolders within the folder to be decrypted as well. If you choose to decrypt the folder only, the encrypted files and folders within the decrypted folder remain encrypted. However, new files and folder that you create within the decrypted folder will not be automatically encrypted.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable a remote server for file encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable a remote server for file encryption**

1. Open Active Directory Users and Computers, locate the remote server computer account.
2. Right-click the remote server computer account, and then click **Properties**.
3. Click the **Delegation** tab, select the **Trust this computer for delegation to specified services only** option.
4. Ensure that Use **Kerberos** only is selected. Click **Add**.
5. Click **Users or Computers**. Use **Select Users or Computers** to locate and add the account for a local domain controller.
6. From the list of available services, select the **protectedstorage** and the **cifs** services.
7. Repeat steps 5, and 6 for each domain controller computer account in the domain.
8. Once all domain controller computer objects have been added, click OK on the remote computer's **Properties** dialog box.

| **Important** |
| --- |
| The list must be updated when domain controllers are added or removed from the domain. |

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- When encrypting files on a WebDAV server, the computer does not need to be trusted for delegation.
- You cannot configure a computer in another forest for encryption, even if there is a trust relationship established.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

Delegating authentication

# Encrypt a file or folder on a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To encrypt a file or folder on a remote computer**

1. Open Windows Explorer.
2. On the **Tools** menu, click **Map Network Drive**, and then follow the instructions in the **Map Network Drive** dialog box.
3. Right-click the file or folder that you want to encrypt, and then click **Properties**.
4. On the **General** tab, click **Advanced**.
5. Select the **Encrypt contents to secure data** check box.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- You can only encrypt files and folders on NTFS file system volumes.
- Files or folders that are compressed cannot also be encrypted. If you encrypt a compressed file or folder, that file or folder will be uncompressed.
- Files that are marked with the System attribute or are in the systemroot directory cannot be encrypted.
- In a domain environment, remote encryption is not enabled by default. To enable encryption for a specific computer, your network administrator can make that computer trusted for delegation. For more information, consult your network administrator.
- When you encrypt a folder, you are asked if you want all files and subfolders within the folder to be encrypted as well. If you choose to do so, all future files and subfolders that are added to the folder are automatically encrypted.
- Programs that create temporary work files can compromise file encryption security. When working with such programs, encrypt the folder rather than the individual files.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Copy or Move Encrypted Files or Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Copy or move encrypted files or folders**

- Copy an encrypted file or folder
- Move an encrypted file or folder

# Copy an encrypted file or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy an encrypted file or folder**

1. Open Windows Explorer.
2. Click the encrypted file or folder that you want to copy.
3. On the **Edit** menu, click **Copy**.
4. Open the folder or disk where you want to store the copy.
5. On the **Edit** menu, click **Paste**.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- An encrypted file or folder is decrypted if you copy it to a volume that is not an NTFS file system volume. The exception to this is when copying to a WebDAV folder on a server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Recover Files or Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recover files or folders**

- Recover an encrypted file or folder if you are a designated recovery agent
- Recover an encrypted file or folder without your file encryption certificate
- Back up default recovery keys to a floppy disk
- Add a recovery agent for the local computer
- Change the recovery policy for the local computer
- Add a recovery agent for a domain
- Create a recovery policy for a domain
- Not require a recovery agent for a domain
- Disable Encrypting File System for the local computer
- Disable Encrypting File System for a domain

# Recover an encrypted file or folder if you are a designated recovery agent

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To recover an encrypted file or folder if you are a designated recovery agent**

1. Use Backup or another backup tool to restore a user's backup version of the encrypted file or folder to the computer where your file recovery certificate and recovery key are located.
2. Open Windows Explorer.
3. Right-click the file or folder and then click **Properties**.
4. On the **General** tab, click **Advanced**.
5. Clear the **Encrypt contents to secure data** check box.
6. Make a backup version of the decrypted file or folder and return the backup version to the user.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- You can return the backup version of the decrypted file or folder to the user as an e-mail attachment, on a floppy disk, or on a network share.
- An alternate procedure would involve physically transporting the recovery agent's private key and certificate, importing the private key and certificate, decrypting the file or folder, and then deleting the imported private key and certificate. This procedure exposes the private key more than the procedure above but does not require any backup or restore operations or file transportation.
- If you are the recovery agent, use the **Export** command from Certificates in Microsoft Management Console (MMC) to export the file recovery certificate and private key to a floppy disk. Keep the floppy disk in a secure location. Then, if the file recovery certificate or private key on your computer is ever damaged or deleted, you can use the **Import** command from Certificates in MMC to replace the damaged or deleted certificate and private key with the ones you have backed up on the floppy disk.
- For more information about using Certificates in MMC, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Recovering data
Recover an encrypted file or folder without your file encryption certificate
Add a recovery agent for the local computer

# Recover an encrypted file or folder without your file encryption certificate

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To recover an encrypted file or folder without the file encryption certificate**

1. Open Backup.
2. Use Backup to make a copy of the file in case of loss or damage.
3. Send the original encrypted file to the designated recovery agent.
4. Have the recovery agent use their recovery certificate and private key to decrypt the file.
5. Have the recovery agent send the decrypted file back to you, using any file transfer method that you want.

## Notes

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.
- There is no default recovery agent on a local computer unless the computer is in an Active Directory domain environment. In an Active Directory domain environment, the administrator that initially logged on to the first domain controller is the default recovery agent.
- Sending the file to the designated recovery agent can be done in a number of ways, including backing up the file to tape or floppy disk.
- Files backed up using Backup or any other backup tool retain their encryption while in their backup storage location. The original files can be decrypted or modified without affecting the encrypted state of the backup copies.
- You can recover an encrypted file or folder yourself if you have kept a backup copy of your file encryption certificate and private key in a .pfx file format on a floppy disk. Use the **import** command from Certificates in Microsoft Management Console (MMC) to import the .pfx file from the floppy disk into the **Personal** store.
- For more information about using Certificates in MMC, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Back up default recovery keys to a floppy disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To back up default recovery keys to a floppy disk**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Add Standalone Snap-in**, click **Certificates**, and then click **Add**.
4. Click **My user account**, and then click **Finish**.
5. Click **Close**, and then click **OK**.
6. Double-click **Certificates - Current User**, double-click **Personal**, and then double-click **Certificates**.
7. Click the certificate that displays the words **File Recovery** in the **Intended Purposes** column.
8. Right-click the certificate, point to **All Tasks**, and then click **Export**.
9. Follow the instructions in the Certificate Export Wizard to export the certificate and associated private key to a .pfx file format.

## Notes

- This operation must be performed by the recovery agent account that has the recovery certificate and private key in their private store.
- In a home or non-domain environment, there is no default recovery agent. To configure a recovery agent, see Related Topics.
- Before making any changes to the default recovery policy, be sure to secure the default recovery private key. The default recovery keys in a domain are stored on the first domain controller for the domain. The domain administrator is the default recovery agent.
- For more information about using Certificates in MMC, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable Encrypting File System for the local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable Encrypting File System for the local computer**

1. Open Registry Editor.

   **Caution**

   - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. You can also use the **Last Known Good Configuration** startup option if you encounter problems after manual changes have been applied.

2. In Registry Editor, navigate to the following registry key:

   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\EFS**

3. Click **Edit**, point to **New**, and then click **DWORD Value**.

4. In the text box that appears, type **EfsConfiguration**, and then press **Enter**.

5. Double-click the **EfsConfiguration** registry key you just created, and then change **Value Data** to 1.

6. Click **OK**, and then close Registry Editor.

7. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add users to or remove users from a file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add users to or remove users from a file**

1. Open Windows Explorer.
2. Right-click the encrypted file that you want to change, and then click **Properties**.
3. On the **General** tab, click **Advanced**.
4. In **Advanced Attributes**, click **Details**.
5. To add a user to this file, click **Add**, and then do one of the following:
   - To add a user whose certificate is on this computer, click the certificate and then click **OK**.
   - To view a certificate on this computer before adding it to the file, click the certificate and then click **View Certificate**.
   - To add a user from the Active Directory, click **Find User**, then locate the user in the list and click **OK**.
6. To remove a user from this file, click the user name and then click **Remove**.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- You cannot add groups to file encryption access.
- All users that are added to the file must have a certificate located on the computer. For details on how to copy the certificate to the computer, see Related Topics.
- All users that can decrypt the file must also have access to read the file. NTFS permissions must be set properly to allow this access. If a user is denied access through NTFS permissions, they cannot read the encrypted file and cannot decrypt the data. For more information on setting permissions on files, see Related Topics.
- When a user is added to a file and their certificate is imported, the certificate's chain is validated to a trusted root CA. The certificate is then stored in the user's *Other People* certificate store.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Back up an EFS certificate with the private key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To back up an EFS certificate with the private key**

- To back up the EFS certificate currently in use
- To back up any EFS certificate

**To back up the EFS certificate currently in use**

1. Open Certificate Export Wizard.
2. In the Certificate Export Wizard, click **Next**, and then click **Yes, export the private key**. (This option will appear only if the private key is marked as exportable and you have access to the private key.)
3. Under **Export File Format**, ensure that the **Enable strong protection (requires IE 5.0, NT 4.0 SP4 or above)** check box is selected, and then click **Next**.
4. In **Password**, type a password to encrypt the private key you are exporting. In **Confirm password**, type the same password again, and then click **Next**.
5. In **File name**, type a file name and path for the PKCS #12 file that will store the exported certificate and private key, click **Next**, and then click **Finish**.

**To back up any EFS certificate**

1. Open Certificates - Current User.
2. In the console tree, click **Certificates**.

   **Where?**

   - Certificates - Current User/Personal/Certificates

3. In the details pane, click the certificate that has **Encrypting File System** listed in the **Intended Purposes** column.
4. On the **Action** menu, point to **All Tasks**, and then click **Export**.
5. In the Certificate Export Wizard, click **Next**, and then click **Yes, export the private key**. (This option will appear only if the private key is marked as exportable and you have access to the private key.)
6. Under **Export File Format**, ensure that the **Enable strong protection (requires IE 5.0, NT 4.0 SP4 or above)** check box is selected, and then click **Next**.
7. In **Password**, type a password to encrypt the private key you are exporting. In **Confirm password**, type the same password again, and then click **Next**.
8. In **File name**, type a file name and path for the PKCS #12 file that will store the exported certificate and private key, click **Next**, and then click **Finish**.

**Notes**

- To open Certificates, click **Start**, click **Run**, type **certmgr.msc**, and then click **OK**.

- If more than one certificate has an intended purpose of Encrypting File System, each certificate should be backed up individually. This will help to ensure that all encrypted files can be accessed when necessary.

- Strong protection (also known as *iteration count*) is enabled by default in the Certificate Export Wizard when you export a certificate with its associated private key.

  Strong protection is not compatible with older programs, so you must clear the **Enable strong protection** check box if you are going to use the private key with any browser earlier than Microsoft Internet Explorer 5.0.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Encrypting File System Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section covers:

- Encrypting File System overview
- Using Encrypting File System

# Encrypting File System overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encrypting File System overview**

Encrypting File System (EFS) provides the core file encryption technology used to store encrypted files on NTFS file system volumes. Once you encrypt a file or folder, you work with the encrypted file or folder just as you do with any other files and folders.

Encryption is transparent to the user that encrypted the file. This means that you do not have to manually decrypt the encrypted file before you can use it. You can open and change the file as you normally do.

Using EFS is similar to using permissions on files and folders. Both methods can be used to restrict access to data. However, an intruder who gains unauthorized physical access to your encrypted files or folders will be prevented from reading them. If the intruder tries to open or copy your encrypted file or folder he receives an access denied message. Permissions on files and folders does not protect against unauthorized physical attacks.

You encrypt or decrypt a folder or file by setting the encryption property for folders and files just as you set any other attribute such as read-only, compressed, or hidden. If you encrypt a folder, all files and subfolders created in the encrypted folder are automatically encrypted. It is recommended that you encrypt at the folder level.

You can also encrypt or decrypt a file or folder using the **cipher** command. For more information, see Cipher.

When you work with encrypted files and folders, keep in mind the following information:

- Only files and folders on NTFS volumes can be encrypted. Because WebDAV works with NTFS, NTFS is required when encrypting files over WebDAV (Web distributed authoring and versioning).
- Files or folders that are compressed cannot also be encrypted. If the user marks a file or folder for encryption, that file or folder will be uncompressed.
- Encrypted files can become decrypted if you copy or move the file to a volume that is not an NTFS volume.
- Moving unencrypted files into an encrypted folder will automatically encrypt those files in the new folder. However, the reverse operation will not automatically decrypt files. Files must be explicitly decrypted.
- Files marked with the System attribute cannot be encrypted, nor can files in the systemroot directory structure.
- Encrypting a folder or file does not protect against deletion or listing files or directories. Anyone with the appropriate permissions can delete or list encrypted folders or files. For this reason, using EFS in combination with NTFS permissions is recommended.
- You can encrypt or decrypt files and folders located on a remote computer that has been enabled for remote encryption. However, if you open the encrypted file over the network, the data that is transmitted over the network by this process is not encrypted. Other protocols, such as SSL/TLS (Secure Socket Layer/Transport Layer Security) or Internet Protocol security (IPSec) must be used to encrypt data over the wire. WebDAV, however, is able to encrypt the file locally and transmit it in encrypted form.

# Using Encrypting File System

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Encrypting File System**

This section covers:

- Encrypting and decrypting data
- Recovering data
- Managing certificates

# Encrypting and decrypting data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encrypting and decrypting data**
With Encrypting File System (EFS) you can store data securely. EFS does this by encrypting data in selected NTFS file system files and folders.

Because EFS is integrated with the file system, it is easy to manage, difficult to attack, and transparent to the user. This is particularly useful for securing data on computers that may be vulnerable to theft, such as mobile computers.

Files and folders cannot be encrypted or decrypted on FAT volumes. Also, EFS is designed to store data securely on local computers. As such, it does not support the secure transmission of files over a network. Other technologies, such as Internet Protocol Security (IPSec), can be used in conjunction with EFS to provide a larger solution. For more information, see Internet Protocol Security (IPSec).

**Using encryption keys**
Once a user has specified that a file be encrypted, the actual process of data encryption and decryption is completely transparent to the user. The user does not need to understand this process. However, the following explanation of how data encryption and decryption works might be useful for administrators.

*Encryption* of files works as follows:

- Each file has a unique *file encryption key*, which is later used to decrypt the file's data.
- The file encryption key is itself encrypted--it is protected by the user's public key corresponding to the user's EFS certificate.
- The file encryption key is also protected by the public key of each additional EFS user that has been authorized to decrypt the file and each recovery agent.

For steps on how to encrypt a file or folder, see Encrypt a file or folder

The EFS certificate and private key used can be issued by a number of sources, including automatically-generated certificates, certificates created by Microsoft certification authorities (CAs), or third-party CAs. For more information about third-party certificates and EFS, see article Q273856, "Third-Party Certificate Authority Support for Encrypting File System," in the Microsoft Knowledge Base.

*Decryption* of files works as follows:

- To decrypt a file, the file encryption key must first be decrypted. The file encryption key is decrypted when the user has a private key that matches the public key.
- The original user may not be the only person that can decrypt the file encryption key. Other designated users or recovery agents can also decrypt the file encryption key, by using their own private key.

For steps on how to decrypt a file or folder, see Decrypt a file or folder

Private keys are securely held in a protected key store, and not in the Security Account Manager (SAM) or in a separate directory. For more information, see the Microsoft TechNet on the Microsoft Web site.

**Storing encrypted files on remote servers**
If users in your Windows XP or Windows Server 2003 family computing environment want to store encrypted files on remote servers, it is useful to know the following:

- Windows XP and the Windows Server 2003 family support the storage of encrypted files on remote servers.
- Users can use EFS remotely only when both computers are members of the same Windows Server 2003 family forest.

- Encrypted data is not encrypted when in transit over the network, but only when stored on disk. The exceptions to this are when your system includes Internet Protocol security (IPSec) or Web Distributed Authoring and Versioning (WebDAV). IPSec encrypts data while it is transported over a Transmission Control Protocol/Internet Protocol (TCP/IP) network. If the file is encrypted before being copied or moved to a WebDAV folder on a server, it will remain encrypted during the transmission and while it is stored on the server.

- Encrypted files are not accessible from Macintosh clients.

- Storing EFS certificates and private keys on smartcards is not currently supported.

- Strong private key protection for EFS private keys is not currently supported.

Before users can encrypt files that reside on a remote server, an administrator must designate the remote server as *trusted for delegation*. This allows all users with files on that server to encrypt those files. For more information, see Enable a remote server for file encryption and Encrypt a file or folder on a remote computer.

# Recovering data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovering data**

Data recovery is important when you need to be able to recover data encrypted by an employee after the employee leaves, or when the user loses the private key. Data recovery is available through the Encrypting File System (EFS) as a part of the overall security policy for the system. For example, if you should ever lose your file encryption certificate and associated private key through disk failure, arson, or any other reason, the person who is the designated recovery agent can recover the data. In a business environment, an organization can recover data encrypted by an employee after the employee leaves.

**Recovery policy**

EFS uses recovery policies to provide built-in data recovery. A *recovery policy* is a type of public key policy that provides for one or more user accounts to be designated as recovery agents.

A recovery policy is configured locally for stand-alone computers. For computers that are part of a network, a recovery policy is configured at the domain, organizational unit, or individual computer level, and applies to all Windows XP and Windows Server 2003 family-based computers that the policy applies to. A certification authority (CA) issues recovery certificates, and you use Certificates in Microsoft Management Console (MMC) to manage them.

In a domain, the Windows Server 2003 family implements a default recovery policy for the domain when the first domain controller is set up. The self-signed certificate is issued to the domain administrator. That certificate designates the domain administrator as the recovery agent. To change the default recovery policy for a domain, log on to the first domain controller as an administrator. Additional recovery agents can be added to this policy and the original recovery agent can be removed at any time.

Because the Windows XP and Windows Server 2003 family security subsystems handle enforcing, replicating, and caching of the recovery policy, users can implement file encryption on a system that is temporarily offline, such as a portable computer. This process is similar to logging on to their domain account using cached credentials. For more information, see Change the recovery policy for the local computer and Create a recovery policy for a domain.

**Recovery agents**

A recovery agent is an individual authorized to decrypt data that was encrypted by another user. Recovery agents do not need any other permissions to function in this role. Recovery agents are useful, for example, when employees leave the company and their remaining data needs to be decrypted. Before you can add a recovery agent for a domain, you must ensure that each recovery agent has been issued an X.509v3 certificate.

Each recovery agent has a special certificate and associated private key that allows data recovery wherever the recovery policy applies. If you are the recovery agent, you should be sure to use the **Export** command in Certificates in MMC to back up the recovery certificate and the associated private key to a secure location. After backing them up, you should use Certificates in MMC to delete the recovery certificate. Then, when you need to perform a recovery operation for a user, you should first restore the recovery certificate and associated private key using the **Import** command from Certificates in MMC. After recovering the data, you should again delete the recovery certificate. You do not have to repeat the export process.

To add recovery agents for a domain, you add their certificates to the existing recovery policy. For steps on how to add recovery agents to a domain, see Add a recovery agent for a domain.

### Note

- Recovery agent information that has been added and removed is not automatically updated on existing EFS files. The information in these files is updated the next time the file is accessed. New files always use the current recovery agent information.

# Managing certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing certificates**

Encrypting File System (EFS) uses public key cryptography to encrypt the contents of files. The keys that are used are obtained from the certificate of the user and any additional users and designated recovery agents configured. Because the certificates may also contain private key information, they must be managed correctly.

Certificates that are used by EFS can be obtained from a certification authority (CA) or created automatically by the computer. When obtaining an EFS certificate from a CA, the cryptographic service provider (CSP) and the appropriate object identifier (also known as an OID) must be referenced by the certificate. EFS can use either a base or enhanced CSP. If these two attributes are not set correctly in the certificate, EFS is unable to use it.

The certificate and private key of all designated recovery agents should be exported to removable disk and stored securely until needed. For more information, see Export a certificate with the private key. When exporting the certificate and private key, ensure that, in the **Intended Purposes** column, the selected certificate includes **Encrypting File System** and that you have the associated private key.

Certificates and private keys can be used on multiple computers. If your Windows XP network is configured to use roaming profiles, the certificates will be available on any computer you logon to. Otherwise, the certificates and private keys must be exported and imported manually. To manually export a certificate and private key, use the above procedure. To import this information, see Import a certificate.

**Verification of certificate validity**

Certificates are not expected to be valid indefinitely. Over time, an attacker can determine the corresponding private key and render the data encrypted with that key vulnerable. Because of this, certificates have a validity period that defines the length of time during which they can be considered valid. Once the validity period expires, a new certificate must be obtained to encrypt new data. However, the existing certificate and private key are normally retained so older data can still be decrypted.

Certificates can also be revoked by the issuing CA, even when they are still within their validity period. There are a number of reasons why a certificate could become untrustworthy, including compromise of the certificate subject's private key or discovery that a certificate was obtained fraudulently. When a certificate is revoked, it is placed on a certificate revocation list (CRL) maintained by the CA.

When a file is encrypted, EFS checks the validity period on the certificate of the user as well as the recovery agent. When a new user is added to an existing file, EFS checks for both the revocation of the certificate being added and the chaining of the certificate to a trusted root CA. If the certificate is found to be invalid (either because of expiration, revocation or inability to chain) the certificate is not used and the user is typically notified.

# Encrypting File System Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The Advanced button is unavailable.
- When encrypting a file, a message appears: "Recovery policy configured for this system contains invalid recovery certificate" or "ERROR_BAD_RECOVERY_POLICY."
- The "Access denied" message appears when opening an encrypted file.
- The message "Key not valid for use in specified state" appears when encrypting a file on a remote computer.
- The message "You do not have permission to request a certificate based on the selected certificate template" appears when using theCreate Data Recovery Agentoption to create an EFS data recovery agent.

**The Advanced button is unavailable.**
**Cause:** Encrypting File System (EFS) only works on files and folders on NTFS file system volumes. If the folder or file you are trying to encrypt is on a FAT or FAT32 volume, the **Advanced** button does not appear in the properties of that folder or file.

**Solution:** Convert the volume to NTFS with the **convert** utility.

1. Open Command Prompt.
2. Type:

   **convert** *drive* **/fs:ntfs**

   where *drive* is the drive letter of the intended drive.

**See also:** Convert.

**When encrypting a file, a message appears: "Recovery policy configured for this system contains invalid recovery certificate" or "ERROR_BAD_RECOVERY_POLICY."**
**Cause:** The Encrypting File System (EFS) recovery policy that is implemented on this computer contains one or more EFS recovery agent certificates that have expired. These certificates cannot be used.

**Solution:** Either renew the existing certificates or generate new certificates for the EFS recovery agents and reapply the recovery agent policy with those certificates.

**See also:** Requesting certificates or Renewing certificates.

**The "Access denied" message appears when opening an encrypted file.**
**Cause:** The file was encrypted by Encrypting File System (EFS) using a public key certificate, and the associated private key for this certificate is not available on this computer.

**Solution:** Locate the private key for the appropriate certificate and import it onto this computer using the Certificates snap-in.

**See also:** Import a certificate and **Encrypting File System** at the Microsoft Windows XP Resource Kits Web site.

**The message "Key not valid for use in specified state" appears when encrypting a file on a remote computer.**
**Cause:** Both computers must reside in the same Active Directory domain to use Encrypting File System (EFS) on remote shares. The remote computer must also be trusted for delegation in the Active Directory.

**Solution:** Join both computers to the same Active Directory domain and trust the remote computer for delegation.

**See also:** Join a domain and Enable a remote server for file encryption.

**The message "You do not have permission to request a certificate based on the selected certificate template" appears when using theCreate Data Recovery Agentoption to create an EFS data recovery agent.**

**Cause:** EFS is unable to connect to a certification authority (CA) to obtain a new certificate and store it in Active Directory.

**Solution:** Install a certification authority to issue certificates for EFS.

**See also:** Certificate Services.

# Public Key Infrastructure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Public Key Infrastructure**
A *public key infrastructure*, often shortened to PKI, is a system of digital certificates, certification authorities (CAs) and other registration authorities (RAs) that verify and authenticate the validity of each party involved in an electronic transaction through the use of public key cryptography.

# Manage certificates for your user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage certificates for your user account**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, double-click **Certificates**, and then:
   - If you are logged on as an administrator, click **My user account**, and then click **Finish**.
   - If you are logged on as a user, Certificates automatically loads.
4. Click **Close**.

   **Certificates - Current User** appears on the list of selected snap-ins for the new console.
5. If you have no more snap-ins to add to the console, click **OK**.
6. To save this console, on the **File** menu, click **Save**.

## Notes

- To switch between managing certificates for your user account, a computer, or a service, you must have separate instances of Certificates added into the console.
- For additional help with creating and using MMC consoles, on the **Help** menu, click **Help Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage certificates for a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage certificates for a computer**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, double-click **Certificates**, click **Computer account**, and then click **Next**.
4. Do one of the following:
   - To manage certificates for the local computer, click **Local computer**, and then click **Finish**.
   - To manage certificates for a remote computer, click **Another computer** and type the name of the computer, or click **Browse** to select the computer name, and then click **Finish**.
5. Click **Close**.

   **Certificates (*Computer Name*)** appears on the list of selected snap-ins for the new console.
6. If you have no more snap-ins to add to the console, click **OK**.
7. To save this console, on the **File** menu, click **Save**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To manage certificates for another computer, you can either create another instance of Certificates in the console, or right-click **Certificates (*Computer Name*)** and click **Connect to Another Computer**.
- For more information on using Microsoft Management Console (MMC), on the **Help** menu, click **Help Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Manage certificates for a computer

# Set Display Options of the Certificates Snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set display options of the Certificates snap-in**

- Display certificate stores in Logical Store mode
- Display certificate stores in Purpose mode
- Display certificate stores storage structure
- Display archived certificates

# Display certificate stores in Logical Store mode

Updated: February 28, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display certificate stores in Logical Store mode**

1. Open the Certificates console for the user, computer, or service you want to manage.

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. With the **Certificates** <*console type*>, where <console type> is Current User, Computer, or Service, selected in the console pane, click the **View** menu, and then click **Options**.

3. Under **Organize view mode by**, click **Logical Certificate Stores**.

**Note**

- When you look at the contents of a certificate store in Logical Store mode, you will occasionally see what appears to be two copies of the same certificate in the store. This occurs because the same certificate is stored in separate physical stores under a logical store. When the contents of the physical certificates stores are combined into one logical store view, both instances of the same certificate are displayed.

  You can verify this by setting the view option to show the physical certificate stores and then noting that the certificate is stored in separate physical stores under the same logical store. You can verify that it is the same certificate by comparing the serial numbers.

  For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Display certificate stores in Purpose mode

Updated: January 21, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display certificate stores in Purpose mode**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. On the **View** menu, click **Options**.

3. Under **Organize view mode by**, click **Certificate purpose**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Display certificate stores storage structure

Updated: January 21, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display the certificate stores storage structure**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. On the **View** menu, click **Options**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. Under **Organize view mode by**, click **Logical Certificate Stores**.

4. Under **Show the following**, select the **Physical certificate stores** check box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Display archived certificates

Updated: January 24, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Display archived certificates**

Archived are certificates that have expired or have been renewed. In many cases, it is good practice to retain archived certificates instead of deleting them. For example, you would need to keep an archived certificate to verify digital signatures on old documents signed using the key on the now-expired or renewed certificate.

**To display archived certificates**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. Ensure you have **Certificates** <*console type*> selected. Where <console type> is Current User, Computer, or Service, depending upon the category of certificates you want to view.

3. click the **View** menu, and then click **Options**.

4. In the **View Options** dialog box, in **Show the following**, select the **Archived certificates**.

**Tip**

For more information on the **Certificates console** and changing **View Options**, see Certificates Console (http://go.microsoft.com/fwlink/?LinkID=209851).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Request Certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Request certificates**

- Request a certificate
- Request a certificate with the same key
- Renew a certificate with a new key
- Renew a certificate with the same key
- Request Certificates

# Request a certificate

Updated: January 21, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To request a certificate**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. In the console tree, select the correct store that has the certificate you want to request. For example, under **Certificates – Current User**, expand **Personal**, click **Certificates**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. In the details pane, click the certificate associated with the public key you want to associate a new certificate.

4. On the **Action** menu, point to **All Tasks**, and then click **Request New Certificate** to start the Certificate Request Wizard.

5. In the Certificate Request Wizard, provide the following information:

   - Click the type of certificate you want to request.
   - (Optional) If you have selected the **Advanced** check box, click the cryptographic service provider (CSP) you are using.
   - (Optional) If you have selected the **Advanced** check box, click the key length (measured in bits) of the public key associated with the certificate.
   - (Optional) If you have selected the **Advanced** check box and you want to enable strong private key protection, select the **Enable strong private key protection** check box. Enabling strong private key protection will ensure that you are prompted for a password every time the private key is used. This is useful if you want to make sure that the private key is not used without your knowledge.
   - (Optional) If you have selected the **Advanced** check box and if you have more than one certification authority (CA) available, choose the name of the certification authority that will issue the certificate.
   - A friendly name for your new certificate.

6. After the Certificate Request Wizard has successfully finished, click **OK**.

**Note**

- You can use this procedure to request certificates from an enterprise certification authority only. To request certificates from a stand-alone certification authority, you need to request certificates via Web pages. A Windows certification authority has its Web pages located at http://*servername*/certsrv, where *servername* is the name of the server hosting the certification authority.

- You can use this procedure to request certificates based on templates where the subject name is generated by Windows only. To request a certificate based on a template configured to obtain the subject name from the subject, you need to request certificates via Web pages.

- If the requested certificate type requires approval before it is issued, you need to retrieve the completed certificate via Web pages. A Windows certification authority has its Web pages located at http:// *servername*/certsrv, where *servername* is the name of the server hosting the certification authority.

- In order to request a Digital Signature Standard (DSS) certificate from an enterprise CA, you must select the User Signature Only certificate template in the Certificate Request Wizard.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Request a certificate with the same key

Updated: January 24, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To request a certificate with the same key**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. In the console tree, select the correct store that has the certificate you want to request. For example, under **Certificates – Current User**, expand **Personal**, click **Certificates**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. In the details pane, click the certificate associated with the public key you want to associate a new certificate.

4. On the **Action** menu, point to **All Tasks**, and then click **Request Certificate with Same Key** to start the Certificate Request Wizard.

5. In the Certificate Request Wizard, provide the following information:

   - Click the type of certificate you want to request.
   - (Optional) If you have selected the **Advanced** check box and you have more than one certification authority available, choose the name of the certification authority that will issue the certificate.
   - Type a friendly name for your new certificate.

6. After the Certificate Request Wizard has successfully finished, click **OK**.

**Warning**

- To perform this procedure, the view mode must be organized by Logical Certificate Stores. For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).
- You can use this procedure to request certificates from an enterprise certification authority only. To request certificates from a stand-alone certification authority, you must request certificates by way of Web pages. On Microsoft Certification Authority (CA) installations, Web pages of a Windows certification authority are located at http://*servername*/certsrv, where *servername* is the name of the server hosting the certification authority, by default.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Renew a certificate with a new key

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To renew a certificate with a new key**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. Confirm that you are in Certificate purpose view. For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. In the console tree, under **Personal**, click **Certificates**.

4. In the details pane, click the certificate you are renewing.

5. On the **Action** menu, point to **All Tasks**, and then click **Renew Certificate with New Key** to open the Certificate Renewal Wizard.

6. In the **Certificate Renewal Wizard**, do one of the following:

   - Use the default values to renew the certificate.

   - (For advanced users only) Provide your own certificate renewal settings. You need to know the cryptographic service provider (CSP) and the certification authority (CA) issuing the certificate.

     You need to select the key length (measured in bits) of the public key associated with the certificate.

     You can also choose to enable strong private key protection. Enabling strong private key protection ensures that you are prompted for a password every time the private key is used. This is useful if you want to make sure that the private key is not used without your knowledge.

7. After the Certificate Renewal Wizard has successfully finished, click **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Renew a certificate with the same key

Updated: February 14, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To renew a certificate with the same key**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. In the console tree, select the correct store that has the certificate you want to request. For example, under **Certificates – Current User**, expand **Personal**, click **Certificates**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. In the details pane, click the certificate you are renewing.

4. On the **Action** menu, point to **All Tasks**, and then click **Renew Certificate with Same Key** to start the Certificate Renewal Wizard.

5. In the Certificate Renewal Wizard, do one of the following:

   - Use the default values to renew the certificate.
   - Provide your own certificate renewal settings. You need to know the certification authority issuing the certificate.

6. After the Certificate Renewal Wizard has successfully finished, click **OK**.

**Note**

- To perform this procedure, the view mode must be organized by Logical Certificate Stores. For more information, see Related Topics.
- Once renewed, the old certificate will be archived. For information on how to view archived certificates, see Related Topics.
- You can use this procedure to request certificates from an enterprise certification authority only. To request certificates from a stand-alone certification authority, you need to request certificates via Web pages. A Windows certification authority has its Web pages located at http://*ServerName*/certsrv, where *ServerName* is the name of the server that hosts the certification authority.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Trigger automatic enrollment for certificates

Updated: February 28, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To trigger automatic enrollment for certificates**

1. Open the Certificates console for the user or computer certificate console you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account or computer account, see the appropriate article from the following list

   - Manage certificates for your user account
   - Manage certificates for a computer
   - For more information on the Certificates console and changing View Options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkID=209851).

2. On the **Action** menu, point to **All Tasks**, and then click **Automatically Enroll Certificates**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Find a certificate

Updated: January 24, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find a certificate**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. On the console tree, click **Certificates** - *Certificate Holder*, where Certificate Holder is a Certificates instance (user, computer or service). For more information regarding Certificate console View Options, see Certificates Console(http://go.microsoft.com/fwlink/?LinkID=209851)

3. On the **Action** menu, click **Find Certificates**.

4. Enter the following criteria to find certificates:

   - The certificate store to search
   - Text to search for
   - The certificate field to search for the specified text. You can look for text in the **Issued By**, **Issued To**, **MD5 Hash**, **Serial Number**, and **SHA1 Hash** fields.

5. Click **Find Now**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Move a certificate

Updated: January 24, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To move a certificate**

1. Open the certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. Under the appropriate logical store (e.g. **Personal**, **Trusted Root Certification Authorities**, **Intermediate Certification Authorities**, and so on) where the certificate is stored, click **Certificates**.

3. In the details pane, click the certificate you are moving. (To select more than one certificate, hold down CTRL and click each certificate.)

4. On the **Action** menu, click **Cut**.

5. Click the logical certificate store where you want to move the certificate.

6. On the **Action** menu, click **Paste**.

**Note**

- To perform this procedure, the view mode must be organized by Logical Certificate Stores. For more information, see Display certificate stores in Logical Store mode.

- You can only move an object within certificate stores in Certificates. For example, you cannot move an object to a folder in Windows Explorer. See Related Topics for information about importing and exporting certificates.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: February 14, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a certificate**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. In the console tree, select the correct store that has the certificate you want to request. For example, under **Certificates – Current User**, expand **Personal**, click **Certificates**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. In the details pane, click the certificate you are copying. (To select multiple certificates, hold down CTRL and click each certificate.)

4. On the **Action** menu, click **Copy**.

5. Click the logical certificate store where you want to copy the certificate.

6. On the **Action** menu, click **Paste**.

**Note**

1. To perform this procedure, the view mode must be organized by Logical Certificate Stores. For instructions on changing to Logical Certificate Stores view mode, see Display certificate stores in Logical Store mode.

2. You can only copy a certificate within certificate stores in Certificates. For example, you cannot copy a certificate to a folder in Windows Explorer. See Related Topics for information about importing and exporting certificates.

# Delete a certificate

Updated: January 21, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a certificate**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. In the console tree, select the correct store that has the certificate you want to request. For example, under **Certificates – Current User**, expand **Personal**, click **Certificates**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. In the details pane, click the certificate (or certificates) you want to delete. (To select multiple certificates, hold down CTRL and click each certificate.)

4. On the **Action** menu, click **Delete**.

5. Click **Yes** if you are sure you want to permanently delete the certificate.

**Note**

- In some instances, there is not a **Certificates** folder in the console tree. In that case, navigate in the console tree until the certificate you want appears in the details pane, and then continue the procedure.
- You might want to back up the certificate by exporting it before you delete it. For the procedure to export a certificate, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify the properties of a certificate

Updated: January 24, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify the properties of a certificate**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. On the **Action** menu, click **Properties**.

3. To change the friendly name of the certificate, in **Friendly name**, type the new name.

4. To change the description of the certificate, in **Description**, type the new description.

5. To enable all purposes for the certificate, based on the certificate type, in **Certificate purposes**, click **Enable all purposes for this certificate**.

6. To disable all purposes for the certificate, in **Certificate purposes**, click **Disable all purposes for this certificate**.

7. To designate specific purposes for the certificate, in **Certificate purposes**, click **Enable only the following purposes** and select the appropriate check boxes.

**Note**

- If you are logged on as a user, you can only modify the properties of certificates in the **Personal** store.
- To modify the properties of a certificate, double-click the certificate, click the **Details** tab, and then click **Edit Properties**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import and Export Certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Import and export certificates**

- Import a certificate
- Export a certificate
- Export a certificate with the private key
- View the certificates in a PKCS #7 file

# Import a certificate

Updated: February 28, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import a certificate**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   - Manage certificates for your user account
   - Manage certificates for a computer
   - Manage certificates for a service
   - For more information on the Certificates console and changing View Options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkID=209851).

2. Select a certificate store for the certificate type you want to import. For example, you might select the **Personal** store under **Certificates (Local Computer)**.

3. On the **Action** menu, point to **All Tasks** and then click **Import** to start the Certificate Import Wizard.

4. Type the file name containing the certificate to be imported. (You can also click **Browse** and navigate to the file.)

5. If it is a PKCS #12 file, do the following:

   - Type the password used to encrypt the private key.
   - (Optional) If you want to be able to use strong private key protection, select the **Enable strong private key protection** check box.
   - (Optional) If you want to back up or transport your keys at a later time, select the **Mark key as exportable** check box.

6. Do one of the following:

   - If the certificate should be automatically placed in a certificate store based on the type of certificate, click **Automatically select the certificate store based on the type of certificate**.
   - If you want to specify where the certificate is stored, select **Place all certificates in the following store**, click **Browse**, and choose the certificate store to use.

**Note**

- To perform this procedure, the view mode must be organized by Logical Certificate Stores. For more information on the **Certificates console** and changing **View Option**s, see Certificates Console (http://go.microsoft.com/fwlink/?LinkID=209851).

- You should only import certificates obtained from trusted sources. Importing an altered or unreliable certificate could compromise the security of any system component that uses the imported certificate.

- You can import a certificate into any logical store. In most cases, you will import certificates into the Personal store or the Trusted Root Certification Authorities store, depending on whether the certificate is intended for you or if it is a root CA certificate.

- Enabling strong private key protection will ensure that you are prompted for a password every time the private key is used. This is useful if you want to make sure that the private key is not used without your knowledge.

- To open the Certificate Import Wizard, you can open Windows Explorer. Then, in the cases of DER (.cer), Base-64 (.cer), and PKCS #7 (.p7b) files, right-click the file and click **Install Certificate**. In the case of a PKCS #12 (.pfx) file, right-click the file and click **Install PFX**.

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

- The file from which you import certificates will remain intact after you have completed importing the certificates. You can use Windows Explorer to delete the file if it is no longer needed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export a certificate

Updated: January 21, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export a certificate**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. In the console tree, select the correct store that has the certificate you want to request. For example, under **Certificates – Current User**, expand **Personal**, click **Certificates**.

   **Note**

   For information on the different view options, see Certificates Console (http://go.microsoft.com/fwlink/?LinkId=209851).

3. In the details pane, click the certificate you want to manage.

4. On the **Action** menu, point to **All Tasks**, and then click **Export**.

5. In the **Certificate Export Wizard**, click **No, do not export the private key**. (This option will appear only if the private key is marked as exportable and you have access to the private key.)

6. Provide the following information in the **Certificate Export Wizard**:

   - Click the file format you want to use to store the exported certificate: a DER-encoded file, a Base64-encoded file, or a PKCS #7 file.

   - If you are exporting the certificate to a PKCS #7 file, you also have the option to include all certificates in the certification path.

**Warning**

- For the procedure to export a certificate with the private key, see Related Topics.

- After the **Certificate Export Wizard** is finished, the certificate will remain in the certificate store in addition to being in the new file. If you want to remove the certificate from the certificate store, you must delete it.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export a certificate with the private key

Updated: January 24, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export a certificate with the private key**

1. Open the Certificates console for the user, computer, or service you want to manage.

   **Tip**

   For instructions on creating a Microsoft Management Console (MMC) that allows you to manage the certificates of a user account, computer account, or service account, see the appropriate article from the following list

   a. Manage certificates for your user account

   b. Manage certificates for a computer

   c. Manage certificates for a service

2. In the console pane, select the certificate store and container holding the certificate that you want to export.

   **Tip**

   For more information on the **Certificates console** and changing **View Option**s, see Certificates Console (http://go.microsoft.com/fwlink/?LinkID=209851).

3. In the details pane, click the certificate you want to export.

4. On the **Action** menu, point to **All Tasks**, and then click **Export**.

5. In the Certificate Export Wizard, click **Yes, export the private key**. (This option will appear only if the private key is marked as exportable and you have access to the private key.)

6. Under **Export File Format**, do one or all of the following, and then click **Next**.

   - To include all certificates in the certification path, select the **Include all certificates in the certification path if possible** check box.
   - To enable strong protection, select the **Enable strong protection (requires IE 5.0, NT 4.0 SP4 or above)** check box.
   - To delete the private key if the export is successful, select the **Delete the private key if the export is successful** check box.

7. In **Password**, type a password to encrypt the private key you are exporting. In **Confirm password**, type the same password again, and then click **Next**.

8. In **File name**, type a file name and path for the PKCS #12 file that will store the exported certificate and private key, click **Next**, and then click **Finish**.

**Note**

- If a certificate was issued from a Windows Server 2003 certification authority, the private key for that certificate is only exportable if the certificate request was made via the Advanced Certificate Request certification authority Web page with the **Mark keys as exportable** check box selected, or if the certificate is for EFS (Encrypting File System) or EFS recovery.

- Strong protection (also known as iteration count) is enabled by default in the Certificate Export Wizard when you export a certificate with its associated private key.

  Strong protection is not compatible with older programs, so you need to clear the **Enable strong protection** option if you are going to use the private key with any browser earlier than Microsoft Internet Explorer 5.

- After the **Certificate Export Wizard** is finished, the certificate will remain in the certificate store in addition to being in the newly-created file. If you want to remove the certificate from the certificate store, you will need to delete it.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the certificates in a PKCS #7 file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the certificates in a PKCS #7 file**

1. Open Windows Explorer.
2. Locate the PKCS #7 file in which you want to view the certificates.
3. In the details pane, right-click the PKCS #7 file and then click **Open**. **Certificates** loads.
4. In the console tree, double-click the folder containing the PKCS #7 file, and then click **Certificates**. The certificates contained in the PKCS #7 file are displayed in the details pane.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- A PKCS #7 file typically has a .p7b file name extension, but this is not always the case. As with any other data file, the creator of the file has control over the name and whether or not the .p7b extension is used.
- For procedures to import and export a PKCS #7 file, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Checklist: Credential roaming

Configure credential roaming Group Policy

# Checklist: Credential roaming

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Credential roaming**

| Step | Reference |
| --- | --- |
| Review concepts about credential roaming. | Using credential roaming |
| Review credential roaming best practices. | Credential roaming best practices |
| Review Active Directory schema concepts and practices. | Extending the schema |
| Extend the Active Directory schema in a test environment by using the credential roaming schema extensions. After verifying the Active Directory schema extension in a test environment, implement the change in the production environment. | Credential roaming schema changes |
| Create the credential roaming administrative template. | Credential roaming administrative template |
| Configure credential roaming Group Policy. | Configure credential roaming Group Policy |

# Configure credential roaming Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To configure credential roaming Group Policy, you need to:

- Install the Credential Roaming administrative template.
- Set credential roaming Group Policy options.

**Install the DIMS administrative template**

To install the CredentialRoaming.adm template:

1. Open the **Active Directory Users and Computers** MMC snap-in.
2. In the console tree, highlight the domain node, right-click and select **Properties**.
3. With the domain properties window open, select the **Group Policy** tab.
4. Highlight the domain policy in the domain policy objects area and click **Edit**.
5. In the console tree, expand **User Configuration\Administrative Templates**.
6. Right-click **Administrative Templates**. Choose **Add/Remove Templates**.
7. Click **Add**.
8. Navigate to the folder where the CredentialRoaming.adm file is located. Select the CredentialRoaming.adm file, click **Open**, and then click **Close**. **Credential Roaming** will now appear as a template under **Administrative Templates**.

**Setting credential roaming Group Policy options**

To configure credential roaming Group Policy options:

1. Open the **Group Policy Object Editor**, and go to:

   ```
   User Configuration)/Administrative Templates/ Credential Roaming
   ```

2. In the details pane, select and right-click **X.509 Certificate and Key Roaming**. Click **Properties**.
3. Under **X.509 Certificate and Key Roaming Settings**, click **Enabled**.
4. In the **Enable Credential Roaming** drop-down list, select the type of credential roaming policy appropriate for your organization:

   - **Roam all using strict arbitration rules**
   - **Roam all x.509 certificates and keys**
   - **Roam Encryption only with strict arbitration**
   - **Roam only encryption certificates and keys**

   **Note**

- In most circumstances, **Roam all x.509 certificates and keys** will be the preferred option. The strict arbitration options can be used when a user may be issued multiple certificates or keys for a similar purpose but with different settings, and you want one specific group of settings to win out.

5. If appropriate for your organization, you can change the default values for the following options:

   - **Maximum tombstone credentials lifetime in days:**
   - **Maximum number of roaming credentials per user:**
   - **Maximum size (in bytes) of a roaming credential:**

6. When you are done, click **OK**.
7. Close the **Group Policy Object Editor**.
8. Click **OK** to accept the new domain Group Policy settings properties and close **Active Directory Users and Computers**.

**Notes**

- You must be a member of the Domain Admins group to define domain Group Policy options.
- New domain Group Policy settings are not applied to clients until after Group Policy is refreshed — typically every eight hours.
- Credential roaming is supported for clients running Windows Server 2003 with Service Pack 1 (SP1). Credential roaming is supported on domain controllers running Windows 2000 Service Pack 3 (SP3) or later or Windows Server 2003. Mixed environments containing domain controllers running Windows 2000 SP3 or later and Windows Server 2003 are also supported. The forest functional level can be either Windows 2000 or Windows Server 2003.
- An update was recently made available that enables credential roaming on clients running Windows XP Professional SP2 and an update is available for Windows Server 2003 (SP1).

  For the best performance and security, it is recommended that the servers be upgraded to Windows Server 2003 SP1. For other best practices, see Credential roaming best practices.
- For an explanation of the different credential roaming Group Policy settings and to create the CredentialRoaming.adm template, see Credential roaming administrative template.

# Use Windows 2000 Certificate Services Web Pages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Windows 2000 Certificate Services Web pages**

- Submit a user certificate request via the Web
- Submit an advanced certificate request via the Web
- Request a certificate using a PKCS #10 or PKCS #7 file
- Save a certificate request to a PKCS #10 file
- Check on a pending certificate request
- Retrieve a certification authority certificate
- Retrieve a certificate revocation list

# Submit a user certificate request via the Web

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To submit a user certificate request via the Web**

1. Open Internet Explorer.
2. In **Address**, type http://*ServerName*/certsrv, where *ServerName* is the name of the Windows 2000 Web server where the certification authority (CA) you want to access is located.
3. Click **Request a certificate**.
4. In **Request a Certificate**, click the type of certificate you want to request.
5. Under ***Certificate Type* -Identifying Information**, do one of the following:
   - If you see the message "No further identifying information is required. To complete your certificate, press submit," click **Submit**.
   - Enter your identifying information for the certificate request, and then click **Submit**.
6. Do one of the following:
   - If you see the **Certificate Pending** Web page, see Related Topics below for the procedure to check on a pending certificate.
   - If you see the **Certificate Issued** Web page, click **Install this certificate**.
7. If you are finished using the Certificate Services Web pages, close Internet Explorer.

## Notes

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- Running Web enrollment on a Windows 2000 Web server acting as a Web enrollment agent for a Windows Server 2003 CA may not provide the full functionality of the CA, because it was not designed to fully integrate with the Windows Server 2003 CA. Limits may occur with smart card enrollment or enrollment for a certificate based on a Version 2 certificate template. To provide full functionality through the Web enrollment agent, run it on a Windows Server 2003, Web Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Use Windows Server 2003 Certificate Services Web Pages

# Submit an advanced certificate request via the Web

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To submit an advanced certificate request via the Web**

1. Open Internet Explorer.
2. In **Address**, type **http://***ServerName***/certsrv**, where *ServerName* is the name of the Windows 2000 Web server where the certification authority that you want to access is located.
3. Click **Request a certificate**.
4. Click **advanced certificate request**.
5. Click **Creae and submit a request to this CA**.
6. Fill in any identifying information requested and any other options you require and click **Submit**.
7. Do one of the following:
   - If you see the **Certificate Pending** Web page, see Related Topics below for the procedure to check on a pending certificate.
   - If you see the **Certificate Issued** Web page, click **Install this certificate**.
8. If you are finished using the Certificate Services Web pages, close Internet Explorer.

**Notes**

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- A Windows XP computer cannot request a certificate on behalf of another subject when using the Windows 2000 certification authority Web pages.
- Running Web enrollment on a Windows 2000 Web server that is acting as a Web enrollment agent for a Windows Server 2003 family CA may not provide the full functionality of the CA, because it was not designed to fully integrate with the Windows Server 2003 family CA. Limits may occur with smart card enrollment or enrollment for a certificate based on a Version 2 certificate template. To provide full functionality through the Web enrollment agent, run it on a Web server that is running a Windows Server 2003 operating system.
- Using the **Advanced Certificate Request** Web page, you can set the following options for each certificate requested:
  - Certificate template (from enterprise certification authorities) or **Intended purposes** (from stand-alone certification authorities). Indicates what applications the public key in the certificate can be used for, such as client authentication or e-mail.
  - Cryptographic service provider (CSP).
  - **Key size.** The length, in bits, of the public key on the certificate. In general, the longer the key, the more secure it is.
  - Hash algorithm

- **Key usage.** How the private key can be used. "Exchange" means that the private key can be used to enable the exchange of sensitive information. "Signature" means that the private key can be used only to create a digital signature. "Both" means that the key can be used for both exchange and signature functions.

- **Create a new key set or use an existing key set.** You can use an existing public and private key pair stored on your computer or create a new public and private key pair for a certificate. For more information about the issues of reusing a key as opposed to generating a new key, see the resources on Certificates Resources.

- **Enable strong private key protection.** When you enable strong private key protection, you are prompted for a password every time the private key needs to be used.

- **Mark keys as exportable.** When you mark keys as exportable, you can save the public and private key to a PKCS #12 file. This is useful if you change computers and want to move the key pair, or if you want to remove the key pair and secure them in another location.

- **Use the local machine store.** Select this option if the computer will need access to the private key associated with the certificate when other users are logged on. Select this option when requesting certificates intended to be issued to computers (such as Web servers) instead of certificates issued to people.

- **Save the request to PKCS #10 file.** This is useful if the certification authority is unavailable for processing certificate requests online. For information on creating and submitting a certificate request using a PKCS #10 file, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Request a certificate using a PKCS #10 or PKCS #7 file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To request a certificate using a PKCS #10 or PKCS #7 file**

1. Open Internet Explorer.
2. In **Address**, type http://*servername*/certsrv, where *servername* is the name of the Windows 2000 Web server where the certification authority (CA) you want to access is located.
3. Click **Request a certificate**, and then click **advanced certificate request**.
4. Click **Submit a certificate request using a base64-encoded CMC or PKCS #10 file, or submit a renewal request by using a base-64-encoded PKCS #7 file**.
5. Do one of the following:
   - Open Notepad. On the **File** menu, click **Open**. Select the PKCS #10 or PKCS #7 file and click **Open**. On the **Edit** menu, click **Select all**, and then, on the **Edit** menu, click **Copy**. On the Web page, click in the **Saved request** scroll box. On the **Edit** menu, click **Paste** to paste the contents of certificate request into the scroll box.
   - If your Web browser security settings do not prohibit a Web page from accessing your disk, you can click **Browse for a file to insert** to locate the file you want to use for the certificate request. If you get a warning about the ActiveX control, click **Yes** to allow it to run, then click **Browse**. After locating and selecting the file you want to use for the certificate request, click **Read!**. On the Web page, click **Read!** to paste the contents of the file into the scroll box. See the note about using **Browse**.
6. If you are connected to an enterprise CA, choose the certificate template you want to use.
7. Click **Submit**.
8. Do one of the following:
   - If you see the **Certificate Pending** Web page, see Related Topics below for the procedure to check on a pending certificate.
   - If you see the **Certificate Issued** Web page, click **Download certificate**. Choose to save the file to your hard disk, and then import the certificate into your certificate store. For the procedure to import a certificate, see Related Topics.

**Notes**

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- To open Notepad, click **Start**, point to **All programs**, point to **Accessories**, and then click **Notepad**.
- In general, you use a PKCS #10 file to submit a request for a new certificate and a PKCS #7 file to submit a request to renew an existing certificate. Submitting requests with files is useful when the certificate requester is unable to submit a request online to the certification authority.
- If you use a PKCS #7 file to submit a request to renew an existing certificate, the renewal request file must be generated by a program. This procedure will not work with a PKCS #7 file that merely contains an exported certificate.

- You might need to make http://*servername* a trusted site for Internet Explorer in order to browse for a file on the computer's disk drive. To make http://*servername* a trusted site, in Internet Explorer, click **Tools**, then point to **Internet Options**, point to **Security**, point to **Trusted Sites**, and click **Sites**. Type **http://*servername***, and click **OK**.

- If you submit the request and immediately get a message asking you if you want to submit the request even though it does not contain a "BEGIN" or "END" tag, click **OK**.

- For the procedure to export a certificate to create a PKCS #7 file, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save a certificate request to a PKCS #10 file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save a certificate request to a PKCS #10 file**

1. Open Internet Explorer.
2. In **Address**, type http://*servername*/certsrv, where *servername* is the name of the Windows 2000 Web server where the certification authority you want to access is located.
3. Click **Request a certificate**, and then click **Next**.
4. Click **Advanced request**, and then click **Next**.
5. Click **Submit a certificate request to this CA using a form**, and then click **Next**.
6. In **Certificate Template** and **Key Options**, select the options which you want to use for the certificate request.
7. Under **Additional Options**, select the **Save request to a PKCS #10 file** check box.
8. In **File name**, type a file name and click **Save**.
9. If you are finished using the Certificate Services Web pages, close Internet Explorer.

## Notes

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- The file is saved to your computer's desktop.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To check on a pending certificate request**

1. Open Internet Explorer.
2. In **Address**, type http://*servername*/certsrv, where *servername* is the name of the Windows 2000 Web server where the certification authority (CA) you want to access is located.
3. Click **Check on a pending certificate**, and then click **Next**.
4. If there are no pending certificate requests, you will see a message to that effect. Otherwise, select the certificate request you want to check and **Next**, and check the pending certificate request.
5. If you are finished using the Certificate Services Web pages, close Internet Explorer.

## Notes

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- The available status messages are:
  - **Still pending.** You must wait for the administrator of the certification authority to issue the certificate. To remove the certificate request, click **Remove**.
  - **Issued.** To install the certificate, click **Install this certificate**.
  - **Denied.** Contact the administrator of the certification authority for further information.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Retrieve a certification authority certificate

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To retrieve a certification authority certificate**

1. Open Internet Explorer.
2. In **Address**, type http://*servername*/certsrv, where *servername* is the name of the Windows 2000 Web server where the certification authority (CA) you want to access is located.
3. Click **Retrieve the CA certificate or certificate revocation list**, and then click **Next**.
4. Do one of the following:
   - If you want to trust all the certificates issued by this certification authority (CA), click **Install this CA certification path**.
   - If the certification authority has been renewed, you will have the choice of which version of the CA certificate you want to download.
5. Under **Choose file to download**, click the CA certificate you want to download, and then click **Download CA Certificate**.
6. In **File Download**, click **Open this file from its current location**, and then click **OK**.
7. When the **Certificate** dialog box appears, click **Install certificate**.
8. In the Certificate Import Wizard, click **Automatically select the certificate store based on the type of certificate**.
9. If you are finished using the Certificate Services Web pages, close Internet Explorer.

## Notes

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- Choosing **Install this CA certification path** is useful when you want to establish trust in a subordinate CA, but you do not currently have the certificate of the root CA of the certification hierarchy in your certificate store.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Retrieve a certificate revocation list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To retrieve a certificate revocation list**

1. Open Internet Explorer.
2. In **Address**, type http://*servername*/certsrv, where *servername* is the name of the Windows 2000 Web server where the certification authority (CA) you want to access is located.
3. Click **Retrieve the CA certificate or certificate revocation list (CRL)**, and then click **Next**.
4. Click **Download latest certificate revocation list**.
5. When the **File Download** dialog box appears, click **Save this file to disk**, and then click **OK**. Select a folder on your computer in which to store the .crl file, click **Save**, and then click **Close**.
6. Open Windows Explorer and locate the .crl file you just saved.
7. Right-click the .crl file and click **Install CRL**.
8. When the Certificate Import Wizard opens, click **Automatically select the certificate store based on the type of certificate**.
9. After completing the Certificate Import Wizard, close Internet Explorer if you are finished using the Certificate Services Web pages.

## Notes

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

# Submit a user certificate request via the Web to a Windows Server 2003 CA

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To submit a user certificate request via the Web to a Windows Server 2003 CA**

1. Open Internet Explorer.
2. In Internet Explorer, connect to http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority (CA) you want to access is located.
3. Click **Request a certificate**.
4. On **Request a Certificate**, click **User Certificate**.
5. On the User Certificate - Identifying Information page, do one of the following:
   - Read the message "No further identifying information is required. To complete your certificate, press submit".
   - Enter your identifying information for the certificate request.
6. (Optional) Click **More Options** to specify the cryptographic service provider (CSP) and whether you want to enable strong private key protection. (This means that you will receive a prompt every time that the private key associated with the certificate is used.)
7. Click **Submit**.
8. Do one of the following:
   - If you see the **Certificate Pending** Web page, see Related Topics below for the procedure to check on a pending certificate.
   - If you see the **Certificate Issued** Web page, click **Install this certificate**.
9. If you are finished using the Certificate Services Web pages, close Internet Explorer.

### Note

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Submit an advanced certificate request via the Web to a Windows Server 2003 CA

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To submit an advanced certificate request via the Web to a Windows Server 2003 CA**

1. Open Internet Explorer.
2. In Internet Explorer, connect to http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority that you want to access is located.
3. Click **Request a certificate**.
4. Click **advanced certificate request**.
5. Click **Create and submit a certificate request to this CA**.
6. Fill in any identifying information requested and any other options you require.
7. Click **Submit**.
8. Do one of the following:
   - If you see the **Certificate Pending** Web page, see Related Topics below for the procedure to check on a pending certificate.
   - If you see the **Certificate Issued** Web page, click **Install this certificate**.
9. If you are finished using the Certificate Services Web pages, close Internet Explorer.

**Notes**

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- Using the **Advanced Certificate Request** Web page, you can set the following options for each certificate requested:
  - **The Certificate template** (from an enterprise certification authorities) or **Intended purposes** (from a stand-alone certification authorities). Indicates what applications the public key in the certificate can be used for, such as client authentication or e-mail.
  - **The Cryptographic service provider (CSP).** A CSP is responsible for creating keys, destroying them, and using them to perform a variety of cryptographic operations. Each CSP provides a different implementation of the CryptoAPI. Some provide stronger cryptographic algorithms, while others use hardware components, such as smart cards
  - **Key size.** The length, in bits, of the public key on the certificate. In general, the longer the key, the more secure it is.
  - **The Hash algorithm.** A good hash algorithm makes it computationally infeasible to construct two independent inputs that have the same hash. Typical hash algorithms include MD2, MD4, MD5, and SHA-1.

- **Key usage.** How the private key can be used. "Exchange" means that the private key can be used to enable the exchange of sensitive information. "Signature" means that the private key can be used only to create a digital signature. "Both" means that the key can be used for both exchange and signature functions.

- **Create a new key set or use an existing key set.** You can use an existing public and private key pair stored on your computer or create a new public and private key pair for a certificate. For more information that compares reusing a key and generating a new key, see the resources on Certificates Resources.

- **Enable strong private key protection.** When you enable strong private key protection, you will be prompted for a password every time the private key needs to be used.

- **Mark keys as exportable.** When you mark keys as exportable, you can save the public and private key to a PKCS #12 file. This is useful if you change computers and want to move the key pair, or if you want to remove the key pair and secure them in another location.

- **Use the local machine store.** Select this option if the computer will need access to the private key associated with the certificate when other users are logged on. Select this option when requesting certificates intended to be issued to computers (such as Web servers) instead of certificates issued to people.

- **Save the request to PKCS #10 file.** This is useful if the certification authority is unavailable for processing certificate requests online. For information on creating and submitting a certificate request using a PKCS #10 file, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Request a certificate from a Windows Server 2003 CA using a PKCS #10 or PKCS #7 file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To request a certificate from a Windows Server 2003 CA using a PKCS #10 or PKCS #7 file**

1. Open Internet Explorer.
2. In Internet Explorer, connect to http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority (CA) you want to access is located.
3. Click **Request a certificate** and then click **advanced certificate request**.
4. Click **Submit a certificate request using a base-64-encoded CMC or PKCS #10 file, or submit a renewal request by using a base-64-encoded PKCS #7 file**.
5. Do one of the following:
   - In Notepad, click **File**, click **Open**, select the PKCS #10 or PKCS #7 file, click **Edit**, click **Select all**, click **Edit**, and click **Copy**. On the Web page, click in the **Saved request** scroll box. Click **Edit** and then click **Paste** to paste the contents of certificate request into the scroll box.
   - Click **Browse for a file to insert** to locate the file you want to use for the certificate request. If you get a warning about the ActiveX control, click **Yes** to allow it to run, then click the **Browse** button. After locating and selecting the file you want to use for the certificate request, click **Open**. On the Web page, click **Read!** to paste the contents of the file into the scroll box. See the note about using **Browse**.
6. If you are connected to an enterprise CA, choose the certificate template you want to use. By default, the appropriate template is named **Subordinate Certification Authority**.
7. If you have any attributes to add to the certificate request, enter them into **Additional Attributes**.
8. Click **Submit**.
9. Do one of the following:
   - If you see the **Certificate Pending** Web page, see Related Topics below for the procedure to check on a pending certificate.
   - If you see the **Certificate Issued** Web page, click **Download certificate chain**. Choose to save the file to your hard disk, and then import the certificate into your certificate store. For the procedure to import a certificate, see Related Topics.

**Notes**

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- To open Notepad, click **Start**, point to **All programs**, point to **Accessories**, and then click **Notepad**.
- In general, you use a PKCS #10 file to submit a request for a new certificate and a PKCS #7 file to submit a request to renew an existing certificate. Submitting requests with files is useful when the certificate requester is unable to submit a

request online to the certification authority.

- You might need to make http://*servername* a trusted site for Internet Explorer in order to browse for a file on the computer's disk drive. To make http://*servername* a trusted site, in Internet Explorer, click **Tools**, then point to **Internet Options**, point to **Security**, point to **Trusted Sites**, and click **Sites**. Type **http://*servername***, and click **OK**.

- If you submit the request and immediately get a message asking you if you want to submit the request even though it does not contain a BEGIN or END tag, click **OK**.

- For the procedure to export a certificate to create a PKCS #7 file, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save a certificate request to a Windows Server 2003 CA in a PKCS #10 file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save a certificate request to a Windows Server 2003 CA in a PKCS #10 file**

1. Open Internet Explorer.
2. In Internet Explorer, open http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority you want to access is located.
3. Click **Request a certificate**, and then click **advanced certificate request**.
4. Click **Create and submit a request to this CA**.
5. Enter any identifying information requested and any other options you require.
6. Under **Additional Options**, select the **Save request to a PKCS #10 file** check box.
7. In the **Full path name** field, type a path and file name.
8. Click **Submit**. The file is saved to your computer's desktop.
9. If you are finished using the Certificate Services Web pages, close Internet Explorer.

**Note**

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Check on a pending certificate request to a Windows Server 2003 CA

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To check on a pending certificate request to a Windows Server 2003 CA**

1. Open Internet Explorer.
2. In Internet Explorer, open http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority you want to access is located.
3. Click **View the status of a pending certificate request**.
4. If there are no pending certificate requests, you will see a message to that effect. Otherwise, select the certificate request you want to check, and click **Next**.
5. Check the pending certificate requests:
   - **Still pending.** You must wait for the administrator of the certification authority to issue the certificate. To remove the certificate request, click **Remove**.
   - **Issued.** To install the certificate, click **Install this certificate**.
   - **Denied.** Contact the administrator of the certification authority for further information.
6. If you are finished using the Certificate Services Web pages, close Internet Explorer.

**Note**

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.

# Retrieve a certification authority certificate from a Windows Server 2003 CA

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To retrieve a certification authority certificate from a Windows Server 2003 CA**

1. Open Internet Explorer.
2. In Internet Explorer, connect to http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority (CA) you want to access is located.
3. Click **Download a CA certificate, certificate chain, or CRL**.
4. Do one of the following:
   - If you want to trust all the certificates issued by this certification authority (CA), click **Install this CA certificate chain**.
   - If the certification authority has been renewed, you will have the choice of which version of the CA certificate you want to download.
5. Select the encoding method you want for the CRL: **DER** or **Base 64**.
6. Under **CA Certificate**, click the CA certificate you want to download, and then click **Download CA certificate** or click **Download CA certificate chain**.
7. In **File Download**, click **Open this file from its current location**, and then click **OK**.
8. When the **Certificate** dialog box appears, click **Install this certificate**.
9. In the Certificate Import wizard, click **Automatically select the certificate store based on the type of certificate**.
10. If you are finished using the Certificate Services Web pages, close Internet Explorer.

## Notes

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- Choosing **Install this CA certification path** is useful when you want to establish trust in a subordinate CA, but you do not currently have the certificate of the root CA of the certification hierarchy in your certificate store.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Retrieve a certificate revocation list from a Windows Server 2003 CA

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To retrieve a certificate revocation list from a Windows Server 2003 CA**

1. Open Internet Explorer.
2. In Internet Explorer, connect to http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority (CA) you want to access is located.
3. Click **Download a CA certificate, certificate chain, or CRL**.
4. Click the encoding method you want for the CRL, **DER** or **Base 64**.
5. Do one of the following:
   - Click **Download CA certificate**.
   - Click **Download CA certificate chain**.
   - Click **Download latest base CRL**.
   - Click **Download latest delta CRL**. (You need to have the latest base CRL already installed for the delta CRL to be functional.)
6. When the **File Download** dialog box appears, click **Save**. Select a folder on your computer in which to store the .crl file, and click **Save**.
7. Open Windows Explorer and locate the .crl file you just saved.
8. Right-click the .cer or .crl file and click **Install Certificate** or **Install CRL**, and then click **Next**.
9. When the Certificate Import Wizard opens, click **Automatically select the certificate store based on the type of certificate**.
10. After completing the Certificate Import Wizard, close Internet Explorer if you are finished using the Certificate Services Web pages.

### Note

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.

# Disable trust of third-party root CAs for a Windows Server 2003 domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable trust of third-party root CAs for a Windows Server 2003 domain**

1. Open the Group Policy object that you want to edit.

2. In the console tree, right-click **Trusted Root Certification Authorities**, and click **Properties**.

   **Where?**

   - *Policy Object Name*/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Trusted Root Certification Authorities

3. In **Client computers can trust the following certificate stores**, select the **Enterprise Root Certification Authorities** option.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a Group Policy object, see Related Topics.

- This procedure does not apply to Local Policy objects.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable trust of user-selected root CAs for a Windows Server 2003 domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable trust of user-selected root CAs for a Windows Server 2003 domain**

1. On the domain controller, open Active Directory Users and Computers.
2. Click the domain name and, on the **Action** menu, click **Properties**.
3. Click the **Group Policy** tab and then click the **Edit** button.
4. In the console tree, click **Trusted Root Certification Authorities**.

   **Where?**

   - Default Domain Policy/Computer Configuration/Windows Settings/Security Settings/Public Key Policies/Trusted Root Certification Authorities

5. On the **Action** menu, click **Properties**.
6. Clear the **Allow users to select new root certification authorities (CAs) to trust** check box and then click **OK**.
7. Close the Group Policy snap-in.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- When you disable the trust of user-selected CAs, these are the consequences:
  - When the users access any secure Web sites that are validated by these user-selected root CAs, they will receive security alert warnings informing them that the sites are not trusted.
  - In Internet Explorer, under **Certificates**, any previous user-selected root CAs will no longer be listed under Trusted Root Certification Authorities.
- If you don't want to disable trust of user-selected CA certificates for an entire domain, you can follow steps 4-7 for any Group Policy object that applies to all the computers for which you do want to have this trust disabled.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Certificates overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificates overview**

**Certificates**
A public key certificate, usually just called a certificate, is a digitally-signed statement that binds the value of a public key to the identity of the person, device, or service that holds the corresponding private key. Most certificates in common use are based on the X.509v3 certificate standard. For references to extensive information about public key cryptography, see Certificates Resources.

Certificates can be issued for a variety of functions such as Web user authentication, Web server authentication, secure e-mail (using Secure/Multipurpose Internet Mail Extensions, also called S/MIME), Internet Protocol security (IPSec), Transport Layer Security (TLS), and code signing. Certificates are also issued from one certification authority (CA) to another in order to establish a certification hierarchy.

The entity that receives the certificate is the *subject* of the certificate. The issuer and signer of the certificate is a certification authority.

Typically, certificates contain the following information:

- The subject's public key value.
- The subject's identifier information, such as the name and e-mail address.
- The validity period (the length of time that the certificate is considered valid).
- Issuer identifier information.
- The digital signature of the issuer, which attests to the validity of the binding between the subject's public key and the subject's identifier information.

A certificate is valid only for the period of time specified within it; every certificate contains *Valid From* and *Valid To* dates, which set the boundaries of the validity period. Once a certificate's validity period has passed, a new certificate must be requested by the subject of the now-expired certificate.

In instances where it becomes necessary to undo the binding that is asserted in a certificate, a certificate can be revoked by the issuer. Each issuer maintains a certificate revocation list that can be used by programs when checking the validity of any given certificate.

One of the main benefits of certificates is that hosts no longer have to maintain a set of passwords for individual subjects who need to be authenticated as a prerequisite to access. Instead, the host merely establishes trust in a certificate issuer.

When a host, such as a secure Web server, designates an issuer as a trusted root authority, the host implicitly trusts the policies that the issuer has used to establish the bindings of certificates it issues. In effect, the host trusts that the issuer has verified the identity of the certificate subject. A host designates an issuer as a trusted root authority by placing the issuer's self-signed certificate, which contains the issuer's public key, into the trusted root certification authority certificate store of the host computer. Intermediate or subordinate certification authorities are trusted only if they have a valid certification path from a trusted root certification authority.

For more information about certificates, see Understanding Certificates.

**Certificate uses**
Because certificates are generally used to establish identity and create trusts for the secure exchange of information, certification authorities (CAs) can issue certificates to people, to devices (such as computers), and to services running on computers (such as IPSec).

In some cases, computers must be able to exchange information with a high degree of confidence in the identity of the other device, service, or person involved in the transaction. In some cases, people need to exchange information with a high degree

of confidence in the identity of the other person, computer, or service involved in the transaction. Applications and services that run on computers also frequently need to verify that they are accessing information from a trusted source.

In circumstances where two entities--such as devices, persons or applications or services--attempt to establish identity and trust, the fact that both entities trust the same certification authority allows the bond of identity and trust to be established between them. Once a certificate subject has presented a certificate issued by a trusted CA, the entity attempting to establish trust can proceed with an information exchange by storing the certificate subject's certificate in its own certificate store, and, where applicable, using the public key contained in the certificate to encrypt a session key so that all subsequent communications to the certificate subject are secure.

For example, when using the Internet for online banking, it is important to know that your Web browser is communicating directly and securely with your bank's Web server. Your Web browser must be able to achieve Web server authentication before a safe transaction can occur. That is, the Web server must be able to prove its identity to your Web browser before the transaction can proceed. Microsoft® Internet Explorer uses Secure Sockets Layer (SSL) to encrypt messages and transmit them securely across the Internet, as do most other modern Web browsers and Web servers.

When you connect using an SSL-enabled browser to an online banking Web server that has a server certificate from a certification authority such as Verisign, the following events occur:

- You access your bank's secured online banking login Web page using your Web browser. If you use Internet Explorer, a locked-padlock icon will appear in the lower right corner of the browser status bar to indicate that the browser is connected to a secure Web site. Other browsers depict secure connections in other ways.

- The bank's Web server automatically sends a server certificate to your Web browser.

- To authenticate the Web server, your Web browser checks the certificate store on your computer. If the certification authority that issued the certificate to your bank is trusted, the transaction can proceed, and the bank certificate is stored in your certificate store.

- To encrypt all communications with the bank Web server, your Web browser creates a unique session key. Your Web browser encrypts the session key with the bank Web server certificate so that only the bank Web server can read messages sent by your browser. (Some of these messages will contain your login name and password and other sensitive information, so this level of security is necessary.)

- The secure session is established, and sensitive information can be sent between your Web browser and the bank's Web server in a secure manner.

For more information, see Security with Certificates.

Certificates can also be used to verify the authenticity of software code that you download from the Internet, install from your company intranet, or purchase on CD-ROM and install on your computer. Unsigned software--software that does not have a valid software publisher's certificate--can pose a risk to your computer and the information you store on your computer.

When software is signed with a valid certificate from a trusted certification authority, you know that the software code has not been tampered with and can be safely installed on your computer. During software installation, you are prompted to verify that you trust the software manufacturer (for example, Microsoft Corporation). You may also be offered the option to always trust software content from that particular software manufacturer. If you choose to trust content from the manufacturer, their certificate goes into your certificate store and other software installations of their products can occur with a circumstance of predefined trust. In the circumstance of predefined trust, you can install software from the manufacturer without being prompted to indicate whether they are trusted; the certificate on your computer states that you trust the manufacturer of the software.

As with other certificates, those certificates used to verify the authenticity of software and the identity of a software publisher can have other purposes. For example, when the Certificates snap-in is set to view certificates by purpose, the Code Signing folder might contain a certificate issued to Microsoft Windows Hardware Compatibility by the Microsoft Root Authority. This single certificate has three purposes:

- It ensures that the software came from the software publisher.

- It protects software from alteration after publication.

- It provides Windows hardware driver verification.

**Certificate use in organizations**
Many organizations install their own certification authorities and issue certificates to internal devices, services, and employees to create a more secure computing environment. Large organizations may have multiple certification authorities, set up in a hierarchy that leads to a root certification authority. Thus, an employee of an organization may have a multitude of certificates in their certificate store that have been issued by a variety of internal certification authorities, all of whom share a trust connection via the certification path to the root certification authority.

When an employee logs in to the organization's network from home using a virtual private network (VPN), the VPN server can present a server certificate to establish its identity. Because the corporate root authority is trusted and the corporate root certification authority issued the certificate of the VPN server, the client computer can proceed with the connection and the employee knows his computer is actually connected to his organization's VPN server.

The VPN server must also be able to authenticate the VPN client before data can be exchanged over the VPN connection. Either computer-level authentication occurs with the exchange of computer certificates or user-level authentication occurs though the use of a Point-to-Point Protocol (PPP) authentication method. For L2TP (Layer 2 Tunneling Protocol)/IPSec connections, computer certificates are required for both the client and server.

For more information, see Authentication of VPN clients, Computer certificates for L2TP/IPSec VPN connections, and Remote access VPN design considerations.

The client computer certificate may serve multiple purposes, most of which are based in authentication, allowing the client to use many organizational resources without the need for individual certificates for each resource. For example, the client certificate might allow VPN connectivity as well as access to the company store intranet site, to product servers, and to the human resources database where employee data is stored.

The VPN server certificate might also serve multiple purposes. The same certificate might have the purpose of verifying the identity of e-mail servers, Web servers, or application servers. The certification authority that issues the certificate determines the number of purposes for each certificate.

**Certificates issued to persons**
You can purchase a certificate from a commercial certification authority, such as Verisign, to send personal e-mail messages that are encrypted for security or digitally signed to prove authenticity.

Once you have purchased a certificate and you use it to digitally sign an e-mail message, the message recipient can verify that the message has not been altered during transit and that the message came from you--assuming, of course, that the message recipient trusts the certification authority that issued your certificate.

When you encrypt an e-mail message, nobody can read the message while it is in transit, and only the message recipient can decrypt and read the message.

**Certificates and applications**
Most e-mail clients allow you to automatically sign or encrypt e-mail messages or to encrypt or sign messages on an individual basis. Microsoft applications that allow e-mail messages to be digitally signed or encrypted are Microsoft Outlook® 2000, Microsoft Outlook Express and Microsoft Outlook 98.

Many Windows applications use certificates. Here are some links and information about how certificates can be used with Microsoft Internet Information Services (IIS), Microsoft Outlook 2003, Microsoft Outlook Express, and Microsoft Internet Explorer.

### Internet Information Services certificates information

IIS certificate storage is integrated with the CryptoAPI storage. The Certificates snap-in provides a single point of entry that lets administrators store, back up, and configure server certificates.

IIS comes with three security task wizards that simplify most of the security tasks necessary to maintain a secure Web site. You can use the Web Server Certificate Wizard to manage Secure Sockets Layer (SSL) features in IIS and server certificates. Certificates are used in negotiating a secure link between your server and a user's browser. You can use the CTL Wizard to manage certificate trust lists (CTLs). Certificate trust lists are lists of trusted certification authorities for each Web site or virtual directory. You can use the IIS Permissions Wizard to assign Web and NTFS access permissions to Web sites, virtual directories, and files on your server.

For more information about the use of certificates in IIS, see the Microsoft Web site.

**Outlook 2003 certificates information**

- "Set Up Security for Internet E-mail Messages" on the Microsoft Web site.

**Internet Explorer certificates information:**

- Internet Explorer 6.0 Resource Kit on the Microsoft Web site.

Other Microsoft resources on certificates include Knowledge Base articles:

- "Description of Symmetric and Asymmetric Encryption" on the Microsoft Web site.
- "Using a Certificate Authority for the Encrypting File Service" on the Microsoft Web site.
- "Best Practices for Encrypting File System" on the Microsoft Web site.

**Note**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

**Certificate import and export**
If you have certificates you want to use on other computers, you can export your certificates for import to other computers. For more information, see Importing and exporting certificates and Import and Export Certificates.

**The certificate store**
There are four basic sources for the certificates found in the certificate stores on your computer:

- The certificate is included with your installation of Windows Server 2003 and comes on the Windows Server 2003 CD.
- You use an application such as an Internet browser to engage in a SSL session, during which certificates are stored on your computer after establishment of trust.
- You explicitly choose to accept a certificate, as when you install software or receive an encrypted or digitally signed e-mail from others.
- You request a certificate from a certification authority, such as a certificate needed to access specific organizational resources.

Over time, as you use the Internet and connect to servers that use certificates for authentication and other purposes, the certificate store on your computer will gain entries. Some certificates may have one purpose, such as server authentication or client authentication, while other certificates may serve multiple purposes. The certification authority that issues the certificate determines the purpose or purposes the certificate may serve.

Although Internet Explorer and Windows store certificates in the same certificate stores, they allow different views of the certificate stores. For more information, see Set Display Options of the Certificates Snap-in in Certificates Help. To better understand how the Certificates snap-in displays the certificate store, see Certificate stores.

By using the Certificates snap-in, you can view certificates by logical store or by purpose. If you view certificates by purpose, a certificate with multiple purposes will appear listed in every folder that defines a purpose for which the certificate can be used.

**The Certificates snap-in**
You can use the Certificates snap-in to manage certificates for users, computers, or services.

Users and administrators can use the Certificates snap-in to request new certificates from Windows 2000 and enterprise certification authorities. In addition, users can find, view, import, and export certificates from within certificate stores. However, in most cases, users do not have to personally manage their certificates and their certificate stores. That can be accomplished by administrators, by policy settings, and through programs that use certificates.

Administrators are the primary users of the Certificates snap-in and, as such, they are able to perform a wide variety of

certificate management tasks in their personal certificate store as well as the certificate stores for any computer or service that they have the right to administer.

For more information, see Requesting certificates

# Understanding Certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section covers the following topics:

- Certificates and certification authorities
- Generating encryption keys and certificate requests
- Certificate stores
- Security with Certificates

# Certificates and certification authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificates and certification authorities**

When a certificate is presented to an entity as a means of identifying the certificate holder (the *subject* of the certificate), it is useful only if the entity receiving the certificate trusts the issuer, which is often referred to as the certification authority (CA).

When you *trust* a certification authority, that means you have confidence that the certification authority has the proper policies in place when evaluating certificate requests and will deny certificates to any entity that does not meet those policies. In addition, you trust that the certification authority will revoke certificates that should no longer be considered valid by publishing an up-to-date certificate revocation list. Certificate revocation lists are considered valid until they expire. So even if the CA publishes a new certificate revocation list with newly revoked certificates listed, all clients that have an old certificate revocation list will not look for, nor retrieve the new one until the old one expires or is deleted. Clients can use the CA Web pages to manually retrieve the most current certificate revocation list if necessary.

For Windows Server 2003 users, computers, and services, trust in a certification authority is established when you have a copy of the root certificate in the trusted root certification authorities store, as well as having a valid certification path, meaning that none of the certificates in the certification path has been revoked or has had its validity period expire. The certification path includes every certificate issued to each CA in the certification hierarchy from a subordinate CA to the root CA. For example, for a root CA, the certification path is one certificate, its own self-signed certificate. For a subordinate CA, just below the root CA in the hierarchy, its certification path is two certificates: its own certificate and the root CA certificate.

If your organization is using Active Directory, then trust in your organization's certification authorities will typically be established automatically, based on decisions and settings made by the system administrator.

A related concept with which you should be familiar is certificate store inheritance. If you place a root CA certificate into the computer's trusted root certification authorities store or enterprise trust store, then any user of the computer will see that certificate in their own user trusted root certification authorities store or enterprise trust store even though the root certificate is actually in the computer's store. Essentially, users will trust any CA that their computer trusts. Certificate store inheritance does not work the other way around: certificates in the user's trusted root certification authorities store and enterprise trust store are not inherited by the computer.

If your organization is using the version of Certificate Services installed with the Windows Server 2003 family to run its certification authority, the certification authority is one of two types: enterprise or stand-alone. The differences between the two standard types of Windows Server 2003 certification authorities for certificate users and requesters are summarized below.

**Enterprise certification authority**

An enterprise certification authority depends upon Active Directory being present.

You can use the Certificate Request Wizard (which is started from within the Certificates snap-in), as well as certification authority Web pages, to request certificates from an enterprise certification authority.

An enterprise certification authority offers different types of certificates to a requester based on the certificates it is configured to issue as well as the security permissions of the requester. An enterprise certification authority uses information available in

Active Directory to help verify the requester's identity. An enterprise certification authority publishes its certificate revocation list to Active Directory as well as to a shared directory.

**Stand-alone certification authority**
A stand-alone certification authority is less automated for a user than an enterprise certification authority because it does not depend on the use of Active Directory.

By default, users can request certificates from a stand-alone certification authority only by using Web pages.

Stand-alone certification authorities that do not use Active Directory will generally have to request that the certificate requester provide more complete identifying information. A stand-alone certification authority makes its certificate revocation list available from a shared folder, or from Active Directory, if it is available.

### Notes

- For more information about the Certificate Services policy and exit modules, which determine whether a Windows Server 2003 certification authority is enterprise or stand-alone, see Policy and exit modules.

- It is possible to customize a Windows Server 2003 certification authority with a policy module that is different from the one installed with the Windows Server 2003 operating system. In that case, the certification authority is technically neither a stand-alone nor an enterprise certification authority, but may have qualities of one or the other.

For more information, see Certification Authorities, Certificate Services overview, Requesting certificates, Using Windows 2000 Certificate Services Web pages, Certificate stores, and Certificates Resources

# Generating encryption keys and certificate requests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Generating encryption keys and certificate requests**

How you request and receive a certificate depends upon the policies and processes of the certification authority (CA) that issues the certificate. For example, some certification authorities have Web pages to which you can submit a reques or, if you are in an organization that has deployed Active Directory and Certificate Services, you can use the Certificates snap-in to request a certificate, if your computer is a member of a domain and you are authorized to request certificates.

In any case, when you generate a request for a new certificate, the information in that request is first passed from the requesting program to CryptoAPI. CryptoAPI will pass the proper data to a program known as a cryptographic service provider (CSP) that is installed on your computer or on a device that is accessible to your computer. If the CSP is software-based, it will generate a public key and a private key, often referred to as a key pair, on your computer. If the CSP is hardware-based, such as a smart card CSP, it will instruct a piece of hardware to generate the key pair.

After the keys are generated, a software CSP encrypts and then secures the private key. A smart card CSP stores the private key on a smart card and the smart card controls access to the key. The public key is sent to the certification authority, along with the certificate requester information. Once the CA verifies the certificate request according to its policies, it will use its own private key to create a digital signature in the certificate and then issue it to the requester. The certificate requester will then be presented with the certificate from the CA and the option to install it in the appropriate certificate store on the computer or hardware device.

For more information about keys and certificates, see Certificates Resources.

For more information, see Requesting certificates.

# Certificate stores

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate stores**

Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition, store a certificate locally on the computer or device that requested it or, in the case of a user, on the computer or device that the user used to request it. The storage location is called the certificate store. A certificate store will often have numerous certificates, possibly issued from a number of a different certification authorities.

Using the Certificates snap-in, you can display the certificate store for a user, a computer, or a service according to the purpose for which the certificates were issued or by using their logical storage categories. When you display certificates according to their storage categories, you can also choose to display the physical stores, showing the certificate storage hierarchy. (This is recommended for advanced users only.)

If you have the user rights to do so, you can import or export certificates from any of the folders in the certificate store. Additionally, if the private key associated with a certificate is marked as available for export, you can export both into a PKCS #12 file.

Windows can also publish certificates to Active Directory. Publishing a certificate in Active Directory enables all users or computers with adequate permissions to retrieve the certificate as needed.

Certificates can be displayed by purpose or by logical stores, as shown in the following table. Displaying certificates by logical stores is the Certificates default. (Note that the list of certificate purpose stores does not include all the possible purpose stores.)

| Display by | Folder name | Contents |
|---|---|---|
| Logical Store | Personal | Certificates associated with private keys to which you have access. These are the certificates that have been issued to you, or to the computer or service for which you are managing certificates.<br><br>Note to administrators: Computers in a Windows Server 2003 Active Directory domain can have certificates automatically placed in this store through the use of Group Policy-based autoenrollment. For more information, see Automatic certificate request settings. |
| | Trusted Root Certification Authorities | Implicitly trusted certification authorities. Includes all of the certificates in the Third-Party Root Certification Authorities store plus root certificates from your organization and Microsoft.<br><br>If you are an administrator and want to add third-party certification authority certificates to this store for all computers in a Windows Server 2003 Active Directory domain, you can use Group Policy to distribute trusted root certificates to your organization. For more information, see Trusted root certification authority policy. |
| | Enterprise Trust | A container for certificate trust lists. A certificate trust list provides a mechanism for trusting self-signed root certificates from other organizations and limiting the purposes for which these certificates are trusted. For more information about Enterprise trust see Enterprise trust policy. |
| | Intermediate Certification Authorities | Certificates issued to subordinate certification authorities. |
| | Trusted People | Certificates issued to people or end entities that are explicitly trusted. Most often these are self-signed certificates or certificates explicitly trusted in an application such as Microsoft Outlook. |
| | Other People | Certificates issued to people or end entities that are implicitly trusted. These certificates must be part of a trusted certification hierarchy. Most often these are cached certificates for services like Encrypting File System, where certificates are used for creating authorization for decrypting an encrypted file. |
| | Trusted Publishers | Certificates from certification authorities that are trusted by Software Restriction policies. |

| | | |
|---|---|---|
| | Disallowed Certificates | These are certificates that you have explicitly decided not to trust using either Software Restriction policy or by clicking "Do not trust this certificate" when the decision is presented to you in mail or a Web browser. |
| | Third-Party Root Certification Authorities | Trusted root certificates from certification authorities other than Microsoft and your organization. |
| | Certificate Enrollment Requests | Pending or rejected certificate requests. |
| | Active Directory User Object | Certificates associated with your user object and published in Active Directory. |
| Purpose | Server Authentication | Certificates that server programs use to authenticate themselves to clients. |
| | Client Authentication | Certificates that client programs use to authenticate themselves to servers. |
| | Code Signing | Certificates associated with key pairs used to sign active content. |
| | Secure Email | Certificates associated with key pairs used to sign e-mail messages. |
| | Encrypting File System | Certificates associated with key pairs that encrypt and decrypt the symmetric key used for encrypting and decrypting data by Encrypting File System (EFS). |
| | File Recovery | Certificates associated with key pairs that encrypt and decrypt the symmetric key used for recovering encrypted data by Encrypting File System (EFS). |

When you look at the contents of a certificate store in Logical Store mode, you will occasionally see what appears to be two copies of the same certificate in the store. This occurs because the same certificate is stored in separate physical stores under a logical store. When the contents of the physical certificates stores are combined into one logical store view, both instances of the same certificate are displayed.

You can verify this by setting the view option to show the physical certificate stores and then noting that the certificate is stored in separate physical stores under the same logical store. You can verify that it is the same certificate by comparing the serial numbers.

For more information, see Generating encryption keys and certificate requests, Importing and exporting certificates, Display certificate stores in Purpose mode, Display certificate stores in Logical Store mode, Display archived certificates, Display certificate stores storage structure

# Security with Certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security with certificates**

Certificates can be used for:

- Authentication, which verifies the identity of someone or something.
- Privacy, which ensures that information is only available to the intended audience.
- Encryption, which disguises information so that unauthorized readers are unable to decipher it.
- Digital signatures, which provide nonrepudiation and message integrity.

These security services can be important to the security of your communications.

- Certificates and Authentication
- Privacy
- Encryption
- Digital signatures

# Certificates and Authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication**

Authentication is crucial to secure communication. Users must be able to prove their identity to those with whom they communicate and must be able to verify the identity of others. Authentication of identity on a network is complex because the communicating parties do not physically meet as they communicate. This can allow an unethical person to intercept messages or to impersonate another person or entity.

The digital certificate is a common credential that provides a means to verify identity. Certificates use cryptographic techniques to address the problem of the lack of physical contact between those communicating. Using these techniques limits the possibility of an unethical person intercepting, altering, or counterfeiting messages. These cryptographic techniques make certificates difficult to modify. Thus, it is difficult for an entity to impersonate someone else.

The data in a certificate includes the public cryptographic key from the certificate subject's public and private key pair. A message signed with its sender's private key can be verified by the message's recipient as authentic by using the sender's public key. This key can be found on a copy of the sender's certificate. Verifying a signature with a public key from a certificate proves that the signature was produced using the certificate subject's private key. If the sender has been vigilant and has kept the private key secret, the receiver can be confident in the identity of the message sender.

A few of the ways certificates are used to provide authentication are:

- Authentication of a user to a secure Web site via the Transport Layer Security (TLS) or the Secure Sockets Layer (SSL) protocol.
- Authentication of a server to a user via TLS.
- Logging on to a Windows Server 2003 domain.

For more information about authentication and certificates, see Certificates Resources.

# Privacy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Privacy**

Communications on a network, such as the Internet, are subject to possible monitoring by unknown and, perhaps, malicious users. Public networks are treacherous for unencrypted sensitive information because anyone can access the network and analyze the data being transmitted between two points. Even private local area networks (LANs) are vulnerable to determined efforts by intruders to acquire physical access to the network. Consequently, if sensitive information is transmitted between computing devices on any type of network, users will almost certainly want to use some sort of encryption to keep their data private.

Public key encryption is not used to encrypt large amounts of data. Instead, data is typically protected with secret key encryption and, in turn, that secret key is encrypted with the public key of the recipient of the data. The encrypted secret key will then be transmitted to the recipient along with encrypted data itself. The recipient will use the private key to decrypt the secret key. The secret key will then be used to decrypt the message itself.

Certificates enable privacy of transmitted data using a number of different methods. Some of the commonly used privacy-enabling protocols that use certificates are:

- Secure Multipurpose Internet Mail Extensions (S/MIME)
- Transport Layer Security (TLS)
- Internet Protocol security (IPSec). For more information, see Introducing IPSec.

For more information about privacy and certificates, see Certificates Resources.

# Encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encryption**

Encryption can be thought of as locking something valuable into a strong box with a key. Conversely, decryption can be compared to opening the box and retrieving the valuable item. On computers, sensitive data in the form of e-mail messages, files on a disk, and files being transmitted across the network can be encrypted using a key. Encrypted data and the key used to encrypt data are both unintelligible.

Typically, public key encryption is not used to encrypt large amounts of data. However, public key cryptography does offer an efficient method to send someone the secret key that is used when a symmetric encryption operation is performed on a large amount of data.

As an example, suppose Bob wants to send Alice a large number of encrypted files. For performance reasons, he will use a symmetric encryption key algorithm, such as Data Encryption Standard (DES), to encrypt the data. To send the encrypted data and the DES secret key needed to decrypt the data securely, Bob will encrypt the secret key with Alice's public key obtained from her certificate. Because her public key was used to encrypt the secret key, Alice, using her private key, will be the only one able to decrypt the DES secret key and thus decrypt the DES-encrypted data.

For more information, see Encrypting File System overview. For more information about encryption and certificates, see Certificates Resources.

# Digital signatures

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Digital signatures**

A digital signature is a way to ensure the integrity and origin of data. A digital signature provides strong evidence that the data has not been altered since it was signed and it confirms the identity of the person or entity who signed the data. This enables the important security features of *integrity* and *nonrepudiation*, which are essential for secure electronic commerce transactions.

Digital signatures are typically used when data is distributed in plaintext, or unencrypted form. In these cases, while the sensitivity of the message itself may not warrant encryption, there could be a compelling reason to ensure that the data is in its original form and has not been sent by an impostor because, in a distributed computing environment, plaintext can conceivably be read or altered by anyone on the network with the proper access, whether authorized or not.

For more information about digital signatures and certificates, see Certificates Resources.

# Using Certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using certificates**

This section covers the following topics:

- Starting the Certificates snap-in
- Requesting certificates
- Renewing certificates
- Certificate autoenrollment
- Importing and exporting certificates
- Using credential roaming
- Viewing certificate information
- Using Windows 2000 Certificate Services Web pages
- Using Windows Server 2003 Certificate Services Web pages
- Managing Certificate Trusts

# Starting the Certificates snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Starting the Certificates snap-in**

You use the Microsoft Management Console (MMC) Certificates snap-in to manage public key certificates.

If you are the administrator of the computer, when you add Certificates to your MMC console, you have the option of managing certificates that are issued to one of the following:

- Yourself (**My user account** option)
- Your computer (**Computer account** option)
- Local services (**Service account** option)

If you are a user, when you add Certificates to your MMC console, you can manage certificates only for your user account.

A separate instance of Certificates must be loaded for each entity for which you are managing certificates.

For more information, see Manage certificates for your user account, Manage certificates for a computer, Manage certificates for a service, and Certificates overview.

# Requesting certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Requesting certificates**

Certificate requests must be made by the user, computer, or service that has access to the private key associated with the public key that will be part of the certificate. Depending upon the public key policies established by your system administrator, machines and services can automatically request certificates without user intervention. In addition, administrators can request smart card user certificates and smart card certificates for logging on to the system on behalf of other users by using their enrollment agent certificate.

There are two primary ways to explicitly request certificates in a Windows Server 2003 operating system.

**Request certificates using the Certificate Request Wizard**

When you request certificates from a Windows Server 2003 enterprise certification authority, you can use the Certificate Request Wizard located in the Certificates snap-in. This wizard guides you through the following steps:

- Selecting the certification authority to which you will submit the request.

  Only enterprise certification authorities that are available in your Windows domain will be able to issue certificates using the Certificate Request Wizard.

- Selecting the appropriate certificate template to use for the new certificate.

  Certificate templates are predefined configurations that provide common settings for the certificate request. Certificate templates describe the purpose for which the requested certificate is to be used. The list of certificate templates that is available to you is determined by the certificate types which the certification authority is configured to issue and whether you have been granted the access rights to the certificate template by the system administrator.

- (Optional) Using **Advanced Options** in the Certificate Request Wizard to select the cryptographic service provider (CSP) for the key pair associated with the certificate request.

Only Basic EFS (Encrypting File System) and EFS Recovery Agent certificates have their associated private keys marked as available for export when you use the Certificate Request Wizard. If you want to request another type of certificate and have its private key available for export to a PKCS #12 file, you will need to use the **Advanced request** option on the Windows Server 2003 Certificate Services Web pages.

For instructions on opening and using the Certificate Request Wizard, see Request a certificate.

You can also use the Certificate Request Wizard to request a new certificate from an enterprise certification authority by using an existing key pair that is already associated with another certificate. For more information, see Request a certificate with the same key.

**Request certificates using the Windows Server 2003 Certificate Services Web pages**

Each certification authority that is installed on a computer running Windows Server 2003 has Web pages that users can access to submit basic and advanced certificate requests. By default, these pages are located at http://*servername*/certsrv, where *servername* is the name of the computer running Windows Server 2003.

When you request certificates from a Windows Server 2003 stand-alone certification authority, you use the Certificate Services Web pages. Web pages can also be used to request certificates from Windows Server 2003 enterprise certification authorities if you want to set optional request features that are not available in the Certificate Request Wizard, such as marking the keys as exportable, setting key length, choosing the hash algorithm, or saving the request to a PKCS #10 file.

For more information on using Certificate Services Web pages, see Using Windows Server 2003 Certificate Services Web pages.

**Processing certificate requests**

When you submit a certificate request to a Windows Server 2003 enterprise certification authority, it is immediately processed, as opposed to being set to "pending." The certificate request will either immediately fail or be granted. If it is granted, the certificate is issued, and you will be prompted to install it.

When you submit a certificate request to a Windows Server 2003 stand-alone certification authority, it will either be immediately processed or, by default, it will be considered pending until the administrator of the certification authority approves or rejects the request. In the case of a pending request, the certificate requester will have to use the Certificate Services Web pages to check the status of pending certificates. For more information, see Check on a pending certificate request to a Windows Server 2003 CA.

For more information about certificates and certification authorities, see Certificates and certification authorities.

# Renewing certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Renewing certificates**

Every certificate has a validity period. After the end of the validity period, the certificate is no longer considered an acceptable or usable credential. The Certificates snap-in enables you to renew a certificate issued from a Windows Server 2003 enterprise certification authority before or after the end of its validity period by using the Certificate Renewal Wizard.

You can either renew the certificate with the same key set you used before, or you can renew a certificate with a new key set. For information comparing reusing a key set and generating a new key set for certificate renewal, see Certificates Resources.

Before you renew a certificate, you will need to know:

- The issuing certification authority.
- (Optional) If you want a new public key and private key pair for the certificate, the cryptographic service provider (CSP) that should be used to generate the key pair.

For more information, see Renew a certificate with a new key and Renew a certificate with the same key.

In addition, you can renew certificates issued from both Windows Server 2003 enterprise certification authorities and Windows Server 2003 stand-alone certification authorities with the Certificate Services Web pages by pasting in the contents of a PKCS #7 file. For more information, see Request a certificate using a PKCS #10 or PKCS #7 file.

# Certificate autoenrollment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate autoenrollment**

Administrators of a network frequently require certificates users and computers to hold one or more certificates. The manual certificate enrollment process for a user can be somewhat confusing and time-consuming. The administrator may not have control of the enrollment process, so many users or computers could get useless or incorrect certificates. A process for obtaining, storing and updating the certificates for subjects without intervention is ideal. That is the purpose of certificate autoenrollment.

Certificate autoenrollment is a process that allows clients to automatically submit certificate requests to a certification authority and retrieve and store issued certificates. It is controlled by the administrator so the certificates are obtained by the appropriate subject with the correct settings. Periodically the client computer will check for any autoenrollment tasks that may be required and perform them. This includes requesting new certificates, retrieving fulfilled requests from a certification authority, or renewing an existing certificate.

Although the process is automatic, starting the process manually may be desired. The Certificates snap-in has a menu option to trigger certificate autoenrollment for the current user or local computer immediately.

For more information, see Trigger automatic enrollment for certificates and Certificate Services example implementation: Establishing autoenrollment for user certificates

# Importing and exporting certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Importing and exporting certificates**
The Certificates snap-in provides administrative tools to export and import certificates, including their certification paths and private keys, if needed. You can export certificates to or import certificates from PKCS #12 files, PKCS #7 files, and binary-encoded X.509 certificate files.

**Importing a certificate**
You might want to import a certificate:

- To install a certificate that was sent to you in a file by another user, computer, or certification authority.
- To restore a damaged or lost certificate that you previously backed up.
- To install a certificate and its associated private key from a computer that the certificate holder was previously using.

When you import a certificate, you copy the certificate from a file that uses a standard certificate storage format to a certificate store for your user account or your computer account.

**Exporting a certificate**
You might want to export a certificate:

- To back up a certificate.
- To back up a certificate and its associated private key.
- To copy a certificate for use on another computer.
- To remove a certificate and its private key from the certificate holder's current computer for installation on another computer.

When you export a certificate, you are copying the certificate from its certificate store to a file that uses a standard certificate storage format.

**Standard certificate file formats**
You can import and export certificates in the following formats:

- **Personal Information Exchange (PKCS #12)**

  The Personal Information Exchange format (PFX, also called PKCS #12) enables the transfer of certificates and their corresponding private keys from one computer to another or from a computer to removable media.

  PKCS #12 (Public Key Cryptography Standard #12) is an industry format that is suitable for transport or backup and restoration of a certificate and its associated private key. This can be between products from the same vendor or different vendors.

  To use the PKCS #12 format, the cryptographic service provider (CSP) must recognize the certificate and keys as exportable. If a certificate was issued from a Windows Server 2003 or Windows 2000 certification authority, the private key for that certificate is only exportable if one of the following is true:

  - The certificate is for EFS (Encrypting File System) or EFS recovery.
  - The certificate was requested through the Advanced Certificate Request certification authority Web page with the **Mark keys as exportable** check box selected.

Because exporting a private key might expose it to unintended parties, the PKCS #12 format is the only format supported in the Windows Server 2003 family for exporting a certificate and its associated private key.

- **Cryptographic Message Syntax Standard (PKCS #7)**

  The PKCS #7 format enables the transfer of a certificate and all the certificates in its certification path from one computer to another, or from a computer to removable media. PKCS #7 files typically use the .p7b extension, and are compatible with the ITU-T X.509 standard. PKCS #7 allows for attributes, such as countersignatures, to be associated with signatures, and attributes such as signing time can be authenticated along with message content. For more information on PKCS #7, see the PKCS #7 page at the RSA Labs Web site.

- **DER Encoded Binary X.509**

  DER (Distinguished Encoding Rules) for ASN.1, as defined in ITU-T Recommendation X.509, is a more restrictive encoding standard than the alternative BER (Basic Encoding Rules) for ASN.1, as defined in ITU-T Recommendation X.209, upon which DER is based. Both BER and DER provide a platform-independent method of encoding objects such as certificates and messages for transmission between devices and applications.

  During certificate encoding, most applications use DER because a portion of the certificate (the CertificationRequest's CertificationRequestInfo) must be DER-encoded to be signed.

  This format might be used by certification authorities that are not on computers running Windows Server 2003 , so it is supported for interoperability. DER certificate files use the .cer extension.

  For more information, see the document "ITU-T Recommendation X.509, Information Technology--Open Systems Interconnection--The Directory: Authentication Framework," at the International Telecommunication Union (ITU) Web site.

- **Base64 Encoded X.509**

  This is an encoding method developed for use with Secure/Multipurpose Internet Mail Extensions (S/MIME), which is a popular, standard method for transferring binary attachments over the Internet. Base64 encodes files into ASCII text format, making corruption less likely as the files are sent through Internet gateways, while S/MIME provides some cryptographic security services for electronic messaging applications, including non-repudiation of origin using digital signatures, privacy and data security using encryption, authentication, and message integrity.

  The MIME (Multipurpose Internet Mail Extensions) specification (RFC 1341 and successors) defines a mechanism for encoding arbitrary binary information for transmission by electronic mail.

  Because all MIME-compliant clients can decode Base64 files, this format might be used by certification authorities that are not on computers running Windows Server 2003 , so it is supported for interoperability. Base64 certificate files use the .cer extension.

  For more information, see the document "RFC 2633 S/MIME Version 3 Message Specification, 1999," at the Internet Engineering Task Force (IETF) Web site.

**Choosing an export format**

If you are exporting certificates to be imported onto a computer running Windows, PKCS #7 format is the preferred export format, primarily because this format preserves the chain of certification authorities, or the certification path, of any certificate that includes countersignatures associated with signatures.

If you are exporting certificates for import onto a computer running another operating system, it is possible that the PKCS #7 format is supported. If it is not supported, the DER Encoded Binary format or the Base64 Encoded format are provided for interoperability.

For more information, see Import a certificate, Export a certificate, Export a certificate with the private key, and View the certificates in a PKCS #7 file.

**Note**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Using credential roaming

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A growing number of organizations and users rely on certificates to secure critical transactions such as signing, encrypting, and decrypting e-mail and authenticating identity on wireless networks.

But many organizations require users to log onto and use more than one computer. Thus, a typical user of multiple computers who has been issued certificates for signing e-mail, encrypting and decrypting documents, and authentication might have separate sets of certificates and private keys on each computer.

Credential roaming enables using a single set of certificates and private keys on multiple computers in a manner that is extremely secure, easy to implement and manage, and transparent to the user.

Credential roaming only supports x.509 v3 certificates and RSA or DSA key pairs that are stored in the user's credential store. Only credentials in the user's MY and REQUEST stores are roamed. Credentials that use non-Microsoft cryptographic service providers (CSPs) or are located in other certificate stores are not supported.

**Note**

- Version 1 x.509 certificates are not stored in the user's credential store and cannot be used with credential roaming. The Microsoft Exchange Cryptographic Provider v1.0 does not use the default key container and cannot be used for credential roaming. In addition, keys stored on smart cards and within hardware security modules (HSMs) cannot be used with credential roaming.

Credential roaming is supported for clients running Windows Server 2003 with Service Pack 1 (SP1). Credential roaming is supported on domain controllers running Windows 2000 with SP3 or later or Windows Server 2003. Mixed environments containing domain controllers running Windows 2000 with SP3 or later and Windows Server 2003 are also supported. The forest functional level can be either Windows 2000 or Windows Server 2003.

- An update was recently made available that enables credential roaming on clients running Windows XP Professional (SP2) and an update is available for Windows Server 2003 SP1.

**Note**

- For the best performance and security, it is recommended that the servers be upgraded to Windows Server 2003 SP1. For other best practices, see Credential roaming best practices.

# Understanding credential roaming

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Credential roaming, enabled allows organizations to store certificates and private keys in Active Directory apart from application state or configuration information.

**How credential roaming works**
Credential roaming uses existing logon, Group Policy, and auto-enrollment mechanisms. These mechanisms make it possible to safely and securely download certificates and keys to a local computer whenever a user logs on and, if desired, remove them when the user logs off. In addition, the integrity of these credentials is maintained under any conditions, such as when certificates are updated and when users log onto more than one computer at a time.

The following steps describe how digital credential roaming works.

1. A user logs onto a client computer that is connected to an Active Directory domain.

2. As part of the logon process, credential roaming Group Policy is applied to the user's computer.

3. If this is the first time that credential roaming is being used, the certificates in the user's store on the client computer are copied to Active Directory.

4. If the user already has certificates in Active Directory, the certificates in the user's certificate store on the client computer are compared to the certificates stored for the user in Active Directory.

5. If the certificates in the user's certificate store are current, then no further action is taken. However, if more recent certificates for the user are stored in Active Directory, then these credentials are copied to the client computer.

6. After the user's certificate store on the client computer has been updated, then outstanding certificate auto-enrollment requests are processed.

   **Note**

   - Newly issued certificates are stored in the certificate store on the client and replicated to the domain controller for the domain.

7. Later, when the user logs onto another client computer connected to the domain, the same Group Policy is applied and credentials are once again replicated from Active Directory. Credential roaming synchronizes and resolves any conflicts between certificates and private keys from any number of client computers that the user logs onto, as well as Active Directory.

   **Important**

   - In multidomain environments and domains with multiple domain controllers, credentials may not be immediately available when a user logs on to the network using one domain controller shortly after being issued a certificate on a computer that validates the user's identity against a different domain controller. The credentials will only become available after replication has been completed between the two domains or domain controllers.

8. On subsequent logons, the certificate in the local certificate and key stores are compared to the certificates and keys in Active Directory:

   - If the certificates and keys are current, no further action is taken.

   - If the certificates and keys need to be renewed, the certification authority (CA) is contacted from the laptop or

workstation, the renewal process occurs and the updated certificates and keys are replicated to Active Directory.

9. When the user logs onto the other computer, the updated certificates and keys are replicated to the certificate and key stores on this computer as well.

10. When the user's certificate expires, the old certificate is automatically archived in the client's profile and in Active Directory.

Credential roaming is triggered any time a private key or certificate in the user's local certificate store changes, whenever the user locks or unlocks their computer, and whenever Group Policy is refreshed.

All Credential roaming-related communication between components on the local computer and between the local computer and Active Directory is signed and encrypted.

# Credential roaming schema changes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following schema attributes and attribute values will be used in Active Directory for storing user credentials and data relating to credential roaming:

- **ms-PKI-DPAPIMasterKey.** This multivalued attribute contains master key files and information for DPAPI. The following objects will be roamed and contained within this attribute:

- **All master key files.** There can be multiple master key files. New master key files can be created every 90 days by the domain. Master key files must be maintained and roamed in perpetuity.

- **The Preferred file that specifies the master key to be used for encryption.** This attribute is updated every time a new master key is created.

- **ms-PKI-AccountCredentials.** This multivalued attribute contains binary blobs of encrypted credential objects from the Stored User Names and Passwords store, private keys, certificates and requests. Each binary blob stored in Active Directory may contain a delete flag with a timestamp that persists for 60 days to ensure that all clients delete the object.

- **ms-PKI-RoamingTimeStamp.** This attribute is used by credential roaming to record the time of the latest change to the user object in Active Directory.

These schema attributes and attribute values must be added to Active Directory before credential roaming is deployed. Copy the following text into Notepad and Save it as CredRoam.ldf (be sure to use the .ldf extension), then refer to Preparing Active Directory to store user certificates and keys in order to configure your schema extensions.

# Credential roaming administrative template

Updated: October 2, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Credential Roaming administrative template allows you to configure the following credential roaming options:

- **Not Configured**. The default setting.
- **Enabled**. Enables credential roaming.
- **Disabled**. Prevents credential roaming from being enabled locally.

You can also configure specific Credential Roaming settings:

- **Maximum tombstone credentials lifetime in days:** Allows you to define how long a roaming credential will remain in Active Directory for a certificate or key that has been deleted locally.
- **Maximum number of roaming credentials per user:** Allows you to define a maximum number of certificates and keys that can be used with credential roaming.
- **Maximum size (in bytes) of a roaming credential:** Allows you to restrict roaming for credentials that exceed a defined size.

To create the Credential Roaming administrative template, copy the following code, paste it into a text file, and save the file with the name DIMS.adm or a name of your choice.

```
CLASS USER
CATEGORY  !!CertSvcClient
KEYNAME "Software\Policies\Microsoft\Cryptography\AutoEnrollment"
POLICY !!CredentialRoaming

EXPLAIN !!CredentialRoaming_Explain
VALUENAME "DIMSRoaming"
VALUEON NUMERIC 1

PART !!CredentialRoaming_Box TEXT
END PART

PART !!CredentialRoaming_TombstoneValue NUMERIC REQUIRED
VALUENAME "DIMSRoamingTombstoneDays"
MIN 1 MAX 3650 DEFAULT 60 SPIN 30
END PART

PART !!CredentialRoaming_MaxNumTokens NUMERIC REQUIRED
VALUENAME "DIMSRoamingMaxNumTokens"
MIN 1 MAX 10000 DEFAULT 2000 SPIN 100
END PART

PART !!CredentialRoaming_MaxTokenSize NUMERIC REQUIRED
VALUENAME "DIMSRoamingMaxTokenSize"
MIN 1 MAX 100000 DEFAULT 65535 SPIN 1000
END PART

END POLICY
END CATEGORY

[strings]
CertSvcClient="Certificate Services Client"
CredentialRoaming_Explain="This policy setting specifies the behavior for user X.509
certificates, requests, and key roaming.\n\n
User certificates and keys will be roamed and synchronized between the local user
profile on the desktop and the user object in
```

```
Active Directory when a user logs on interactively.\n\nIf you enable this policy
setting, all X.509 certificates, keys, and enrollment
requests will be uploaded and synchronized with the user object in Active Directory.
You should also enable folder exclusion policies
for roaming user profiles to avoid any conflicts in the use of multiple roaming
technologies.\n\nIf you disable this policy setting,
all future synchronization and roaming will cease, but no keys or certificates will be
deleted from the local user profile or
Active Directory user object.\n\nIf you do not configure this policy setting, user
certificate and key roaming will not be performed.\n\n
Note: Folder exclusion policy settings may be configured in the user profiles section
of the System administrative template.\n\n"
DisableAll="None"
CredentialRoaming="X.509 certificate and key roaming"
CredentialRoaming_Box="Specific Credential Roaming settings:"
CredentialRoaming_TombstoneValue="Maximum tombstone credentials lifetime in days:"
CredentialRoaming_MaxNumTokens="Maximum number of roaming credentials per user:"
CredentialRoaming_MaxTokenSize="Maximum size (in bytes) of a roaming credential:"

The role of Administrative Templates

# Credential roaming best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Certificates and private keys are important elements of an organization's security infrastructure. Therefore, you need to consider the following best practices and other considerations when planning and implementing credential roaming:

- Credential roaming is supported for clients running Windows Server 2003 with Service Pack 1 (SP1). Credential roaming is supported on domain controllers running Windows 2000 Service Pack 3 or later or Windows Server 2003. Mixed environments containing domain controllers running Windows 2000 SP3 or later and Windows Server 2003 are also supported. The forest functional level can be either Windows 2000 or Windows Server 2003.

- An update was recently made available that enables credential roaming on clients running Windows XP Professional (SP2) and an update is available for Windows Server 2003 SP1.

  **Note**

  - For the best performance and security, it is recommended that the servers be upgraded to Windows Server 2003 SP1.

- Organizations should not enable both roaming user profiles and credential roaming for the same user. Although the two capabilities are not mutually exclusive, unexpected results can occur if both are used by a given user. For example, if certificates and private keys are stored in both Active Directory and as part of their roaming user profile, the user might use the less current versions.

  **Note**

  - For more information about configuring roaming user profiles, see Implementing Roaming User Profiles in the Windows Server 2003 Deployment Kit.

- Credential roaming does not provide complete protection for certificates and private keys if they are accidentally deleted by a user. Use certificate and key archival and recovery to protect credentials from accidental deletion. For more information, see Key archival and recovery.

- Credentials such as enrollment agent certificates that require very strong protection of private keys should not be used in conjunction with credential roaming; instead, these credentials should be stored on smart cards and usage of the smart card should be required each time the user logs on.

- Organizations that are concerned about keys being left on computers that might be stolen and subject to brute force attacks should seriously consider whether to implement credential roaming for their most sensitive users and data. If the benefits of credential roaming outweigh the potential risks, they can configure the user's profile by using Group Policy to delete on logoff the user's profile that includes the certificates and private keys. For more information, see Using User Profiles. Alternately, require smart cards to be used for every logon.

- If Encrypting File System (EFS) is used, it is recommended that the data recovery certificate (DRA) and private key not be imported into the end user's account profile. Importing DRA certificates into the user's account profile would unintentionally roam the DRA key and certificate to the user's account in Active Directory. It is a best practice to use a dedicated DRA or separate user account for the purposes of EFS data recovery. In addition, DRA keys should never be imported into a non-administrator account.

- Organizations that are concerned about an administrator resetting a user password and logging onto the system as the user to steal or use their keys should use smart cards or strong private key protection to prevent this from happening. Credential roaming is not supported for clients who are migrated from one domain to another. The user must export all keys and certificates before the account is migrated and then reimport all keys and certificates after the account is migrated to the new domain.

# Viewing certificate information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing certificate information**

Using Certificates, you can view information about the fields, extensions, and properties that define an issued certificate by double-clicking any certificate displayed in the certificate store.

| To view this | Use this |
|---|---|
| Overview of the certificate information | **General** tab |
| Supported uses of the certificate | **General** tab |
| Entity to which the certificate was issued | **General** tab |
| Validity period of the certificate | **General** tab |
| Path of certificate to a trusted root certification authority | **Certification path** tab |
| Root certificate | **Certification path** tab |
| Subordinate certification authorities' certificates | **Certification path** tab |
| Whether root certification authority is trusted or not | **Certification path** tab |
| Certificate status | **Certification path** tab |

The **Details** dialog box provides the following information about the certificate.

| Certificate field | Description |
|---|---|
| Version | The X.509 version number. |
| Serial number | The unique serial number that the issuing certification authority assigns to the certificate. The serial number is unique for all certificates issued by a given certification authority. |
| Signature algorithm | The hash algorithm that the certification authority uses to digitally sign the certificate. |
| Issuer | Information regarding the certification authority that issued the certificate. |
| Valid from | The beginning date for the period in which the certificate is valid. |
| Valid to | The final date for the period in which the certificate is valid. |
| Subject | The name of the individual or certification authority to whom the certificate is issued. If the issuing certification authority exists on a domain member server in your enterprise, this will be a distinguished name within the enterprise. Otherwise, this may be a full name and e-mail name or some other personal identifier. |
| Public key | The public key type and length associated with the certificate. |
| Thumbprint algorithm | The hash algorithm that generates a digest of data (or thumbprint) for digital signatures. |
| Thumbprint | The digest (or thumbprint) of the certificate data. |
| Friendly name | (Optional) A friendly, or common, name for the name in the Subject field. |

| | |
|---|---|
| Enhanced key usage | (Optional) The purposes for which this certificate can be used. |

There are additional possible X.509v3 extensions that could be in a certificate. If they are present, they will be displayed as well.

For the procedure that shows how to see the properties of a certificate, see View a certificate.

# Using Windows 2000 Certificate Services Web pages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Windows 2000 Certificate Services Web pages**

By default, every certification authority that is hosted on a server running Windows 2000 has Web pages available for users and administrators. These are used to perform a variety of tasks related to requesting certificates. These Web pages are located at http://*servername*/certsrv, where *servername* is the name of the server running Windows 2000 that hosts the certification authority. The **certsrv** portion of the URL should always be in lowercase letters; otherwise, users may have trouble checking and retrieving pending certificates. Users can access these Web pages using Microsoft Internet Explorer version 5.0 and greater or Netscape Navigator version 3.01 and greater.

The Web pages are the *only* way for users to request certificates from stand-alone certification authorities. They are optional for users who want to request certificates from enterprise certification authorities. For more information about certification authorities, see Certificates and certification authorities.

If you have been granted access permissions, you can perform the following tasks from these Web pages:

- Request a basic certificate. For more information, see Submit a user certificate request via the Web.
- Request a certificate with advanced options. For more information, see Submit an advanced certificate request via the Web.

  This gives you greater control over the certificate request. Some of the user-selectable options that are available in an advanced certificate request include:

  - **Cryptographic service provider (CSP) options.** The name of the cryptographic service provider, the key size (512, 1024, and so on), the hash algorithm (SHA/RSA, SHA/DSA, MD2, MD5) and the key spec (exchange or signature).
  - **Key generation options.** Create a new key set or use an existing key set, mark the keys as exportable, enable strong key protection, and use the local computer store to generate the key.
  - **Additional options.** Save the request to a PKCS #10 file or add any specific attributes you want to add to the certificate.

  Netscape clients cannot use the advanced option Web pages.

- Check on a pending certificate request. If you have submitted a certificate request to a stand-alone certification authority, you will need to check the status of the pending request to see if the certification authority has issued the certificate. If the certificate has been issued, it will be available for you to install it. For more information, see Check on a pending certificate request.
- Retrieve the certification authority's certificate to place in your trusted root store. For more information, see Retrieve a certification authority certificate.
- Retrieve the current certificate revocation list. For more information, see Retrieve a certificate revocation list.
- Submit a certificate request using a PKCS #10 file or a PKCS #7 file. For more information, see Request a certificate using a PKCS #10 or PKCS #7 file.
- (For administrators only) Request a certificate for a smart card on behalf of another user. For more information, see Set up a smart card for user logon.

# Using Windows Server 2003 Certificate Services Web pages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Windows Server 2003 Certificate Services Web pages**

By default, every Windows Server 2003 certification authority has Web pages available for users and administrators. These can be used to perform a variety of tasks related to requesting certificates. These Web pages are located at http://*servername*/certsrv, where *servername* is the name of the server that hosts the certification authority. The **certsrv** portion of the URL should always be in lowercase letters; otherwise, users may have trouble checking and retrieving pending certificates. Users can access these Web pages using Microsoft Internet Explorer version 5.0 and greater, or Netscape Navigator version 3.01 and greater.

The Web pages are the *only* way for users to request certificates from stand-alone certification authorities. They are optional for users who want to request certificates from enterprise certification authorities. For more information about certification authorities, see Certificates and certification authorities.

If you have been granted access permissions, you can perform the following tasks from these Web pages:

- Request a basic certificate. For more information, see Submit a user certificate request via the Web to a Windows Server 2003 CA.

- Request a certificate with advanced options. For more information, see Submit an advanced certificate request via the Web to a Windows Server 2003 CA.

  This gives you greater control over the certificate request. Some of the user-selectable options available in an advanced certificate request include:

  - **Cryptographic service provider (CSP) options.** The name of the cryptographic service provider, the key size (512, 1024, and so on), the hash algorithm (SHA/RSA, SHA/DSA, MD2, MD5) and the key spec (exchange or signature).

  - **Key generation options.** Create a new key set or use an existing key set, mark the keys as exportable, enable strong key protection, and use the local computer store to generate the key.

  - **Additional options.** Save the request to a PKCS #10 file or add any specific attributes you want to add to the certificate.

  Netscape clients cannot use the advanced option Web pages.

- Check on a pending certificate request to a Windows Server 2003 CA. If you have submitted a certificate request to a stand-alone certification authority, you will need to check the status of the pending request to see if the certification authority has issued the certificate. If the certificate has been issued, it will be available for you to install it. For more information, see Check on a pending certificate request to a Windows Server 2003 CA.

- Retrieve the certification authority's certificate to place in your trusted root store or install the entire certificate chain in your certificate store. For more information, see Retrieve a certification authority certificate from a Windows Server 2003 CA.

- Retrieve the current base certificate revocation list (CRL) and delta CRL. For more information, see Retrieve a certificate revocation list from a Windows Server 2003 CA.

- Submit a certificate request using a PKCS #10 file or a PKCS #7 file. For more information, see Request a certificate from a Windows Server 2003 CA using a PKCS #10 or PKCS #7 file.

- (For administrators only) Request a certificate for a smart card on behalf of another user. For more information, see Set up a smart card for user logon.

# Managing Certificate Trusts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing certificate trusts**

This section covers:

- Automatic updating of trusted root authorities
- Managing trust of third-party certification authorities
- Managing trust of user-selected certification authorities

# Automatic updating of trusted root authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automatic updating of trusted root authorities**

You typically use a certificate when you use a secure Web site or when you send and receive secure e-mail. Theoretically, anyone can issue certificates, but to have truly secure transactions, certificates must be issued by a trusted entity or organization. Microsoft has included a list--in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; and other products--of companies and organizations that it considers to be trusted authorities.

Typically, when you are presented with a certificate issued by an authority that is not in the trusted authority list that is provided with your browser or operating system, you are asked if you want to establish trust in the certification authority (CA) which issued the certificate. Many users do not want to establish trust to an authority in this way, since they have limited resources to verify the trustworthiness and issuing policies of the CA.

In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition, you can use the Update Root Certificates function for this. Update Root Certificates is turned on by default. With this feature turned on, if you are presented with a certificate issued by an untrusted root authority, your computer will contact the Windows Update Web site to see if Microsoft has added the CA to its list of trusted authorities. If it has been added to the Microsoft list of trusted authorities, its certificate will automatically be added to your trusted certificate store.

For more information, see Turn off automatic updating of trusted root authority certificates, Turn on automatic updating of trusted root authority certificates, and Certificate stores.

# Managing trust of third-party certification authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing trust of third-party certification authorities**

By default, when you install Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition, a large number of certification authority (CA) certificates are listed in the Third-Party Root Certification Authorities physical store.

To view the certificates in this store, you can follow the procedures in Manage certificates for a computer and Display certificate stores storage structure. In the console tree, click **Certificates -*Certificate Holder***, click **Third-Party Root Certification Authorities**, and then click **Certificates**.

The Third-Party Root Certification Authorities store contains the trusted root certification authorities (CAs) from companies outside your organization. Administrators can disable the trust of these CAs by selecting **Trusted Root Certification Authorities only** option in Group Policy. Then, when users access any secure Web site that is validated by one of the third-party root CAs, they receive a security alert message that informs them that the site is not trusted.

To disable trust in third-party root CAs for a domain (or for any Group Policy object), see Disable trust of third-party root CAs for a Windows Server 2003 domain.

For more information, see Managing trust of user-selected certification authorities and Certificate stores.

# Managing trust of user-selected certification authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing trust of user-selected certification authorities**

For users, all trusted root certificates are stored under Trusted Root Certification Authorities.

You can view the certificates in this store by following the procedures in Manage certificates for your user account and Display certificate stores storage structure. In the console tree, click **Certificates - Current User**, then click **Trusted Root Certification Authorities**, and then click **Certificates**.

Administrators can use Group Policy to disable the trust of user-selected root certification authorities (CAs). Then, when network users access any secure Web site that is validated by one of these user-selected root CAs, they receive a security alert message that informs them that the site is not trusted. To disable trust in user-selected root CAs for a domain (or for any Group Policy object), see Disable trust of user-selected root CAs for a Windows Server 2003 domain.

For more information, see Managing trust of third-party certification authorities and Certificate stores.

# Certificates Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

The following books provide detailed information about certificates, certification authorities, public key encryption, and public key infrastructure (PKI):

- Austin, Thomas, *PKI:A Wiley Tech Brief*. John Wiley & Sons, December 2000.
- Feghhi, Jalal and Jalil Feghhi, *Secure Networking with Windows 2000 and Trust Services*. Addison-Wesley Pub Co., February 2001.
- Housley, R.P., and T. Polk. 2001. *Planning for PKI*. New York, New York: John Wiley & Sons, Inc.
- Howard, Michael, *Designing Secure Web-Based Applications for Microsoft Windows 2000*. Microsoft Press, August 2000.
- Kaufman, C., Perlman, R., and M. Speciner. 1995. *Network Security: Private Communication in a Public World*. Upper Saddle River, New Jersey: Prentice-Hall Inc.
- Schneier, Bruce, *Applied Cryptography: Protocols, Algorithms, and Source Code in C*. John Wiley & Sons, December 1995.

The following resources have in-depth information about planning, deploying, and using a public key infrastructure with Windows Certificate Services:

- Microsoft Security on the Microsoft Web site.

For updated technical information, see:

- For more information about certificate services architecture, see "Designing a Public Key Infrastructure" at the Microsoft Windows Resource Kits Web site.
- Microsoft TechNet on the Microsoft Web site.
- Updated technical information on the Microsoft Web site.

# Certificates Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The certificate template name is a long string of alphanumeric characters in the Certificates snap-in.
- When trying to use the Certification Authority Web enrollment pages, the following error appears: "The proper version of the ActiveX control failed to download and install. You may not have sufficient permissions. Please ask your system administrator for assistance."

**The certificate template name is a long string of alphanumeric characters in the Certificates snap-in.**
**Cause:** The string is an object identifier (also known as an OID). Each certificate template is represented by an object identifier. The snap-in has not received the full name of the template from the certification authority.

**Solution:** Close and reopen the Certificates snap-in.

**See also:** Add the Certificates Snap-in to the MMC Console.

**When trying to use the Certification Authority Web enrollment pages, the following error appears: "The proper version of the ActiveX control failed to download and install. You may not have sufficient permissions. Please ask your system administrator for assistance."**
**Cause:** The user who is accessing the Web pages is not a member of the Administrators or Power Users group on the local computer. When a newer version of the Web enrollment software is available on the certification authority (CA), the client computer must install that software. The user must be a member of the Administrators or Power Users group to install the software.

**Solution:** Log on to the network as a user who is a member of the Administrators or Power Users group to access the Web enrollment pages and download the newer version of the software.

# Certificate Services

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Certificate Services provides customizable services for issuing and managing certificates that are used in software security systems that employ public key technology. Certificate Services is available on computers running Microsoft® Windows Server® 2003, Standard Edition; Microsoft® Windows Server™ 2003, Enterprise Edition; and Microsoft® Windows Server™ 2003, Datacenter Edition.

**Tip**

Overviews for more recent versions of certificate services are available:

- Windows Server® 2012: What's New in AD CS?
- Windows Server® 2008 and Windows Server® 2008 R2: Active Directory Certificate Services.
- Community Overview: Active Directory Certificate Services (AD CS) Overview.

- Before deploying certification authorities and a public key infrastructure, see Checklist: Creating a certification hierarchy with an offline root certification authority.
- Before configuring certification authorities and clients for certificate autoenrollment, see Checklist: Configuring certificate autoenrollment.
- Before removing a deployed certification authority from your enterprise, see Checklist: Decommissioning a certification authority.
- For tips about using Certificate Services, see Certificate Services Best practices.
- For help with specific tasks, see Certificate Services How To....
- For general background information, see Certificate Services Concepts.
- For problem-solving instructions, see Certificate Services Troubleshooting.

# Checklist: Creating a certification hierarchy with an offline root certification authority

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| **Note** |
| --- |
| A revised version of this information has been placed on the TechNet Wiki in the Offline Root Certification Authority (CA) article (http://social.technet.microsoft.com/wiki/contents/articles/2900.aspx). The Checklist section (http://social.technet.microsoft.com/wiki/contents/articles/2900.aspx#Checklist_Creating_a_certification_hierarchy_with_an_offline_root_certification_authority) is the replacement for the information below. |

**Checklist: Creating a certification hierarchy with an offline root certification authority**

This checklist is provided for the cases where the root certification authority (CA) is not connected to your organization's network. You might choose to have an isolated, offline root CA for security reasons in order to protect it from possible attacks by intruders by way of the network.

Administrators of public key infrastructures (PKIs) must provide certificate verifiers with online certificate revocation checking. This checklist helps them to set up functional certificate revocation checking for certificates issued by an offline root CA.

| Step | Reference |
| --- | --- |
| **Review concepts** | |
| Review public key infrastructure concepts. | Deploying a Public Key Infrastructure |
| Review certificates concepts. | Certificates Concepts |
| Review concepts about certification authorities. | Certificate Services Concepts |
| **Set up the offline root certification authority** | |
| Plan the certification hierarchy. | Certification authority hierarchies |
| Set up a server that runs Windows that you will use for the root certification authority. The server should not be a member of any domain, should be disconnected from the network, and should be physically secure. The server should also have Internet Information Services (IIS) installed as part of the setup process, although this is not required. | Checklist: Performing a new installation |
| Plan the renewal strategy you are going to use for the root certification authority | Renewing a certification authority |
| Log on to the server as the administrator and install Certificate Services to create a stand-alone root certification authority. | Install a stand-alone root certification authority |
| **Prepare the offline root certification authority to issue certificates** | |
| On the new root CA, change the default action upon receipt of a certificate request so that all requested certificates are set to pending. This is to ensure only authorized requests are issued by the top-level CA. | Set the default action upon receipt of a certificate request |
| On the new root CA, change the URL location of the certificate revocation list (CRL) distribution point to a location of your choice that is accessible to all users in you organization's network. It is possible to enter multiple URLs. It is necessary to do this because the offline root CA's default CRL Distribution Points (CDPs) are not accessible to users on the network and, if they are left unchanged, certificate revocation checking will fail. | Specify certificate revocation list distribution points in issued certificates |
| On the new root CA, change the URL location of the authority information access (AIA) distribution points to a location of your choice that is accessible to all users in you organization's network. It is possible to enter multiple URLs. It is necessary to do this because the offline root CA's default AIA points are not accessible to users on the network and, if they are left unchanged, certificate chain verification will fail. | Specify CA certificate access points in issued certificates |
| Schedule the publication of the certificate revocation list. Since publishing the CRL from an offline CA has the administrative overhead of having to physically copy the CRL to a server on the network, you may want to have a lengthy validity period. | Schedule the publication of the certificate revocation list |
| On the root certification authority, publish the certificate revocation list. | Manually publish the certificate revocation list |
| In Windows Explorer on the root CA, locate the certificate revocation list you just published. The CRL's default location is:<br><br>**** *systemroot* **\system32\CertSrv\CertEnroll** *CAname* **.crl**<br><br>Right-click the CRL file and send it to a drive that has portable storage media. | |
| Retrieve the certification authority's certificate and save it to a drive that has portable storage media. | Retrieve a certification authority certificate |

| | | |
|---|---|---|
| | Copy the certificate revocation list file and the CA certificate to every URL location that you specified as a CRL distribution point in the root CA's policy settings. | |
| | Copy the CA certificate file to every URL location that you specified as an authority information access distribution point in the root CA's policy settings. | |
| | **If you are deploying your PKI in an Active Directory directory service environment** | |
| | Publish the root certificate to the enterprise root store and add the certificate to the customary Authority Information Access (AIA) points in the directory. You need to use certutil.exe. You can also use this command to put the CA certificate from a third party root CA into Active Directory. | At a command prompt, type: **certutil-dspublish-f**.*Crt File Name***RootCA** |
| | Publish the CRL to the customary location in Active Directory. To do this, use certutil.exe. You can also use this command to put the CRL from a third-party root CA into Active Directory. | From the command line, type: **certutil-dspublish-f**.*Crl File Name* |
| | **To create a online certification authority that is subordinate to an offline root certification authority** | |
| | Set up a server running Windows to use for the subordinate certification authority | Checklist: Performing a new installation |
| | Install subordinate certification authorities, as required by your planned certification hierarchy. These can be stand-alone certification authorities or, if you are using Active Directory, enterprise certification authorities. During setup for each subordinate CA, choose to save the CA certificate request to a file, which will be a PKCS #10 request. | Install a stand-alone subordinate certification authority;Install an enterprise subordinate certification authority |
| | Copy the CA certificate request file from the subordinate certification authority to some portable storage media. Take the CA certificate request to the root certification authority. | |
| | Using the Certificates Microsoft Management Console (MMC) on the offline CA, submit the certificate request (*requestfilename*) to the CA and copy the new certificate (*newcertname*) to the portable storage media. | Manage certificates for a computer |
| | Take the portable storage media back to the subordinate certification authority. In Windows Explorer, locate the certificate and certification path files you just copied, then right-click each file and choose **Install Certificate**. Have the Certificate Import Wizard automatically place the certificates in stores based on the type of certificate. | Import a certificate |

# Checklist: Configuring certificate autoenrollment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring certificate autoenrollment**

| Step | Reference |
|---|---|
| Install and configure an enterprise certification authority (CA) | Install an enterprise root certification authority; Install an enterprise subordinate certification authority |
| Create a new certificate template | Create a new certificate template |
| Configure the certificate template to provide the intended functionality for the certificate | Modify a Certificate Template |
| Configure the certificate template to allow autoenrollment | Planning for autoenrollment deployment |
| Grant Enroll and Autoenroll permissions for the certificate template to intended users | Allow subjects to request a certificate that is based on the template |
| Configure the certification authority to issue certificates based on the template | Add a certificate template to a certification authority |
| Configure Active Directory directory service users to request certificates with autoenrollment | Certificate Services example implementation: Establishing autoenrollment for user certificates |
| (Optional) Retrieve updated Group Policy information before scheduled replication occurs | Gpupdate |

**Notes**

- Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition is required to configure version 2 certificate templates for autoenrollment requests. However, autoenrollment manages certificates or pending certificate requests that are based on any version of certificate template.

# Checklist: Decommissioning a certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Decommissioning a certification authority**

Once a certification authority (CA) is configured and operating in an enterprise, it becomes an important security resource. The certification authority is required by existing clients to renew certificates, by new clients to issue certificates, and by users of certificates to verify the trustworthiness of issued certificates. If a CA is removed from an enterprise without following the appropriate procedure, functionality may be impaired and extensive cleanup work may be required to restore clients to functionality.

| | Step | Reference |
|---|---|---|
| | Perform a backup of the certification authority (CA) database to ensure recoverability of data at a later date. | Back up a certification authority |
| | Deny all pending certificate requests currently stored on the CA. | Review pending certificate requests |
| | (Optional) Allow the Active Directory directory service to replicate the certificate denials and allow Group Policy to inform the clients that the certificate request is denied. The denied clients are then informed that their request was denied so they can remove the request from their list of outstanding requests. | Replication overview |
| | Revoke the CA's certificate from its parent CA. When revoking the CA certificate, specify the reason as "Cessation of Operation." | Revoke an issued certificate |
| | Manually publish a new certificate revocation list (CRL) to ensure the CRL contains revocation information about the CA that was recently revoked. | Manually publish the certificate revocation list |
| | Uninstall the Certificate Services component. | Uninstall a certification authority |
| | Remove remaining information about this CA from Active Directory. | At a command prompt, type **certutil.exe -dsdel *CAName*** and press ENTER, where *CAName* is the name of the CA you are removing. |

# Certificate Services Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate Services Best practices**

**Plan your public key infrastructure (PKI) before deploying certification authorities (CAs)**

- For information that will assist you with planning a PKI, see Certificate Services Concepts in Certificate Services and Certificates Resources in Public Key Infrastructure.

**Place database and transaction log files on separate hard drives**

- As in many databases, the certification authority's database is a file on the hard drive. In addition to this file, other files serve as the transaction logs and receive all modifications to the database before the changes are made. Because these files may be accessed frequently and simultaneously, it is best to keep the database and transaction logs on separate hard drives or high-performance disk configurations, such as striped volumes.

  For more information, see Disk Management.

**Keep the root certification authority offline and secure its signing key by hardware and keep it in a vault to minimize potential for key compromise**

- For more information, see Checklist: Creating a certification hierarchy with an offline root certification authority.

**If you are going to use a custom policy module for a Microsoft CA, install Certificate Services using stand-alone policy and then replace stand-alone policy with your custom policy**

- Replacing enterprise policy on a certification authority with a custom policy is not supported and will have unpredictable results.

**When changing security permissions for the certification authority (CA), always use the Certification Authority snap-in**

- Setting permissions using other tools (such as the Active Directory Sites and Services snap-in) may create problems for users who attempt to access and request certificates from the certification authority.

  For more information, see Set security permissions and delegate control of a certification authority.

**Do not issue certificates to users or computers directly from the root certification authority**

- Instead, deploy at least a two-level CA hierarchy comprised of Root-Issuer CAs to provide flexibility and insulate the root certification authority from attempts to compromise its private key by malicious individuals.

  For more information, see Certification authority hierarchies and Establishing a certification hierarchy.

**Back up the CA database, the CA certificate, and the CA keys**

- This is essential to protect against the loss of critical data. The CA should be backed up on a regular basis (daily, weekly, monthly), based on the number of certificates issued over the same interval. The more certificates issued, the more frequently you should back up the CA. Full backups should be used to provide the fastest recovery and most reliable data redundancy possible.

  For more information, see Backing up and restoring a certification authority.

**Ensure that key lifetimes are long enough to avoid renewal issues**

- A certification authority can issue a certificate with a lifetime equal to or less than the remaining lifetime on its own CA certificate. When the CA certificate has less valid time remaining than the renewal overlap period on issued certificates, the issued certificates are very short lived. In this case, it is possible that clients will be unable to renew their certificates. To avoid this, ensure the CA certificate is renewed long enough before the certificates it issues become short lived.

  For more information, see Renew a root certification authority and Renew a subordinate certification authority.

**Review the concepts of security permissions and access control, since enterprise certification authorities issue certificates based on the security permissions of the certificate requester**

- For general information about access control and security permissions in the Windows Server 2003 family, see Access control overview. For the procedure to set access control on a CA, see Set security permissions and delegate control of a certification authority.

  For the procedure to set access control on certificate templates, see Controlling enrollment access to certificate templates.

**Use Secure Sockets Layer (SSL) when using Web-based certificate enrollment**

- Web enrollment pages provide a simple but insecure method for users to obtain certificates from the CA. The communication between the client and the Web server could be forged or altered in route, compromising security. To mitigate the risk of this occurring, you can use Secure Sockets Layer (SSL) communications between the client and the Web server. This will provide both confidentiality and integrity of the certificate request and response.

  For more information, see Configuring SSL on your server and Set up certification authority Web enrollment support.

# Certificate Services How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Administer a Certification Authority

# Set Up a Certification Authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up a certification authority**

- Install an enterprise root certification authority
- Install an enterprise subordinate certification authority
- Install a stand-alone root certification authority
- Install a stand-alone subordinate certification authority
- Uninstall a certification authority
- Set up certification authority Web enrollment support
- Perform qualified subordination

# Install an enterprise root certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install an enterprise root certification authority**

1. Log on as a member of both the Enterprise Admins group and the root domain's Domain Admins group.
2. If any Windows 2000 enterprise certification authorities (CAs) currently exist or have ever existed in your enterprise, open Certificate Templates and, when prompted to install new certificate templates, click **OK**.
3. Open Add or Remove Programs in Control Panel.
4. Click **Add/Remove Windows Components**.
5. In the Windows Components Wizard, select the **Certificate Services** check box. A dialog box appears to inform you that the computer cannot be renamed and that the computer cannot be joined to or removed from a domain after Certificate Services is installed. Click **Yes**, and then click **Next**.
6. Click **Enterprise root CA**.
7. (Optional) Select the **Use custom settings to generate the key pair and CA certificate** check box, and then click **Next** to specify the following.

| To set this | Do this |
|---|---|
| Cryptographic service provider (CSP) | In **CSP**, click the CSP that you want to use. The default is the Microsoft Strong Cryptographic Provider. Certificate Services does support third party CSPs, but you must refer to the CSP vendor's documentation for information about using their CSP with Certificate Services. |
| Hash algorithm | In **Hash algorithm**, click the hash algorithm you want to use. The default is SHA-1. |
| Use an existing key | Select the **Use existing key** check box, click **Import**, and then, in **Open PFX File**, type the file name and password of the public and private key pair. This is helpful if you are relocating or restoring a previously installed certification authority (CA). Note that, when using an existing key, a new certificate is generated.<br>**Important**<br>• Be sure that you select an existing key that you know to be uncompromised and trustworthy. Using a key that may be compromised or untrusted could cause this CA and all its issued certificates to be insecure. |
| Key length | In **Key length**, type or select a key length. The default key length using the Microsoft Strong Cryptographic Provider is 2048 bits. Default key lengths for other CSPs vary. In general, the longer the key length, the more secure the key is. Also, longer key lengths require more system resources for operations such as signing, encryption, and chain verification. For a root CA, you should use a key length of at least 2048 bits. This option is not available if you use existing keys. |
| Allow this CSP to interact with the desktop | Select the **Allow this CSP to interact with the desktop** check box. Without this option, system services cannot interact with the desktop of the user who is currently logged on. |
| Import | Click **Import**. This imports an existing key in the PKCS #12 PFX format. |

| | |
|---|---|
| View certificate | Click **View certificate**. This allows you to view the certificate that you select or generate during installation. |

When you are done, click **Next**.

8. In **Common name for this CA**, type the common name of the certification authority.

9. In **Validity period**, specify the validity duration for the root CA and click **Next**.

10. Specify the storage locations of the certificate database, the certificate database log, and the shared folder and click **Next**.

11. If Internet Information Services (IIS) is running, you will see a request to stop the service before proceeding with the installation and click **OK**.

12. If prompted, type the path to the Certificate Services installation files.

**Notes**

- The preliminary information that is supplied during setup, such as the name of the certification authority, cannot be changed after the CA setup is complete.

- Before installing a certification authority, you should configure the computer's domain settings first, such as joining a domain or promoting a server to a domain controller. These settings cannot be changed once the certification authority is installed.

- If Active Server Pages are not enabled through Internet Information Services, you will be prompted to activate them. The Web interface for the certification authority requires running Active Server Pages.

- The enterprise root CA selection requires that the host computer be a member of a domain and that it use the Active Directory directory service. The administrator who is installing an enterprise CA must have Write permission to Active Directory.

- If you have Write permission to Active Directory, then specifying the shared folder is optional, and is not typically done for enterprise certification authorities.

- The validity duration you choose for the CA will determine when the CA "expires." For information about renewing CAs, see Related Topics.

- If you installed the enterprise certification authority as an Enterprise Admin or delegated user, then you must use the Enterprise Admin or delegated user account when you uninstall the enterprise certification authority.

- To open Add/Remove Windows Components, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

- Once the certification authority is installed, add certificate templates to the certification authority and configure the certification authority to allow subjects to request a certificate that is based on a template. For more information, see Related Topics.

- For more information on any installation settings, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install an enterprise subordinate certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install an enterprise subordinate certification authority**

1. Log on as a member of both the Enterprise Admins group and the root domain's Domain Admins group.
2. If any Windows 2000 enterprise certification authorities (CAs) currently exist or have ever existed in your enterprise, open Certificate Templates and when prompted to install new certificate templates, click **OK**.
3. Open Add or Remove Programs in Control Panel.
4. Click **Add/Remove Windows Components**.
5. In the Windows Components Wizard, select the **Certificate Services** check box. A dialog box appears to inform you that the computer cannot be renamed and that the computer cannot be joined to or removed from a domain after Certificate Services is installed. Click **Yes**, and then click **Next**.
6. Click **Enterprise subordinate CA**.
7. (Optional) Select the **Use custom settings to generate the key pair and CA certificate** check box, and then click **Next** to specify the following.

| To set this | Do this |
|---|---|
| Cryptographic service provider (CSP) | In **CSP**, click the CSP that you want to use. The default is the Microsoft Strong Cryptographic Provider. Certificate Services does support third party CSPs, but you must refer to the CSP vendor's documentation for information about using their CSP with Certificate Services. |
| Hash algorithm | In **Hash algorithm**, click the hash algorithm you want to use. The default is SHA-1. |
| Use an existing key | Select the **Use existing key** check box, click **Import**, and then, in **Open PFX File**, type the file name and password of the public and private key pair. This is helpful if you are relocating or restoring a previously installed certification authority (CA). Note that, when using an existing key, a new certificate is generated.<br>**Important**<br>• Be sure that you select an existing key that you know to be uncompromised and trustworthy. Using a key that may be compromised or untrusted could cause this CA and all its issued certificates to be insecure. |
| Key length | In **Key length**, type or select a key length. The default key length using the Microsoft Strong Cryptographic Provider is 2048 bits. Default key lengths for other CSPs vary. In general, the longer the key length, the more secure the key is. Also, longer key lengths require more system resources for operations such as signing, encryption, and chain verification. For a root CA, you should use a key length of at least 2048 bits. This option is not available if you use existing keys. |
| Allow this CSP to interact with the desktop | Select the **Allow this CSP to interact with the desktop** check box. Without this option, system services cannot interact with the desktop of the user who is currently logged on. |
| Import | Click **Import**. This imports an existing key in the PKCS #12 PFX format. |

| | |
|---|---|
| View certificate | Click **View certificate**. This allows you to view the certificate that you select or generate during installation. |

When you are done, click **Next**.

8. Type the common name (CN) of the CA and click **Next**.

9. Specify the storage locations of the certificate database, the certificate database log, and the shared folder. Click **Next**.

10. Obtain the certificate for the subordinate CA. For instructions on how to do this, see Notes.

11. If Internet Information Services is running, the system will request that you stop the service before proceeding with the installation. Click **OK**.

12. If prompted, type the path to the Certificate Services installation files.

13. Once the certification authority is installed, add certificate templates to the certification authority and configure the certification authority to allow subjects to request a certificate that is based on a template.

    For more information, see Related Topics.

**Notes**

- The name of the CA and the other initial information cannot be changed after the CA setup is complete.

- If Active server Pages are not enabled through Internet Information Services, you will be prompted to activate them. The Web interface for the certification authority requires running Active server Pages.

- To obtain the certificate for a subordinate CA, you must submit a certificate request to a parent CA. The procedure for doing so differs depending on whether the parent CA is available online.

    - If a parent CA is available online:

Click **Send the request directly to a CA already on the network**.

In **Computer Name**, type the name of the computer on which the parent CA is installed.

In **Parent CA**, click the name of the parent CA.

- If a parent CA is not available online:

Click **Save the request to a file**.

In **Request file**, type the path and file name of the file that will store the request.

Obtain this subordinate CA's certificate from the parent CA.

The procedure for doing this will be unique to the parent CA. At a minimum, the parent CA should provide a file containing the subordinate CA's newly issued certificate and, preferably, its full certification path. For the procedure to submit a certificate request using a file to a Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition CA, see Related Topics.

If you get a subordinate CA certificate that does *not* include the full certification path, the new subordinate CA you are installing must be able to build a valid CA chain when it starts. Thus you must install the parent CA's certificate in the Intermediate Certification Authorities certificate store of the computer (if the parent CA is not a root CA), as well as the certificates of any other intermediate CA in the chain, and you must install the certificate of the root CA in the chain into the Trusted Root Certification Authorities store. These certificates should be installed in the certificate store before you install the CA certificate on the subordinate CA you have just set up.

Open Certification Authority.

In the console tree, click the name of the CA.

**Where?**

- Certification Authority (*Computer*)/*CA name*

On the **Action** menu, point to **All Tasks**, and then click **Install CA Certificate**.

Locate the certificate file received from the parent certification authority, click this file, and then click **Open**.

If the root CA is untrusted, click **OK** to trust the root CA's certificate.

Once the certificate is installed, start Certificate Services.

To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

- The enterprise subordinate CA selection requires that the host computer be a member of a domain and that it use the Active Directory directory service. The administrator who is installing an enterprise CA must have Write permission to Active Directory.

- If you have Write permission to Active Directory, then specifying the shared folder is optional, and is not typically done for enterprise CAs.

- To open Certification Authority, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Certification Authority**.

- If you installed the enterprise subordinate certification authority as an Enterprise Admin or delegated user, then you must use the Enterprise Admin or delegated user account when you uninstall the enterprise subordinate certification authority.

- To open Add/Remove Windows Components, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install a stand-alone root certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a stand-alone root certification authority**

1. Log on to the system as an Administrator, or if you have the Active Directory directory service, log on to the system as a Domain Administrator.

2. Click **Start**, point to **Settings**, and then click **Control Panel**.

3. Double-click **Add or Remove Programs** and then click **Add/Remove Windows Components**.

4. In the Windows Components Wizard, select the **Certificate Services** check box. A dialog box appears to inform you that the computer cannot be renamed and that the computer cannot be joined to or removed from a domain after Certificate Services is installed. Click **Yes**, and then click **Next**.

5. Click **Stand-alone root CA**.

6. (Optional) Select the **Use custom settings to generate the key pair and CA certificate** check box, and then click **Next** to specify the following.

| To set this | Do this |
|---|---|
| Cryptographic service provider (CSP) | In **CSP**, click the CSP that you want to use. The default is the Microsoft Strong Cryptographic Provider. Certificate Services does support third party CSPs, but you must refer to the CSP vendor's documentation for information about using their CSP with Certificate Services. |
| Hash algorithm | In **Hash algorithm**, click the hash algorithm you want to use. The default is SHA-1. |
| Use an existing key | Select the **Use existing key** check box, click **Import**, and then, in **Open PFX File**, type the file name and password of the public and private key pair. This is helpful if you are relocating or restoring a previously installed certification authority (CA). Note that, when using an existing key, a new certificate is generated.<br>**Important**<br>• Be sure that you select an existing key that you know to be uncompromised and trustworthy. Using a key that may be compromised or untrusted could cause this CA and all its issued certificates to be insecure. |
| Key length | In **Key length**, type or select a key length. The default key length using the Microsoft Strong Cryptographic Provider is 2048 bits. Default key lengths for other CSPs vary. In general, the longer the key length, the more secure the key is. Also, longer key lengths require more system resources for operations such as signing, encryption, and chain verification. For a root CA, you should use a key length of at least 2048 bits. This option is not available if you use existing keys. |
| Allow this CSP to interact with the desktop | Select the **Allow this CSP to interact with the desktop** check box. Without this option, system services cannot interact with the desktop of the user who is currently logged on. |
| Import | Click **Import**. This imports an existing key in the PKCS #12 PFX format. |
| View certificate | Click **View certificate**. This allows you to view the certificate that you select or generate during installation. |

When you are done, click **Next**.

7. Type the common name of the certification authority. None of this information can be changed after the CA setup is complete.

8. In **Validity period**, specify the validity duration for the root CA. See the note below about considerations when setting this value. Click **Next**.

9. Specify the storage locations of the certificate database, the certificate database log, and the shared folder. Click **Next**.

10. If Internet Information Services (IIS) is running, you will receive a request to stop the service before proceeding with the installation. Click **OK**.

11. If prompted, type the path to the Certificate Services installation files.

### Notes

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

- If Active Directory is available and you have Write permission to Active Directory, then specifying the shared folder is optional.

- If Active Server Pages are not enabled through Internet Information Services, you will be prompted to activate them. The Web interface for the certification authority requires running Active Server Pages.

- The validity duration you choose for the CA will determine when the CA "expires." For information about renewing CAs, see Related Topics.

- To open Add/Remove Windows Components, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

- For more information on any installation settings, see Related Topics.

#### Information about functional differences

# Install a stand-alone subordinate certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a stand-alone subordinate certification authority**

1. Log on to the system as an Administrator, or if you have the Active Directory directory service, log on to the system as a Domain Administrator.

2. Open Add or Remove Programs in Control Panel.

3. Click **Add/Remove Windows Components**.

4. In the Windows Components Wizard, select the **Certificate Services** check box. A dialog box appears to inform you that the computer cannot be renamed and that the computer cannot be joined to or removed from a domain after Certificate Services is installed. Click **Yes**, and then click **Next**.

5. Click **Stand-alone subordinate CA**.

6. (Optional) Select the **Use custom settings to generate the key pair and CA certificate** check box, and then click **Next** to specify the following.

| To set this | Do this |
|---|---|
| Cryptographic service provider (CSP) | In **CSP**, click the CSP that you want to use. The default is the Microsoft Strong Cryptographic Provider. Certificate Services does support third party CSPs, but you must refer to the CSP vendor's documentation for information about using their CSP with Certificate Services. |
| Hash algorithm | In **Hash algorithm**, click the hash algorithm you want to use. The default is SHA-1. |
| Use an existing key | Select the **Use existing key** check box, click **Import**, and then, in **Open PFX File**, type the file name and password of the public and private key pair. This is helpful if you are relocating or restoring a previously installed certification authority (CA). Note that, when using an existing key, a new certificate is generated.<br>**Important**<br>• Be sure that you select an existing key that you know to be uncompromised and trustworthy. Using a key that may be compromised or untrusted could cause this CA and all its issued certificates to be insecure. |
| Key length | In **Key length**, type or select a key length. The default key length using the Microsoft Strong Cryptographic Provider is 2048 bits. Default key lengths for other CSPs vary. In general, the longer the key length, the more secure the key is. Also, longer key lengths require more system resources for operations such as signing, encryption, and chain verification. For a root CA, you should use a key length of at least 2048 bits. This option is not available if you use existing keys. |
| Allow this CSP to interact with the desktop | Select the **Allow this CSP to interact with the desktop** check box. Without this option, system services cannot interact with the desktop of the user who is currently logged on. |
| Import | Click **Import**. This imports an existing key in the PKCS #12 PFX format. |
| View certificate | Click **View certificate**. This allows you to view the certificate that you select or generate during installation. |

When you are done, click **Next**.

7. Type in the common name (CN) and distinguished name suffix of the CA. None of this information can be changed after the CA setup is complete. Click **Next**.

8. Specify the storage locations of the certificate database, the certificate database log, and the shared folder. Click **Next**.

9. Obtain the certificate for the subordinate CA. For instructions on how to do this, see Notes.

10. If Internet Information Services is running, the system will request that you stop the service before proceeding with the installation. Click **OK**.

11. If prompted, type the path to the Certificate Services installation files.

**Notes**

- If Active Server Pages (ASP) are not enabled through Internet Information Services, you will be prompted to activate them. The Web interface for the certification authority requires running Active Server Pages.

- To obtain the certificate for a subordinate CA, you must submit a certificate request to a parent CA. The procedure for doing so differs depending on whether the parent CA is available online.

    - If a parent CA is available online:

Click **Send the request directly to a CA already on the network**.

In **Computer Name**, type the name of the computer on which the parent CA is installed.

In **Parent CA**, click the name of the parent CA.

- If a parent CA is not available online:

Click **Save the request to a file**.

In **Request file**, type the path and file name of the file that will store the request.

Obtain this subordinate CA's certificate from the parent CA.

The procedure for doing this will be unique to the parent CA. At a minimum, the parent CA should provide a file containing the subordinate CA's newly-issued certificate and, preferably, its full certification path. For the procedure to submit a certificate request using a file to a Microsoft CA, see Related Topics.

If you get a subordinate CA certificate that does *not* include the full certification path, the new subordinate CA you are installing must be able to build a valid CA chain when it starts. Because of this, you must install the parent CA's certificate in the Intermediate Certification Authorities certificate store of the computer (if the parent CA is not a root CA), as well as the certificates of any other intermediate CA in the chain, and you must install the certificate of the root CA in the chain into the Trusted Root Certification Authorities store. These certificates should be installed in the certificate store before you install the CA certificate on the subordinate CA you have just set up.

Open Certification Authority.

In the console tree, click the name of the CA.

**Where?**

Certification Authority (*Computer*)/*CA name*

On the **Action** menu, point to **All Tasks**, and then click **Install CA Certificate**.

Locate the certificate file received from the parent certification authority, click this file, and then click **Open**.

If the root CA is untrusted, click **OK** to trust the root CA's certificate.

Once the certificate is installed, start the Certificate Services service.

- If Active Directory is available and you have Write permission to Active Directory, then specifying the shared folder is optional.

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

- To open Add/Remove Windows Components, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Uninstall a certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To uninstall a certification authority**

1. Log on to the system as the user who installed the certification authority.
2. Open Add or Remove Programs in Control Panel.
3. Click **Add/Remove Windows Components**.
4. In the Windows Components Wizard, clear the **Certificate Services** check box, and then click **Next**.
5. If Internet Information Services is running, the system requests that you stop the service before proceeding with the uninstall process. If this happens, click **OK**.

## Notes

- To open Add/Remove Windows Components, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- You should back up the entire server before uninstalling the certification authority (CA).
- When you uninstall a CA, the following information is left on the server:
  - The CA database
  - The CA public and private keys
  - The CA's certificates in the Personal store
  - The CA's certificates in the shared folder, if a shared folder was specified during Certificate Services setup
  - The CA chain's root certificate in the Trusted Root Certification Authorities store
  - The CA chain's intermediate certificates in the Intermediate Certification Authorities store
  - The CA's certificate revocation list (CRL)

  This information is kept on the server by default, in case you are uninstalling and then reinstalling the CA. For example, you might uninstall and reinstall if you wanted to change a stand-alone CA to an enterprise CA.
- If you installed the enterprise or enterprise subordinate certification authority as an Enterprise Admin or delegated user, then you must use the Enterprise Admin or delegated user account when you uninstall the certification authority.
- If you are permanently decommissioning the CA before its expected expiration date, then the CA certificate should be revoked from its parent CA for a certificate revocation reason of "Cease of operation". If the CA is a self-signed root CA, then all of the certificates that have not expired should be revoked and a CRL generated with the same reason. This will indicate that the certificates are no longer valid because the CA has been decommissioned.
- When uninstalling an enterprise CA, it is important that it be uninstalled properly to ensure that their CA enrollment object is removed from the Active Directory directory service. Failure to do so may result in Active Directory clients continuing to attempt to enroll against that CA. If an enterprise CA cannot be uninstalled normally, Active Directory tools

should be used to manually remove the CA objects from Active Directory.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up certification authority Web enrollment support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up certification authority Web enrollment support**

1. Log on to the system as an Administrator, or if you have the Active Directory directory service, log on to the system as a Domain Administrator.

2. Open Add or Remove Programs in Control Panel.

3. Click **Add/Remove Windows Components**.

4. In the Windows Components Wizard, select the **Certificate Services** check box. A dialog box appears to inform you that the computer cannot be renamed and that the computer cannot be joined to or removed from a domain after Certificate Services is installed. Click **Yes**, and then click **Details**.

5. Clear the **Certificate Services CA** check box, verify that the **Certificate Services Web Enrollment Support** check box remains selected, click **OK**, and then click **Next**.

6. In **Computer Name**, type in the name of the computer on which the certification authority (CA) is installed, the CA for which these Web enrollment pages will be used. The name of the CA will appear in the list. Click **Next**.

7. If Internet Information Services is running, the system will request that you stop the service before proceeding with the installation. If this happens, click **Yes**.

8. If prompted, type in the path to the Certificate Services installation files.

**Notes**

- If you installed the CA Web enrollment pages on a computer that is not a CA, the computer account must be trusted for delegation in Active Directory. For more information on trusting a computer for delegation, see Related Topics.

- CA Web enrollment pages are installed by default when you set up Certificate Services on a server that has Internet Information Services (IIS) installed. This procedure is necessary only if you want to install the CA Web enrollment pages on a server that is separate from the server on which the CA is installed.

- If you installed the CA Web enrollment pages before installing IIS, the required virtual roots are not created. You can create the virtual roots after installing IIS by typing **certutil -vroot** at a command prompt. The command **certutil -vroot** does not install the Web enrollment pages. It creates the IIS virtual roots which point to the Web enrollment pages, CA certificate, CRLs, and enrollment controls (xenroll.dll and scrdenrl.dll).

  For more information on creating or deleting the related set of Certificate Services Web server virtual roots and file shares, see Certutil tasks for configuring a Certification Authority (CA).

- When you initially install IIS, the service is installed in a highly secure mode. Because IIS only serves static content by default, you must enable features such as ASP. To enable ASP and allow the CA Web enrollment pages to work correctly, see Enabling and Disabling Dynamic Content in Microsoft Internet Information Services.

- Installation of the Web enrollment pages configures the computer as a registration authority (RA). This computer is also known as a "CA Web proxy" or a "Web enrollment station."

- To open Add/Remove Windows Components, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Perform qualified subordination

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To perform qualified subordination**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Create the information file for the qualified subordinate certification authority.
2. Save the information file as CAPolicy.inf in the systemroot directory on the computer where you are installing the qualified subordinate certification authority.

   For more information, see Notes.
3. Install the qualified subordinate certification authority.

## Notes

- The information file should contain the certificate extensions needed to specify the qualified subordination constraints for the qualified subordinate certification authority you are installing.
- When you set up a qualified subordinate CA, you can add a CA policy statement to the CA certificate that is created during setup or a CA certificate renewal, in the form of a text file (CAPolicy.inf) or a pointer to a Web site. The CA policy can contain all the qualified subordination extensions and provide legal and other pertinent information about the CA and its issuing policies, limitations of liability, and so on. An end user will see this CA policy statement when they view the CA certificate and click Issuer Statement.

  For more information about CAPolicy.inf, see "Certificate Services" at the Microsoft Windows Resource Kits Web site.
- When qualified subordinate CA certificates and cross-certificates are revoked, they should also be deleted from the Active Directory directory service. This deletion is not required for security reasons, but is considered a best practice, as it also removes the certificates from the Local Machine certificates store of client computers.

**Using a command line**

1. Open Command Prompt.
2. Type the following to construct a qualified subordination request from an existing CA certificate or from an existing request:

   **certreq-policy**[*Options*] [*RequestFileIn* [*PolicyFileIn*[*RequestFileOut* [*PKCS10FileOut*]]]]
3. Type the following to sign the qualified subordination request:

   **certreq-sign-cert***CertId*[*RequestFileIn*[*RequestFileOut*]]
4. Type the following to submit the request to the certification authority:

   **certreq**[**-submit**] **-config***CAComputerName******CAName*[*RequestFileIn* [*CertFileOut*[*CertChainFileOut* [*FullResponseFileOut*]]]]

5. Install the enterprise qualified subordinate certification authority.

   For more information, see Related Topics.

| Value | Description |
|---|---|
| **certreq** | Requests certificates from a certification authority (CA) from the command prompt. |
| **-policy** | Required. Sets the policy for a request. |
| **-sign** | Required. Signs a cross-certification or qualified subordination request. |
| **-cert** *CertId* | Option. Specifies the signing certificate by common name, serial number, or by SHA-1 key or certificate hash. |
| **-attrib** *AttributeString* | Option. Specifies the Name and Value string pairs, separated by a colon. |
| **-binary** | Option. Formats output files as binary instead of Base64-encoded. |
| **-config** *CAComputerName* **** *CAName* | Option. Processes the operation using the CA that is identified in the configuration string specified by *CAComputerName******CAName*.<br>**Notes**<br>• Using **-config -** processes the operation using the default CA.<br>• If no **-config** option is used, the **Select Certification Authority** dialog box displays a list of all available CAs. |
| **-crl** | Option. Includes certificate revocation lists (CRLs) in the Base64-encoded PKCS #7 file, *CertChainFileOut*, or to the Base64-encoded file, *RequestFileOut*. |
| **-rpc** | Option. Instructs Certificate Services to use the RPC server connection instead of DCOM. |
| *RequestFileIn* | Specifies the Base64-encoded or binary input file name. May be a PKCS #10 certificate request, PKCS #7 certificate renewal request, KeyGen tag format certificate request, or a CMC request. |
| *CertFileOut* | Specifies to send output to either a binary or a Base64-encoded X.509 file. |
| *CertChainFileOut* | Specifies to send output to either a binary or a Base64-encoded PKCS #7 file. |
| *FullResponseFileOut* | Specifies to send output to either a binary or a Base64-encoded Full Response file. For **-submit**, this is the name of the qualified subordinate certificate file (for example, *QualifiedSub.cer*). |
| *PolicyFileIn* | Requires Certificate Services to get input from an .inf file containing a textual representation of extensions that are used to qualify a request. |
| *RequestFileOut* | Requires Certificate Services to send output to a Base64-encoded file. *RequestFileOut* for Step 2 will become *RequestFileIn* for Step 3. |
| *PKCS10FileOut* | Requires Certificate Services to send output to a Base64-encoded PKCS #10 file. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at a command prompt, type one of the following:
  - **certreq -?**

- **certreq -policy -?**
- **certreq -sign -?**
- **certreq -submit -?**

- Signing the qualified subordination request may require Enterprise Administrator credentials. This is a best practice for issuing signing certificates for qualified subordination.
- The certificate used to sign the qualified subordination request is created using the qualified subordination template. Enterprise Admins will have to sign the request or grant user permissions for the individuals that will sign the certificate.
- In Step 3, if you omit **-cert** *CertId*, you are prompted to supply the name of the signing certificate.
- When you install a qualified subordinate CA using the **certreq** command-line tool, the information (.inf) file can have any name. This is different from when you are using an information file as an issuer policy statement. In that case, the information file must be named *CAPolicy.inf*, as described in the Windows interface procedure above.
- When you sign the CMC request, you may need to have multiple personnel sign this request, depending on the assurance level that is associated with the qualified subordination.
- In some cases, if you omit values at the command line, you will be prompted to supply the necessary information.
- Once the qualified subordination request is signed, it is automatically published to Active Directory.
- If the parent CA of the qualified subordinate CA you are installing is offline, you must obtain the CA certificate for the qualified subordinate CA from the offline parent. If the parent CA is online, specify the CA certificate for the qualified subordinate CA during the Certificate Services Installation Wizard.
- When qualified subordinate CA certificates and cross-certificates are revoked, they should also be deleted from Active Directory. This deletion is not required for security reasons, but is considered a best practice as it also removes the certificates from the Local Machine certificates store of client computers.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Administer a Certification Authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administer a certification authority**

- Start or stop the certification authority service
- Set security permissions and delegate control of a certification authority
- View the certification authority certificate
- Back up a certification authority
- Restore a certification authority from a backup copy
- Set security for access to certification authority Web pages
- Configure certificate manager restrictions
- Configure event auditing
- Renew a root certification authority
- Renew a subordinate certification authority
- Publish certificates in a foreign Active Directory forest
- Send e-mail when a certification event occurs
- Use the Certification Authority snap-in
- Manage Certificate Revocation
- Manage Certificate Requests on a Stand-alone Certification Authority
- Manage Certificate Templates for an Enterprise Certification Authority
- Manage Key Archival and Recovery
- Change Policy Settings of a Certification Authority
- Change the Policy or Exit Modules of a Certification Authority
- Manage Role-based Administration

# Start or stop the certification authority service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start or stop the certification authority service**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, point to **All Tasks**, and click **Start Service** to start the service or click **Stop Service** to stop the service.

**Notes**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- You can also start or stop Certificate Services if you open Computer Management, double-click **Services and Applications**, and then click **Services**. In the details pane, click **Certificate Services**. On the **Action** menu, click **Stop** or **Start**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **net start certsvc** to start the service or type **net stop certsvc** to stop the service.

| Value | Description |
|---|---|
| start | Start the specified service. |
| stop | Stop the specified service |
| certsvc | Specifies the Certification Authority service as the service to act on. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **net /?**

**Information about functional differences**

# Set security permissions and delegate control of a certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set security permissions and delegate control of a certification authority**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. Click the **Security** tab and specify the security permissions.

   For general information about setting access control security permissions, see Related Topics.

**Note**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the certification authority certificate

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the certification authority certificate**

1. Log on to the system as any CA role holder.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **General** tab, click **View Certificate**.

**Note**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Back up a certification authority

Updated: January 19, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To back up a certification authority**

**Warning**

The procedures discussed in this article demonstrate how to back up only the certification authority (CA) database and private key. If you want to back up the CA database, private key, and CA configuration, see the backup procedures in AD CS Migration: Migrating the Certification Authority (http://technet.microsoft.com/library/ee126140.aspx). To back up all the configuration data for a computer, run a System State Data backup (http://technet.microsoft.com/library/cc781353.aspx).

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Log on to the system as a Backup Operator or a Certification Authority Administrator.
2. Open the Certification Authority console.
3. In the console tree, click the name of the certification authority (CA).
   - Certification Authority (*Computer*)/*CA name*
4. On the **Action** menu, point to **All Tasks**, and then click **Back Up CA**.
5. Follow the instructions in the Certification Authority Backup Wizard.

**Note**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- This procedure is useful if you want to back up a CA database and private key, without backing up the entire server or CA configuration on which the CA is installed.

  In general, you should use Backup to back up and restore both the CA and the server. For more information about backing up a computer running a Windows Server 2003 operating system, see Related Topics.
- By default, members of the local Administrators group of CA computer can also back up the CA.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **certutil** -backup <*BackupFolder*>

| Value | Description |
| --- | --- |
| backup | Specifies a full backup of the CA's database. |
| *BackupDirectory* | Specifies the path to use to store the backup data. |

**Tip**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at a command prompt, type:

  **certutil -backup -?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restore a certification authority from a backup copy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore a certification authority from a backup copy**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Log on to the system as a Backup Operator or a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, point to **All Tasks**, and click **Restore CA**.
5. Follow the instructions in the Certification Authority Restore Wizard.

**Notes**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- This procedure is useful if you want to restore a CA without restoring the entire server on which the CA is installed. To back up the CA for later restoration using this procedure, see Related Topics.

  In general, you should use Backup to back up and restore both the CA and the server. For more information about backing up a computer running a Windows Server 2003 operating system, see Related Topics.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **certutil** -restore *BackupDirectory*

| Value | Description |
|---|---|
| restore | Specifies a full restore of the CA's data. |
| *BackupDirectory* | Specifies the path where the backup data is located. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command**

**prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -restore -?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set security for access to certification authority Web pages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set security for access to certification authority Web pages**

1. Log on to the system as an Internet Information Services Administrator.
2. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Internet Information Services**.
3. In the console tree, right-click **CertSrv**, and click **Properties**.

   **Where?**

   - Internet Information Services/*Computer Name*/Web Sites/Default Web Site/CertSrv

4. On the **Directory Security** tab, under **Anonymous access and authentication control**, click **Edit**.
5. Clear all check boxes *except***Integrated Windows authentication**.

### Important

- An enterprise certification authority (CA) requires that the certificate requester be authenticated by the page so that it can determine the correct information to put in the certificate. If you don't have authentication set for the Web pages in an enterprise CA, then the pages will fail to generate a certificate or, if a certificate is generated, it will be useless. For this reason, integrated Windows authentication is set by default on enterprise CAs. This procedure is provided so that you can confirm the default setting or fix an erroneous change to the IIS Directory Security settings for an enterprise certification authority.

### Notes

- You do not need to perform this procedure on a stand-alone certification authority.
- If you cannot locate CertSrv in the console tree, confirm that Certificate Services is installed.
- If Certificate Services is installed and the CertSrv virtual directory doesn't exist, run **certutil -vroot** from the command prompt to create it.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure certificate manager restrictions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure certificate manager restrictions**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Certificate Manager Restrictions** tab, click **Restrict certificate managers**.
6. In **Available certificate managers**, select the certificate manager subject or group you want.
7. Click **Add** to add groups, users or computers to manage for the selected certificate manager.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- If a CA is running on a member server and the Restrict certificate managers property is enabled, then the member server needs to be added to the Pre-Windows 2000 Compatible Access built-in group of every domain from which it will receive certificate requests. Once added to these groups, the administrator of the CA is allowed to issue a certificate for subjects in those domains.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure event auditing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure event auditing**

1. Log on to the system as a Certification Authority Administrator or a CA Auditor.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Auditing** tab, click the events you want to audit.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- To audit events, the computer must also be configured for auditing of object access. Also, the auditor must perform this operation if the certification authority has been configured to enforce role-based administration. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Renew a root certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To renew a root certification authority**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, point to **All Tasks**, and click **Renew CA Certificate**.
5. Do one of the following:

   - If you want to generate a new public and private key pair for the certification authority's certificate, click **Yes**.
   - If you want to reuse the current public and private key pair for the certification authority's certificate, click **No**.

**Note**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Renewing a certification authority
Renew a subordinate certification authority

# Renew a subordinate certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To renew a subordinate certification authority**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, point to **All Tasks**, and click **Renew CA Certificate**.
5. Do one of the following:

   - If you want to generate a new public and private key pair for the certification authority's certificate, click **Yes**.
   - If you want to reuse the current public and private key pair for the certification authority's certificate, click **No**.

6. Get the CA certificate from the parent CA. For more information, see Notes.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- To obtain the certificate for a subordinate CA, you must submit a certificate request to a parent CA. The procedure for doing so differs depending on whether the parent CA is available online.

  - If a parent CA is available online
  - If a parent CA is not available online

**If a parent CA is available online**

1. Click **Send the request directly to a CA already on the network**.
2. In **Computer Name**, type the name of the computer on which the parent CA is installed.
3. In **Parent CA**, click the name of the parent CA.

#### If a parent CA is not available online

1. Click **Save the request to a file**.

2. In **Request file**, type the path and file name of the file that will store the request.

3. Obtain this subordinate CA's certificate from the parent CA.

   The procedure for doing this will be unique to the parent CA. At a minimum, the parent CA should provide a file containing the subordinate CA's newly issued certificate and, preferably, its full certification path. For the procedure to submit a certificate request using a file to a Microsoft CA, see Related Topics.

   If you get a subordinate CA certificate that does *not* include the full certification path, the new subordinate CA you are installing must be able to build a valid CA chain when it starts. Thus you must install the parent CA's certificate in the Intermediate Certification Authorities certificate store of the computer (if the parent CA is not a root CA), as well as the certificates of any other intermediate CA in the chain, and you must install the certificate of the root CA in the chain into the Trusted Root Certification Authorities store. These certificates should be installed in the certificate store before you install the CA certificate on the subordinate CA you have just set up.

4. Open Certification Authority.

5. In the console tree, click the name of the CA.

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

6. On the **Action** menu, point to **All Tasks**, and then click **Install CA Certificate**.

7. Locate the certificate file received from the parent certification authority, click this file, and then click **Open**.

#### Using a command line

1. Open Command Prompt.

2. Type:

   **certutil** -renewcert

| Value | Description |
|---|---|
| renewcert | Instructs the CA to renew its certificate. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -renewcert -?**

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Publish certificates in a foreign Active Directory forest

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To publish certificates in a foreign Active Directory forest**

1. Log on to the system as an administrator.
2. Open Command Prompt.
3. Type:

   **certutil -setreg CA\AlternatePublishDomains +"***DomainName***"**

| Value | Description |
|---|---|
| **certutil** | Specifies the name of the command-line program. |
| **-setreg** | Modifies the registry. |
| **CA\AlternatePublishDomains** | Indicates the registry value that contains a list of Active Directory domains that receive certificate publication. |
| **+** | Indicates that if there are current entries stored in this registry value, append this entry to those. |
| *DomainName* | Specifies the fully-qualified DNS domain name of the foreign Active Directory domain to publish certificates in. |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- A forest trust relationship must exist between the CA's forest and the forest that certificates will be published in before publication in the foreign domain. For more information, see Related Topics.
- The default permissions in a trust across forests do not allow certificate publication from a foreign forest. To grant the appropriate permissions, use the Delegation of Control Wizard on the foreign Active Directory's root domain to make the following settings:

| Setting | Value |
|---|---|
| Selected users and groups | **Certificate Publishers** group in the foreign Active Directory domain |
| Tasks to delegate | **Create a custom task to delegate** |

| | |
|---|---|
| Delegate control of: | Under **Only the following objects in the folder**, select **Contact objects** |
| Show these permissions | Click **Property-specific**, then select **Read userCertificate** and **Write userCertificate** |

For more information on running the Delegation of Control Wizard, see Related Topics.

- The default membership of the foreign Active Directory's Cert Publishers group does not include the source CA. The source CA's Active Directory computer account must be added to the foreign Cert Publishers group before publishing across forests will work. Because computer accounts cannot be found across trusts across forests by browsing, ensure you know the name of the CA to add.

- Publication of certificates in a foreign Active Directory requires the e-mail property in the source forest's User object match the e-mail property in the destination forest's Contact object. The e-mail property must be populated on User objects for this to happen. For more information on changing properties of a User object, see Related Topics.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -setreg -?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Send e-mail when a certification event occurs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To send e-mail when a certification event occurs**

1. Open Command Prompt.
2. Type:

   **certutil -setreg exit\smtp\smtpserver***ServerName*

   and then type:

   **certutil -setreg exit\smtp\eventfilter +***Event*

| Value | Description |
|---|---|
| **certutil** | Specifies the name of the command-line program. |
| **-setreg** | Modifies the registry. |
| **exit\smtp\smtpserver** | Indicates the registry value that contains the name of the Simple Mail Transfer Protocol (SMTP) server. |
| **exit\smtp\eventfilter** | Indicates the registry value that contains the list of events that the certification authority (CA) should monitor. When any of these events occur, the CA will send e-mail. |
| **+** | Indicates that, if there are current entries stored in this registry value, this entry should be appended to them. |
| *Event* | Specifies the event to add to the list of events for the CA to monitor. An event can be any value in the following table: |

| Event value | Description |
|---|---|
| ExitEvent_CertIssued | Specifies the action of issuing a certificate. |
| ExitEvent_CertPending | Specifies the action of a certificate request being received by the CA and set to Pending. |
| ExitEvent_CertDenied | Specifies the action of a certificate request being received by the CA and that request being denied. |
| ExitEvent_CertRevoked | Specifies the action of a revocation of an existing certificate. |
| ExitEvent_CRLIssued | Specifies the action of a certificate revocation list being issued. |
| ExitEvent_Startup | Specifies the action of the certification authority starting. |
| ExitEvent_Shutdown | Specifies the action of the certification authority shutting down. |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- When the ExitEvent_CRLIssued, ExitEvent_Startup and ExitEvent_Shutdown events occur, the CA does not know where to send the e-mail, as there is no user associated with this event. Therefore, an e-mail address must be configured when using these events. To configure the e-mail address to send e-mail to when these events occur, type the following certutil.exe commands at a command prompt:

  **certutil -setreg exit\smtp\CRLIssued\To***E-mailString*

  **certutil -setreg exit\smtp\Startup\To***E-mailString*

  **certutil -setreg exit\smtp\Shutdown\To***E-mailString*

  *E-mailString* specifies an e-mail address or a string of e-mail addresses that are separated by semicolons.

- If the SMTP server is not set to accept anonymous connections, the CA must be configured to provide a user name and password when it connects. To configure the CA to authenticate with the SMTP server, type the following **certutil.exe** commands at a command prompt:

  **certutil -setreg exit\smtp\SMTPAuthenticate 1**

  **certutil -setsmtpinfo***UserName*

  *UserName* specifies the user name of a valid account on the SMTP server. Certutil will prompt you to provide the password for this user name.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -setreg -?**

  For more information about configuring a certification authority for e-mail, see "Designing a Public Key Infrastructure" at the Microsoft Windows Resource Kits Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Administer the certification authority on another computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To administer the certification authority on another computer**

1. Log on to the system as a Certification Authority Administrator of the remote CA.
2. Open Certification Authority.
3. On the **Action** menu, click **Retarget Certification Authority**.
4. Click **Another computer** and type the name of the computer.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- As an alternate way to manage a CA on another computer, perform the following steps:

  1. Log on to the system as an Administrator.
  2. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
  3. On the **File** menu, click **Add/Remove Snap-in**. Click **Add**.
  4. In **Snap-in**, double-click **Certification Authority**.
  5. Click **Another computer** and type the name of the computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set display filters for the Certification Authority snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set display filters for the Certification Authority snap-in**

1. Log on to the system as any CA role holder.
2. Open Certification Authority.
3. In the console tree, double-click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. Click any of the displayed folders except **Certificate templates**.
5. On the **View** menu, click **Filter**.
6. For each of the selection criteria:

   - Click **Add**.
   - In **Field**, click the field on which to filter.
   - In **Operation**, click the operation to qualify the filter value for this field.
   - In **Value**, type the qualification value.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- Display filters are essentially a way to make simple queries against a CA's database. By using filters, you can restrict the items displayed in the details pane of the Certification Authority snap-in to items that meet a set of criteria you establish. For example, you can create a filter that will display in the **Issued Certificates** folder only those certificates that were effective after a specific date.
- To remove a filter, click it in the **Filter** dialog box, and then click **Remove**.
- To remove all existing filters, in the **Filter** dialog box, click **Reset**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Customize the display of columns in Certification Authority

# Customize the display of columns in Certification Authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To customize the display of columns in Certification Authority**

1. Log on to the system as any CA role holder.
2. Open Certification Authority.
3. In the console tree, double-click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. Click any of the displayed folders, such as **Revoked Certificates** or **Issued Certificates**.
5. On the **View** menu, click **Add/Remove Columns**.
6. Do any of the following until you have made all of the changes that you want.

| To | Do this |
|---|---|
| Add a new column to the details pane | In **Available Columns**, click the column you want to add to the details pane. Click **Add**. |
| Remove a column from the details pane | In **Displayed Columns**, click the column you want to remove from the details pane. Click **Remove**. |
| Change the order of columns in the details pane | In **Displayed Columns**, click the column you want to move up or down in the order of the details pane. Click **Move Up** or **Move Down** as appropriate. |
| Restore the default columns | Click **Restore Defaults**. |

**Notes**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- To sort the results, click the column heading in the details pane. You can only sort results based on columns (indicating the fields) that are indexed in the database of the certification authority. There will be a small arrow on the column heading you are sorting by.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Certificate Revocation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage certificate revocation**

- Specify certificate revocation list distribution points in issued certificates
- Configure CRL and delta CRL overlap period
- Specify online certificate status protocol responder in issued certificates
- Configure an offline root certification authority to support certificate revocation with Active Directory
- Revoke an issued certificate
- Schedule the publication of the certificate revocation list
- Schedule the publication of the delta certificate revocation list
- Manually publish the certificate revocation list
- View the certificate revocation list

# Specify certificate revocation list distribution points in issued certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can add, remove, or modify certificate revocation list distribution points (CDPs) in issued certificates by using the following procedure. However, modifying the URL for a CDP only affects newly issued certificates. Previously issued certificates will continue to reference the original location.

**To specify certificate revocation list distribution points in issued certificates**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the certification authority.

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Extensions** tab, confirm that **Select extension** is set to **CRL Distribution Point (CDP)**.
6. Do one or more of the following. (The list of CRL distribution points is in the **Specify locations from which users can obtain a certificate revocation list (CRL)** box.)

| To | Do this |
|---|---|
| Add a new certificate revocation list (CRL) distribution point. | Click **Add**, type the name of the new CRL distribution point, and click **OK**. |
| Remove a CRL distribution point from the list. | Click the CRL distribution point, and then click **Remove** and click **OK**. |
| Indicate that you want to use a URL as a CRL distribution point. | Click the CRL distribution point, select the **Include in the CDP extension of issued certificates** check box, and then click **OK**. |
| Indicate that you do not want to use a URL as a CRL distribution point. | Click the CRL distribution point, clear the **Include in the CDP extension of issued certificates** check box, and then click **OK**. |
| Indicate that you want to use a URL as a delta CRL distribution point. | Click the CRL distribution point, select the **Publish Delta CRLs to this location** check box, and then click **OK**. |
| Indicate that you do not want to use a URL as a delta CRL distribution point. | Click the CRL distribution point, clear the **Publish Delta CRLs to this location** check box, and then click **OK**. |
| Indicate that you want to publish this location in CRLs to point clients to a delta CRL. | Click the CRL distribution point, select the **Include in CRLs. Clients use this to find Delta CRL locations.** check box, and then click **OK**. |
| Indicate that you do not want to publish this location in CRLs to point clients to a Delta CRL. | Click the CRL distribution point, clear the **Include in CRLs. Clients use this to find Delta CRL locations.** check box, and then click **OK**. |

7. Click **Yes** to stop and restart the Certificate Services service.

**Notes**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

- Certificate revocation list URLs can be either HTTP, FTP, LDAP, or FILE addresses. You can use the following variables when specifying the address of the CRL.

| Variable | Value |
|---|---|
| CAName | The name of the certification authority |
| CAObjectClass | The object class identifier for a certification authority, used when publishing to an LDAP URL |
| CATruncatedName | The "sanitized" name of the certification authority, truncated to 32 characters with a hash on the end |
| CDPObjectClass | The object class identifier for CRL distribution points, used when publishing to an LDAP URL |
| CertificateName | The renewal extension of the certification authority |
| ConfigurationContainer | The location of the Configuration container in Active Directory |
| CRLNameSuffix | Inserts a name suffix at the end of the file name when publishing a CRL to a file or URL location |
| DeltaCRLAllowed | When a delta CRL is published, this replaces the CRLNameSuffix with a separate suffix to distinguish the delta CRL |
| ServerDNSName | The DNS name of the certification authority server |
| ServerShortName | The NetBIOS name of the certification authority server |

- To stop and restart the Certificate Services service, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure CRL and delta CRL overlap period

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure CRL and delta CRL overlap period**

1. Open Command Prompt.
2. Type:

   **certutil -setreg ca\CRLOverlapUnits***Value*

   **certutil -setreg ca\CRLOverlapPeriod***Units*

   **certutil -setreg ca\CRLDeltaOverlapUnits** *Value*

   **certutil -setreg ca\DeltaOverlapPeriod***Units*
3. Open Certification Authority.
4. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*
5. On the **Action** menu, point to **All Tasks**, and click **Stop Service** to stop the service.
6. On the **Action** menu, point to **All Tasks**, and click **Start Service** to start the service.

| Value | Description |
|---|---|
| **certutil** | Specifies the name of the command-line program. |
| **-setreg** | Modifies the registry. |
| **ca\CRLOverlapUnits** | Indicates the registry value that stores the value for the CRL overlap setting. |
| **ca\CRLDeltaOverlapUnits** | Indicates the registry value that stores the value for the delta CRL overlap setting. |
| *Value* | Provides the numerical value to set this option to. |
| **ca\CRLOverlapPeriod** | Indicates the registry value that stores the value for the CRL overlap unit type setting. |
| **ca\DeltaOverlapPeriod** | Indicates the registry value that stores the value for the delta CRL overlap unit type setting. |
| *Units* | Provides the type of units for the overlap period. Valid values are **Minutes** and **Hours**. |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have

been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

- The maximum value for either the CRL or delta CRL overlap period is 12 hours.

- The overlap period for CRLs is the amount of time at the end of a published CRLs lifetime that a client can use to obtain a new CRL before the old CRL is considered unusable. The default setting for this value is 10% of the CRL lifetime. Because some environments may require longer periods to replicate a CRL, this setting can be configured manually.

- When both a base CRL and delta CRL have been recently published, a revoked certificate may appear in both. This is because the newer delta CRL may still point at the older base CRL while the new base CRL is being replicated. Having the certificate appear in both CRLs ensures the revocation information is available.

- If your environment is not configured to issue delta CRLs, the settings for **CRLDeltaOverlapUnits** and **DeltaOverlapPeriod** will have no effect.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -setreg -?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify online certificate status protocol responder in issued certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify online certificate status protocol (OCSP) responder in issued certificates**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the certification authority.

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Extensions** tab, under **Select extension**, click **Authority Information Access (AIA)**.
6. Do one or more of the following. (The list of OCSP responders is in the **Specify locations from which users can obtain a certificate revocation list (CRL)** box.)

| To | Do this |
|---|---|
| Add a new OCSP responder. | Click **Add**, type in the URL of the new CRL distribution point, and then click **OK**. |
| Remove a OCSP responder from the list. | Click the OCSP responder, click **Remove**, and then click **OK**. |
| Indicate that you do not want to use a URL as an OCSP responder. | Click the OCSP responder, clear the **Include in the online certificate status protocol (OCSP) extension** check box, and then click **OK**. |
| Indicate that you want to use a URL as an OCSP responder. | Click the OCSP responder, select the **Include in the online certificate status protocol (OCSP) extension** check box, and then click **OK**. |

7. On the **Action** menu, point to **All Tasks**, click **Stop Service**, and on the **Action** menu, point to **All Tasks**, and then click **Start Service**.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- OCSP responder list URLs must be formatted as HTTP addresses.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure an offline root certification authority to support certificate revocation with Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure an offline root certification authority to support certificate revocation with Active Directory**

1. Log on to the system as a Certification Authority Administrator.
2. Open Command Prompt.
3. Type the following, and then press ENTER.

   **certutil -setreg ca\DSConfigDN "CN=Configuration,** *DNpath***"**

4. Type the following, and then press ENTER.

   **certutil -setreg ca\DSDomainDN "***DNpath***"**

5. Open Certification Authority.
6. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

7. On the **Action** menu, point to **All Tasks**, and click **Stop Service** to stop the service.
8. On the **Action** menu, point to **All Tasks**, and click **Start Service** to start the service.

| Value | Description |
|---|---|
| **certutil** | Specifies the name of the command-line program. |
| **-setreg** | Modifies the registry. |
| **ca\DSConfigDN** | Indicates the registry value for the distinguished name value of the path to the Configuration container in the Active Directory directory service. |
| **ca\DSDomainDN** | Indicates the registry value for the distinguished name value of the Active Directory domain. |
| *DNpath* | Specifies the distinguished name value in Active Directory. For more information, see Related Topics. |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

- To ensure clients have the ability to locate the certificate revocation list (CRL), the certification authority (CA) must be configured with the appropriate LDAP path to retrieve this CRL from Active Directory. This is done by selecting the **Include in the CDP extension of issued certificates** check box when configuring the CDP. For more information, see Related Topics.

- This procedure should be used as part of a larger plan to deploy an offline root CA. For more information about deploying an offline root CA, see Related Topics.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -setreg -?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Revoke an issued certificate

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To revoke an issued certificate**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Log on to the system as a Certification Authority Administrator or Certificate Manager.
2. Open Certification Authority.
3. In the console tree, click **Issued Certificates**

   **Where?**

   - Certification Authority (*Computer*)/*CA name*/Issued Certificates

4. In the details pane, click the certificate you want to revoke.
5. On the **Action** menu, point to **All Tasks**, and click **Revoke Certificate**.
6. Select the reason for revoking the certificate and click **Yes**.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- The certificate is marked as revoked and is moved to the Revoked Certificates folder. The revoked certificate will appear on the certificate revocation list (CRL) the next time it is published.
- Certificates revoked with the reason code "Certificate Hold" can be unrevoked, left on "Certificate Hold" until they expire, or have their revocation reason code changed. "Certificate Hold" is the only revocation reason that will allow you to unrevoke the certificate. It is useful if the status of the certificate is questionable and is meant to provide some flexibility to the CA administrator.
- To unrevoke a certificate revoked with the reason code "Certificate Hold," at a command prompt on the CA, type:

  **certutil -revoke** *CertificateSerialNumber* **unrevoke**

- To identify the certificate serial number, in the Revoked Certificates folder, in the details pane, double-click the revoked certificate, and then click the **Details** tab.
- To change the reason code for a certificate previously revoked with the reason code "Certificate Hold," type the appropriate command at a command prompt on the CA.

| New reason code | Command |
|---|---|

| | |
|---|---|
| Unspecified | **certutil -revoke***CertificateSerialNumber***0** |
| Key Compromise | **certutil -revoke***CertificateSerialNumber***1** |
| CA Compromise | **certutil -revoke***CertificateSerialNumber***2** |
| Affiliation Changed | **certutil -revoke***CertificateSerialNumber***3** |
| Superseded | **certutil -revoke***CertificateSerialNumber***4** |
| Cessation of Operation | **certutil -revoke***CertificateSerialNumber***5** |

- You can also unrevoke a certificate in the Certification Authority by right-clicking the certificate you want, clicking **All Tasks**, then clicking **Unrevoke Certificate**. This certificate must be revoked for the reason of "Certificate Hold".

**Using a command line**

1. Open Command Prompt.

2. Type:

   **certutil** -revoke *SerialNumberReasonCode*

| Value | Description |
|---|---|
| revoke | Specifies the revocation of an existing certificate. |
| *SerialNumber* | Specifies the serial number of the certificate for revocation. |
| *ReasonCode* | Specifies the reason code for this certificate revocation. For values, see Notes. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -revoke -?**

- The valid reason codes for certificate revocation are:

| Reason forrevoking a certificate | Reason code |
|---|---|
| Unspecified | **0** |
| Key Compromise | **1** |
| CA Compromise | **2** |
| Affiliation Changed | **3** |
| Superseded | **4** |
| Cessation of Operation | **5** |
| Certificate Hold | **6** |

- Certificates that are revoked with the reason code "Certificate Hold" can be unrevoked, left on "Certificate Hold" until they expire, or have their revocation reason code changed. "Certificate Hold" is the only revocation reason that will allow you to unrevoke the certificate. It is useful if the status of the certificate is questionable and is meant to provide some

flexibility to the CA administrator.

- To unrevoke a certificate that is revoked with the reason code "Certificate Hold," at a command prompt on the CA, type:

  **certutil -revoke** *CertificateSerialNumber* **unrevoke**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Schedule the publication of the certificate revocation list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To schedule the publication of the certificate revocation list**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click **Revoked Certificates**.

   **Where?**

   - Certification Authority (*Computer*)/*CA name/*Revoked Certificates

4. On the **Action** menu, click **Properties**.
5. In **CRL publication interval**, type the increment and click the unit of time to use for the automatic publishing of the certificate revocation list (CRL).

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- The certificate revocation list (CRL) is published by default in:

  *systemroot*\system32\CertSrv\CertEnroll\

- If the computer is a domain member and has permission to write to the Active Directory directory service, then the CRL is also published to Active Directory.
- The publishing period for a CRL is not the same as the validity period for a CRL. By default, the validity period of a CRL exceeds the publishing period of a CRL by 10% (up to a 12-hour maximum) to allow for directory replication. For more information about revoking certificates and publishing CRLs, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Schedule the publication of the delta certificate revocation list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To schedule the publication of the delta certificate revocation list**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click **Revoked Certificates**.

   **Where?**

   - Certification Authority (*Computer*)/*CA name*/Revoked Certificates

4. On the **Action** menu, click **Properties**.
5. Select the **Publish Delta CRLs** check box.
6. In **Publication interval**, type the increment and click the unit of time to use for the automatic publishing of the delta certificate revocation list (CRL).

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- The delta certificate revocation list (CRL) is published by default in:

  *Systemroot*\system32\CertSrv\CertEnroll\

  If the computer is a domain member and has permission to write to Active Directory, then the delta CRL is also published to Active Directory.

- The publishing period for a CRL is not the same as the validity period for a CRL. By default, the validity period of a CRL exceeds the publishing period of a CRL by 10% (up to a 12-hour maximum) to allow for directory replication. For more information about revoking certificates and publishing CRLs, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manually publish the certificate revocation list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manually publish the certificate revocation list**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click **Revoked Certificates**.

   **Where?**

   - Certification Authority (*Computer*)/*CA name*/Revoked Certificates

4. On the **Action** menu, point to **All Tasks**, and click **Publish**.
5. Select **New CRL** to overwrite the previously-published certificate revocation list (CRL), or select **Delta CRL only** to publish a current delta CRL.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- Clients that have a cached copy of the previously-published CRL or delta CRL will continue using it until its validity period has expired, even though a new CRL has been published. Manually publishing a CRL does not affect cached copies of CRLs that are still valid; it only makes a new CRL available for systems that do not have a valid CRL.
- See Related Topics for the procedure clients can use to get the most recent CRL published by the certification authority (CA) even if they still have a valid CRL cached.
- By default, on the server on which the CA is installed, the CRL and delta CRL are published in:

  *Systemroot*\system32\CertSrv\CertEnroll\

- If the Active Directory directory service is available, they are also published to Active Directory.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **certutil** -crl

| Value | Description |
| --- | --- |
| crl | Specifies that a full certificate revocation list will be published. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -crl -?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Certificate Requests on a Stand-alone Certification Authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage certificate requests on a stand-alone certification authority**

- Review pending certificate requests
- Set the default action upon receipt of a certificate request

# Review pending certificate requests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To review pending certificate requests**

1. Log on to the system as a Certification Authority Administrator or Certificate Manager.
2. Open Certification Authority.
3. In the console tree, click **Pending Requests**.

   **Where?**

   - Certification Authority (Computer)/CA name/Pending Requests

4. In the details pane, examine the certificate request by noting the values for requester name, requester e-mail address, and any other fields that you consider critical information for issuing the certificate.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- Failed certificate requests can also be issued using the same procedure in the **Failed Requests** container. However, not all of the security requirements for the certificate can be verified when issuing a failed request. Caution should be used.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the default action upon receipt of a certificate request

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the default action upon receipt of a certificate request**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Policy Module** tab, click **Properties**.
6. Click the option you want:

| To | Do this |
|---|---|
| Have the certification authority administrator review every certificate request before issuing a certificate. | Click **Set the certificate request status to pending**. |
| Have the certification authority issue certificates based on the configuration of the certificate template | Click **Follow the settings in the certificate template, if applicable. Otherwise, automatically issue the certificate.**. |

7. Stop and restart the Certificate Services service.

**Caution**

- In most cases, for security reasons, it is strongly recommended that all incoming certificate requests to a stand-alone CA be marked as "pending." Unlike enterprise certification authorities, stand-alone CAs do not use the Active Directory directory service, even if it is available, to verify that an individual or computer is authorized to be issued a certificate from the CA automatically. For stand-alone CA's, the CA administrator is responsible for verifying the identity of the certificate requestor.

**Notes**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- If you change the setting from **Set the certificate request status to pending** to **Always issue the certificate**, this will apply only to certificate requests submitted to the CA after the default action has been changed. If there are pending requests held by the CA, these requests will stay pending until the CA administrator issues the certificates or denies the requests.
- To review pending certificate requests, see Related Topics.
- To stop and restart the Certificate Services service, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Certificate Templates for an Enterprise Certification Authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage certificate templates for an enterprise certification authority**

- Install new templates and upgrade existing templates
- Create a new certificate template
- Delete a certificate template
- Add a certificate template to a certification authority
- Allow subjects to request a certificate that is based on the template
- Re-enroll all certificate holders
- Remove a certificate template from a certification authority
- Modify a Certificate Template

# Install new templates and upgrade existing templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install new templates and upgrade existing templates**

1. Open Certificate Templates.

2. When prompted to install new certificate templates, click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.

- If this procedure has already been performed in your enterprise, you will not receive a prompt when you open Certificate Templates.

- This procedure must be performed before any Windows 2000 enterprise certification authorities are upgraded to Windows Server 2003 family certification authorities. If any Windows 2000 enterprise certification authorities currently exist or have ever existed in your enterprise, you must perform this procedure to ensure the certificate templates are added and updated correctly.

- This procedure must be performed on a certification authority (CA) in the certification hierarchy. Performing this procedure on a different computer may not work correctly.

- Performing this procedure is important to apply the proper security permissions on the existing certificate templates as well as create new certificate templates. If you do not perform this procedure before upgrading your certification authorities to the Windows Server 2003 family, you will be prompted when opening the Certification Authority snap-in.

- You must prepare the Active Directory schema with Adprep.exe for the upgrade before installing the new certificate templates. For more information on Adprep.exe, see Related Topics.

# Create a new certificate template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new certificate template**

1. Open Certificate Templates.
2. Right-click the template to copy from and then click **Duplicate Template**.
3. Type a new name for this certificate template.
4. Make any necessary changes and click **OK**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- New certificate templates must be created by copying an existing template and using the existing template's properties as the default for the new template. Copy the existing certificate template closest to the configuration of the intended new template to minimize the work necessary.
- Although Version 2 templates can be created and duplicated in Windows Server 2003, Standard Edition, certificates based on Version 2 templates can only be issued by a certification authority running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.

# Delete a certificate template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a certificate template**

1. Open Certificate Templates
2. Right-click the template, and then click **Delete**.

### Caution

- When you delete a certificate template, certificates can no longer be issued based on it. If you are using Enterprise CAs, this will affect all CAs in the forest. Certificate templates cannot be recovered once they are deleted.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.

# Add a certificate template to a certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a certificate template to a certification authority**

1. Open **Certification Authority**
2. Right-click the **Certificate Templates** container, click **New**, then click **Certificate Template to Issue**.
3. Select the certificate template and click **OK**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press **Enter**.
- This procedure is applicable to version 2 templates. For more information about version 2 templates, see Related Topics.

# Allow subjects to request a certificate that is based on the template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow subjects to request a certificate that is based on the template**

1. Open Certificate Templates.
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. On the **Security** tab, add the groups, computers, or users that you want.
4. In **Group or user names**, click one of the new objects, and then, on **Permissions for *ObjectName***, under the **Allow** column, select the **Read** and **Enroll** check boxes.
5. Repeat the previous step for each new object.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- The **Autoenroll** permission must also be set if the subject will be using client autoenrollment to obtain certificates. For more information on autoenrollment, see Related Topics.
- To disallow subjects from requesting a certificate based on a template, clear the **Read** and **Enroll** check boxes using the same steps as above.

# Re-enroll all certificate holders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To re-enroll all certificate holders**

1. Open Certificate Templates.
2. Right-click the template that you want to use and then click **Reenroll All Certificate Holders**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is used when a critical change is made to the certificate template and you want all subjects that hold a certificate that is based on this template to re-enroll as quickly as possible. The next time the subject verifies the version of the certificate against the version of the template on the certification authority, the subject will re-enroll.

# Supersede templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To supersede templates**

1. Open Certificate Templates
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. Click the **Superseded Templates** tab.
4. Click **Add**.
5. Click one or more templates to supersede, then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is applicable to version 2 templates. For more information about version 2 templates, see Related Topics.
- This procedure is used when a template replaces another template and you want subjects of certificates based on the old template to obtain new certificates based on the new template. It forces subjects to obtain a new certificate before their configured renewal period.

# Configure a certificate template for client autoenrollment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a certificate template for client autoenrollment**

1. Open Certificate Templates.
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. On the **Security** tab, add the users or groups that you want and, under **Allow**, select the **Read**, **Enroll**, and **Autoenroll** check boxes.
4. (Optional) To automatically enroll the subject without any more user input, on the **Request Handling** tab, click **Enroll subject without requiring any user input**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is applicable to version 2 templates. For more information about version 2 templates, see Related Topics.
- In addition to this procedure, other settings must be configured to allow client autoenrollment. For more information, see Related Topics.
- Clients must be re-enrolled to receive a certificate based on the changed template if they already have a valid certificate based on the old template. For more information about re-enrolling clients, see Related Topics.
- When autoenrollment retrieves a certificate that is configured to be stored on a smart card, you will receive a popup message when the certificate is ready to be stored on the smart card. If the message refers to a type of smart card that you do not have, click **Cancel** until the correct smart card type appears. You then provide the smart card PIN and the certificate will be stored on the smart card.
- When autoenrollment enrolls for a certificate that requires user interaction for the enrollment process, you will receive a **Certificate Enrollment** popup message and an icon will appear on your taskbar. Clicking that icon or message begins the certificate autoenrollment process.

# Configure a certificate template for key archival and recovery

Updated: November 7, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a certificate template for key archival and recovery**

1. Open Certificate Templates.
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. On the **Request Handling** tab, select the **Archive subject's encryption private key** check box.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is applicable to version 2 templates. For more information about version 2 templates, see Related Topics.
- In addition to this procedure, the certification authority must be configured to archive keys. For more information, see Related Topics.
- Clients must be re-enrolled to receive a certificate that is based on the changed template if they already have a valid certificate that is based on the old template. For more information about re-enrolling clients, see Related Topics.

# Identify a key recovery agent

Updated: November 5, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To identify a key recovery agent**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Recovery Agents** tab, click **Archive the key**.
6. In the **Number of recovery agents to use** box, type the number of key recovery agents that will be used to encrypt the archived key.
7. Click **Add** to add key recovery agent certificates.

**Notes**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- To add key recovery agents, the **Number of recovery agents to use** must be 1 or more.
- If the **Number of recovery agents to use** value exceeds the number of recovery agent certificates with the status of "Valid," enrollment requests that require key archival will fail.
- This procedure configures a certification authority to archive private keys when issuing certificates based on templates that have key archival configured. For more information about configuring certificate templates for key archival, see Related Topics.
- When the recovery agent certificates are added to the CA, a status is displayed for each certificate. Status can be one of the following values and causes:

| Status | Cause |
|---|---|
| Expired | The certificate's expiration date has passed so the certificate cannot be used. |
| Invalid | The certificate may be malformed or causes and error when loading. |
| Not found | The certificate was configured but cannot be located by the CA. |
| Not loaded | The certificate was configured but has not yet been loaded by the CA. |
| Revoked | The certificate has been revoked and cannot be used. |

| | |
|---|---|
| Untrusted | The root CA for this certificate is not trusted by the CA. |
| Valid | The certificate has been loaded by the CA and is operating normally. |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable key archival

Updated: November 5, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable key archival**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. Click the **Recovery Agents** tab and click **Archive the key**.
6. In the **Number of recovery agents to use** box, specify the number of recovery agents required to recover an archived key, and then add the recovery agents that you want to the **Key recovery agent certificates** list.

**Note**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Certutil tasks for key archival and recovery

Updated: November 5, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certutil tasks for key archival and recovery**

You can use **certutil** to retrieve and recover archived keys.

To view the syntax for a specific task, click a task:

- To retrieve an archived private key recovery blob
- To recover an archived private key

**To retrieve an archived private key recovery blob**

**Syntax**

**certutil -getkey** [**-f**] [**-gmt**] [**-seconds**] [**-v**] *SearchToken* [*RecoveryBlobOutFile*]

**Parameters**

**-getkey**
Retrieves the archived private key.

**-f**
Overwrites existing files or keys.

**-gmt**
Displays time as Greenwich mean time.

**-seconds**
Displays time with seconds and milliseconds.

**-v**
Specifies verbose output.

***SearchToken***
Specifies the keys and certificates that you want to recover.

***RecoveryBlobOutFile***
Specifies the output file containing a certificate chain and an associated private key, still encrypted to one or more key recovery agent (KRA) certificates.

**-?**
Displays a list of **certutil** commands.

**Remarks**

- *SearchToken* can be a certificate common name, a certificate serial number, a certificate Secure Hash Algorithm (SHA-1) hash, a requester name (that is, domain\user), or a user principal name (UPN) (that is, domain@user).

**To recover an archived private key**

**Syntax**

**certutil -recoverkey** [**-f**] [**-user**] [**-gmt**] [**-seconds**] [**-split**] [**-v**] [**-p***Password*] *RecoveryBlobInFile* [*PFXOutFile*] [*RecipientIndex*]]

**Parameters**

**-recoverkey**
Recovers the archived private key.

**-f**
Overwrites existing files or keys.

**-user**
Uses the **HKEY_CURRENT_USER** keys or certificate store.

**-gmt**
Displays time as Greenwich mean time.

**-seconds**
Displays time with seconds and milliseconds.

**-split**
Splits the embedded Abstract Syntax Notation One (ASN.1) elements, and saves them to files.

**-v**
Specifies verbose output.

**-p *Password***
Specifies a password.

***RecoveryBlobInFile***
Specifies the input file that contained the recovery blob retrieved from the CA.

***PFXOutFile***
Specifies the file where you want to save the recovered key and associated PKCS #12 certificate.

***Password***
Encrypts *PFXOutFile* to a password.

***RecipientIndex***
Specifies the index of the key recovery agent (KRA) certificate to be used for decrypting the private key blob. If you do not specify this parameter, **certutil** tries all of the KRA certificates.

**-?**
Displays a list of **certutil** commands.

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Change Policy Settings of a Certification Authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Change policy settings of a certification authority**

- Specify CA certificate access points in issued certificates
- Publish certificates to the file system

# Specify CA certificate access points in issued certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify CA certificate access points in issued certificates**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Extensions** tab, click **Select extension**, and then click **Authority Information Access (AIA)**.
6. Specify the locations from which users can obtain the certificate for this CA.

| To | Do this |
|---|---|
| Add a URL that will be published as part of any certificate issued by a CA. | Click **Add**, then type a URL where users can obtain the CA's certificate. |
| Remove an authority information URL from the list on issued certificates. | Click the URL and then click **Remove**. |
| Indicate that that you do not want to use a URL as an authority information access point in certificates without removing it from the list. | Clear the **Include in the AIA extension of issued certificates** check box. |
| Indicate that a URL can now be used as an authority information access point. | Select the **Include in the AIA extension of issued certificates** check box. |
| Indicate that a URL can now be used for online certificate status protocol (OCSP). | Select the **Include in the online certificate status protocol (OCSP) extension** check box. |
| Indicate that that you do not want to use a URL for online certificate status protocol (OCSP) in certificates without removing it from the list. | Clear the **Include in the online certificate status protocol (OCSP) extension** check box. |

7. Stop and restart the Certificate Services service.

**Notes**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- Authority information access URLs can be either HTTP, FTP, LDAP, or FILE addresses. You can use the following variables when specifying the address of the authority information access point:

| Variable | Value |
|---|---|

| | |
|---|---|
| CAName | The name of the certification authority. |
| CAObjectClass | The object class identifier for a certification authority, used when publishing to an LDAP URL |
| CATruncatedName | The "sanitized" name of the certification authority, truncated to 32 characters with a hash on the end |
| CDPObjectClass | The object class identifier for CRL distribution points, used when publishing to an LDAP URL |
| CertificateName | The renewal extension of the certification authority |
| ConfigurationContainer | The location of the Configuration container in Active Directory |
| CRLNameSuffix | Inserts a name suffix at the end of the file name when publishing a CRL to a file or URL location |
| DeltaCRLAllowed | When a delta CRL is published, this replaces the CRLNameSuffix with a separate suffix to distinguish the delta CRL |
| ServerDNSName | The DNS name of the certification authority server |
| ServerShortName | The NetBIOS name of the certification authority server |

- To stop and restart the Certificate Services service, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Publish certificates to the file system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To publish certificates to the file system**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Exit Module** tab, click **Properties**.
6. On the **Publication Settings** tab, select the **Allow certificates to be published to the file system** check box, and then click **OK**.
7. Stop and restart the Certification Authority service.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- To stop and restart Certificate Services, see Related Topics.
- To request a certificate and have it published to the file system, certificate requestors must include a **certfile:true** attribute in their request. After the certificate is issued, it is copied to *FileName*.cer, where *FileName* is the request ID of the certificate request.
  - The file is written in the CertEnroll share on the CA.
  - You cannot overwrite files using this method.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the Policy or Exit Modules of a Certification Authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Change the policy or exit modules of a certification authority**

- Select a different policy module
- Select a different exit module

# Select a different policy module

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To select a different policy module**

1. Log on to the system as a Certification Authority Administrator.
2. Open Certification Authority.
3. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

4. On the **Action** menu, click **Properties**.
5. On the **Policy Module** tab, click **Select**.
6. Click the new policy module, and then click **OK**.
7. If the policy module has its own configuration interface, you can configure it by clicking **Properties**.
8. Stop and restart the Certificate Services service.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.
- To register a new policy module so that it is available in the list of policy modules, refer to the *Microsoft Platform Software Development Kit*.
- Only one policy module can be active.
- To stop and restart the Certificate Services service, at the command prompt, type:

  **net stop certsvc**

  **net start certsvc**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Role-based Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing role-based administration**

- Add a certification authority administrator
- Add a certificate manager
- Add a certification authority auditor
- Add a certification authority backup operator
- Enable role separation
- Disable role separation

# Add a certification authority administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a certification authority administrator**

1. Open Certification Authority.
2. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

3. On the **Action** menu, click **Properties**.
4. Click the **Security** tab, in **Group or user names**, confirm that **Administrators** is selected, and then click **Add**.
5. In **Permissions for Administrators**, type the name of the group or user you want to make a CA Administrator, and then click **OK**.
6. In **Permissions for** *Added User or Group*, for **Manage CA**, select the **Allow** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a certificate manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a certificate manager**

1. Open Certification Authority.
2. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

3. On the **Action** menu, click **Properties**.
4. Click the **Security** tab, click **Add** and, in **Enter the object names to select**, type the user or group you want to make a Certificate Manager, and then click **OK**.
5. In the **Permissions for***Added User or Group* box, for **Issue and Manage Certificates**, select the **Allow** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

# Add a certification authority backup operator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a certification authority backup operator**

1. Open Local Security Settings.
2. In the console tree, click **User Rights Assignment**.

   **Where?**

   - Security Settings/Local Policies/User Rights Assignments

3. In the details pane, double-click **Back up file and directories**.
4. Click **Add User or Group** and, in **Enter the object names to select**, type the name of the user or group to add as a backup operator, and then click **OK**.
5. In the details pane, double-click **Restore file and directories**.
6. Click **Add User or Group** and, in **Enter the object names to select (examples)**, type the name of the user or group to add as a backup operator, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

Add a certification authority administrator
Add a certificate manager
Role-based administration
Add a certification authority auditor

# Enable role separation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable role separation**

**Caution**

- Before enabling role separation, make certain that no user is assigned to more than one role. If a user is assigned to more than one role and role separation is enabled, then the user will not be permitted to perform any activity for the Certificate Services service. For more information, see Role-based administration.

1. Open Command Prompt.
2. Type:

   **certutil -setreg ca\RoleSeparationEnabled 1**

3. Open Certification Authority.
4. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*

5. On the **Action** menu, point to **All Tasks**, and click **Stop Service** to stop the service.
6. On the **Action** menu, point to **All Tasks**, and click **Start Service** to start the service.

| Value | Description |
|---|---|
| **certutil** | Specifies the name of the command-line program. |
| **-setreg** | Modifies the registry. |
| **ca\RoleSeparationEnabled** | Indicates the registry value for role separation. |
| **1** | Specifies a value for the registry entry. A value of 1 enables role separation. |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-

click **Certification Authority**.

- Once role separation is enabled, a local Administrator will not be able to perform any role-based administration of the CA. This is because the local Administrator account has both the CA Backup Operator and CA Auditor user rights.

- You can assign certification authority roles for role-based administration on servers running any version of the Windows Server 2003 family, but you can only enable role separation on servers running Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, including the 64-bit versions of Windows Server 2003, Enterprise Edition and 64-bit versions of Windows Server 2003, Datacenter Edition.

- To display the role separation setting, type:

  **certutil -getreg ca\RoleSeparationEnabled**

- To view the complete syntax for this command, at a command prompt, type:

  **certutil -setreg -?**

- To stop and restart the Certificate Services service at the command prompt, type:

  **net stop certsvc**

  **net start certsvc**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable role separation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable role separation**

1. Open Command Prompt.
2. Type:

   **certutil -delreg ca\RoleSeparationEnabled**
3. Open Certification Authority.
4. In the console tree, click the name of the certification authority (CA).

   **Where?**

   - Certification Authority (*Computer*)/*CA name*
5. On the **Action** menu, point to **All Tasks**, and click **Stop Service** to stop the service.
6. On the **Action** menu, point to **All Tasks**, and click **Start Service** to start the service.

| Value | Description |
|---|---|
| **certutil** | Specifies the name of the command-line program. |
| **-delreg** | Modifies the registry. |
| **ca\RoleSeparationEnabled** | Indicates the registry value for role separation. |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To display the role separation setting, type the following at a command prompt:

  **certutil -getreg ca\RoleSeparationEnabled**
- To view the complete syntax for this command, at a command prompt, type:

  **certutil -delreg -?**

- To stop and restart the Certificate Services service at the command prompt, type:

  **net stop certsvc**

  **net start certsvc**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Deploying a Public Key Infrastructure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Public key infrastructure**

Computer networks are no longer closed systems in which a user's mere presence on the network can serve as proof of identity. In this age of information interconnection, an organization's network may consist of intranets, Internet sites, and extranets--all of which are potentially susceptible to access by unauthorized individuals who intend to maliciously view or alter an organization's digital information assets.

There are many potential opportunities for unauthorized access to information on networks. A person can attempt to monitor or alter information streams such as e-mail, electronic commerce transactions, and file transfers. Your organization may work with partners on projects of limited scope and duration, with employees whom you know nothing about, but who, nonetheless, must be given access to some of your information resources. If your users have a multitude of passwords to remember for accessing different secure systems, they may choose weak or common passwords to more easily remember them. This not only provides an intruder with a password that is easy to crack, but also one that will provide access to multiple secure systems and stored data.

How can a system administrator be sure of the identity of a person accessing information and, given that identity, control which information that person has access to? Additionally, how can a system administrator easily and securely distribute and manage identification credentials across an organization? These are issues that can be addressed with a well-planned public key infrastructure.

A public key infrastructure (PKI) is a system of digital certificates, certification authorities (CAs) and other registration authorities (RAs) that verify and authenticate the validity of each party that is involved in an electronic transaction through the use of public key cryptography. Standards for PKIs are still evolving, even as they are being widely implemented as a necessary element of electronic commerce. For detailed information about planning a PKI and using public key cryptography, see Certificates Resources on public key infrastructure.

There are a number of reasons why an organization may choose to deploy a PKI using Windows:

- **Strong security.** You can have strong authentication with smart cards. You can also maintain confidentiality and the integrity of transmitted data on public networks by using Internet Protocol security and the confidentiality of stored data by using EFS (encrypting file system).

- **Simplified administration.** Your organization can issue certificates and in conjunction with other technologies eliminate the use of passwords. You can revoke certificates as necessary and publish certificate revocation lists (CRLs). There is the ability to use certificates to scale trust relationships across an enterprise. You can also take advantage of Certificate Services integration with the Active Directory directory service and policy. The capability to map certificates to user accounts is also available.

- **Additional opportunities.** You can exchange files and data securely over public networks, such as the Internet. You have the ability to implement secure e-mail using Secure Multipurpose Internet Mail Extensions (S/MIME) and secure Web connections using Secure Sockets Layer (SSL) or Transport Layer Security (TLS). You can also implement security enhancements to Wireless Networking.

The Windows Server 2003 family has features to help your organization implement a public key infrastructure include:

- **Certificates.** A certificate is basically a digital statement issued by an authority that vouches for the identity of the certificate holder. A certificate binds a public key to the identity of the person, computer, or service who holds the corresponding private key. Certificates are used by a variety of public key security services and applications that provide authentication, data integrity and secure communications across networks such as the Internet.

  The standard certificate format used by Windows certificate-based processes is X.509v3. An X.509 certificate includes information about the person or entity to whom the certificate is issued, information about the certificate, plus optional information about the certification authority issuing the certificate. Subject information may include the entity's name, the public key, and the public-key algorithm.

Users can manage certificates using the Certificates MMC console. For more information, see Certificates overview. Users can also allow certificate autoenrollment to manage their certificates automatically. For more information, see Planning for autoenrollment deployment.

- **Certificate Services**. On Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition, Certificate Services is the component that is used to create and manage certification authorities (CAs). A CA is responsible for establishing and vouching for the identity of certificate holders. A CA also revokes certificates if they should no longer be considered valid and publishes certificate revocation lists (CRLs) to be used by certificate verifiers. The simplest PKI design has only one root CA. In practice, however, the majority of organizations deploying a PKI will use a number of CAs, organized into certification hierarchies.

  Administrators can manage Certificate Services using the Certification Authority MMC console. For more information, see Certificate Services overview.

- **Certificate templates.** Certificates are issued by the CA based on information provided in the certificate request and settings contained in a certificate template. A certificate template is the set of rules and settings that are applied against incoming certificate requests. For each type of certificate that an enterprise CA can issue, a certificate template must be configured.

  Certificate templates are customizable in Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition enterprise CAs, and are stored in Active Directory for use by all CAs in the forest. This allows the administrator to choose one or more of the default templates installed with Certificate Services or to create templates that are customized for specific tasks or roles.

  Administrators can manage Certificate Templates using the Certificate Templates MMC console. For more information, see Certificate Templates.

- **Certificate autoenrollment.** Autoenrollment allows the administrator to configure subjects to automatically enroll for certificates, retrieve issued certificates, and renew expiring certificates without requiring subject interaction. This requires no knowledge by the subject of any certificate operations, unless the certificate template is configured to interact with the subject or the CSP requires interaction (such as with a smart card CSP). This greatly simplifies the experience of the client with certificates and minimizes administrative tasks.

  Administrators can configure autoenrollment through configuration of Certificate Templates and CA settings. For more information see Planning for autoenrollment deployment.

- **Web enrollment pages.** These are a separate component of Certificate Services. These Web pages are installed by default when you set up a CA and allow certificate requesters to submit certificate requests using a Web browser. Additionally, the CA Web pages can be installed on servers running Windows that do not have a certification authority installed. In this case, the Web pages are used to direct certificate requests to a CA that, for whatever reason, you do not want requesters to directly access. If you choose to create custom Web pages for your organization to access a CA, the Web pages provided in your operating system can be used as samples. Refer to the *Microsoft Platform Software Development Kit* for information about customizing Certificate Services and CA Web pages.

- **Smart card support.** Windows supports logon via certificates on smart cards, as well as the use of smart cards to store certificates and private keys. They can be used for Web authentication, secure e-mail, wireless networking and other public key cryptography-related activities. For more information, see Smart Cards.

- **Public key policies.** You can use Group Policy in Windows to distribute certificates to subjects automatically, establish common trusted certification authorities, as well as managing recovery policies for EFS (Encrypting File System). For more information, see Public Key Policies overview

# Certificate Services overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate Services overview**

Certificate Services provides customizable services for issuing and managing certificates used in software security systems employing public key technologies. For background information about public key cryptography and the benefits of having a public key infrastructure (PKI), see Deploying a Public Key Infrastructure.

You can use Certificate Services in the Windows® operating system to create a certification authority (CA) which will receive certificate requests, verify the information in the request and the identity of the requester, issue certificates, revoke certificates, and publish a certificate revocation list (CRL).

For more information about CAs, see Certification Authorities

Certificate Services can also be used to:

- Enroll users for certificates from the CA using the Web or the Certificates Microsoft Management Console (MMC) snap-in, or transparently through autoenrollment.
- Use certificate templates to help simplify the choices a certificate requester has to make when requesting a certificate, depending upon the policy used by the CA.
- Take advantage of the Active Directory® directory service for publishing trusted root certificates, publishing issued certificates, and publishing CRLs.
- Implement the ability to log on to a Windows operating system domain using a smart card.

**Certificate policy**

A certificate policy is a set of instructions or rules that are used when processing certificate requests, issuing certificates, revoking certificates, and publishing CRLs. These instructions are a combination of administrative policy and configuration settings on the CA.

When you install Certificate Services, the CA is configured with a default set of rules and settings. These define CA-specific settings such as the CA's certificate, its default issuance behavior, and its key recovery agents. The CA may also install a number of preconfigured certificate templates, which define what information a certificate request must have and how to process incoming requests for a certificate based on that template. The combination of applying CA settings and certificate template settings, plus the defined administrative guidelines, results in the certificate policy that governs the operation of a CA.

**Processing certificate requests**

A user can request certificates using Microsoft® Internet Explorer 5.0 or later or a browser such as Netscape Navigator 4.7*x* or later. In addition, a user can use the Certificates snap-in to request a certificate from an enterprise CA or an administrator can configure certificate autoenrollment to transparently request and install certificates for users.

When a user initiates a certificate request, a cryptographic service provider (CSP) on their computer generates a public key and private key pair for the user. The user's public key is sent with their necessary identifying information to the CA. If the user's identifying information meets the CA criteria for granting a request, the CA generates the certificate, which is retrieved by the client application and stored locally. For more information about certificates, see Understanding Certificates.

**Security considerations for CAs**

CAs are valuable resources, and you should provide them with a high degree of protection. Specific actions that should be considered include:

- **Physical protection.** Since CAs represent highly-trusted entities within an enterprise, you should protect them from tampering, depending on the inherent value of the certification made by the CA. Physical isolation of the CA server, in a facility accessible only to security administrators, can dramatically reduce the possibility of such attacks.
- **Restoration.** A CA might be lost if there is a hardware failure. This can create a number of administrative and operational problems, and can prevent revocation of existing certificates. Certificate Services supports the backup of a CA

using Backup so that it can be restored at a later time. This is an important part of the overall CA management process.

- **Key management.** The CA's keys are its most valuable asset, because the private key provides the basis for trust in the certification process. Cryptographic hardware modules can provide tamper-resistant key storage and isolate the cryptographic operations from other software running on the server. This reduces the likelihood of a CA key being compromised. Certificate Services supports cryptographic service providers (CSPs) from other sources, but the documentation included with Windows is specific to the software CSPs that are included with Windows. If you use a CSP from another source, you should confirm with the vendor that the CSP can work with Certificate Services.

**Customizing Certificate Services**

Certificate Services includes programmable interfaces so that developers can create support for additional transports, policies, and certificate properties and formats. Refer to the *Microsoft Platform Software Development Kit* for information about customizing Certificate Services.

For more information about Certificate Services, see Understanding Certificate Services

# New features in Certificate Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features in Certificate Services**
Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition have a number of new features and improvements related to Certificate Services and public key infrastructure (PKI). A few new procedures are also provided to demonstrate certificate template editing features and certificate autoenrollment for users and computers.

**New PKI features**
Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition implement new PKI features and improvements.

- **Editable certificate templates and the Certificate Templates MMC snap-in**

  Certificate templates were available in Windows 2000 Certificate Services, but they could not be modified or changed. There is a new Certificate Templates MMC snap-in that enables administrators to:

  - Create a new certificate template by duplicating and renaming an existing template.
  - Modify template properties such as certificate validity period, renewal period, cryptographic service provider (CSP), key size, key archival
  - Establish and apply enrollment policies, issuance policies and application policies.

    For example, a user can enroll themselves for a certificate or an enrollment agent certificate can enroll for a certificate on their behalf. A significant issue with this scenario is that an enrollment agent can enroll for any user in the enterprise. This means the enrollment agent certificate is very powerful and only very trusted people may have access to it.
  - Allow for autoenrollment for certificates based on the template.
  - Set access control on certificate templates to establish which users or computers can enroll and autoenroll for certificates.

  There are now two different versions of certificate templates for Windows Server operating systems. Windows 2000 clients and certificate services can only use version 1 templates. Windows XP and Windows Server 2003 family clients and certificate services will support both version 1 and version 2 templates. Version 1 templates are read-only, but when they are duplicated, the duplicate template is an editable version 2 template.

- **Certificate autoenrollment and autorenewal for all subjects**

  In Windows 2000, it was possible to autoenroll for EFS certificates and computer certificates, however, autoenrollment for users was not possible. The new autoenrollment feature improves both the user and computer enrollment experience. A member of the Enterprise Admins group can specify the types of certificates that any entity should automatically be issued. The enterprise administrator controls autoenrollment by setting security permissions on certificate templates using the Certificate Templates snap-in. A Windows XP or Windows Server 2003 family client then accesses the templates in the Active Directory directory service and, if access has been granted, then it will enroll for those certificates.

  For an example of establishing autoenrollment for user certificates, see Certificate Services example implementation: Establishing autoenrollment for user certificates.

  Autorenewal is a new feature similar to autoenrollment and the same mechanism on the templates is used to control who can autorenew a certificate. Every certificate in the certificate store that has a template extension can potentially be

autorenewed by the system. This means that applications no longer need to worry about certificates expiring.

- **Delta CRLs**

  Many applications require up-to-date certificate revocation status information. This requires the certification authority (CA) to frequently publish a new certificate revocation list (CRL). A CRL is the entire list of revoked certificates, so for a CA with a large amount of issued certificates, this can become a very large list. Even if there are no changes, a CA has to republish the entire list so that applications have the latest information, which involves a lot of repetition. Frequent publication of large objects will in turn generates a large amount of replication traffic.

  Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition have a new feature called delta CRLs, an option in RFC 2459. Delta CRLs are CRLs which contain the list of changes in revocation status from a full "base" CRL. Because delta CRLs are a list of changes and not a restatement of the entire CRL, they are typically much smaller and generate significantly less replication traffic than large base CRLs.

- **Role-based administration**

  Certificate Services in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition allows for the separation of roles for the management and maintenance of a CA. Role separation is not enforced by default, but you can select to enforce assigned roles.

  For more information, see Role-based administration.

- **Key archival and recovery**

  You can configure a CA to archive the keys associated with the certificates it issues. If necessary, you can then recover lost keys through the use of a key recovery agent certificate.

  For more information, see Certificate Services example implementation: Key archival and recovery.

- **Event auditing**

  Event auditing provides the ability to log most events that occur on a CA. This can be useful for monitoring the activities of a CA or the administrative functions, such as certificate issuance and role changes.

  For more information, see Configure event auditing.

- **Qualified subordination**

  Qualified subordination is an extension of standard CA subordination that allows you to:

  - Define the namespaces for which a subordinate CA will issue certificates.
  - Specify the acceptable uses of certificates issued by a qualified subordinate CA.
  - Enable a certificate to be used in separate certification hierarchies.

  For more information, see Qualified subordination.

- **New Certutil.exe commands**

  **certutil -dspublish** [**cert**|**crl**]

  Publishes the CA certificate or the certificate revocation list to Active Directory

  For examples of using **certutil -getkey** and **certutil -recoverkey** to recover archived keys, see Certificate Services example implementation: Key archival and recovery.

# Understanding Certificate Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Certificate Services**
This section covers:

- Processing certificate requests
- Certificate revocation
- Key archival and recovery
- Requesting certificate templates
- Policy and exit modules
- Certification authority hierarchies
- Certification authority database
- Certification authority Web enrollment services
- Interoperability in Certificate Services
- Role-based administration
- Certification Authorities

# Processing certificate requests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Processing certificate requests**

A certification authority (CA) performs the following operations when processing a certificate request:

- **Request reception.** The certificate request is sent by the client application (such as the Certificate Request Wizard in the Certificates snap-in), which formats it into a PKCS #10 or CMC format request and submits it to the CA. On receipt, the CA server engine stores the private key in its certificate database if it is configured for key recovery.

- **Request approval.** The CA server engine calls the CA policy module, which queries the request properties, decides whether the request is authorized or not, and sets optional certificate properties. If the request is denied or set to Pending, the requestor is notified.

- **Certificate formation.** If the request is approved, the CA server engine takes the request and any properties requested by the policy module, and then builds a complete certificate.

- **Certificate publication.** The CA server engine stores the completed certificate in its certificate database and notifies the intermediary application of the request status. If the exit module has requested it, the server engine notifies it of a certificate issuance event. This allows the exit module to perform further operations, such as sending e-mail to the subject or the CA administrator. Meanwhile, the client application gets the issued certificate from the certificate database and saves it in its own local certificate store.

# Certificate revocation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate revocation**
Revocation of a certificate invalidates a certificate as a trusted security credential prior to the natural expiration of its validity period. There are a number of reasons why a certificate, as a security credential, could become untrustworthy prior to its expiration. Examples include:

- Compromise, or suspected compromise, of the certificate subject's private key.
- Compromise, or suspected compromise, of a certification authority's private key.
- Discovery that a certificate was obtained fraudulently.
- Change in the status of the certificate subject as a trusted entity.
- Change in the name of the certificate subject.

A public key infrastructure (PKI) depends on distributed verification of credentials in which there is no need for direct communication with the central trusted entity that vouches for the credentials. This creates a need to distribute certificate revocation information to individuals, computers, and applications attempting to verify the validity of certificates. The need for revocation information and its timeliness will vary, according to the application and its implementation of certificate revocation checking.

To effectively support certificate revocation, the client must determine whether the certificate is valid or has been revoked. To support a variety of scenarios, Certificate Services supports industry-standard methods of certificate revocation. These include publication of certificate revocation lists (CRLs) and delta CRLs in several locations for clients to access, including the Active Directory directory service, Web servers, and network file shares.

CRLs are complete, digitally-signed lists of unexpired certificates that have been revoked. This list is retrieved by clients who can then cache it (based on the configured lifetime of the CRL) and use it to verify certificates presented for use. Because CRLs can get large, depending on the size of the certification authority, delta CRLs can also be published. Delta CRLs contain only the certificates revoked since the last base CRL was published. This allows clients to retrieve the smaller delta CRL and quickly build a complete list of revoked certificates. The use of delta CRLs also allows more frequent publishing, because the size of the delta CRL usually does not require as much overhead as a full CRL.

For conceptual information about using certificate revocation in Certificate Services, see Revoking certificates and publishing CRLs. For procedures to manage certificate revocation, see Manage Certificate Revocation.

# Key archival and recovery

Updated: November 5, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Key archival and recovery**
Windows Server 2003, Enterprise Edition can be configured to archive the private key of specific certificates when they are issued. This private key archive allows the key to be recovered at a later time if the private key is lost. This process is implemented in two separate phases: key archival and key recovery.

| **Tip** |
| --- |
| For updated information, see Active Directory Certificate Services PKI - Key Archival and Management. |

**Key archival**
The process of obtaining a certificate includes the subject locating the appropriate certificate template, gathering the information required by that template, and supplying it to a certification authority. This information normally contains information such as the subject name, public key and supported cryptographic algorithms. When key archival is configured, the subject will also provide their private key to the certification authority. The certification authority stores that private key in its database until you want to perform key recovery.

By default, the private key of issued certificates is not archived. This is because the storage of the private key in multiple locations, by definition, allows more attacks against it. To configure a certification authority to issue certificates with key archival enabled, see Certificate Services example implementation: Key archival and recovery.

**Key recovery**
Subjects can lose their private key in a variety of ways such as accidental deletion or deliberate misuse. An administrator may also want to recover the key of a particular subject to access data protected by that key. Key recovery can be used whenever the key archival process has stored the subject's private key.

The key recovery process requires an administrator to retrieve the encrypted certificate and private key and then a key recovery agent (KRA) to submit to the certification authority. When a correctly signed key recovery request is received, the subject's certificate and private key are provided to the requestor. The requestor would then use the key as appropriate or securely transfer the key to the subject for continued use. No recertification or rekeying is necessary, as the private key is not necessarily compromised.

For more information, see Manage Key Archival and Recovery.

# Requesting certificate templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate templates**

A certificate template profiles certificates based on their intended use. When requesting a certificate from a Microsoft certification authority (CA), the certificate requester will, depending on their access rights, be able to select from a variety of certificate types that are based on certificate templates, such as User and Basic EFS. The certificate template saves users from low-level, technical decisions about the type of certificate that they need. Instead, they can rely on the judgment of their administrators and use the template name that indicates the purpose of the certificate. If none of the preset certificate templates meet your needs, you can create new certificate templates and customize them for a variety of different uses.

For more information, see Certificate Templates.

# Policy and exit modules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policy and exit modules**

One powerful administrative feature of Certificate Services is the ability to control and customize the behavior of the certification authority (CA) through the use of policy and exit modules.

Policy modules can determine whether a certificate request should be automatically approved, denied, or marked as Pending. Exit modules provide an opportunity to perform post-processing after a certificate is issued.

Certificate Services comes with one exit module (Certxds.dll) and one policy module (Certpdef.dll). The policy module includes two separate policies: enterprise and stand-alone. To compare a CA using enterprise policy and a CA using stand-alone policy, see Enterprise certification authorities and Stand-alone certification authorities.

As a CA administrator, you can replace these default modules with your own custom policy and exit modules or commercial policy and exit modules. In addition, if you have upgraded to Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition Certificate Services from an earlier version of Certificate Services, you will have the option of using the policy module you have been using prior to upgrading. It will either be listed as a *legacy* policy module when you look at the properties of the CA or with its original name, depending on how it was created.

The policy module provided with the Microsoft CA performs the following function:

- **Determines the default action of a certification authority upon receiving a certificate request.** Upon receiving a certificate request, a certification authority can either automatically issue a certificate or hold it as Pending until an administrator reviews the request.

  Microsoft certification authorities can either issue a certificate automatically upon receiving a request or hold the request as Pending. In the majority of instances, the administrator of a stand-alone CA will want to have all incoming certificate requests set to Pending. Otherwise, because the stand-alone CA does not verify the identity of requesters via the Active Directory directory service, there is no way to verify the identity and validity of the certificate requester.

The CA can only have one policy module loaded at a time. The Windows 2000 CA policy module contained a great deal of functionality that has been integrated into the core certification authority functionality. This allows the policy module to be more easily replaced without losing functionality.

The exit module that is provided with the Microsoft CA performs the following functions:

- **Sends e-mail when a certification event occurs.** If the CA is configured to send e-mail when specific events occur, the exit module will do so.

- **Allows certificate publication to the file system.** If the certificate request specifies a location to publish the certificate in the file system, the exit module will do so.

Please note that this is not an exhaustive list of the functions of the exit module. Unlike the policy module, multiple exit modules can be used by a CA simultaneously.

To configure the settings of the default policy and exit modules, see Configuring the policy and exit modules. To configure e-mail sending options, see Send e-mail when a certification event occurs.

**Customizing Certificate Services policy and exit modules**

Programmable interfaces are included in Certificate Services for developers to create customized policy modules. For more information, refer to the *Microsoft Platform Software Development Kit*.

If you have created a customized policy module using the guidelines in the *Microsoft Platform Software Development Kit* and you want to change the policy module, see Select a different policy module.

If you have created a customized exit module using the guidelines in the *Microsoft Platform Software Development Kit* and you want to change or add an exit module, see Select a different exit module.

# Certification authority hierarchies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certification authority hierarchies**

The Microsoft public key infrastructure (PKI) supports a hierarchical certification authority (CA) model. A certification hierarchy provides scalability, ease of administration, and consistency with a growing number of commercial and other CA products.

In its simplest form, a certification hierarchy consists of a single CA. However, in general, a hierarchy will contain multiple CAs with clearly defined parent-child relationships. In this model, the child subordinate certification authorities are certified by their parent CA-issued certificates, which bind a certification authority's public key to its identity. The CA at the top of a hierarchy is referred to as the root authority, or root CA. The child CAs of the root CAs are called subordinate certification authorities (CAs).

In Windows XP and the Windows Server 2003 family, if you trust a root CA (by having its certificate in your Trusted Root Certification Authorities certificate store), you trust every subordinate CA in the hierarchy, unless a subordinate CA has had its certificate revoked by the issuing CA or has an expired certificate. Thus, any root CA is a very important point of trust in an organization and should be secured and maintained accordingly.

Verification of certificates thus requires trust in only a small number of root CAs. At the same time, it provides flexibility in the number of certificate-issuing subordinate CAs. There are several practical reasons for supporting multiple subordinate CAs, including:

- **Usage.** Certificates may be issued for a number of purposes, such as secure e-mail and network authentication. The issuing policy for these uses may be distinct, and separation provides a basis for administering these polices.

- **Organizational divisions.** There may be different policies for issuing certificates, depending upon an entity's role in the organization. Again, you can create subordinate CAs to separate and administer these policies.

- **Geographic divisions.** Organizations may have entities at multiple physical sites. Network connectivity between these sites may dictate a requirement for multiple subordinate CAs to meet usability requirements.

- **Load balancing.** If your PKI is going to support the issuing of a large number of certificates, having only one certification authority issue and manage all of these certificates can result in considerable network load for that single certification authority. Using multiple subordinate certification authorities to issue the same kind of certificates divides the network load between certification authorities.

- **Backup and fault tolerance.** Multiple certification authorities increase the possibility that your network will always have operational certification authorities available to service users.

Such a certification authority hierarchy also provides administrative benefits, including:

- Flexible configuration of the CA security environment to tailor the balance between security and usability, such as key strength, physical protection, and protection against network attacks. For example, you may choose to employ special purpose cryptographic hardware on a root CA, operate it in a physically secure area, or operate it offline. These may be unacceptable for subordinate CAs, due to cost or usability considerations.

- The ability to "turn off" a specific portion of the CA hierarchy without affecting the established trust relationships. For example, you can easily shut down and revoke an issuing CA certificate that is associated with a specific geographic site without affecting other parts of the organization.

For more information, see Establishing a certification hierarchy

# Certification authority database

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certification authority database**
When you install a certification authority (CA), you create a certification authority database on the server. This database should be located on an NTFS file system partition on the server's disk drives to provide the best security possible for the database file. You specify the locations for the database during the setup of a CA. By default, the database is located in:

*systemroot*\system32\certlog

The name of the database file is based on the name of the CA, with an .edb extension.

The Certification Authority MMC console provides a view into the certification authority database on a CA and the ability to administer the database.

A certification authority database stores:

- Every certificate issued by the CA.
- Every private key archived by the CA.
- Every certificate revoked by the CA.
- Every certificate request received by the CA, regardless of the disposition.

You also specify the location of the certificate database log during Certificate Services setup. The certificate database log keeps a record of every transaction involving the certificate database. Certificate database logs are used when restoring the CA from a backup. If a CA is restored from a backup that is one month old, then the certification database logs that have been generated since the last backup can be replayed against the database to restore it to its most current state. When you back up a certification authority, the existing certificate database logs will be truncated in size, because they will no longer be needed to restore the certificate database to its most current state.

For more information about CA backup and restore, see Backing up and restoring a certification authority.

# Certification authority Web enrollment services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certification authority Web enrollment services**

A set of certification authority (CA) Web pages is provided with Certificate Services in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. These Web pages provide a simple user interface to perform many of the common user tasks on a CA, and they are installed by default when you set up Certificate Services.

These Web enrollment pages allow you to connect to the CA via a Web browser and perform common tasks, such as requesting certificates from a CA, requesting the CA's certificate, submitting a certificate request using a PKCS #10 file, retrieving the CA's certificate revocation list (CRL) or performing smart card certificate enrollment. For a stand-alone CA, the Web pages are the primary way a certificate requester can interface with the CA, since the Certificates snap-in cannot be used to request certificates from a stand-alone CA. Enterprise CAs can accept certificate requests via the Certificates snap-in or the Web enrollment pages.

You can install Web enrollment pages for a CA on a Windows server 2003 family server that is not a CA in order to divert Web-based traffic from the actual CA. For more information about installing the Web pages on a server that is not a CA, see Set up certification authority Web enrollment support. You can also configure your Web server to use Secure Sockets Layer (SSL) encryption to protect the network traffic that contains the enrollment request and response. This is especially important when clients are using Windows 95, Windows 98, Windows Millennium Edition and Windows 2000 because of their handling of certificates.

For more information about using the Web enrollment pages, see Using Windows 2000 Certificate Services Web pages or Using Windows Server 2003 Certificate Services Web pages.

# Interoperability in Certificate Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interoperability in Certificate Services**
By using industry-standard X.509v3 certificate formats and open interfaces, Certificate Services operates with many products and technologies that support the use of public key cryptography and public key infrastructure (PKI).

**Internet standards**
PKI standards for the Internet are still evolving as this is being written. However, Certificate Services has been designed to adhere to existing PKI interoperability standards established by the Internet Engineering Task Force (IETF). The IETF working group charged with defining the basis for an interoperable PKI is PKIX. For more information on PKIX, see the PKIX Web page. The Web page also has a link to RFC 2459, "Internet Public Key Infrastructure X.509 Certificate and CRL Profile, Part 1," which is the specification for the basic architecture of PKI.

**Public Key Cryptography Standards**
There is a set of *de facto* cryptographic message standards called Public Key Cryptography Standards (PKCS) which are developed and maintained by RSA Laboratories. (For more information, see the Web page at RSA Laboratories.)

PKCS provides a basic, but well-understood framework for interoperability. The standards that are most relevant to PKI and ones that are used by Certificate Services are PKCS #7, Cryptographic Message Syntax Standard, PKCS #10, Certification Request Syntax Standard, and PKCS #12, Personal Information Exchange Syntax Standard.

**Web servers**
On a corporate intranet or on the Internet, Web servers, such as those using Microsoft Internet Information Services (IIS), can perform client authentication for secure communications using certificates generated by Certificate Services. Certificate Services can also generate server certificates used by IIS and other Web servers to provide server authentication to assure clients that they are communicating with the intended entity.

**Web browsers**
Certificate Services can issue certificates that are used by Web browsers that support client authentication, such as Microsoft Internet Explorer 5.01 or later. Certificate Services also supports Web enrollment, where a Web browser uses Web pages to request and retrieve a certificate.

**Windows**
Windows enables you to map certificates to users and groups. This mapping is automatic if the certificate is issued from an enterprise certification authority (CA). You can then use standard Windows administrative tools, such as security permission sets, to implement Internet and intranet security requirements taking advantage of the relationship established between domain users and the certificates issued to them.

For more information about mapping certificates in Windows see Mapping certificates to user accounts.

### Note

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Role-based administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Role-based administration**

You can use role-based administration to organize your certification authority (CA) administrators into separate, predefined CA roles, each with its own set of tasks. Roles are assigned using each user's security settings. You assign a role to a user by assigning that user the specific security settings that are associated with the role. A user that has one type of permission, such as Manage CA permission, can perform specific CA tasks that a user with another type of permission, such as Issue and Manage Certificates permission, cannot perform. For more information, see Role explanation.

**Note**

- Role-based administration is supported by both Windows server 2003 enterprise and stand-alone certification authorities. For information about using Windows 2000 server certification authorities and role-based administration, see Windows 2000 roles andWindows server 2003role-based administration.

**Role explanation**

Role-based administration involves CA roles, users, and groups. To assign a role to a user or group, you must assign the role's corresponding security permissions, group memberships, or user rights to the user or group. These security permissions, group memberships, and user rights are used to distinguish which users have which roles. The following table describes the CA roles of role-based administration and the groups relevant to role-based administration.

| Roles and groups | Security permission | Description |
|---|---|---|
| CA Administrator | **Manage CA** permission | Configure and maintain the CA. This is a CA role and includes the ability to assign all other CA roles and renew the CA certificate. |
| Certificate Manager | **Issue and Manage Certificates** permission | Approve certificate enrollment and revocation requests. This is a CA role. This role is sometimes referred to as CA Officer. |
| Backup Operator | **Back up file and directories** and **Restore file and directories** permissions | Perform system backup and recovery. This is an operating system role. |
| Auditor | **Manage auditing and security log** permission | Configure, view, and maintain audit logs. This is an operating system role. |
| Enrollees | Authenticated Users | Enrollees are clients who are authorized to request certificates from the CA. This is not a CA role. |

All CA roles are assigned and modified by local Administrators, Enterprise Admins, and Domain Admins. Local Administrators, Enterprise Admins, and Domain Admins are CA Administrators by default on an Enterprise CA. Only local Administrators are CA Administrators by default on a stand-alone CA. If the stand-alone CA is logged on to an Active Directory domain, Domain Admins are also CA Administrators.

The CA Administrator and Certificate Manager roles can be assigned to both Active Directory users or local users in the Security Accounts Manager (SAM) of the local computer, which is the local security account database. As a best practice, assign roles to group accounts instead of individual user accounts.

Only CA Administrator, Certificate Manager, Auditor, and Backup Operator are CA roles. The other users described in the table are relevant to role-based administration and should be understood before assigning CA roles.

Only CA Administrators and Certificate Managers are assigned using the Certification Authority Microsoft Management Console (MMC) snap-in. Other roles, users, and groups are specified in their related consoles. To change the roles of a user, you must change the user's security permissions, group membership, or user rights. For information about assigning roles, see Assigning roles.

When key archival is configured, the subject obtaining a certificate from a CA will provide their private key to the CA. The CA stores that private key in its database until key recovery. Only a Certificate Manager can get the encrypted private key blob out

of the CA database, which is then passed on to key recovery agents (KRAs). For more information, see Key archival and recovery.

**Roles and activities**

Each CA role has a specific list of CA administration tasks associated with it. The following table lists all the CA administration tasks along with the roles in which they are performed.

| Activity | CA Administrator | Certificate Manager | Auditor | Backup Operator | Local Administrator | Notes |
|---|---|---|---|---|---|---|
| Install CA | | | | | X | |
| Configure policy and exit module | X | | | | | |
| Stop and start the Certificate Services service | X | | | | | |
| Configure extensions | X | | | | | |
| Configure roles | X | | | | | |
| Renew CA keys | | | | | X | |
| Define key recovery agents | X | | | | | |
| Configure Certificate Managers restrictions | X | | | | | |
| Delete single row in database | X | | | | | |
| Delete multiple rows in database (bulk deletion) | X | X | | | | The user must be both a CA Administrator and a Certificate Manager. This does not work when Role Separation is enforced. |
| Enable role separation | | | | | X | |
| Issue and approve certificates | | X | | | | |
| Deny certificates | | X | | | | |
| Revoke certificates | | X | | | | |
| Reactivate certificates placed on hold | | X | | | | |
| Renew certificates | | X | | | | |
| Enable, publish, or configure CRL schedule | X | | | | | |

| | | | | | | |
|---|---|---|---|---|---|---|
| Recover archived key | | X | | | | Only a Certificate Manager can retrieve the encrypted key data structure from the database. The private key of a valid Key Recovery Agent is required to decrypt the key data structure and generate a PKCS#12 file. |
| Configure audit parameters | | | X | | | By default, the local Administrator holds the system audit user right. |
| Audit logs | | | X | | | By default, the local Administrator holds the system audit user right. |
| Back up system | | | | X | | By default, the local Administrator holds the system backup user right. |
| Restore system | | | | X | | By default, the local Administrator holds the system backup user right. |
| Read CA database | X | X | X | X | | By default, the local Administrator holds the system audit and backup user rights. |
| Read CA configuration information | X | X | X | X | | By default, the local Administrator holds the system audit and backup user rights. |

**Notes**

- Enrollees are allowed to read CA properties and certificate request lists (CRLs), and can request certificates. On an Enterprise CA, a user must have Read and Enroll permissions on the certificate template to request a certificate. For more information, see Allow subjects to request a certificate that is based on the template.
- CA Administrators, Certificate Managers, Auditor, and Backup Operators have implicit Read permissions.
- An Auditor holds the system audit user right.
- A Backup Operator holds the system backup user right. In addition, the Backup Operator has the ability to start and stop the Certificate Services service.

**Assigning roles**

The CA Administrator for a CA assigns users to the separate roles of role-based administration by giving each user the security settings required by a role. The CA Administrator can assign a user to more than one role, but the CA is more secure when each user belongs to one role only. When each CA role belongs to one user only, then there are fewer CA tasks that can be compromised if a user's account becomes compromised.

For more information on assigning roles, see Manage Role-based Administration.

**Administrator concerns**

The default installation setting for a stand-alone CA is to have members of the local Administrators security group as CA Administrators. The default installation setting for an Enterprise CA is to have local Administrators, Enterprise Admins, and Domain Admins as CA Administrators. To limit the power of any of these accounts, they should be removed from the CA Administrator and Certificate Manager roles once all CA roles are assigned.

As a best practice, group accounts that have been assigned CA Administrator or Certificate Manager roles should not be members of the local Administrators security group. Also, CA roles should only be assigned to group accounts and not individual user accounts.

**Note**

- Membership in the local Administrators group on the CA is required to renew the CA certificate. Members of this group are considered to be all powerful on the CA, with administrative authority over all other CA roles.

**Windows 2000 roles and Windows server 2003 role-based administration**

Windows 2000 server CA administration is changed in Windows Server 2003, Standard Edition CA role-based administration. Windows 2000 server administrators can perform any activity on a Windows 2000 server CA, but once CA roles are assigned using Windows server 2003 role-based administration, its administrators are subject to its roles. An administrator that could perform all tasks on a Windows 2000 server CA will only be able to perform the tasks associated with his or her role on the Windows server 2003 CA. After upgrading a Windows 2000 server CA to a Windows server 2003 CA, its administrators need to be assigned to the roles defined in the role-based administration for the Windows server 2003 CA.

**Certificate Services service level functionality**

Role-based administration applies to the Certificate Services service only. Any services other than Certificate Services service are unaffected by the assignment of CA roles.

**Role separation**

The separation of CA roles can be enforced using *role separation*. Once enforced, role separation allows a user to be assigned only a single role. If a user is assigned to more than one role and attempts to perform an operation on the CA, the operation is denied. For this reason, before role separation is enabled, a user should be assigned only one CA role.

This feature is valuable for large enterprises where the separation of roles ensures that the compromise of a user's account does not compromise the entire CA administered by the user. For more information, see Using role separation.

# Certification Authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certification authorities**
A certification authority (CA) is an entity entrusted to issue certificates to individuals, computers, or organizations that affirm the identity and other attributes of the certificate subject to other entities.

- Types of certification authorities
- Enterprise certification authorities
- Stand-alone certification authorities
- Qualified subordination

# Types of certification authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Types of certification authorities**

A certification authority (CA) accepts a certificate request, verifies the requester's information according to the policy of the CA, and then uses its private key to apply its digital signature to the certificate. The CA then issues the certificate to the subject of the certificate for use as a security credential within a public key infrastructure (PKI). A CA is also responsible for revoking certificates and publishing a certificate revocation list (CRL).

A CA can be an outside entity, such as VeriSign, or it can be a CA that you create for use by your organization by installing Microsoft Certificate Services. Each CA can have distinct proof-of-identity requirements for certificate requesters, such as a Windows Server 2003 family domain account, employee badge, driver's license, notarized request, or physical address. Identification checks such as this often warrant an onsite CA, so that organizations can validate their own employees or members.

Microsoft enterprise CAs use a person's user account credentials as proof of identity. In other words, if you are logged on to a Windows Server 2003 family domain and request a certificate from an enterprise CA, the CA knows that you are who the Active Directory directory service says you are.

Every CA also has a certificate to confirm its own identity, issued by another trusted CA or, in the case of root CAs, issued by itself. It is important to remember than anyone can create a CA. The real question revolves around whether you, as a user or an administrator, trust that CA and, by extension, the policies and procedures that CA has in place for confirming the identity of the entities issued certificates by that CA.

For more information about certificates, see Certificates overview.

**Root and subordinate certification authorities**

A *root CA*, sometimes called a root authority, is meant to be the most trusted type of CA in an organization's PKI. Typically, both the physical security and the certificate issuance policy of a root CA are more rigorous than those for subordinate CAs; if the root CA is compromised or issues a certificate to an unauthorized entity, then any certificate-based security in your organization is suddenly vulnerable. While root CAs can be used to issue certificates to end users for such tasks as sending secure e-mail, in most organizations they will only be used to issue certificates to other CAs, called subordinate CAs.

A *subordinate CA* is a CA that has been certified by another CA in your organization. Typically, a subordinate CA will issue certificates for specific uses, such as secure e-mail, Web-based authentication, or smart card authentication. Subordinate CAs can also issue certificates to other, more subordinate CAs. Together, a root CA, the subordinate CAs that have been certified by the root, and subordinate CAs that have been certified by other subordinate CAs form a certification hierarchy.

For more information about certification hierarchies, see Certification authority hierarchies.

**Enterprise and stand-alone certification authorities**

This version of Certificate Services supports the installation of stand-alone CAs and enterprise CAs. For information about the operational characteristics of enterprise CAs and stand-alone CAs, see Enterprise certification authorities and Stand-alone certification authorities.

# Enterprise certification authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enterprise certification authorities**

The Enterprise Administrator can install Certificate Services to create an enterprise certification authority (CA). Enterprise CAs can issue certificates for purposes such as digital signatures, secure e-mail using S/MIME (Secure Multipurpose Internet Mail Extensions), authentication to a secure Web server using Secure Sockets Layer (SSL) or Transport Layer Security (TLS), and logging on to a Windows Server 2003 family domain using a smart card.

An enterprise CA has the following features:

- An enterprise CA requires the Active Directory directory service.
- When you install an enterprise root CA, it uses Group Policy to propagate its certificate to the Trusted Root Certification Authorities certificate store for all users and computers in the domain. You must be a Domain Administrator or be an administrator with write access to Active Directory to install an enterprise root CA.
- Certificates can be issued for logging on to a Windows Server 2003 family domain using smart cards.
- The enterprise exit module publishes user certificates and the certificate revocation list (CRL) to Active Directory. In order to publish certificates to Active Directory, the server that the CA is installed on must be a member of the Certificate Publishers group. This is automatic for the domain the server is in, but the server must be delegated the proper security permissions to publish certificates in other domains. For more information about the exit module, see Policy and exit modules.

An enterprise CA uses certificate types, which are based on a certificate template. The following functionality is possible when you use certificate templates:

- Enterprise CAs enforce credential checks on users during certificate enrollment. Each certificate template has a security permission set in Active Directory that determines whether the certificate requester is authorized to receive the type of certificate they have requested.
- The certificate subject name can be generated automatically from the information in Active Directory or supplied explicitly by the requestor.
- The policy module adds a predefined list of certificate extensions to the issued certificate. The extensions are defined by the certificate template. This reduces the amount of information a certificate requester has to provide about the certificate and its intended use.

For more information, compare Stand-alone certification authorities. For more information about certificate templates, see Requesting certificate templates. For general information about CAs, see Certification Authorities.

# Stand-alone certification authorities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Stand-alone certification authorities**

You can install Certificate Services to create a stand-alone certification authority (CA). Stand-alone CAs can issue certificates for purposes such as digital signatures, secure e-mail using S/MIME (Secure Multipurpose Internet Mail Extensions), and authentication to a secure Web server using Secure Sockets Layer (SSL) or Transport Layer Security (TLS).

A stand-alone CA has the following characteristics:

- Unlike an enterprise CA, a stand-alone CA does not require the use of the Active Directory directory service. Stand-alone CAs are primarily intended to be used as Trusted Offline Root CAs in a CA hierarchy or when extranets and the Internet are involved. Additionally, if you want to use a custom policy module for a CA, you would first install a stand-alone CA and then replace the stand-alone policy module with your custom policy module.

- When submitting a certificate request to a stand-alone CA, a certificate requester must explicitly supply all identifying information about themselves and the type of certificate that is wanted in the certificate request. (This does not need to be done when submitting a request to an enterprise CA, since the enterprise user's information is already in Active Directory and the certificate type is described by a certificate template). The authentication information for requests is obtained from the local computer's Security Accounts Manager database.

- By default, all certificate requests sent to the stand-alone CA are set to Pending until the administrator of the stand-alone CA verifies the identity of the requester and approves the request. This is done for security reasons, because the certificate requester's credentials are not verified by the stand-alone CA.

- Certificate templates are not used.

- No certificates can be issued for logging on to a Windows Server 2003 family domain using smart cards, but other types of certificates can be issued and stored on a smart card.

- The administrator has to explicitly distribute the stand-alone CA's certificate to the domain user's trusted root store or users must perform that task themselves.

When a stand-alone CA uses Active Directory, it has these additional features:

- If a member of the Domain Administrators group or an administrator with write access to Active Directory, installs a stand-alone root CA, it is automatically added to the Trusted Root Certification Authorities certificate store for all users and computers in the domain. For this reason, if you install a stand-alone root CA in an Active Directory domain, you should *not* change the default action of the CA upon receiving certificate requests (which marks requests as Pending). Otherwise, you will have a trusted root CA that automatically issues certificates without verifying the identity of the certificate requester.

- If a stand-alone CA is installed by a member of the Domain Administrators group of the parent domain of a tree in the enterprise, or by an administrator with write access to Active Directory, then the stand-alone CA will publish its CA certificate and the certificate revocation list (CRL) to Active Directory.

For more information, compare Enterprise certification authorities. For general information about CAs, see Certification Authorities.

# Qualified subordination

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Qualified subordination**

Qualified subordination is an extension of standard certification authority (CA) subordination that allows you to:

- Define the namespaces for which a subordinate CA will issue certificates.
- Specify the acceptable uses of certificates issued by a qualified subordinate CA.
- Create trust between separate certification hierarchies.

For more information, see Qualified subordination overview.

**Qualified subordination properties**

Qualified subordination properties are defined in the CA certificate request for a subordinate CA. The CA certificate that is used to install a qualified subordinate CA contains extensions where the different qualified subordination properties are listed. The following table describes the extensions in the CA certificate that are used to install a qualified subordinate CA:

| Extension | Description |
|---|---|
| Name constraints | The range of namespaces that are permitted or excluded by the qualified subordinate CA and its subordinates. |
| Policies | The list of acceptable policies for a certificate, included in the certificates issued by the qualified subordinate CA. These policies are identified in a certificate by object identifiers (also known as OIDs) and include both Issuance policies and Application policies policies. The object identifiers that are used are enterprise-dependent (or dependent within the scope of the object identifiers you use). The object identifier for an application in one PKI deployment must be different from another. |
| Mapping policies between trust hierarchies | Determines how a policy object identifier from one trust hierarchy is mapped to a policy object identifier of another trust hierarchy. |
| Policy constraints | Defines the certification path length required and allowed for policy identifiers and policy mapping. |

All features of qualified subordinate CAs are new to the Windows Server 2003 family and are not available on Windows 2000 Server. To use these new features, you must use a Windows Server 2003 certification authority.

**Note**

- The constraints and policy types listed above are defined in RFC 2459. For more information on RFCs, see the RFC Editor Web site.

**Intranet and extranet qualified subordination**

Qualified subordination may be used in both intranet and extranet environments. Intranet-qualified subordination involves a parent CA issuing a CA certificate to a qualified subordinate CA within a company's intranet. For example, you might install a qualified subordinate CA to issue certificates for a specific network domain in your network. Extranet qualified subordination establishes trust between CAs in separate networks.

Extranet qualified subordination is also commonly called *cross-certification* because trust is being established across separate certification hierarchies. For Windows Server 2003 certification authorities, *cross-certification* is synonymous with *qualified subordination*.

**Name constraints**

Name constraints specify a range of permitted and excluded namespaces that a qualified subordinate CA and its subordinates will use when evaluating certificate requests. A user requesting a certificate from a qualified subordinate CA is identifiable by one or more of the namespaces required by the certificate template for which the request is made. Name constraints are defined using the namespaces used in your network, such as DNS domain names. By permitting or excluding a namespace, the qualified subordinate CA permits or exclude all subjects that are identifiable by that namespace from receiving one of its certificates.

Name constraints apply to subtrees of a namespace. A permitted name constraint defines the namespace within which the CA may issue certificates. An excluded name constraint is used to exclude a subspace of a permitted namespace. For example, a CA with the permitted name constraint example.microsoft.com may have an excluded name constraint of TestDomain.example.microsoft.com. In this case, the CA and its subordinates will issue certificates for users within the example.microsoft.com namespace but not for users within the TestDomain.example.microsoft.com namespace.

**Name constraint definition and usage**

When the CA certificate for the qualified subordinate CA is created, name constraints are defined to determine what namespaces the qualified subordinate CA will permit or exclude. When the installed qualified subordinate CA receives a certificate request from an entity such as a user, name constraints determine whether the qualified subordinate CA will issue the certificate.

When someone submits a certificate request for a qualified subordinate CA to the parent CA, the parent CA uses the certificate path to verify that the qualified subordinate CA will not permit names that are excluded by any other CA in the certification path. If the name constraints defined in the CA certificate request permit names that a CA in the certification path excludes, then the certificate request is denied. If the permitted namespaces defined in the CA certificate request do not conflict with the permitted namespaces of the CAs in the certification path, then the CA certificate request is successful.

For a certificate request that is submitted to a qualified subordinate CA to be successful, all namespaces identified with the user in the certificate request must be within permitted namespaces and none may be within an excluded namespace.

The following name forms are allowed as name constraints. The RFCs listed may be found at the RFC Editor Web site.

| Name form | Resource |
|---|---|
| Directory name (for example, Active Directory distinguished name) | Object names |
| DNS | RFC 1024 |
| E-mail | RFC 822 |
| URI/URL | RFC 1738 |
| User principal name (UPN) | For more information, see Active Directory naming. |
| IP address | IPv4 RFC 791; IPv6 RFC 1883 |

**Policies**

Certificate policies describe the policies according to which a certificate was issued and define how it may be used. There are two types of policies used in qualified subordination:

- Issuance policies
- Application policies

Both policy types can be included in all types of certificates, including CA certificates and user certificates. This availability is in contrast to name constraints, policy mapping, and policy constraints, which are only used in creating the CA certificate for a qualified subordinate CA.

The policies that are available to a certificate template are first defined in the CA certificate for the qualified subordinate CA that will use certificate templates. Each policy listed has a corresponding object identifier (also known as an OID) identifying the policy. The object identifiers used are restricted to that policy for the entire public key infrastructure (PKI). The object identifiers assigned to policies in one PKI may be mapped to the policies in a separate PKI to facilitate trust. For more information, see Mapping policies between trust hierarchies.

The issuance and application policies that are placed on a qualified subordinate CA must be within the set of policies object

identifiers defined for all the CAs in the certification path of the qualified subordinate CA. When a qualified CA certificate request is evaluated, the policy object identifiers contained in the request are evaluated against the policy object identifiers used in the entire certification path to determine that the policy object identifiers contained in the request are a subset of the object identifiers used in the path. For a qualified subordinate CA to use issuance policies, policies must be present at every CA in the certificate hierarchy between the root CA and itself. For this reason, policy cannot be removed from a certification hierarchy, but can only be constrained when installing a qualified subordinate CA.

**Issuance policies**
The issuance policies that are contained in a certificate identify the assurance level of the certificate's subject when that subject presents the certificate to another entity. *Assurance* describes the extent to which a CA trusts a subject's identification; for example, whether the user is recognized by domain authentication only or if the user has passed multiple authentication stages. Assurance levels are defined for a PKI and issuance policies are used to represent them in certificates.

When a subject uses a certificate that contains an issuance policy, security entities can identify the assurance level of that subject and react accordingly. The security credentials that these assurance levels represent depend on how the policies are defined in the PKI.

For more information, see Issuance policies.

**Application policies**
Application policies are included in a certificate because they are required by the applications that will receive these certificates. Some applications have policy requirements and maintain a list of the policies that they will accept. When an application receives signed information, it compares the application policy object identifiers in the received certificate to its list or required policies. For example, a remote access server may require that a Client Authentication application policy be present in a certificate that is presented by a client performing a remote logon.

Application policies are similar to the Extended Key Usage extension in a certificate, as both use one or more object identifiers to prescribe how the public key in a certificate must be used. Extended Key Usage is still supported by Windows Server 2003 CAs to provide for PKIs that use this extension, but application policies replace them.

For more information, see Application policies.

**Policy mapping**
Policy mapping allows you to map a certificate policy object identifier in one trust hierarchy to a policy object identifier used in another trust hierarchy in your intranet or extranet. The policy mappings are defined in the CA certificate request for a qualified subordinate CA. Each pair of policies that is configured on the qualified subordinate CA indicates that it considers its trust hierarchy's policies equivalent to those in the other trust hierarchy.

For an example of policy mapping, see Qualified subordination overview.

When mapping the policies used in an external trust hierarchy, the qualified subordinate CA that contains the policy mappings is said to *subordinate* the CA in the external trust hierarchy whose policies it has mapped. This subordination does not require the administrator of the external trust hierarchy's CA to perform any task. This allows you to set up a trust relationship with another trust hierarchy by subordinating a single subordinate CA or the root CA of the external PKI.

For more information, see Mapping policies between trust hierarchies.

**Policy constraints**
Policy constraints restrict certificate validation in two ways:

- They require that each CA certificate in a certification path contain a specific policy.
- They specify the number of CA certificates that are permitted in a certification path before policy mapping is no longer allowed.

Policy constraints are applied to both issuance and application policies. For more information, see Policy constraints.

**Unexpected trust**
When mapping policies between trust hierarchies in two different companies, there could be a problem of unexpected trust if a third company maps its policy object identifier to the mapped policies of one of the two companies. In this case, the third company is trusted by both of the other companies, which may not be wanted. In addition, either of the companies could make modifications to their certification hierarchies that would have the same effect. Policy constraints resolve this unexpected trust by restricting the certification path depth in which policy mapping may be used.

For more information, see Mapping policies between trust hierarchies; Policy constraints

**Notes**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.
- Qualified subordination is performed by the parent CA on any subordinate CA and can therefore by applied to any type of CA, such as Windows NT 4.0, Windows 2000 Server, or other CAs.
- Qualified subordinate CA certificate renewal is the same as standard subordinate CA renewal.
- When qualified subordinate CA certificates and cross-certificates are revoked, they should also be deleted from the Active Directory directory service. This deletion is not required for security reasons, but is considered a best practice, because it also removes the certificates from the Local Machine certificates store of client computers.

# Using Certificate Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Certificate Services**
This section covers:

- Installing and configuring a certification authority
- Configuring the policy and exit modules
- Establishing a certification hierarchy
- Backing up and restoring a certification authority
- Revoking certificates and publishing CRLs
- Mapping certificates to user accounts
- Renewing a certification authority
- Managing Certificate Services from a command prompt
- Certificate Services Example Implementations
- Using Qualified Subordination

# Installing and configuring a certification authority

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing and configuring a certification authority**
This section will give you additional information you need to install and configure a certification authority (CA).

**Planning the installation of a certification authority**
Before installing Certificate Services, you should plan the deployment of certification authorities (CAs) and Deploying a Public Key Infrastructure in your organization.

For more information about deploying a PKI, see Certificates Resources in public key infrastructure and Microsoft Windows Deployment and Resource Kits.

**Ways to install Certificate Services to create a certification authority**
If you are installing Certificate Services, there are a number of situations in which you may want to set up a CA. (The most typical is listed first here.)

- **After base setup has completed**:

  To install Certificate Services on a server that already has Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition installed, open **Add or Remove Programs** in **Control Panel**. (To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.) After you select Certificate Services for installation, the Certificate Services Installation Wizard guides you through the installation process.

  For the procedures to set up a certification authority (CA) as part of the base setup, see Set Up a Certification Authority.

- **As part of** Windows Server 2003 **family base setup**:

  Although Certificate Services is a service and is included with the Windows Server 2003 family, it is not installed as part of the initial installation process by default. (You do not want every file server to be a CA.)

  To install Certificate Services during the initial base installation of the Windows Server 2003 family, you must select it from the optional components list that is displayed during setup. Certificate Services will not actually be installed until you log on to the server after setup has completed. Then, a message will prompt you to complete the setup of the CA.

  This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**Setup options and information**
When you set up Certificate Services, you will be prompted for the following information:

**Certification authority type selection**
During the Certificate Services installation, you can choose to set up any of the following types of certification authority (CA):

| Certification Authority Type | Description |
|---|---|
| Enterprise root CA | An enterprise root CA is a top-level CA in a certification hierarchy. An enterprise root CA requires the Active Directory directory service. It self-signs its own CA certificate and uses Group Policy to publish that certificate to the Trusted Root Certification Authorities store of all servers and workstations in the domain. Normally, an enterprise root CA does not directly provide resources for user and computer certificates, but is the foundation for a certificate hierarchy. For more information, see Enterprise certification authorities |

| | |
|---|---|
| Enterprise subordinate CA | An enterprise subordinate CA must obtain its CA certificate from another CA. An enterprise subordinate CA requires Active Directory. You use enterprise subordinate CAs when you want to take advantage of Active Directory, certificate templates, and smart card logon to Windows XP and computers running Windows Server 2003 family operating systems |
| Stand-alone root CA | A stand-alone root CA is a top-level CA in a certification hierarchy. The stand-alone root CA may or may not be a member of a domain and, therefore, does not require Active Directory. However, it will use Active Directory if it exists for publishing certificates and certificate revocation lists. Since a stand-alone root CA does not require Active Directory, it can easily be disconnected from the network and placed in a secure area, which is useful when creating a secure offline root CA. For more information, see Stand-alone certification authorities |
| Stand-alone subordinate CA | A stand-alone subordinate CA must obtain its CA certificate from another CA. The stand-alone subordinate CA may or may not be a member of a domain and, therefore, does not require Active Directory. However, it will use Active Directory if it exists for publishing certificates and certificate revocation lists. It must obtain its CA certificate from another CA. |

**Note**

- Certificate Services should not be installed on any node in a server cluster as this configuration may not allow Certificate Services to run properly and is therefore not supported.

**Installing Web enrollment support**

You may want to install a certification authority infrastructure within a defined security boundary and only allow specific computers to communicate with your certification authority. This means clients cannot connect directly to a CA to request and retrieve certificates. Or you may want to set up a CA that supplies certificates to Internet-based subjects. You may want to place a layer of insulation between these clients and the CA. Web enrollment allows these scenarios to be implemented easily.

Web enrollment is the component of a Microsoft CA that allows clients to submit certificate issuance and retrieval requests based on Web pages. It is installed when you install a Microsoft CA. It can also be installed on a non-CA computer to provide a Web front-end to your CA infrastructure on the back-end. In this configuration, clients make requests with the Web pages and only the computer that has Web enrollment installed needs to communicate with your CA.

For more information on installing Web enrollment, see Set up certification authority Web enrollment support.

**Public and private key pair: cryptographic service providers, key lengths, hash algorithms**

If you select the **Use custom settings to generate the key pair and CA certificate** check box when you choose the type of CA to install, you can select the cryptographic service provider (CSP) to use. The CSP generates the public key and private key pair and performs cryptographic operations on behalf of the CA.

You can set the key length for the public key cryptographic keys that the CA uses to sign certificates. In general, the longer the key length, the more secure it is. Note that a longer key will take more time to generate during setup and longer to transmit on the network when building certificate trust lists.

You can also choose the message hash algorithm used by the CA, as well as specifying the use of existing cryptographic keys instead of generating new ones.

**Note**

- A CA may be installed using a smart card CSP. Once a CA is installed using a smart card CSP, the smart card must be available and inserted with the personal identification number (PIN) in order for the CA to start and perform its operations. This is a higher security option for CA operations than other options, but a disadvantage of using smart card CSPs is that CA performance may be slower and key length may be smaller.

**Certification authority identifying information**

The following are some guidelines for completing the CA identifying information in Certificate Services setup:

| Field | Description |
|---|---|

| | |
|---|---|
| CA Name | The name you want to give to the CA. You can enter a string using any Unicode character. The name of the CA will also be the common name of the CA's distinguished name in Active Directory.<br><br>When special characters exist in the CA name, a sanitized CA name is used for operations that are unable to use the unmodified CA name. A CA's sanitized name is the name of the CA with all special characters encoded in a form that will allow them to be used for file names, CryptoAPI key container names, and Active Directory object names. Special characters are those characters that cannot be used in one or more of these names; the list includes all characters which are not ASCII characters and many ASCII punctuation characters.<br><br>Further, Active Directory object names are limited to 64 characters by the Lightweight Directory Access Protocol (LDAP) standard. To accommodate this limit, Active Directory object names are constructed by truncating the sanitized name and appending a hash computed over the truncated part of the sanitized name. The distinguished name suffix field is automatically filled with the distinguished name of the Active Directory domain. If you edit this distinguished name, you must conform with the LDAP standard.<br><br>Type **certutil.exe** at a command prompt without arguments to see the sanitized name for all of the published CAs. Type **certutil.exe -v -ds** to see all of the CA-related Active Directory names. The first column is a truncated CA name with the hash appended (the actual Active Directory object's container name, with special characters reverted back to their original form). A second column is displayed only if the truncated, sanitized name does not match the truncated CA name, and it is the actual Active Directory object's container name. |
| Distinguished name suffix | The X.500 distinguished name suffix that will be appended to the CA name. |
| Validity period | The length of time the CA's certificate should be valid. The CA will obtain a certificate that is valid for this length of time and use that certificate's private key for signing issued certificates and certificate revocation lists. |

**Database and configuration storage**

Certificate Services uses local storage for its database, configuration data, backup data and logging data. You can specify locations for the database and log during CA setup. By default, the certificates issued by a CA are stored in:

*Systemroot*\system32\certlog

For best performance, the database and log files should be kept on separate physical disk drives, preferably on separate disk controllers. This will maximize disk throughput and allow the CA to perform better.

You also have the option of specifying a shared folder when setting up a CA. The shared folder acts as a location where computer users can find information about certification authorities. This option is only useful if you are installing a stand-alone CA and do not use Active Directory.

If the host computer for Certificate Services is a member of a domain, information about the CA is automatically published to the Active Directory. However, the Active Directory does not act as the database for Certificate Services. This function remains with the local computer.

### Note

- It is considered unsafe to install Certificate Services on an FAT file system because FAT does not support domain-based security. Always install Certificate Services on a NTFS file system to take advantage of support for a variety of features including Active Directory, which is needed for domains, user accounts, and other important security features.

**(Optional) Creating an issuer policy statement for the CA**

When you set up a CA, you can add a CA policy statement to the CA certificate that is created during setup or a CA certificate renewal, in the form of text or a pointer to a Web site. The CA policy statement gives legal and other pertinent information about the CA and its issuing policies, limitations of liability, and so on. An end user will see this CA policy statement when they view the CA certificate and click **Issuer Statement**.

Here are the steps you need to follow to attach a policy statement to a CA's certificate:

- The policy statement file must be installed *before* you set up Certificate Services. This file, named CAPolicy.inf, must be placed in the systemroot directory. URLs in CAPolicy.inf should use the replaceable parameter syntax that also appears in the **Extensions** tab. If you don't use the replaceable parameter syntax, then CDP and AIA extensions in renewed CA root certificates may point to the same location that was specified in the previous CA root certificate. To see the syntax for replaceable parameters, see Specify certificate revocation list distribution points in issued certificates.

- The first two lines of CAPolicy.inf must be:

  **[Version]**

  **Signature="$Windows NT$"**

- The next two lines of the file list the name of the policies for this CA. Multiple policies can be listed in **Policies=** if they are separated by commas. The name *LegalPolicy* is used here as an example, but the name can be whatever the CA administrator chooses when creating CAPolicy.inf:

  **[CAPolicy]**

  **Policies=***LegalPolicy*

- For each policy, you need to provide a user-defined object identifier (also known as an OID) and either the text you want displayed as the policy statement or a URL pointer to the policy statement. (The URL can be in the form of an HTTP, FTP, file, or LDAP address.) Continuing on with the example, if you are going to have text in the policy statement, the next three lines of CAPolicy.inf will read:

  **[***LegalPolicy***]**

  **OID=***1.1.1.1.1.1.1.1.1*

  **Notice="***Legal policy statement text***"**

  If you are going use a URL to host the CA policy statement, the next three lines would instead read:

  **[***LegalPolicy***]**

  **OID=***1.1.1.1.1.1.1.1.1*

  **URL="http://***CompanyWebSite/CAPolicy/default.asp***"**

  (Please note that the "OID=" entry used in this example is arbitrary and is shown only for illustrative purposes.)

  In addition:

  - Multiple URLs are supported
  - Multiple notices are supported
  - Mixed notices and URLs are supported
  - URLs with spaces or text with spaces must be surrounded by quotes

  An example of multiple notices and URLs in a policy section might be:

  **[***LegalPolicy***]**

  **OID=***1.1.1.1.1.1.1.1.1*

  **URL = "http://***http.microsoft.com/somewhere/default.asp* **"**

  **URL = "ftp://***ftp.microsoft.com/somewhere else/default.asp***"**

  **Notice = "***Legal policy statement text.***"**

- You can specify CRL Distribution Points (CDPs) in CAPolicy.inf. Note that any CDP in CAPolicy.inf will take precedence for certificate verifiers over the CDP's specified in the CA policy module. If you want to specify the CDP using CAPolicy.inf, a sample of the syntax is:

  **[CRLDistributionPoint]**

  **URL="http://***CompanyWebSite/Public/myCA.crl***"**

  Some additional notes about the CRL section:

  - Multiple URLs are supported.
  - HTTP, file, FTP, and LDAP URLs are supported.
  - This section can be used during CA setup or CA certificate renewal.
  - This section is only used if you are setting up a root CA or renewing a root CA certificate. Subordinate CA CRL distribution point extensions are determined by the CA which issued the subordinate CA's certificate.
  - URLs with spaces must be surrounded by quotes.
  - If no URLs are specified (in other words, if the **[CRLDistributionPoint]** section is empty), the default CRL Distribution Point extension will be suppressed.

- You can specify the authority information access points in CAPolicy.inf. The syntax is:

  **[AuthorityInformationAccess]**

  **URL="http://***CompanyWebSite/Public/myCA.crl***"**

  Some additional notes about the authority information access section:

  - Multiple URLs are supported.
  - HTTP, file, FTP, and LDAP URLs are supported.
  - This section can be used during CA setup or CA certificate renewal.
  - This section is only used if you are setting up a root CA or renewing a root CA certificate. Subordinate CA authority information access extensions are determined by the CA which issued the subordinate CA's certificate.
  - If no URLs are specified (in other words, if the **[AuthorityInformationAccess]** section is empty), the default Authority Information Access extension will be suppressed.

- Another optional section of CApolicy.inf is **[EnhancedKeyUsage]**, which is used to specify Enhanced Key Usage extension object identifiers (also known as OIDs).

  - Multiple object identifiers are supported.
  - This section can be used during CA setup or CA certificate renewal.
  - This section is only used if you are setting up a root CA or renewing a root CA certificate. The Enhanced Key Usage extension for a subordinate CA is determined by the CA which issued the subordinate CA's certificate.

  An example of this section is:

  **[EnhancedKeyUsage]**

**OID=***1.2.3.4.5*

**OID=***1.2.3.4.6*

- Another optional section of CApolicy.inf is **[certsrv_server]**, which is used to specify renewal key length, the renewal validity period, and the certificate revocation list (CRL) validity period for a CA that is being renewed or installed.

  An example would be:

  **[certsrv_server]**

  **RenewalKeyLength=***2048*

  **RenewalValidityPeriod=***Years*

  **RenewalValidityPeriodUnits=***5*

  **CRLPeriod=***Days*

  **CRLPeriodUnits=***2*

  **CRLDeltaPeriod=***Hours*

  **CRLDeltaPeriodUnits=***4*

  - **RenewalKeyLength** sets key size for renewal only. This is only used when CA renewal is generating new keys.
  - **RenewalValidityPeriod** and **RenewalValidityPeriodUnits** establish the lifetime of new root CA certificate when renewing the old CA certificate.
  - **CRLPeriod** and **CRLPeriodUnits** establish the validity period for the full CRL, while **CRLDeltaPeriod** and **CRLDeltaPeriodUnits** establish the validity period for the delta CRL.
  - **RenewalKeyLength**, **RenewalValidityPeriod** and **RenewalValidityPeriodUnits** are only processed when the CA is being renewed.
  - **LoadDefaultTemplates** is not processed when the CA is a subordinate CA.

# Configuring the policy and exit modules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring the policy and exit modules**
The administrator of a certification authority (CA) can configure settings in the default policy and exit modules provided with Certificate Services by using the Certification Authority snap-in.

**Policy module setting you can change:**

- **The default action of the certification authority upon receiving a valid certificate request.** You can specify whether a stand-alone CA will hold incoming certificate requests as Pending or automatically issue the certificate. In most cases, for security reasons, it is recommended that all incoming certificate requests to a stand-alone CA be marked as Pending.

- For the procedure to change the default action of a certification authority upon receipt of a certificate request, see Set the default action upon receipt of a certificate request.

**Exit module settings you can change:**

- **Allow certificate publication to the file system.** You can select whether to allow the publishing of certificates to the file system. Actual publication will only occur if the certificate request specifies a file system location where the certificate is to be published.

- For the procedure to allow or disallow the publishing of certificates to the file system, see Publish certificates to the file system.

- **Sends e-mail when a certification event occurs.** You can configure the CA to send e-mail when a certification event occurs, such as the issuance of a certificate or when a certificate request is set to pending.

- To configure e-mail sending options, see Send e-mail when a certification event occurs.

For more information about policy and exit modules, see Policy and exit modules.

If you want to replace the policy module provided with Certificate Services with a custom policy module or a policy module developed for Certificate Server 1.0 and Windows NT 4.0, you must first register the policy module .dll file by typing **rgsrv32 *yourmodule*.dll** at a command prompt and then follow the procedure in Select a different policy module.

# Establishing a certification hierarchy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Establishing a certification hierarchy**
The first step to establish a certification hierarchy is that a Domain Admin installs a root certification authority (CA).

**Using a Microsoft certification authority as your root authority**
The installation process for a Certificate Services root authority generates a root CA certificate containing the CA's public key and the digital signature created using the root's private key. If the root authority is installed using Certificate Services on a server that has access to the Active Directory directory service, the root authority's certificate will automatically be placed in all users' Trusted Root Certification Authorities certificate store, thereby establishing forest-wide trust in the root CA.

**Using a certification authority outside of your organization as your root authority**
If your organization is using a non-Microsoft certification authority from outside your organization as the root authority, you will need to obtain the root certificate and distribute it to any user and computer that needs to establish trust in the root authority. One way to distribute this type of root certificate to Windows XP and Windows Server 2003 family users is to use a certificate trust list (CTL) by way of Group Policy. For more information about distributing third party root certificates using Group Policy, see Enterprise trust policy.

**Using a non-Microsoft certification authority inside your organization as your root authority**
If your organization is using its own non-Microsoft certification authority (CA) as the root authority, you will need to obtain the root certificate and distribute it to any user and computer that needs to establish trust in the CA root authority. One way to distribute a root certificate to Windows XP and Windows Server 2003 family users is to use the Trusted Root Certification Authorities policy setting via Group Policy. For more information about distributing non-Microsoft root certificates using Group Policy, see Policies to establish trust of root certification authorities.

**Subordinate certification authorities**
After trust in a root authority has been established, you can install certification authorities (CAs) that are subordinate to the root CA as well as installing subordinate CAs that are subordinate to other subordinate CAs. By doing this, you can create a chain of parent-child relationships between CAs that serve different functions in an organization's public key infrastructure (PKI). The only significant difference in the installation process between a root CA and a subordinate CA is that a certificate request is generated for submission to another CA by a subordinate CA instead of creating a self-signed certificate. This request may be routed automatically to online CAs located via Active Directory, or routed manually, if offline. In either case, the resulting certificate must be installed on the new subordinate CA before it can begin operation.

Note that there is a relationship between the enterprise CAs and the Windows Server 2003 family domain trust model, but this does not imply a direct mapping between CA trust relationships and domain trust relationships. There is nothing that prevents a single CA from servicing entities in multiple domains or even entities outside the domain boundary. Similarly, a given domain may have multiple enterprise and root CAs.

For a brief overview of certification hierarchies, see Certification authority hierarchies.

For extensive information about planning certification hierarchies, refer to the Microsoft Windows Deployment and Resource Kits.

# Backing up and restoring a certification authority

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backing up and restoring a certification authority**

The purpose of backup and restore operations is to protect the certification authority (CA) and its operational data from accidental loss due to hardware or storage media failure. The recommended method to back up a CA is to use Backup (included with the operating system) to back up the entire server, including the system state which contains the CA's data.

| **Warning** |
| --- |
| The procedures discussed in this article demonstrate how to back up only the certification authority (CA) database and private key. If you want to back up the CA database, private key, and CA configuration, see the backup procedures in AD CS Migration: Migrating the Certification Authority (http://technet.microsoft.com/library/ee126140.aspx). To back up all the configuration data for a computer, run a System State Data backup (http://technet.microsoft.com/library/cc781353.aspx). |

It is also possible to back up and restore a CA using the Certification Authority snap-in, but this backup method is intended for use only in special cases where you do not want to back up the entire server on which the CA is installed. Using the Certification Authority snap-in, you can back up and restore the following types of information:

- Private key, and the certificate that the CA uses for digitally signing
- Certificate database

The public key and private key are backed up or restored using the PKCS #12 PFX format.

The Backup or Restore Wizard will ask you to supply a password when backing up the public and private keys and CA certificate. This password will be needed to restore the CA. For procedures on backing up a CA using the Certification Authority snap-in, see Back up a certification authority.

After performing the initial full backup of the CA, you can do incremental backups from that point on. When restoring, you will need to restore the full backup first and then each incremental backup in the order that they were created. For procedures on restoring a CA using the Certification Authority snap-in, see Restore a certification authority from a backup copy.

**Important**

- In general, you should use **Backup** to back up and restore both the CA and the server. For more information about backing up a Windows Server 2003 family computer, see Backup.

Upon restoring a CA, the Internet Information Services (IIS) metabase must also be restored if it has been damaged or lost. If a damaged or missing IIS metabase is not restored, IIS will fail to start, and that will result in Certificate Services Web pages failing to load. The IIS snap-in is used to back up the IIS metabase. Backup should be used to back up the IIS Web content pages and the CA. An alternative method is to recreate the IIS metabase and then use the **certutil.exe -vroot** command at a command line to reconfigure the IIS server to support the CA Web pages.

When restoring a CA, if the database logs are not manually deleted before the restore, the CA will be restored to the point in time of the restore--the database logs will be replayed, and changes made since the last backup will be applied to the database. (The default location of the database logs is *systemroot*\system32\certlog). If the database logs are manually deleted before the restore, the CA will be restored to the point in time that the backup was performed.

For more information on backup, restore, and verification of a CA backup, see Certutil tasks for backing up and restoring certificates.

# Revoking certificates and publishing CRLs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Revoking certificates and publishing CRLs**

You can use the Certification Authority snap-in to revoke a certificate, to administer certificate revocation list (CRL) publication, and to specify the CRL Distribution Points (CDPs) published in every certificate issued by the certification authority (CA).

**Revoking a certificate**

To help maintain the integrity of an organization's public key infrastructure (PKI), the administrator of a CA must revoke a certificate if the subject of certificate leaves the organization, if the certificate subject's private key has been compromised, or if some other security-related event dictates that it is no longer desirable to have a certificate considered "valid." When a certificate is revoked by a CA, it is added to that CA's certificate revocation list (CRL). This may take the form of a new CRL or a delta CRL, which is a small CRL that lists the certificates that have been revoked since the last full CRL.

For conceptual information about the role of certificate revocation and revocation checking in a PKI, see Certificate revocation. For the procedure to revoke a certificate, see Revoke an issued certificate. For instructions on how to display the current CRL, see View the certificate revocation list.

**Scheduling certificate revocation list (CRL) publication**

One of the features of Certificate Services is that every CA automatically publishes an updated CRL after an interval of time specified by the administrator of the CA. This interval of time is known as the CRL "publish period." After the initial setup of a CA, the CRL publish period is set to one week (based upon the local computer's time, starting from the date when the CA is first installed). For the procedure to change a certification authority's CRL publishing interval, see Schedule the publication of the certificate revocation list. The CRL and delta CRL publish periods can be scheduled independently.

A CA administrator should understand that there is a difference between a CRL publish period and the validity period of a CRL. The validity period of a CRL is the period of time that the CRL is considered authoritative by a verifier of a certificate. As long as the verifier of a certificate has a valid CRL in its local cache, it will not attempt to retrieve another CRL from the CA which publishes it.

The publish period of a CRL is established by the CA administrator. However, the validity period of the CRL is extended from the publish period to allow for Active Directory replication. By default, Certificate Services extends the publish period by 10% (up to a maximum of 12 hrs) to establish the validity period. So, for example, if a CA is publishing a CRL every 24 hours, the validity period is set to 26.4 hours.

Additionally, there is a clock skew of an additional 10 minutes added to the validity period on either side of the publish period, so a CRL will be valid 10 minutes before the beginning of its publish period to account for variances in computer clock settings.

There are registry entries which allow an administrator to control the variance between publish period and validity period to allow for slower directory replication. For information about these registry entries, see the Microsoft Windows Deployment and Resource Kits.

When determining the schedule for CRL publishing, there is a trade-off between performance and security. The more often CRLs are published, the more current clients can be with the list of revoked CRLs and the less likely they are to accept recently-revoked certificates. However, frequent publishing can negatively impact network and client performance. To help mitigate this trade off, delta CRLs can be used if the environment supports them.

**Using delta certificate revocation lists**

CRLs can become very long on large CAs that have experienced significant amounts of certificate revocation. This can become a burden for clients to download frequently. To help minimize frequent downloads of lengthy CRLs, delta CRLs can be published. This allows the client to download the most current delta CRL and combine that with the most current base CRL to have a complete list of revoked certificates. Because the client will normally have the CRL cached locally, the use of delta CRLs can potentially improve performance.

To use delta CRLs, the client application must be aware of and explicitly use delta CRLs for revocation checking. If the client does not use delta CRLs, it will retrieve the CRL from the CA every time it refreshes its cache, regardless of whether a delta CRL exists or not. For this reason, you should verify that the intended applications use delta CRLs and configure the CA accordingly. If the clients do not support the use of delta CRLs, you should either not configure the CA to publish delta CRLs or configure it so CRLs and delta CRLs are published at the same interval. This would still allow future applications that support delta CRLs to use them, while providing current CRLs to all applications. Note that all applications that use CryptoAPI in Windows XP and the Windows Server 2003 family use delta CRLs.

**Publishing a CRL before the next scheduled publish period**
You can also publish a CRL on demand at any time, such as when a valuable certificate becomes compromised. Choosing to publish a CRL outside the established schedule resets the scheduled publication period to begin at that time. In other words, if you manually publish a CRL in the middle of a scheduled publish period, the CRL publish period is restarted.

It is important to realize that clients that have a cached copy of the previously published CRL will continue using it until its validity period has expired, even though a new CRL has been published. Manually publishing a CRL does not affect cached copies of CRLs that are still valid; it only makes a new CRL available for systems that do not have a cached copy of a valid CRL.

For the procedure to force the immediate publication of a CRL or delta CRL, see Manually publish the certificate revocation list.

**CRL distribution points and the CRL file name**
Every certificate that is issued by a Microsoft certification authority has CRL distribution points as part of its content. A CRL distribution point provides a certificate verifier with the network location where it can retrieve the current copy of the CRL or delta CRL. For procedures to designate the certificate revocation list distribution points in certificates, see Specify certificate revocation list distribution points in issued certificates.

By default, CRL and delta CRL files are published on the CA in the following location:

*Systemroot*\System32\Certsrv\Certenroll

The format of the CRL file name is the "sanitized name" of the CA plus, in parentheses, the "key id" of the CA (if the CA certificate has been renewed with a new key) and a .crl extension. Refer to the table for some sample CRL file names based on sample renewal histories of a CA:

| Scenario | Name of CRL file |
|---|---|
| A certification authority named "MyCA" that has never had its CA certificate renewed | myca.crl |
| A certification authority named "MyCA" that has been renewed once with the same key | myca.crl |
| A delta CRL for a certification authority named "MyCA" that has been renewed once with the same key | myca+.crl |
| A certification authority named "MyCA" that has been renewed once with a new key | myca(1).crl |
| A certification authority named "MyCA" that has been renewed twice with a new key | myca(2).crl |

See Installing and configuring a certification authority for information about a CA's "sanitized name."

See Renewing a certification authority for more information about CA renewal.

**Enabling Netscape-compatible Web-based revocation checking**
To enable Netscape-compatible Web-based revocation check extensions to be added to every certificate, run the following **certutil** command from the command prompt on the certification authority:

**certutil -SetReg Policy\RevocationType +AspEnable**

Then, stop and start the Certification Authority service. Certificates issued by the certification authority after it is restarted will contain the extension.

**Important**

- Because clients that use this type of revocation checking will access the CA through Web pages, Internet Information Services must have access to read the revocation information from the CA. If IIS does not have at least read-only access to the CA, access is denied by the CA and the revocation information will not be available.

For more information on the **certutil** command, see Certutil.

# Mapping certificates to user accounts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Mapping certificates to user accounts**

It is possible to *map* (or create an association from) a certificate that has been issued to a user to the user's account. A server application can then use public key cryptography technology to authenticate the user using this certificate. If the user is authenticated, then the user's account is logged on. The end result is the same as if the user provided a user ID and password, yet the process is much more manageable.

Traditionally, computer systems have used a centralized accounts database to manage users, their user rights, and their access controls. This technique has worked well and is well understood. However, as systems become more and more distributed--with hundreds of thousands to millions of users--this form of centralized control becomes unwieldy. The problems range from trying to verify an account against a database located on the other side of the Internet to administering a lengthy list of users.

Public key certificates can help simplify these problems. Certificates can be widely distributed, issued by numerous parties, and can be verified by simply examining the certificate, without having to refer to a centralized database. However, existing operating systems and administration tools can only deal with accounts, not certificates. The simple solution--one that maintains the advantages of both certificates and user accounts-- is to create a mapping between a certificate and a user account. This allows the operating system to continue using accounts while the larger "system" and the user use certificates.

In this model, when a user presents a certificate, the system looks at the mapping to determine which user account should be logged on. (Note that this should not be confused with logging on with a smart card. Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition support logging on with a smart card using account mapping that is automatic.)

**Types of mapping**

In most cases, a certificate is mapped to a user account in one of two ways: a single certificate is mapped to a single user account (one-to-one mapping) or multiple certificates are mapped to one user account (many-to-one mapping).

**User principal name mapping**

User principal name mapping is a special case of one-to-one mapping. To use user principal name mapping, you must use the Active Directory directory service. With user principal name mapping, the user principal name is used to find the user's account in Active Directory and log it onto the network or host. The user principal name looks very much like an e-mail name, and is unique within a Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition domain. Enterprise certification authorities (CAs) place the user principal name of the certificate holder into each certificate. Thus, for accessing a secure IIS server or logging on to Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition with a smart card, the mapping of user names to accounts is automatic on these certificates.

For more information on using Active Directory for certificate mapping, see Map a certificate to a user account.

**One-to-one mapping**

One-to-one mapping maps a single user certificate to a single user account. For example, imagine you want to provide a Web page to your employees that will allow them to view and modify their deductions, manage their health care, and a number of other benefits options. This page should work over the Internet and should be secure. As a solution, you decide to use certificates and certificate mapping on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. You can either issue certificates to each of your employees from your own certificate service, or you can have your employees get certificates from a certification authority approved by your company. You can then take these user certificates and map them to the employee's user account. This allows a user to connect to the Web page using SSL (Secure Sockets Layer) or TLS (Transport Layer Security) from anywhere by providing his or her client certificate. The user then logs onto his or her own user account and normal access controls can be applied.

**Many-to-one**

Many-to-one mapping maps many certificates to a single user account. For example, you have a partnership with an agency that provides temporary workers for your job openings. You would like to allow the agency personnel to view Web pages that describe current job openings that only company employees can see. The agency has its own certification authority that it uses to issue certificates to its employees. After installing the agency certification authority's root certificate as a trusted root in your enterprise, you can set a rule that maps all certificates issued by that certification authority to a single Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition account. You can then set the access rights of the account so this account can access that Web page.

# Renewing a certification authority

Updated: November 20, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Renewing certification authorities**

**Why certification authorities need to be renewed**
A certification authority may need to be renewed for either of the following reasons:

- Change in the policy of certificates issued by the CA
- Expiration of the CA's issuing certificate

**Certification authority validity periods**
Every certificate issued by a certification authority (CA) has a validity period. The validity period is the range of time where the certificate can be accepted as an authoritative credential of the identity of the subject of the certificate. This is, of course, assuming the certificate is not revoked before the validity period ends and that the issuing CA is trusted. The primary purpose of the validity period is to limit the time in which a certificate is exposed to the possibility of being compromised.

Since a CA is really just another entity that has been issued a certificate--either issued by itself (in the case of a root CA) or issued by a parent (in the case of a subordinate CA)--every CA has a built-in expiration date, as determined by the end of the validity period on its CA certificate. This is not meant to imply that the lifetime of a CA is equivalent to the validity period of its CA certificate, only that a CA cannot issue certificates if it does not have a valid certificate of its own. The lifetime of a CA includes the validity periods of all its CA certificates--past and present. With these considerations in mind, an organization with a public key infrastructure (PKI) has to plan for the renewal of every certificate that is issued to a CA in the certification hierarchy in order to maintain the existing trust relationships in the PKI and to extend the lifetimes of CAs.

**The validity period of a CA and the validity period of the certificates it issues**
Before discussing the renewal of a CA certificate, it is helpful to understand how the end of the validity period of a CA affects the validity period of the certificates it issues. Certificate Services enforces a rule that a CA never issues a certificate to be valid beyond the expiration date of its own certificate. Therefore, when a CA's certificate reaches the end of its validity period, all certificates it has issued will also expire. This way, if the CA is purposely not renewed and the CA reaches the end of its lifetime, a PKI administrator can be assured that all the certificates that the now-expired CA has issued can no longer be used as valid security credentials. In other words, there will be no "orphaned" certificates that are still within their validity period but which have been issued by a CA that is no longer valid.

To illustrate how a decreasing validity period works, consider the following scenario: An organization installs a root CA with a certificate validity period of five years. The organization then uses this root CA to issue certificates with a validity period of two years to subordinate CAs. For the first three years every certificate issued to a subordinate CA by the root CA will continue to have a validity period of two years. After three years, when there is less than two years left in the validity period of the root CA certificate, Certificate Services begins to reduce the validity period of the certificates issued by the root CA so that they do not exceed the end of the CA's certificate's expiration date. Therefore, after four years, the CA issues subordinate CA certificates that are valid for one year. After 4.5 years, issued subordinate CA certificates have a validity period of only six months.

Certificate Services allows for the following maximum validity periods that are based on the type of certificate. These validity periods are configurable by the Domain Admin or Enterprise Admin when using version 2 certificate templates:

| Type of certificate | Maximum validity period |
|---|---|
| Root CA | Specified during setup of Certificate Services |
| Subordinate CA, Internet Protocol Security, Enrollment Agent, Domain Controller | Up to 5 years, never more than the Root CA's validity period |
| All other certificates | 1 year, never more than the Issuing CA's validity period |

**Planning for the renewal of a CA**
Since a CA that is approaching the end of its own validity period issues certificates valid for shorter and shorter periods of time,

you need to have a plan in place to renew the CA well before it expires in order to avoid issuing certificates of a very short validity period.

One renewal consideration: When you renew a CA, you have the option of reusing its existing key pair or generating a new key pair. When you generate a new key pair for a CA that is being renewed, a new certificate revocation list (CRL) distribution point is also created. This is to ensure that the key used to sign a certificate issued by the CA also matches the key used to sign the CRL. For more information about how renewing a CA with a new key affects certificate revocation and the name of CRLs, see Revoking certificates and publishing CRLs.

The following strategies are presented as possible approaches an organization could take when planning for CA renewal. You may need to adapt these to your specific situation.

- **Renewing a root certification authority**

  Since the root CA is the most critical CA in the hierarchy, you may prefer to have a strategy here that reduces the need to renew the root certificate often.

  The first consideration is choosing the key length of the root's public key and private key pair during setup of the root authority. By using a long key length, which is generally more secure against brute force attack than a shorter key length, you increase the length of time that the CA can use the same private key and have reasonable confidence that it has not been compromised. The second consideration is establishing the validity period of the root certificate itself. In general, you will want to create a root certificate that has a shorter validity period than the estimated lifetime of the key.

  Keeping these considerations in mind, a possible strategy for setting up a root CA that reduces the need for frequent renewal would be to create a 4096-bit RSA key during Certificate Services setup. Given the current state of computer technology, one estimate is that a 4096-bit private key is reasonably secure from a brute force attack for 15-20 years. After creating the 4096-bit key in Certificate Services setup, you could create a root certificate using the 4096-bit key that is valid for five years. Afterwards, the CA's certificate should be renewed every four years (one year before the expiration of the validity period), each time with a certificate validity of five years. Of course, every time the CA certificate is renewed, the administrator will have to assess whether the same key, given current computer technology and other security considerations, can be used with confidence for the next five years.

- **Renewing a subordinate certification authority**

  **Intermediate CAs**

  Within an organization's certification hierarchy, some subordinate CAs may be "intermediate" CAs . In other words, they do not issue certificates to end users or computers; they only issue certificates to other subordinate CAs that are below them in the certification hierarchy. For these intermediate CAs, given their limited role and the relative ease of monitoring their certificate database logs, a possible strategy may be to renew them a year to six months before they expire and reuse the existing key.

  **Issuing CAs**

  For a subordinate CA that issues certificates to end users and computers, referred as an issuing CA, a preferable strategy may be to renew the CA's certificate regularly with a new key 6-12 months before the end of the CA's validity period, for example. This makes an attack on any one key less valuable, since any compromised key would have a relatively limited lifetime.

  The other advantage of renewing an issuing CA using a new key is CRL management. When a CA is renewed with a new key, it begins to publish a separate CRL for the revoked certificates it has issued using the new key. It also will continue to publish a CRL for certificates signed with the old key, for as long as those revoked certificates validity period is still in effect. This can be advantageous especially if a CA is issuing a large number of certificates and, potentially, revoking a large number of those certificates. This reduces the possibility of having one huge CRL that certificate verifiers have to download. Instead, issue a number of certificates with one key, renew the CA early into its validity period with a new key, then issue a number of certificates using the new key. In this way, you will reduce the size of the CRL that the certificate verifier has to download when presented with a certificate from an issuing CA.

For more detailed information about planning for renewal and renewing Microsoft certification authorities, refer to the Microsoft Windows Deployment and Resource Kits.

**Procedures to renew CAs**

For the procedure to renew a root CA, see Renew a root certification authority.

For the procedure to renew a subordinate or intermediate CA, see Renew a subordinate certification authority.

# Managing Certificate Services from a command prompt

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Certificate Services from a command prompt**
There are two utilities you can use to manage certificates at a command prompt:

- Certutil is a useful tool for administrators who are managing CAs and troubleshooting certificate-related issues.
- Certreq requests certificates from a certification authority (CA).

For information about other command-line utilities, see Command-line reference A-Z. For more information about manageability, see Management Strategies and Tools.

# Certificate Services Example Implementations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate Services example implementations**

This section covers:

- Certificate Services example implementation: Establishing autoenrollment for user certificates
- Certificate Services example implementation: Key archival and recovery

# Certificate Services example implementation: Establishing autoenrollment for user certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate Services example implementation: Establishing autoenrollment for user certificates**
These tasks are required for using key recovery on a Microsoft certification authority (CA):

1. Duplicate the User template and use the copy for autoenrollment
2. Configure an enterprise certification authority to issue the Autoenrolled User certificate
3. Establish policy for autoenrollment of Domain Users

## Prerequisites

Before doing these tasks, for the purposes of this walkthrough:

- The Windows Server 2003 domain controller must also be configured as an enterprise subordinate or root CA. The CA is referred to by the name **EntCA** in this walkthrough.

### Duplicate the User template and use the copy for autoenrollment

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, double-click **Certificate Templates**, click **Close**, and then click **OK**.
4. In the console tree, click **Certificate Templates**. All of the certificate templates will be displayed in the details pane.
5. In the details pane, click the **User** template.
6. On the **Action** menu, click **Duplicate Template**.
7. In the **Display Name** field, type **Autoenrolled User**.
8. Make sure that the **Publish Certificate in Active Directory** check box is selected.
9. Click the **Security** tab.
10. In the **Group or user names** field, click **Domain Users**.
11. In the **Permissions for Domain Users** list, select the **Enroll** and **Autoenroll** permission check boxes and then click **OK**.

    Autoenrolling **Domain Users** is an example. These permission settings are variable, depending on who you want to autoenroll for these certificates.

### Configure an enterprise certification authority to issue the Autoenrolled User certificate

1. Open Certification Authority.
2. In the console tree, click **Certificate Templates**.

**Where?**

- Certification Authority/*CA name*/Certificate Templates

3. On the **Action** menu, point to **New**, and then click **Certificate to Issue**.

4. Click **Autoenrolled User** and click **OK**.

**Note**

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

**Establish policy for autoenrollment of Domain Users**

You must be using the Windows Server 2003 Active Directory schema for this procedure to work.

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.

2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.

3. Under **Snap-in**, double-click **Active Directory Users and Computers**, click **Close**, and then click **OK**.

4. In the console tree, click the domain name.

   **Where?**

   - Active Directory Users and Computers/*Domain name*

5. On the **Action** menu, click **Properties**.

6. Click the **Group Policy** tab and click **Edit**.

7. In the console tree, click **Public Key Policies** under **User Configuration**.

   **Where?**

   - Default Domain Policy/User Configuration/Windows Settings/Security Settings/Public Key Policies

8. In the details pane, double-click **Autoenrollment Settings**.

9. Click **Enroll certificates automatically**.

10. Select the **Renew expired certificates, update pending certificates, and remove revoked certificates** check box.

11. Select the **Update certificates that use certificate templates** check box and click **OK**.

12. Click **File**, click **Exit**, and then click **OK**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and

then double-click **Active Directory Users and Computers**.

- Unless users refresh their security policy using the **GPUpdate** command, it will take a number of hours for the autoenrollment policy to take effect.

- When autoenrollment retrieves a certificate that is configured to be stored on a smart card, you will receive a message when the certificate is ready to be stored on the smart card. If the message refers to a type of smart card that you do not have, click **Cancel** until the correct smart card type appears. You then provide the smart card PIN and the certificate will be stored on the smart card.

- When autoenrollment enrolls for a certificate that requires user interaction for the enrollment process, you will receive a **Certificate Enrollment** message and an icon appears on your taskbar. Clicking that icon or message begins the certificate autoenrollment process.

# Certificate Services example implementation: Key archival and recovery

Updated: November 5, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate Services example implementation: Key archival and recovery**

Here are the tasks required for using key recovery with a Microsoft certification authority (CA):

1. Create a key recovery agent account
2. Acquire the key recovery agent certificate
3. Configure the certification authority to allow key recovery
4. Create a new certificate template that allows key archiving
5. Acquire an user certificate that has an archived key
6. Perform key recovery
7. Import the recovered private key

### Note

- Steps 6 and 7 are not required to configure key archival. They are used when a private key is lost and key recovery must take place.

**Prerequisites**

Before doing these tasks, for the purposes of this walkthrough:

- You must have a Windows Server 2003 domain controller. A fictitious domain, adventure-works.com, is used in this walkthrough.
- The Windows Server 2003 domain controller must also be configured as an enterprise root or subordinate CA. The CA is referred to by the name EntCA in this walkthrough.

**Task 1--Creating a Key Recovery Agent account**

Configure and add the Key Recovery Agent certificate template as a template that can be issued by the enterprise CA.

### Important

- Perform the following procedures at the domain controller.

1. Verify who can enroll the Key Recovery Agent template

a. Log on as Administrator@adventure-works.com.

b. Click **Start**, click **Run**, type **certtmpl.msc** and then press Enter.

c. In the console tree, click **Certificate Templates**.

d. In the details pane, right-click **Key Recovery Agent** and click **Properties**.

e. In Key Recovery Agent **Properties**, click the **Security** tab.

By default, the security groups can enroll the Key Recovery Agent certificate template are Domain Administrators and

Enterprise Administrators.

f. If you want another recovery agent, click **Add** to add the user and grant that user **Read** and **Enroll** permissions.

2. Change the default issuance behavior of the Key Recovery Agent template

a. In Key Recovery Agent **Properties**, click the **Issuance Requirements** tab.

b. Clear the **CA certificate manager approval** check box and click **OK**.

c. Close **Certificate Templates**.

3. Configure the EntCA certification authority to issue Key Recovery Agent certificates.

a. On the **Administrative Tools** menu, click **Certification Authority**.

b. In the console tree, double-click **EntCA**, and then click **Certificate Templates**.

c. Right-click **Certificate Templates**, then click **New**, and then click **Certificate to Issue**.

d. In **Select Certificate Template**, click **Key Recovery Agent**, and then click **OK**.

#### Task 2--Acquiring the Key Recovery Agent certificate

In this series of steps, you will acquire a Key Recovery Agent Certificate for the purpose of recovering private keys.

**Important**

- Perform the following procedures at the domain controller.

1. Create an MMC console with the Certificates snap-in loaded.

a. Ensure that you are logged on as administrator@adventure-works.com.

b. On the taskbar, click the **Start** button, and then click **Run**.

c. In **Run**, type **mmc**, and then click **OK**.

d. On the **File** menu, click **Add/Remove Snap-in**.

e. In **Add/Remove Snap-in**, click **Add**.

f. In the **Add Stand-alone Snap-in**, click **Certificates**, and then click **Add**.

g. In **Certificates**, click **User account** and then click **Finish**.

h. Click **Close**, and then click **OK**.

2. Acquire a Key Recovery Agent certificate.

a. In the newly-created MMC console, in the console tree, double-click **Certificates (Current User)**.

b. In the console tree, right-click **Personal**, click **All Tasks**, and then click **Request New Certificate**.

c. In the Certificate Request Wizard, click **Next**.

d. In **Certificate Template**, select **Key Recovery Agent**, and then click **Next**.

e. In the **Certificate Friendly Name and Description**, in **Friendly name**, type **Key Recovery**, and then click **Next**.

f. In **Completing the Certificate Request Wizard**, click **Finish**.

g. In the console tree, double-click **Personal** and then click the Certificates folder.

h. Ensure that a certificate with the friendly name of "Key Recovery" exists.

i. Close the console without saving changes.

#### Task 3--Configuring the CA to allow key recovery

In this series of steps, you configure the EntCA enterprise CA to use the Recovery Agent certificate acquired in Task 2. The CA must load the public key for the Key Recovery Agent to be used for encrypting the recovery data.

**Important**

- Perform the following procedures at the domain controller.

1. Configure the Recovery Agent to be the Administrator's Key Recovery Agent certificate.

a. Ensure that you are logged on as Administrator@adventure-works.com.

b. In **Administrative Tools**, open **Certification Authority**.

c. In the console tree, click **EntCA**.

d. Right-click **EntCA**, and then click **Properties**.

e. On EntCA **Properties**, on the **Recovery Agents** tab, click **Archive the key** and then click **Add**.

f. In **Key Recovery Agent Selection**, click the certificate that is displayed, and then click **OK**.

g. When prompted to restart the CA, click **Yes**.

2. Open the Certificates console, focused on the local computer.

a. On the taskbar, click the **Start** button, and then click **Run**.

b. In **Run**, type **mmc**, and then click **OK**.

c. On the **File** menu, click **Add/Remove Snap-in**.

d. In **Add/Remove Snap-in**, click **Add**.

e. In **Add Standalone Snap-in**, click **Certificates**, and then click **Add**.

f. In **Certificates**, click **Computer account** and then click **Next**.

g. In **Select Computer**, click **Local Computer**, and then click **Finish**.

h. Click **Close**, and then click **OK**.

3. Verify the installation of the KRA certificate.

a. In the console tree, double-click **Certificates (Local Computer)**, double-click **KRA**, and then click **Certificates**.

b. In the details pane, double-click the certificate.

The intended use of the certificate is Key Recovery Agent and the certificate is issued to Administrator. This procedure ensures that the Key Recovery Agent has been successfully configured, and then click **OK**.

d. Close the console without saving changes.

**Task 4--Creating a new certificate template that allows key archiving**

In this series of steps, you will define a new template that allows Key Archival by using the Certificate Templates console. This will allow key recovery in the domain in the event that the private key is lost or corrupted at the client computer.

**Important**

- Perform the following procedures at the domain controller.

1. Open the Certificate Templates console.

a. Log on as Administrator@adventure-works.com.

b. On the taskbar, click the **Start** button, and then click **Run**.

c. In **Run**, type **mmc**, and then click **OK**.

d. On the **File** menu, click **Add/Remove Snap-in**.

e. In **Add/Remove Snap-in**, click **Add**.

f. In **Add Standalone Snap-in**, click **Certificate Templates**, and then click **Add**.

g. Click **Close**, and then click **OK**.

2. Create a duplicate of the Users certificate template with the following properties:

- Template is named "Archive User"
- Key archival is enabled

a. In the console tree, click **Certificate Templates**.

b. In the details pane, right-click the **User** template, and click **Duplicate Template**.

c. In the **Properties** of New Template dialog box, in the **General** tab, in the **Display name** box, type **Archive User**.

d. In the **Request Handling** tab, enable the **Archive subject's private key** option.

The archive key option makes it possible for the Key Recovery Agent to recover the private key from the certificate store.

e. Click the **Security** tab.

Domain Administrators and Domain Users can enroll for this certificate. These permissions were copied from the Users certificate template.

f. Click **OK**.

g. Close the console without saving changes.

**Task 5--Acquiring a User certificate that has an archived key**

In this series of tasks, you configure the EntCA certification authority to issue Archive User certificates. Using a newly created account, you will acquire an Archive User certificate and record the certificate's serial number for later usage.

**Important**

- Perform the following procedures at the domain controller.

1. Configure EntCA to issue the new Archive User certificate template.

a. Ensure that you are logged on as Administrator@adventure-works.com, with a password of **password**.

b. From **Administrative Tools**, open **Certification Authority**.

c. In the console tree, double-click **EntCA**, and then click **Certificates Templates**.

d. Right-click Certificate Templates, click **New**, and then click **Certificate to Issue**.

e. In **Select Certificate Template**, click **Archive User** and then click **OK**.

The Archive User certificate template now appears in the details pane.

f. Close **Certification Authority**.

2. Create a new user account

a. In **Administrative Tools**, open **Active Directory Users and Computers**.

b. Double-click adventure-works.com.

c. In **Users**, create a user account with the following properties:

- First name: Mike
- Last name: Danseglio
- User logon name: Mikedan

- Password: password
- Member of: Server Operators
- E-mail: Mikedan

d. Click **Next**, and then click **Finish**.

e. Double-click the **Mikedan** account, and then select the **Member of** tab.

f. Click **Add**, in **Select Groups**, type **Server Operators**, click **Check Names**, and then click **OK**.

g. Click **OK** to close **Properties**.

h. Close **Active Directory Users and Computers**.

i. Close all open windows and log off of the computer.

3. Log in to the network as Mikedan@adventure-works.com and open the Certificates console.

**Note**

- Mikedan was added to the Server Operators group so he can log on locally to the domain controller.

a. Log on as Mikedan@adventure-works.com.

b. On the taskbar, click the **Start** button, and then click **Run**.

c. In **Run**, type **mmc**, and then click **OK**.

d. From the **Console** menu, click **Add/Remove Snap-in**.

e. In **Add/Remove Snap-in**, click **Add**.

f. In **Add Stand-alone Snap-in**, click **Certificates**, click **Add**, and then click **OK**.

4. Use the Certificates MMC to acquire an Archive User certificate

a. In the newly-created MMC console, in the console tree, double-click **Certificates (Current User)**.

b. In the console tree, right-click **Personal**, click **All Tasks**, and then click **Request New Certificate**.

c. In the Certificate Request Wizard, click **Next**.

d. On **Certificate Template**, select the **Archive User** certificate, and then click **Next**.

e. On **Certificate Friendly Name and Description**, in **Friendly name**, type **Archive User**, and then click **Next**.

f. On **Completing the Certificate Request Wizard**, click **Finish**.

g. On **Certificate Request Wizard**, click **Install Certificate** and then click **OK**.

h. Double-click **Personal**, and then click **Certificates**.

i. In the details pane, double-click the certificate with the friendly name of **Archive User**.

j. In **Certificate**, click the **Details** tab.

Note that the certificate template that used to generate this certificate was ArchiveUser, then click **OK**.

k. Close the new console without saving changes

l. Close all windows and log off of the computer.

**Task 6--Performing a Key Recovery**

In this series of tasks, you will perform a key recovery by using Certutil.exe.

For more information on Certutil, see Certutil.

**Important**

- Perform the following procedures at the domain controller.

1. Log on to the network as Administrator and ensure that the private key is still recoverable by viewing the **Archived Key** column in the Certification Authority console.

a. Log on as Administrator@adventure-works.com.

b. From **Administrative Tools**, open **Certification Authority**.

c. In the console tree, double-click **EntCA**, and then click **Issued Certificates**.

d. From the **View** menu, click **Add/Remove Columns**.

e. In **Add/Remove Columns**, in **Available Column**, select **Archived Key**, and then click **Add**. Archived Key should now appear in **Displayed Columns**.

f. Click **OK** and then, in the details pane, scroll to the right and confirm that the last issued certificate to Mikedan has a **Yes** value in the Archived Key column.

**Note**

- A certificate template must have been modified so that the Archive bit and Mark Private Key as Exportable attributes were enabled. The private key is only recoverable if there is data in the Archived Key column.

g. Double-click the **Archive User** certificate.

h. Click the **Details** tab

Write down the serial number of the certificate. (Do not include spacing between digit pairs.) This is required for recovery.

The serial number will be a hexadecimal string that is 20 characters long. The serial number of the private key is the same as the serial number of the certificate. For the purposes of this walkthrough, the serial number will be referred to as *serialnumber*.

i. Click **OK**.

j. Close **Certification Authority**.

2. Recover the private key into a BLOB output file by using certutil.exe.

a. On the taskbar, click the **Start** button, click **Run**, type **cmd**, then click **OK**.

This opens a command prompt window.

b. Type **cd ** and then press ENTER.

c. Ensure that you are in the **c:** directory.

d. At the command prompt, type:

**Certutil -getkey** *serialnumber* **outputblob**

e. At the command prompt, type **dir outputblob**

**Note**

- If the file *outputblob* does not exist, you probably typed the serial number incorrectly for the certificate.

The *outputblob* file is a PKCS#7 file containing the KRA certificates and the user certificate and chain. The inner content is an encrypted PKCS#7 containing the private key (encrypted to the KRA certificates).

3. Recover the original private/public key pair using Certutil.exe

a. On the taskbar, click the **Start** button, click **Run**, type **cmd**, then click **OK**.

This opens a command prompt window.

b. At a command prompt, type:

**Certutil -recoverkey outputblob Mikedan.pfx**

c. When prompted, enter the following information:

Enter new password: **password**

Confirm new password: **password**

d. Type **exit**, and then press ENTER.

e. Close all windows and log off as the current user.

**Task 7--Importing the recovered private key**

In this series of tasks, you will restore the recovered private key in Mike's certificate store by importing the Mikedan.pfx file.

**Important**

- Perform the following procedures at the domain controller.

1. Log on as Mikedan@adventure-works.com and start the Certificates mmc.

a. Log on as Mikedan@adventure-works.com, with a password of *password*.

b. On the taskbar, click the **Start** button, and then click **Run**.

c. In **Run**, type **mmc**, and then click **OK**.

d. On the **File** menu, click **Add/Remove Snap-in**.

e. In **Add/Remove Snap-in**, click **Add**.

f. In **Add Standalone Snap-in**, click **Certificates**, click **Add**,and then click **OK**.

2. Delete all certificates issued by EntCA to simulate a re-installed computer.

a. Right-click **Certificates (Current User)**, and then click **Find Certificates**.

b. In **Find Certificates**, in **Contains**, type **EntCA** and then click **Find Now**.

c. In **Find Certificates**, on the **Edit** menu, click **Select All**.

d. In **Find Certificates**, on the **File** menu, click **Delete**.

e. In Certificates, click **Yes**.

f. In Root Certificate Store, click **Yes**.

g. Close **Find Certificates**.

3. Import the certificate at c:\Mikedan.pfx and let the certificates be placed automatically.

a. In the console tree, right-click **Personal** and then click **All Tasks** and then click **Import**.

b. In the Certificate Import Wizard, click **Next**.

c. On **Files to Import**, in the **File name** box, type **c:\Mikedan.pfx**, and then click **Next**.

d. In **Password**, type **password** and then click **Next**.

e. On **Certificate Store**, click **Automatically select the certificate store based on the type of certificate** and then click **Next**.

f. On **Completing the Certificate Import Wizard**, click **Finish**

g. If the **Root Certificate Store** dialog box appears, click **Yes**.

h. In **Certificate Wizard Import**, click **OK**.

Two certificates were imported. The Archive User certificate for Mike is located in the Personal certificates store and the EntCA certificate is located in the Trusted Root Certification Authorities store.

4. Verify the serial number of the imported certificate.

a. In the console tree, double-click **Personal** and then click **Certificates**.

b. Double-click the certificate

c. In **Certificate**, click the **Details** tab. Verify that the serial number matches the original.

d. Close all open windows and log off of the network.

# Using Qualified Subordination

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using qualified subordination**

This section covers:

- Qualified subordination overview
- Name constraints
- Mapping policies between trust hierarchies
- Policy constraints

# Qualified subordination overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Qualified subordination overview**
Qualified subordination allows you to place certificate issuance constraints on subordinate CAs and to place usage constraints on the certificates they issue. With qualified subordination, you can focus subordinate CAs according to specific certification needs and administer your public key infrastructure (PKI) more efficiently.

**Certificate-based trust between trust hierarchies**
Qualified subordination also allows you to establish trust between CAs in separate trust hierarchies. This type of trust relationship is also called *cross-certification*. With this trust relationship, qualified subordination is not limited to subordinate CAs. Trust between hierarchies may be established using a subordinate CA in one hierarchy and the root CA in another hierarchy.

**Additional levels of security controls**
Qualified subordination extends your trust hierarchy by allowing you to place additional trust conditions within and between the domains in your PKI. With qualified subordination, the qualified subordinate CAs in your trust hierarchy can each have different rules governing how they will issue certificates and how their certificates may be used. For more information on qualified subordination, see Qualified subordination.

**Qualified subordination extensions**
Each qualified subordination constraint adds an additional trust condition and more narrowly defines the scope of a CA. These conditions are defined in the certificate extensions of a qualified subordinate CA certificate. When you install a qualified subordinate CA, you define the following extensions in its CA certificate:

| Extension | Description |
|---|---|
| Name Constraints | Restricts the namespaces that are permitted or excluded by the qualified subordinate CA and its subordinates when issuing certificates. |
| Policies | Defines the list of acceptable issuance and application policies for certificate usage. These policies are identified in the certificate by object identifiers (also known as object identifiers). |
| Policy Mapping | Allows a policy from one domain to be mapped onto a policy of another domain. |
| Policy Constraints | Restricts the subordination levels in a certificate hierarchy to which a policy is applied. These extensions are used in conjunction with issuance and application policies only. |

All constraints that are placed on a qualified subordinate CA are defined in the complete request for the CA certificate that is used to install the qualified subordinate CA. The complete request is a CMC certificate request that has been generated using an information file (.inf file). All qualified subordinate CA policies, constraints, and mappings can be defined using an information file (.inf). In order to modify the policies and constraints placed on a qualified subordinate CA after installation, the administrator of that qualified subordinate CA's parent CA must reissue the CA certificate for the qualified subordinate CA, thereby reinstalling it. For more information, see Perform qualified subordination.

The constraints and policy types listed above are defined in RFC 2459. For more information on RFCs, see the RFC Editor Web site.

For more information, see Name constraints, Policy constraints, Mapping policies between trust hierarchies, and Policy qualifiers.

**Qualified subordinate CA scenarios**
The following sections show how qualified subordination can be used.

**Name constraints scenarios**
The Humongous Insurance Company has two Active Directory directory service domains hosted in different geographic locations, one domain in North America and one domain in South America. The company's PKI administrator wants the qualified subordinate CAs that are deployed in each domain to issue certificates for users in their local domain only. The two Active Directory domains are *northamerica.humongousinsurance.com* and *southamerica.humongousinsurance.com*.

The administrator performs the following steps:

1. Installs a qualified subordinate CA for the domain *northamerica.humongousinsurance.com* with the following permitted name constraints:

| Name constraint format | Permitted name constraint | Example |
|---|---|---|
| Distinguished name | DC=northamerica,DC=humongousinsurance,DC=com | CN=Mike Danseglio,CN=Users,DC=northamerica,DC=humongousinsurance,DC=com |

| | | |
|---|---|---|
| DNS domain name | .northamerica.humongousinsurance.com | hostname.northamerica.humongousinsurance.com |

1. Installs a qualified subordinate CA for the domain *southamerica.humongousinsurance.com* with the following permitted name constraints:

| **Name constraint format** | **Permitted name constraint** | **Example** |
|---|---|---|
| Distinguished name | DC=southamerica,DC=humongousinsurance,DC=com | CN=Don Funk,CN=Users,DC=southamerica,DC=humongousinsurance,DC=com |
| DNS domain name | .southamerica.humongousinsurance.com | hostname.southamerica.humongousinsurance.com |

As a result, the certificate issuance behavior of each qualified subordinate CA is restricted to users in their respective domains. If a user in *northamerica.humongousinsurance.com* requests a certificate from the qualified subordinate CA for *southamerica.humongousinsurance.com*, the request is denied because the namespace specified in a permitted name constraint automatically excludes any other namespaces.

For more information, see Name constraints.

**Policy scenarios**

Humongous Insurance wants to use application and issuance policies to configure the following PKI scenarios:

- Only allow remote network logon using smart card authentication.
- Create a certificate that allows selected users to make purchases of up to one million dollars.

**Only allow remote network logon using smart card authentication**

To restrict remote network logon to only allow smart card authentication, the company performs the following steps:

1. Configures their remote access server to require smart card authentication.
2. Installs and configures a qualified subordinate CA to issue smart card logon certificates containing a specific application policy that is required by the remote access server.
3. Distributes smart cards containing the specific application policy that is required by the remote access server.

When a user attempts to log in, the following steps occur:

1. Users attempt to log on remotely over a dial-up connection using their smart cards.
2. The remote access server software checks to see if the smart card contains the required application policy.
3. If the smart card contains the required application policy, then the remote access server software forwards the logon request to the nearest domain controller.
4. The domain controller grants the user access to the network.

**Create a certificate that allows selected users to make purchases of up to one million dollars**

To create a certificate that allows selected users to make purchases of up to one million dollars, the company performs the following steps:

1. Creates a signing certificate for the company's accounting department that contains a specific issuance policy object identifier (also known as an OID).
2. When the company creates a Million Dollar Purchase certificate template, it adds an *issuance requirement* for the Accounting department's specific issuance policy object identifier.
3. The user creates a million dollar purchase request using the template.
4. The accounting department manager is notified that there is a pending certificate request which she must accept or reject.
5. The accounting department manager signs the Million Dollar Purchase certificate request with the signing certificate that contains the specific issuance policy object identifier.

6. The signed request is sent to the company's CA.

7. The company's CA receives the signed request, determines that the issuance requirement for the certificate template has been met by identifying the accounting department's specific issuance policy object identifier, and issues the Million Dollar Purchase certificate to the user.

**Policy mapping scenario**
Two companies, Humongous Insurance and Northwind Traders, enter into a partnership and want to establish a trusted communication path where the $1 million issuance policy of Humongous Insurance is considered equal with the two million dollar issuance policy of Northwind Traders.

The CA administrator for the Humongous Insurance domain *humongousinsurance.com* performs the following steps:

1. Obtains the two million dollar issuance policy object identifier for Northwind Traders under a very secure channel.

2. Defines the policy mapping between Humongous Insurance's one million dollar issuance policy and Northwind Traders' two million dollar issuance policy.

3. Installs a qualified subordinate CA in the Humongous Insurance trust hierarchy containing the policy mapping.

The policy mapping results in allowing purchase orders signed in the Northwind Traders trust hierarchy to be validated by the trust hierarchy of Humongous Insurance.

For more information, see Mapping policies between trust hierarchies; Policy constraints

**Enterprise and stand-alone qualified subordinate CAs**
Windows Server 2003 qualified subordinate CAs can be installed as enterprise qualified subordinate CAs or stand-alone qualified subordinate CAs. The difference between the two types of qualified subordinate CAs is how they identify users requesting certificates. Enterprise qualified subordinate CAs require the use of Active Directory and stand-alone qualified subordinate CAs do not.

Enterprise qualified subordinate CAs identify users by some or all of their Active Directory user object attributes. When an enterprise qualified subordinate CA receives a certificate request from a user, it identifies the user according to the authentication credentials that are used by that user during network logon and uses that information to query the Active Directory and obtain the user's user object attributes.

When users request certificates from a stand-alone qualified subordinate CA, the user fills out a Web page form where the user specifies information such as a name, e-mail address, company name, department, and country/region. This information is included in the fields of the certificate request that is sent to the stand-alone qualified subordinate CA, which uses this information to determine certificate issuance. A stand-alone CA cannot publish any issued certificates to Active Directory other than its own CA certificate. However, the more common scenario is to have a stand-alone root CA with an enterprise qualified subordinate CA. For more information, see Stand-alone certification authorities.

**Verification paths for qualified subordinate CAs**
Each qualified subordinate CA's policies and constraints are defined according to a subset of its certification path's policies and constraints. Using qualified subordination, boundaries are established within the certification hierarchy to ensure that all CAs in a hierarchy's paths issue certificates within certain constraints. These constraints may be maintained or more narrowly defined the further the certification hierarchy branches from its trust anchor (root CA).

The following graphic shows how qualified subordinate CAs can only issue CA certificates according to a subset of the rules permitted by their certification path. In the graphic, policies are used as an example and are represented as numbers to demonstrate a subset.

**Qualified subordination certification hierarchy restrictions**

Qualified subordinate CAs CA 1, CA 2, and CA 3 have defined policies from which the qualified subordinate CAs below them may select policies. With each level of the certificate hierarchy, fewer of the acceptable policies are used and the qualified subordinate CAs are more limited in scope.

No trust model will permit the qualified subordinate CA to allow certificate issuance behavior that its certificate path does not allow. To enforce this rule, the following process is followed when a parent CA receives a CA certificate request:

1. The CA verifies the certificate request against all the constraints placed on all the CAs from its root CA down its certification hierarchy to itself.

2. At each intersection in the certification hierarchy, the issuing qualified subordinate CA compares the information contained in the certificate request with those set at the existing CA.

3. If there are no conflicts between the information in the certificate request and those placed on the CAs in the certification hierarchy, then the certificate is issued. If there is a conflict, the certificate request is denied.

**Notes**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

- In addition to the new constraints discussed in this topic, *basic constraints* can be used to control how a CA issues certificates. Basic constraints are available in both Windows 2000 and Windows Server 2003 CAs. For more information, see Basic constraints and Change basic constraints.

# Name constraints

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Name constraints**
You can use qualified subordinate certification authority (CA) name constraints to restrict a qualified subordinate CA's certificate issuance authority to single or multiple namespaces used within your network or public key infrastructure (PKI), such as those used as Active Directory domains. By constraining the qualified subordinate CA's certificate issuance according to one or more namespaces, you will have greater control over which users and computers receive certificates from your qualified subordinate CAs. For more information, see Qualified subordination.

You can use the following naming and addressing formats to constrain the certificate issuance activities of qualified subordinate CAs:

- Directory name (for example, an Active Directory distinguished name)
- DNS domain name
- E-mail name
- User principal name (UPN)
- Universal Resource Identifier (URI)
- Internet Protocol address

The qualified subordinate CA's name constraints define namespaces within which all user names identified in the certificate requests it receives must be located. Name constraints are organized as *permitted* or *excluded* name constraints. If the same name formats used as name constraints are present in the certificate requests received by the qualified subordinate CA, it evaluates them according to its permitted and excluded name constraints.

When using qualified subordination in your PKI deployment, you can leverage the well-planned naming and addressing methods used in your network to support the goals of your PKI. In a sense, you can imprint your trust model onto these existing methods, assigning CAs to different domains and configuring them to issue certificates only to users and computers in those domains. When you deploy a qualified subordinate CA to a network domain, you will need to consider the namespaces and addressing methods used by the resources of that domain, and possibly subdomains and other domains, in order to configure the qualified subordinate CA to issue certificates according to your administrative and security goals.

**Choosing permitted and excluded name constraints**
When choosing a qualified subordinate CA's name constraints, you need to decide on the users that the qualified subordinate CA will receive certificate requests from. Typically, the qualified subordinate CA will be deployed to an Active Directory domain in your network and be responsible for issuing certificates to the users and computers within that domain and possibly its subdomains. The namespaces used by these domains, including Active Directory names, DNS namespaces, and other namespaces, can be used to define the permitted and excluded name constraints of the qualified subordinate CA.

Excluded name constraints are used to exclude a child namespace of a permitted namespace. For example, your qualified subordinate CA may have a permitted name constraint for the DNS namespace *.microsoft.com*, but you do not want it to issue certificates for the subdomain *.betatest.microsoft.com* because that subdomain may be experimenting with software that should not be certified within your PKI. An excluded name constraint of *.betatest.microsoft.com* removes the qualified subordinate CA's ability to issue certificates to users and computers within the namespace *.betatest.microsoft.com*.

If an excluded name constraint is used to exclude a parent namespace of a permitted name constraint, it will exclude the entire permitted namespace. For example, if a permitted name constraint is *.example.microsoft.com* and the excluded name constraint is *.microsoft.com*, then the entire *.microsoft.com* namespace is excluded.

It is also important to note that excluded namespaces take precedence over permitted namespaces, guaranteeing that the qualified subordinate CA will not issue a certificate to a user within an excluded namespace even if the user is also within a permitted namespace. For example, a user could be within the permitted Active Directory namespace *.microsoft.com* but also within the excluded DNS namespace *.widgets.microsoft.com*. In this example, the excluded DNS namespace overrides the

permitted Active Directory namespace and the qualified subordinate CA does not fulfill the user's certificate request.

When choosing permitted and excluded name constraints, you should be aware of how the qualified subordinate CA processes certificate requests. When the qualified subordinate CA is comparing the names identified in a certificate request to its name constraints, all names in a certificate request must be within permitted namespaces and none may be within an excluded namespace. For more information on how a qualified subordinate CA using name constraints when processing certificate requests.

**Directory name constraints**

Active Directory allows you to use distinguished names as name constraints for your qualified subordinate CAs. Distinguished names identify users and resources on the network in Active Directory. This allows you to constrain a qualified subordinate CA to permit or exclude users in the Active Directory using the users' distinguished names. Active Directory also uses distinguished names to create and reference groups of objects in the directory, such as users and computers. The distinguished names of these object groups can also be used as name constraints, allowing you to constrain a qualified subordinate CA to permit and exclude certificate issuance for entire groups in the directory.

The following table describes types of distinguished names that are used as permitted and excluded names.

| Directory object | Distinguished name constraint examples |
|---|---|
| User | `CN=Users,DC=example,DC=microsoft,DC=com` |
| Computer | `CN=Computers,DC=microsoft,DC=com` |
| Domain controller | `CN=Servers,CN=Sites,CN=Configuration,DC=microsoft,DC=com` |
| Contact | `OU=Contacts,DC=microsoft,DC=com` |
| Group | `OU=My Group,DC=microsoft,DC=com` |
| Organizational Unit | `OU=ITServices,DC=microsoft,DC=com` |

X.500 directory names can also be used as name constraints. For example, **o=cities,st=Redmond,c=US**.

**DNS name constraints**

You can apply the DNS namespaces used by your network for name resolution as name constraints for a qualified subordinate CA. When the qualified subordinate CA receives a certificate request, it will compare the DNS name associated with the computer requesting the certificate to its DNS name constraints and decide whether or not to issue a certificate. The subordinate CA will apply name constraints to all entities within the DNS namespaces specified as DNS name constraints. The DNS domain names accepted by the subordinate CA must follow the standard DNS naming conventions as specified in RFCs 1034 and 1035. The permitted and excluded DNS name constraints are specified using the information file (.inf) that is used to install the qualified subordinate CA.

There are two different ways to specify a DNS name constraint:

- **DNS host name**. Specifies a specific DNS host name as a permitted or excluded name constraint, such as `host1.example.microsoft.com`.

- **DNS namespace**. Specifies a DNS name space wherein all DNS host names are permitted or excluded, such as `.example.microsoft.com`.

To specify that a DNS name constraint should apply to all entities within a DNS namespace and not host names containing part of the name, you must use a period (.) after the leftmost label in the domain name, such as `.example.microsoft.com`. This period indicates that all subjects with a DNS name ending in the domain `.example.microsoft.com` are subject to the DNS name constraint, but the host name `host1example.microsoft.com` is not a match because `host1example` contains no period separator between *host1* and *example*.

When the subordinate CA compares the DNS name in a certificate request with its name constraints, it performs a string comparison. The string comparison attempts to locate a match within any part of the names. If the qualified subordinate CA's DNS name constraint is `example.microsoft.com` and the certificate request contains a DNS host name `host1example.microsoft.com`, the qualified subordinate CA will consider those names as a match. Using the same DNS name constraint (`example.microsoft.com`), the domain name `www.example.microsoft.com` is also considered a match.

With DNS name constraints involving domain names, any subdomain of a name constraint satisfies the constraint. If you apply

an excluded DNS name constraint for `.example.microsoft.com` (notice the leftmost period), then names such as `www.example.microsoft.com` and `us.sales.example.microsoft.com` are excluded also. Using the same excluded DNS name constraint, names such as `it.microsoft.com` and `accounts.microsoft.com` would not be excluded.

The following table demonstrates the two different DNS name constraint evaluation methods used by a qualified subordinate CA.

| Certificate request's DNS information | DNS constraint | Qualified subordinate CA evaluation |
|---|---|---|
| host1example.microsoft.com | .example.microsoft.com | No match |
| host1.example.microsoft.com | .example.microsoft.com | Match |
| www.example.microsoft.com | .example.microsoft.com | Match |
| us.sales.example.microsoft.com | .example.microsoft.com | Match |

When creating DNS constraints, you should consider the hierarchies of the DNS namespaces to avoid conflicts between permitted and excluded DNS constraints. If you are permitting and excluding DNS domains for a qualified subordinate CA, the excluded domain names override the permitted names. If you specify the permitted DNS name constraint `www.example.microsoft.com` and also specify the excluded DNS name constraint `.microsoft.com`, the permitted name will be cancelled out by the excluded name because the permitted domain name is a subdomain of the excluded domain name.

A qualified subordinate CA's DNS constraints cannot permit DNS names excluded by its parent CA. For example, if the parent CA excludes the DNS name `.microsoft.com`, then its qualified subordinate CA cannot permit the subdomain `www.example.microsoft.com`.

**URI constraints**

You can specify Uniform Resource Identifiers (URIs) as name constraints for a qualified subordinate CA. URIs are used to identify resources on the Internet using identifiers such as URL, FTP, HTTP, telnet, mailto, news, and gopher. The URI naming conventions supported by the qualified subordinate CA must follow the syntax specified in RFC 2396.

When validating the URI names in a certificate request, the qualified subordinate CA ignores the protocol element in the URI, such as http:// or ftp://, and uses the domain or host names only. For example, if the URI constraint `URL=http://.example.microsoft.com` is compared to the name `ftp://host1.example.microsoft.com`, then the comparison is actually between the URI constraint `.example.microsoft.com` and the name `host1.example.microsoft.com`.

Similar to DNS constraints, URI constraints may specify a host or domain. When specifying a domain, URI name constraints must begin with a period (.), such as `.example.microsoft.com`. This URI constraint also applies to all subdomains of the domain constraint, such as `abc.example.microsoft.com` or `xyz.example.microsoft.com`. Using the same example, if the URI name in a certificate request does not contain a period to the left of example, then the constraint does not apply. For example, the certificate request URI name `example.microsoft.com` (notice that there is no beginning period) does not satisfy the name constraint `.example.microsoft.com`.

When specifying a host, the beginning period is not used, such as `host1example.microsoft.com`. Without the beginning period, the name constraint is satisfied only when the subject in the certificate request has the leftmost label (`host1example`). For example, the name constraint `example.microsoft.com` would be satisfied by the certificate request name `host1example.microsoft.com` but not by `host1.example.microsoft.com`.

The most frequent application of URI name constraints is the validation of certificate requests for subjects wanting to access to a secure Web server. For example, if the Web server certificate request has a name of http://www.microsoft.com and the qualified subordinate CA's permitted URI name constraint is `URL=http://www.microsoft.com`, then this URI constraint would permit the certificate request for the Web server certificate.

**E-mail and UPN constraints**

Both e-mail and UPN naming conventions follow a similar format that must be followed when you format name constraints. E-mail extensions and UPNs used as name constraints follow the naming conventions specified in RFC 822.

You can specify e-mail and UPN name constraints for an individual subject, such as mikedan@example.microsoft.com, or you can specify constraints for all subjects whose e-mail names or UPNs end in a specific name, such as `@example.microsoft.com`. Typically, you will specify e-mail or UPN name constraints for all subjects whose e-mail addresses and UPNs end in a specific name.

The difference in specifying these two name constraints is the at sign (@). If the name constraint contains any characters to the left of the @, the qualified subordinate CA regards the name constraint as applying to a single subject. Conversely, if there are

no characters to the left of the @, then the qualified subordinate CA regards the name constraint as applying to all subjects whose e-mail addresses or UPNs end in the name constraint.

| E-mail and UPN constraints | Certificate name value | Qualified subordinate CA's evaluation |
|---|---|---|
| host1@example.microsoft.com | host1@example.microsoft.com | Match |
| @example.microsoft.com | host1@example.microsoft.com | Match |
| host1@example.microsoft.com | mikedan@example.microsoft.com | No match |

**Note**

- If UPN and e-mail permitted name constraints are not defined when defining the permitted name constraints for a qualified subordinate CA certificate request, then the UPN and e-mail permitted name constraints are automatically entered by the issuing CA's policy module when it creates the qualified subordinate CA certificate. The UPN and e-mail permitted name constraints are left unspecified and therefore permit all names. If you want to apply UPN and e-mail permitted name constraints, you must specify the UPN and e-mail permitted constraints when defining the permitted name constraints for a qualified subordinate CA certificate request.

**IP address constraints**

You can specify IP addresses and IP address ranges as name constraints on a qualified subordinate CA. IP address name constraints follow the formatting conventions specified in RFCs 791 (IPv4) and 1883 (IPv6). The IP addresses that are contained in the certificate requests that are made to a qualified subordinate CA will be compared to the IP addresses in the qualified subordinate CA's name constraints.

**Name constraint processing rules**

For a certificate request to be successful, all names that are identified in a certificate request must be within permitted name spaces and none may be within an excluded namespace. Each permitted and excluded name constraint is processed separately.

Name constraints are processed by the qualified subordinate CA according to the following rules:

- Constraints apply only when the namespace types specified as name constraints are present in the certificate request.
- A certificate request is successful if all names in the certificate request succeed in matching the permitted name constraint.
- A certificate request is unsuccessful if all names in the certificate request succeed in matching the excluded name constraint.
- A certificate request containing names that can not be matched with either the permitted or excluded names is considered excluded and is failed.
- Comparison of the name identifying the subject entity with the qualified subordinate CA's name constraints is performed using Unicode. The comparison is not case sensitive.

To find a match, the qualified subordinate CA starts at the rightmost part of the name in the certificate request and compares that name to its list of permitted and excluded name constraints. For example, when the CA receives a certificate request with the DNS name example.microsoft.com it will attempt to find a name constraint match starting with .com, then microsoft.com, and then example.microsoft.com. The exceptions to this are distinguished names (DNs), where the qualified subordinate CA starts from the leftmost name, and IP addresses, where it attempts to find a match starting with the network address and then the host address.

For a certificate request to be accepted by the qualified subordinate CA, each name in the certificate request should match at least one of the qualified subordinate CA's name constraints of the same name type. If there are two permitted distinguished names on the qualified subordinate CA, then the certificate request subject's name should match at least one of these distinguished names. No comparisons are performed between different types of names.

Excluded names take precedence over permitted names. If a permitted DNS name constraint allows users from the DNS domain `.example.microsoft.com`, but the same name is listed as an excluded name constraint, then users from the DNS domain `.example.microsoft.com` are excluded and the qualified subordinate CA will fail their certificate requests. This

processing rule requires that you pay close attention to the hierarchy of the different name conventions. For example, if a permitted DNS name constraint permits users from the DNS domain `.example.microsoft.com`, but the parent domain `.microsoft.com` is listed as an excluded name constraint, then users from the DNS domain `.example.microsoft.com` are excluded because `.example.microsoft.com` is a child domain of `.microsoft.com`.

# Mapping policies between trust hierarchies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Mapping policies between trust hierarchies**

To establish trust between users and computers in different trust hierarchies, you can map the issuance and application policies of each trust hierarchy. The qualified subordinate CA that contains this mapping is called the *issuer CA* and the subordinate CA whose policies have been mapped is called the *subject CA*. In mapping some or all of the subject CA's policies to the issuer's policies, the issuer CA effectually subordinates the subject CA. The result of this mapping is that users and computers in the issuer CA trust hierarchy who attempt to validate certificates from users and computers in the subject CA trust hierarchy can use their own certification path to perform validation. The separate trust hierarchy can be within the same intranet or in separate PKI environments over an extranet.

Mapping policies across trust hierarchies only requires that you install the issuer CA in your trust hierarchy. All the policies that are used in the subject CA trust hierarchy are mapped to the policies in your trust hierarchy, where you install the qualified subordinate CA. For this reason, you can establish a trust relationship, in fact subordinate, with a CA in another company by obtaining its policy object identifiers (also known as OIDs) and mapping them to the policy object identifiers that are used in your trust hierarchy.

The following steps are performed when using policy mapping for both issuance and application policies:

1. Determine the trust hierarchy with which you want to establish a trust relationship.

2. Establish the equivalence between the assurance levels that are used between the two trust hierarchies involved in the trust relationship.

3. Obtain the issuance and application policy object identifiers that are used in both trust hierarchies involved in the trust relationship.

4. Map the issuance and application policy object identifiers in the separate trust hierarchies and define their policy constraints in the CA certificate request for the qualified subordinate CA you are installing in your trust hierarchy.

5. Install the qualified subordinate CA with the policies, policy mappings, and policy constraints in your trust hierarchy.

When a user in the issuer CA trust hierarchy receives a file signed by a user in the subject CA trust hierarchy, the application of the user in your domain will attempt to validate the certificate using the validation path in your trust hierarchy. Because the object identifier in the certificate maps to an object identifier in your trust hierarchy, the certificate is validated. When a user in the subject CA trust hierarchy receives a file signed by a user in the issuer CA trust hierarchy, the subject CA user's application will attempt to validate the certificate using the validation path in its own certification hierarchy. Because the certificate contains the object identifiers used in the subject CA trust hierarchy, the certificate is validated.

Before defining the policy mapping, you need to obtain all the object identifiers that will correspond between the domains in the trust relationship. If you are creating a qualified subordinate CA for the purpose of establishing a trust relationship between trust hierarchies in different companies or PKIs, you will need to obtain the object identifiers used in the subject CA trust hierarchy by obtaining a certificate used in that hierarchy or from the CA administrator of that hierarchy. This information should only be passed under the most secure channels.

Issuance policy object identifiers in your trust hierarchy can only be mapped to issuance policy object identifiers in the foreign trust hierarchy. Similarly, application policy object identifiers in your trust hierarchy can only be mapped to application policy object identifiers in the foreign trust hierarchy.

For more information, see Qualified subordination; Qualified subordination overview; Name constraints; Issuance policies; Application policies; Policy constraints; Policy qualifiers; and Certificate Templates.

**Constraining policy mapping**

When a qualified subordinate CA uses policy mapping, you can use policy constraints to set the number of subordinate CAs below it in the certificate hierarchy that may map to its policies. An *inhibit policy mapping* policy constraint of 3 will inhibit policy mapping to subordinate CAs four levels below the qualified subordinate CA. A subordinate CA 5 levels below the qualified subordinate CA will not be allowed to define policy mappings.

**Unexpected trust**

When mapping policies between trust hierarchies in two different companies, the problem of unexpected trust could arise should a third company map its policy object identifier to the mapped object identifier of one of the two companies. For example:

- The secure e-mail policy used by *humongousinsurance.com* is mapped to the secure e-mail policy in *wideworldimporters.com*.

- A third company, *northwindtraders.com*, maps its secure e-mail policy to the policy of wideworldimporters.com.

- This allows a user in northwindtraders.com to send signed e-mail to humongousinsurance.com that is considered valid because the e-mail application in humongousinsurance.com sees its own valid policy object identifier in the certificate issued by the CA in northwindtraders.com.

If humongousinsurance.com wants to prevent any additional policy mapping by northwindtraders.com from affecting its domain, it could place an *inhibit policy mapping* of 0 on its issuer CA. The CA for northwindtraders.com is considered a subordinate of the CA for wideworldimporters.com, and is thereby two levels below the issuer CA for humongousinsurance.com. Consequently, an *inhibit policy mapping* of 0 would cause the qualified subordinate CA for humongousinsurance.com to only process the policy mapping in certificates from subjects directly below it in its trust model (wideworldimporters.com) and refuse any certificates issued below that level (northwindtraders.com).

# Policy constraints

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policy constraints**
Qualified subordinate certification authority (CA) policy constraints allow you to constrain the path validation of your certification hierarchy by:

- Defining how far below a qualified subordinate CA in your certification hierarchy that a policy is required.
- Defining how far below a subordinate CA in your certification hierarchy that policy mapping is permitted.

There are two policy constraint settings:

- **Require explicit policy**. Determines the maximum number of additional certificates that may appear below the qualified subordinate CA in the certification hierarchy before a policy is required.
- **Inhibit policy mapping**. Determines the maximum number of additional certificates that may appear below the qualified subordinate CA in the certification hierarchy before policy mapping is no longer permitted.

Policy constraints are set separately for issuance and application policies. The policy constraints for a qualified subordinate CA's issuance policies do not have to be the same as the *Require explicit policy* and *Inhibit policy mapping* settings for its application policies.

When defining policy constraints, the numbering system used begins with 0. For example, if a qualified subordinate CA policy has an inhibit policy mapping of 0, then that policy can only be mapped one level below the qualified subordinate CA in the trust hierarchy.

For more information, see Qualified subordination; Qualified subordination overview; Name constraints; Mapping policies between trust hierarchies; Policy qualifiers; and Certificate Templates.

**Note**

- Policy constraints cannot be specified in certificate templates, but must be specified in the information file (.inf) used to create the CA certificate that, in turn, is used to install the qualified subordinate CA.

# Certificates Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

The following books provide detailed information about certificates, certification authorities, public key encryption, and public key infrastructure (PKI):

- Austin, Thomas, *PKI:A Wiley Tech Brief*. John Wiley & Sons, December 2000.
- Feghhi, Jalal and Jalil Feghhi, *Secure Networking with Windows 2000 and Trust Services*. Addison-Wesley Pub Co., February 2001.
- Housley, R.P., and T. Polk. 2001. *Planning for PKI*. New York, New York: John Wiley & Sons, Inc.
- Howard, Michael, *Designing Secure Web-Based Applications for Microsoft Windows 2000*. Microsoft Press, August 2000.
- Kaufman, C., Perlman, R., and M. Speciner. 1995. *Network Security: Private Communication in a Public World*. Upper Saddle River, New Jersey: Prentice-Hall Inc.
- Schneier, Bruce, *Applied Cryptography: Protocols, Algorithms, and Source Code in C*. John Wiley & Sons, December 1995.

The following resources have in-depth information about planning, deploying, and using a public key infrastructure with Windows Certificate Services:

- Microsoft Security on the Microsoft Web site.

For updated technical information, see:

# Certificate Services Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Clients do not automatically enroll for certificates after autoenrollment is configured.
- General troubleshooting for a certification authority (CA).
- Error when accessing the certification authority Web pages.
- Web pages on an enterprise certification authority (CA) either don't generate certificates or generate certificates that are not valid.
- Can't log into certification authority (CA) Web pages.
- Certification authority (CA) Web enrollment pages that are installed on a remote server other than the CA do not work.
- Internet Information Services (IIS) 4.0 and Certificate Server 1.0 cannot enroll for certificates using Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition Certificate Services Web pages.
- A user tries to log on with the smart card and receives this message: "The system cannot log you on to this domain because the system's computer account in its primary domain is missing or the password on the account is incorrect."
- After renewing a CA, computers are no longer automatically enrolling for certificates from that CA.
- When trying to enroll for a certificate from a computer or account belonging to a child domain of the domain where the CA is located, the following error appears: "No template could be found. There are no CAs from which you have permission to request a certificate, or an error occurred while accessing the Active Directory."

**Clients do not automatically enroll for certificates after autoenrollment is configured.**
**Cause:** The Group Policy information used for autoenrollment has not yet replicated to the client computers. By default, this information can take up to 120 minutes to replicate to all computers.

**Solution:** Wait for Group Policy to complete replication or use the Gpupdate tool to force replication to occur immediately.

**General troubleshooting for a certification authority (CA).**
Check the event log of the server. It often logs more detailed errors than you will notice from doing the procedure you're attempting.

For more information about Certificate Services logging, see article Q305018, "How to Change the Event Logging Level for Certificate Services," in the Microsoft Knowledge Base.

**Error when accessing the certification authority Web pages.**
**Cause:** The user accessing the Web pages is not a member of the Administrators or Power Users groups on the local computer. When a newer version of the Web enrollment software is available on the CA, the client computer must install that software. The user must be a member of the Administrators or Power Users group to install the software.

**Solution:** Log on as a user that is a member of the Administrators or Power Users group to access the Web enrollment pages and download the newer version of the software.

**Cause:** Web pages aren't installed on the certification authority (CA).

**Solution:** From the command prompt on the CA, run **certutil -vroot** to install the Web enrollment pages.

**Cause:** Web pages don't have *execute script* permissions.

**Solution:** From Internet Information Services (IIS), open the CertSrv folder and confirm that there are *execute script* permissions on the folder. The CertSrv folder is:

*Systemroot*/System32/Certsrv

**Web pages on an enterprise certification authority (CA) either don't generate certificates or generate certificates that are not valid.**
**Cause:** For an enterprise CA, Web pages require that the user be authenticated. If the pages are set to allow anonymous connections, then the CA will either not generate certificates or will generate certificates that are not valid.

**Solution:** See Set security for access to certification authority Web pages.

**Can't log into certification authority (CA) Web pages.**
**Cause:** If the Web pages negotiate basic authentication with the browser, then your Windows 2000 user account must have the user right to log on to the server.

**Solution:** By default, only domain administrators have this user right. You will need to change this default security permission setting for the server hosting the CA if you use the Netscape browser.

**Certification authority (CA) Web enrollment pages that are installed on a remote server other than the CA do not work.**
**Cause:** The pages are set to use NTLM authentication instead of basic authentication.

**Solution:** If the Web pages are located on a different server than the CA, then you must set the pages to use basic authentication rather than NTLM if the CA is an enterprise CA. You should also use Secure Sockets Layers (SSL) to secure these pages to protect the passwords. See the Internet Information Services (IIS) documentation to change these settings.

**Internet Information Services (IIS) 4.0 and Certificate Server 1.0 cannot enroll for certificates using Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition Certificate Services Web pages.**
**Cause:** IIS 4.0 and Certificate Server 1.0 cannot process a certification path, rather than just a single certificate.

**Solution:** Use the command-line utility Certreq to process the enrollment request.

**A user tries to log on with the smart card and receives this message: "The system cannot log you on to this domain because the system's computer account in its primary domain is missing or the password on the account is incorrect."**
**Cause:** The computer account may be disabled or the CA that issued the smart card certificate is not trusted by the computer.

**Solution:**

1. Make sure that the computer account is enabled in the domain.

2. Use the Certificates snap-in to verify that the root CA's certificate is in the **Trusted Root Certification Authorities** store on the user's computer.

3. Use the Certificates snap-in to verify that the domain controller has been issued a domain controller certificate that can be verified to a trusted root.

**After renewing a CA, computers are no longer automatically enrolling for certificates from that CA.**
**Cause:** CA renewal requires that all automatic certificate enrollment objects that enroll for certificates from that CA be recreated.

**Solution:** See Create an automatic certificate request for computers in a Group Policy object.

**When trying to enroll for a certificate from a computer or account belonging to a child domain of the domain where the CA is located, the following error appears: "No template could be found. There are no CAs from which you have permission to request a certificate, or an error occurred while accessing the Active Directory."**
**Cause:** You don't have the proper security permissions set on the certificate templates.

**Solution:** Modify the security permissions for the certificate templates to include the child domain accounts from which you want to allow enrollment. To set access control for certificate templates, see Controlling enrollment access to certificate templates. Some access control caches must time out after making changes to security permissions, so you have to wait a short period of time before seeing the new security permissions replicate through the network.

# Certificate Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate Templates**
Certificate Templates allow customization of certificates issued by Certificate Services, including both how certificates are issued and what they contain.

Although all issued certificates are based on a certificate template, certificate templates can only be issued by an enterprise certification authority running on Microsoft® Windows Server™ 2003, Enterprise Edition, or Microsoft® Windows Server™ 2003, Datacenter Edition.

- For tips about using Certificate Templates, see Certificate Templates Best practices.
- For help with specific tasks, see Certificate Templates How To....
- For general background information, see Certificate Templates Concepts.
- For problem-solving instructions, see Certificate Templates Troubleshooting.

**Note**

- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

# Certificate Templates Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Do not delete the Certificate Publishers security group**

- The Certificate Publishers security group contains each certification authority's computer account and is used when publishing certificate templates to Active Directory. If this group is removed, the certification authority may not publish certificates to Active Directory correctly. To avoid this, the group should not be deleted and its membership should not be modified.

**Do not exceed the certificate lifetime of the issuing certification authority**

- Certificate lifetimes work as a subset of the certification authority's (CA) certificate lifetime. All certificates, including the CA certificate, have an expiration date that they are no longer valid after. As a result, a certificate cannot be issued with a lifetime that exceeds the lifetime of the issuing CA. Issuing such a certificate would allow it to be valid for longer than the issuing CA certificate, which is impossible. A CA will therefore continue to issue certificates until the CA's certificate expires or until the requested template's renewal period is greater than the CA's certificate remaining lifetime.

**Plan certificate templates before deployment**

- Certificates can be issued to subjects in many ways, including manual enrollment, autoenrollment and Web enrollment. In addition, there are many certificate strategies including issuing one all-inclusive certificate to all subjects and issuing several application-specific certificates to subjects as needed. Because there are so many options, planning should be done well in advance of certificate deployment.

**Upgrade the certificate templates in Active Directory before upgrading from Windows 2000**

- Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, certification authorities use newer versions of certificate templates than those used by Windows 2000. These templates must be upgraded before the certification authorities are upgraded to ensure proper operation.

  For more information, see Install new templates and upgrade existing templates.

**Duplicate new templates from existing templates closest in function to the intended template**

- New certificate templates are duplicated from existing templates. Many settings are copied from the original template. Because of this, duplicating one template to another of a totally different type may carry over some unintended settings. When duplicating a template, examine the subject type of the original template and ensure that you duplicate one that has a similar function to that of the intended template. Although most settings for certificate templates can be edited once the template is duplicated, the subject type cannot be changed.

  For a list of certificate templates and their subject types, see Default Certificate Templates.

# Certificate Templates How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install new templates and upgrade existing templates
- Create a new certificate template
- Delete a certificate template
- Add a certificate template to a certification authority
- Allow subjects to request a certificate that is based on the template
- Re-enroll all certificate holders
- Remove a certificate template from a certification authority
- Modify a Certificate Template

# Install new templates and upgrade existing templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install new templates and upgrade existing templates**

1. Open Certificate Templates.

2. When prompted to install new certificate templates, click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.

- If this procedure has already been performed in your enterprise, you will not receive a prompt when you open Certificate Templates.

- This procedure must be performed before any Windows 2000 enterprise certification authorities are upgraded to Windows Server 2003 family certification authorities. If any Windows 2000 enterprise certification authorities currently exist or have ever existed in your enterprise, you must perform this procedure to ensure the certificate templates are added and updated correctly.

- This procedure must be performed on a certification authority (CA) in the certification hierarchy. Performing this procedure on a different computer may not work correctly.

- Performing this procedure is important to apply the proper security permissions on the existing certificate templates as well as create new certificate templates. If you do not perform this procedure before upgrading your certification authorities to the Windows Server 2003 family, you will be prompted when opening the Certification Authority snap-in.

- You must prepare the Active Directory schema with Adprep.exe for the upgrade before installing the new certificate templates. For more information on Adprep.exe, see Related Topics.

# Create a new certificate template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new certificate template**

1. Open Certificate Templates.
2. Right-click the template to copy from and then click **Duplicate Template**.
3. Type a new name for this certificate template.
4. Make any necessary changes and click **OK**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- New certificate templates must be created by copying an existing template and using the existing template's properties as the default for the new template. Copy the existing certificate template closest to the configuration of the intended new template to minimize the work necessary.
- Although Version 2 templates can be created and duplicated in Windows Server 2003, Standard Edition, certificates based on Version 2 templates can only be issued by a certification authority running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.

# Delete a certificate template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a certificate template**

1. Open Certificate Templates
2. Right-click the template, and then click **Delete**.

### Caution

- When you delete a certificate template, certificates can no longer be issued based on it. If you are using Enterprise CAs, this will affect all CAs in the forest. Certificate templates cannot be recovered once they are deleted.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.

# Allow subjects to request a certificate that is based on the template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow subjects to request a certificate that is based on the template**

1. Open Certificate Templates.
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. On the **Security** tab, add the groups, computers, or users that you want.
4. In **Group or user names**, click one of the new objects, and then, on **Permissions for *ObjectName***, under the **Allow** column, select the **Read** and **Enroll** check boxes.
5. Repeat the previous step for each new object.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- The **Autoenroll** permission must also be set if the subject will be using client autoenrollment to obtain certificates. For more information on autoenrollment, see Related Topics.
- To disallow subjects from requesting a certificate based on a template, clear the **Read** and **Enroll** check boxes using the same steps as above.

# Re-enroll all certificate holders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To re-enroll all certificate holders**

1. Open Certificate Templates.
2. Right-click the template that you want to use and then click **Reenroll All Certificate Holders**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is used when a critical change is made to the certificate template and you want all subjects that hold a certificate that is based on this template to re-enroll as quickly as possible. The next time the subject verifies the version of the certificate against the version of the template on the certification authority, the subject will re-enroll.

# Modify a Certificate Template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modify a certificate template**

- Supersede templates
- Configure a certificate template for key archival and recovery
- Configure a certificate template for client autoenrollment
- Modify enrollment policy
- Create an application policy
- Create an issuance policy
- Add an application policy
- Add an issuance policy
- Make certificate or application policy critical
- Change key usage
- Change basic constraints

# Supersede templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To supersede templates**

1. Open Certificate Templates
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. Click the **Superseded Templates** tab.
4. Click **Add**.
5. Click one or more templates to supersede, then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is applicable to version 2 templates. For more information about version 2 templates, see Related Topics.
- This procedure is used when a template replaces another template and you want subjects of certificates based on the old template to obtain new certificates based on the new template. It forces subjects to obtain a new certificate before their configured renewal period.

# Configure a certificate template for client autoenrollment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a certificate template for client autoenrollment**

1. Open Certificate Templates.
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. On the **Security** tab, add the users or groups that you want and, under **Allow**, select the **Read**, **Enroll**, and **Autoenroll** check boxes.
4. (Optional) To automatically enroll the subject without any more user input, on the **Request Handling** tab, click **Enroll subject without requiring any user input**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is applicable to version 2 templates. For more information about version 2 templates, see Related Topics.
- In addition to this procedure, other settings must be configured to allow client autoenrollment. For more information, see Related Topics.
- Clients must be re-enrolled to receive a certificate based on the changed template if they already have a valid certificate based on the old template. For more information about re-enrolling clients, see Related Topics.
- When autoenrollment retrieves a certificate that is configured to be stored on a smart card, you will receive a popup message when the certificate is ready to be stored on the smart card. If the message refers to a type of smart card that you do not have, click **Cancel** until the correct smart card type appears. You then provide the smart card PIN and the certificate will be stored on the smart card.
- When autoenrollment enrolls for a certificate that requires user interaction for the enrollment process, you will receive a **Certificate Enrollment** popup message and an icon will appear on your taskbar. Clicking that icon or message begins the certificate autoenrollment process.

# Modify enrollment policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify enrollment policy**

1. Open Certificate Templates
2. In the details pane, right-click the certificate template that you want to change, and then click **Properties**.
3. Click the **Issuance Requirements** tab.
4. Provide the requested information.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Certificate Templates, click **Start**, click **Run**, type **certtmpl.msc**, and then press Enter.
- This procedure is applicable to version 2 templates. For more information about version 2 templates, see Related Topics.
- Clients must be re-enrolled to receive a certificate based on the changed template if they already have a valid certificate based on the old template. For more information about re-enrolling clients, see Related Topics.

# Certificate Templates overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate Templates overview**

Certificate templates are an integral part of an enterprise certification authority (CA). They are an important element of the certificate policy for an environment, which is the set of rules and formats for certificate enrollment, use, and management.

When a CA receives a request for a certificate, groups of rules and settings must be applied to that request to perform the requested function, such as certificate issuance or renewal. These rules can be simple or complex and may apply to all users or specific groups of users. Certificate templates are the sets of rules and settings that are configured on a CA to be applied against incoming certificate requests. Certificate templates also give instructions to the client on how to create and submit a valid certificate request.

Although all issued certificates are based on a certificate template, certificate templates can only be issued by an enterprise CA running on Microsoft® Windows Server™ 2003, Enterprise Edition, or Microsoft® Windows Server™ 2003, Datacenter Edition. The templates are stored in Active Directory for use by every CA in the forest. This allows the CA to always have access to the current standard template and ensures homogenous application of certificate policy across the forest.

# Understanding Certificate Templates

Updated: January 21, 2005

- Subject name
- Certificate Template Extensions

# Key type and cryptographic service provider type

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Key type and cryptographic service provider type**

Certificates contain public key information that is used to encrypt or verify the digital signature of information. Clients store this certificate in their certificate store and also store data that indicates which cryptographic service provider (CSP) stores the associated private key. This CSP could store the private key in memory, on disk, or on a hardware key store, such as a smart card. This allows the client to perform any public-key cryptography action based on the key pair. However, keys are created differently, depending on their purpose. Some keys will work for encrypting data but not signing data and vice versa. This is why key type and cryptographic service provider type must be configured correctly.

**Key type**

When a public/private key pair is generated, several types of keys can be created. Keys can be created to allow their use with encryption, digital signatures, or both. Certificate templates can be configured for a key purpose of encryption, signature, signature and encryption, or signature and smartcard logon. This setting is labeled **Purpose** in the Certificate Templates console.

**Cryptographic service provider type**

Cryptographic service providers (CSPs) are hardware and software components of Windows operating systems that provide generic cryptographic functions. These CSPs can be written to provide a variety of encryption and signature algorithms. Each of the CSPs that are configured to be used by a certificate template can potentially support different cryptographic algorithms and, therefore, different key lengths. This means that certificate templates must be configured to support one or more CSPs. Selecting specific CSPs allows the administrator to control what algorithms and key lengths are used with this certificate. Windows Server 2003 family includes a number of CSPs, and others can be added for enhanced functionality.

# Certificate template enrollment policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate template enrollment policies**

Certificates can be requested by any subject that has at least read and enroll permissions for the corresponding certificate template. In some cases, the administrator may want to place some restrictions on the process that occurs after a certificate request is made. This gives the administrator control of what certificates are issued and how the issuance process is implemented. This type of restriction is known as an *enrollment policy*. Enrollment policies can contain requirements for certificate manager approval, multiple authorized signature requirements, and whether application and issuance policies should be implemented for this certificate. For information about modifying enrollment policies, see Modify enrollment policy.

# Validity and renewal periods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Validity and renewal periods**

Certificate-based cryptography uses public-key cryptography to protect and sign data. Over time, evildoers can obtain data protected with the public key and attempt to derive the private key from it. Given enough time and resources, this private key could be compromised, effectively rendering all protected data unprotected. Also, over time, the names guaranteed by a certificate may need to be changed. Because a certificate is a binding between a name and a public key, when either of these change, the certificate should be renewed.

**Validity periods**

Certificates are enabled for a specific length of time, which is the *validity period*. This time is expressed in a length of time beginning from when a certificate is issued. When that length of time is reached, the certificate is no longer valid and cannot be trusted. Because an expired certificate can cause problems, certificates can be renewed to extend their validity period.

**Renewal periods**

A *renewal period* is the amount of time prior to the end of the validity period when the subject will renew the certificate using autoenrollment. Renewing the certificate during this interval ensures that last-minute requests for certificate renewal can be serviced before certificate expiration to allow uninterrupted use of the certificate.

# Subject name

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Subject name**

The holder of the private key associated with a certificate is known as the *subject*. This can be a user, a program, or virtually any object or service. Because the subject can vary greatly depending on who or what it is, some flexibility is needed when providing the subject name in the certificate request. Windows can either build the subject name automatically or request it from the subject manually. If it automatically provides the subject name, Windows obtains the information from Active Directory. You can configure this process to include or exclude information useful in the environment. If configured to manually provide the subject name, the subject supplies that information in the certificate request, for example by using the Web-based enrollment pages.

# Certificate Template Extensions

Updated: January 21, 2005

**Certificate Template extensions**

This section covers:

- Issuance policies
- Application policies
- Key usage
- Key archival
- Basic constraints

# Issuance policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Issuance policies**

A certification authority (CA) processes each certificate request by a defined set of rules. The certification authority may issue some certificates with no proof of identification and require subjects of another type to submit some proof. This provides different levels of assurance for different certificates. These levels of assurance are represented in certificates as *issuance policies*.

An *issuance policy* (also known as a *certificate policy*) is a group of administrative rules that is implemented when issuing certificates. They are represented in a certificate by an object identifier (also known as an OID) that is defined at the certification authority. This object identifier is included in the issued certificate. When a subject presents its certificate, it can be examined by the target to verify the issuance policy and determine if that level of issuance policy is sufficient to perform the requested action.

# Application policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Application policies**

Application policies give you the important ability to decide which certificates can be used for certain purposes. This allows you to issue certificates widely without being concerned that they are misused for an unintended purpose.

Application policies are settings that inform a target that the subject holds a certificate that can be used to perform a specific task. They are represented in a certificate by an object identifier (also known as an OID) that is defined for a given application. This object identifier is included in the issued certificate. When a subject presents its certificate, it can be examined by the relying party to verify the application policy and determine if it can perform the requested action.

Application policies are sometimes called *extended key usage* or *enhanced key usage*. Because some implementations of public key infrastructure (PKI) applications may not understand application policies, both application policies and enhanced key usage sections appear in certificates issued by a Microsoft CA.

# Key usage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Key usage**

A certificate enables the subject to perform a specific task. To help control the usage of a certificate outside its intended purpose, restrictions are automatically placed on certificates. Key usage is a restriction method and determines what a certificate can be used for. This allows the administrator to issue certificates that can only be used for specific tasks or certificates that be used for a broad range of functions.

# Key archival

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Key archival**
When subjects lose their private keys, any information that was persistently encrypted with the corresponding public key is inaccessible. To help avoid this, Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, have the ability to archive a subject's keys in its database when certificates are issued. These keys are encrypted and stored by the certification authority (CA). If a subject loses its keys, the information can be retrieved from the database and provided to the subject. This allows the encrypted information to be recovered instead of lost.

**Important**

- Key archival and key recovery are only available on Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, running an enterprise CA.

# Basic constraints

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Basic constraints**

Certification authorities (CAs) must have a certificate before they can issue certificates. They use the private key associated with this certificate to digitally sign issued certificates. When a CA obtains a certificate from another CA, the parent CA may want to control whether that certificate can be used to issue certificates to other certificate servers. This is a basic constraint.

Basic constraints are used to ensure a certificate is only used in certain applications. An example is the path length that can be specified as a basic constraint. A path length is the maximum number of CA certificates above this one in a certification path. This path length constraint is used to ensure that CA certificates can only issue end entity certificates, not CA certificates. This is used to ensure that some certificates are used by a CA and some are used by other subjects.

# Deploying Certificate Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying Certificate Templates**
This section covers:

- Planning for autoenrollment deployment
- Certificate templates deployment
- Planning for certificate templates

# Planning for autoenrollment deployment

Updated: January 18, 2013

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning for autoenrollment deployment**

Autoenrollment is a useful feature of certification services in Windows XP and Windows Server 2003, Standard Edition. Autoenrollment allows the administrator to configure subjects to automatically enroll for certificates, retrieve issued certificates, and renew expiring certificates without requiring subject interaction. The subject does not need to be aware of any certificate operations, unless you configure the certificate template to interact with the subject.

To properly configure subject autoenrollment, the administrator must plan the appropriate certificate template or templates to use. Several settings in the certificate template directly affect the behavior of subject autoenrollment.

- On the **Request Handling** tab of the selected certificate template, the selection of an autoenrollment user interaction setting will affect autoenrollment:

| Setting | Affect on autoenrollment behavior |
|---|---|
| Enroll subject without requiring any user input | This setting will allow "silent" autoenrollment without requiring the user to take any action. This setting is preferred when clients require certificates but may not be aware that they are using them. |
| Prompt the user during enrollment | The user will receive a message and may need to take an action when enrollment is performed. This action may be necessary when the certificate is intended for a smart card, which would require the user to provide their personal identification (PIN). |
| Prompt the user during enrollment and require user input when the private key is used | This setting prompts the user both during enrollment and whenever the private key is used. This is the most interactive autoenrollment behavior, as it requires the user to confirm all use of the private key. It is also the setting that provides the highest level of user awareness regarding key usage.<br>**Caution**<br>• This setting is provided to the client during certificate enrollment. The client should follow the configuration setting, but the setting is not enforced by the certification authority. |

- On the **Request Handling** tab of the selected certificate template, the number of CSPs that are selected in the **CSP Selection** list box changes the behavior of autoenrollment for smart card templates. If you select more than one smart card CSP, users may receive more than one dialog box when Windows XP retrieves the autoenrolled certificate and begins to install it on the smart card. It is recommended that only one CSP be selected from this list for each template.

- On the **Subject Name** tab of the selected certificate template, selecting the **Supply in the request** option disables autoenrollment based on this template. Enabling the option prompts the subject to interactively create the subject name in the request, which will not work with autoenrollment.

- On the **Issuance Requirements** tab of the selected certificate template, selecting **This number of authorized signatures** and making the value greater than **1** disables subject autoenrollment based on this template.

- On the **Issuance Requirements** tab of the selected certificate template, selecting **This number of authorized signatures** and setting the value to **1** requires the requester to sign the request with a private key from a valid certificate in their certificate store. This certificate must contain the application and issuance policies that are specified in the **Application policy** and *Issuance policies* lists on the same tab. If an appropriate certificate exists in the requester's certificate store, autoenrollment signs the request with this certificate's private key and obtains and installs the requested certificate automatically.

- On the **Issuance Requirements** tab of the selected certificate template, the **Valid existing certificate** option may affect subject autoenrollment. This option tells the CA that the subject does not need to meet issuance requirements when

renewing a valid certificate. Subjects who may have been unable to autoenroll for the initial certificate may be able to use autoenrollment to renew that certificate.

- On the **General** tab of the selected certificate template, the **Validity period** and **Renewal period** settings specify the valid lifetime of the certificate and how long before the end of its lifetime autoenrollment will request a renewal. Because the validity period can be very short and the renewal period may overlap, autoenrollment will not renew a certificate until at least 80% of the certificate lifetime has expired or when the renewal interval period specified on the template is reached, with preference given to the shortest remaining certificate validity time period. For example:

    - For a certificate with a validity period of 10 days and a renewal period set to 3 days, autoenrollment will not renew the certificate until 8 days (80%) has passed.

    - For a certificate with a validity period of 10 days and a renewal period set to 1 day, autoenrollment will not renew the certificate until 9 days (90%) has passed.

  This prevents autoenrollment from endlessly renewing a certificate due to misconfigured validity and renewal period settings.

**Note**

1. Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, is required to configure version 2 certificate templates for autoenrollment requests. However, autoenrollment manages certificates or pending certificate requests based on any version of certificate template.

2. By default, certificate autoenrollment occurs on an eight hour cycle. Also, there is a built-in tolerance for a one-hour clock skew for checking whether a certificate is expired.

# Certificate templates deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate templates deployment**

When deploying a Windows Server 2003 family enterprise certification authority (CA), certificate templates are stored in Active Directory. This centralizes the location for use by all CAs in the enterprise, as well as simplifies replication and security management. This also allows the CA to upgrade current certificate templates in Active Directory during installation. Note that this requires the root domain's Domain Admins group to have full control access to all certificate templates or for this access to have been granted to another user or group.

Once you have planned and created the appropriate certificate templates, they will be replicated automatically to all domain controllers in the enterprise. This replication normally takes approximately eight hours to complete. Because of this interval, you should create the certificate template and allow it to replicate before deploying it to clients. This is best accomplished during an idle time in your environment. Configuring and using certificates before replication is completed can have unwanted effects.

- Configuring a certification authority to support certificate template options

# Certificate templates design considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate template design considerations**
Before deploying certificates, you must plan in order to ensure that appropriate certificates are issued to subjects. The certificates must provide the capability to perform the tasks expected by the subject but must not allow the subject to use the certificate for unintended or malicious tasks. Some questions that must be considered at this stage are:

- Who or what needs certificates?
- What should I allow the subjects to do with the certificates?
- How long will the certificates be valid for?
- How many certificates could each subject possibly have?
- How will the subjects obtain the certificates?

Each of these questions is further discussed in the following sections.

**Name considerations**
The holder of the private key associated with a certificate is known as the *subject*. This can be a user, a program, or virtually any object or service. Because the subject can vary greatly depending on who or what it is, you need some flexibility when providing the subject name in the certificate request. Windows can either build the subject name automatically or request it from the subject. If Windows automatically provides the subject name, it obtains the information from Active Directory. You can configure this process to include or exclude information that is useful in the environment. If it is configured to manually provide the subject name, the subject supplies that information in the certificate request using the Web-based enrollment pages.

**Certificate lifetime**
Certificate-based cryptography uses public key cryptography to protect and sign data. Over time, evildoers can obtain data that is protected with the public key and attempt to derive the private key from it. Given enough time and resources, this private key could be compromised, effectively rendering all protected data unprotected. Also, over time, the names guaranteed by a certificate may need to be changed. Because a certificate is a binding between a name and a public key, when either of these change, the certificate should be renewed.

**Number of certificates per subject**
Because subjects may have many uses for their certificates, an administrative decision must be made: whether to issue many specific certificates or a few broad certificates. This decision depends on the environment and the level of administration that you want and the possible effects on the subjects, as well as the effects of multiple certificates on applications that will use them.

One strategy of certificate administration creates a number of granular templates, one for each job function, such as file encryption or code signing. Subjects can then enroll for each certificate as needed for the appropriate function. This allows subjects to start with few certificates and only obtain new certificates that they need over time. The drawback to this strategy is that the subject may end up with a large number of certificates and private keys that become harder to manage over time.

A different strategy creates a few broad certificate templates that encompass job functions for most common groups of subjects. For example, if most employees use their certificates for mail signing and encryption as well as file encryption and IP Security, create one template that allows all those functions in the same certificate. This allows most subjects to obtain a single, all-purpose certificate. The drawback to this strategy is that there is no granular control of the usage of the certificates. The administrator cannot decide that subgroups cannot encrypt mail or use IP Security without modifying the template or changing the strategy.

**Cryptographic service providers and key size**
One or more cryptographic service providers (CSPs) are identified as usable by a template. This allows the administrator to control what types of cryptography subjects can use within an enterprise. This is very useful when security is of paramount importance. Because subjects use the CSP for both portions of any cryptographic service--either encryption and decryption or

signing and confirming signature--it is necessary to ensure that all subjects can use the same CSP. Otherwise, subjects may not be able to communicate with each other or perform the necessary job tasks if the key types between their CSPs are not compatible.

The easiest way to do this is to configure each certificate template to identify exactly one CSP. Which CSP should be identified is up to the administrator and depends on the level of security required, the intended purposes of the certificate, and the presence of security hardware, such as smart cards. In addition, new CSPs can easily be installed and used after the certificate template is deployed.

Each CSP provides one or more cryptographic algorithms for encryption or digital signature. Because each algorithm is different and its strength relies directly on the length of the key it uses, the minimum key size is specified in the certificate template. As a general rule, larger keys provide more protection over shorter keys for the same algorithm. However, larger keys take longer to generate and use. Care should be given to select a minimum key size that ensures the necessary amount of protection without impacting performance.

When selecting the CSP to associate with a certificate template, the use of smart cards is also a consideration. Each type of smart card has an associated CSP that must be selected for the smart card to be used. If the correct smart card CSP is not associated with the template, the smart card will not be recognized and the template will fail.

**Obtaining certificates**

There are many ways that subjects can obtain certificates. The two general categories of these ways are *manual* and *automatic*. The subject can either manually obtain a certificate using a Web page or Microsoft Management Console (MMC) snap-in, or they can obtain it via autoenrollment that has been configured by the administrator. While autoenrollment requires a bit more initial configuration, it is effective for deploying required certificates to users and computers without the subject performing additional steps. For more information on autoenrollment, see Planning for autoenrollment deployment.

# Configuring a certification authority to support certificate template options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring a certification authority to support certificate template options**
Certificate templates are useful configuration elements of a Windows Server 2003, Enterprise Edition, certification authority (CA). Many of the benefits of editable templates work in conjunction with a properly configured certification authority. Although the default configuration of a certification authority will support most of the functions available, there may be deployment considerations which require reconfiguration of the certification authority.

**Key archival and recovery**
When you want key archival and recovery on a certification authority, three complimentary configuration settings must be made.

- The certificate template must be configured to allow key archival. For more information, see Configure a certificate template for key archival and recovery.
- One or more key recovery agents must be identified on the certification authority and key recovery agent certificates must be issued to those agents. For more information, see Certificate Services example implementation: Key archival and recovery and Identify a key recovery agent.
- Key archival must be configured on the certification authority. For more information, see Enable key archival.

**Cryptographic service provider**
When a cryptographic service provider (CSP) is selected for a certificate template, the selected CSP must be installed on the client computer (or device, if not a computer) as well as the computer configuring the certificate template. If the CSP is not installed, it will not be available for subject requests. This will render the certificate template useless until the configuration is corrected. The CSP must also be installed on the computer where the certificate template is edited.

When selecting CSPs for a certificate template, the intended use of the certificate must also be considered. The intended functionality of the certificate must be provided by the CSP for the template to be useful. For example, if a template was created for clients to use with Encrypting File System (EFS) and the CSP selected is Microsoft Base DSS and Diffie-Hellman Cryptographic Provider, which does not provide encryption functionality, the issued certificates will not be able to perform that function.

# Certificate Template Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

# Using Certificate Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Certificate Templates**
This section covers:

- Version 1 certificate templates
- Version 2 certificate templates
- Default Certificate Templates
- Controlling enrollment access to certificate templates
- Certificate templates and Active Directory
- Configuring a Certificate Template

# Version 1 certificate templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Version 1 certificate templates**

Microsoft certification authorities (CAs) support two types of certificate templates: version 1 and version 2. Version 1 templates are provided for backwards compatibility and support many general needs for subject certification. They are created by default when a certification authority is installed and cannot be modified or removed. They can be duplicated, creating a version 2 template that can be modified.

Windows Server 2003, Standard Edition, supports only version 1 templates. Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, support both version 1 and version 2 templates. For more information on version 2 templates, see Version 2 certificate templates.

# Version 2 certificate templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Version 2 certificate templates**

Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, certification authorities support two types of certificate templates: version 1 and version 2. Version 2 templates are new to the Windows Server 2003 family. They allow customization of most settings in the template. Several preconfigured version 2 templates are supplied in the default configuration, and more can be added as necessary. This allows complete configuration flexibility for administrators.

Version 2 templates are only available as part of a certification authority that is installed as an enterprise certification authority. For that reason, they require Active Directory. Although Version 2 templates can be created and duplicated in the Windows Server 2003 family, certificates that are based on Version 2 templates can only be issued by a certification authority that is running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.

# Default Certificate Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Default certificate templates**

Windows Server 2003 family certification authorities come with a number of preconfigured certificate templates that are designed to meet the needs of most organizations. These templates are:

| Name | Description | Key Usage | Subject Type | Published to Active Directory? | Template Version |
|---|---|---|---|---|---|
| Administrator | Allows trust list signing and user authentication | Signature and encryption | User | Yes | 1 |
| Authenticated Session | Allows subject to authenticate to a Web server | Signature | User | No | 1 |
| Basic EFS | Used by Encrypting File System (EFS) to encrypt data | Encryption | User | Yes | 1 |
| CA Exchange | Used to store keys that are configured for private key archival | Encryption | Computer | No | 2 |
| CEP Encryption | Allows the holder to act as a registration authority (RA) for simple certificate enrollment protocol (SCEP) requests | Encryption | Computer | No | 1 |
| Code Signing | Used to digitally sign software | Signature | User | No | 1 |
| Computer | Allows a computer to authenticate itself on the network | Signature and encryption | Computer | No | 1 |
| Cross-Certification Authority | Used for cross-certification and qualified subordination. For more information, see Qualified subordination overview. | Signature | CrossCA | Yes | 2 |
| Directory E-mail Replication | Used to replicate e-mail within Active Directory | Signature and encryption | DirEmailRep | Yes | 2 |
| Domain Controller | All-purpose certificates used by domain controllers | Signature and encryption | DirEmailRep | Yes | 1 |
| Domain Controller Authentication | Used to authenticate Active Directory computers and users | Signature and encryption | Computer | No | 2 |
| EFS Recovery Agent | Allows the subject to decrypt files previously encrypted with EFS | Encryption | User | No | 1 |
| Enrollment Agent | Used to request certificates on behalf of another subject | Signature | User | No | 1 |
| Enrollment Agent (Computer) | Used to request certificates on behalf of another computer subject | Signature | Computer | No | 1 |
| Exchange Enrollment Agent (Offline request) | Used to request certificates on behalf of another subject and supply the subject name in the request | Signature | User | No | 1 |

| | | | | | |
|---|---|---|---|---|---|
| Exchange Signature Only | Used by Microsoft Exchange Key Management Service to issue certificates to Exchange users for digitally signing e-mail | Signature | User | No | 1 |
| Exchange User | Used by Microsoft Exchange Key Management Service to issue certificates to Exchange users for encrypting email | Encryption | User | Yes | 1 |
| IPSEC | Used by IP Security (IPSec) to digitally sign, encrypt, and decrypt network communication | Signature and encryption | Computer | No | 1 |
| IPSEC (Offline request) | Used by IP Security (IPSec) to digitally sign, encrypt and decrypt network communication when the subject name is supplied in the request | Signature and encryption | Computer | No | 1 |
| Key Recovery Agent | Recovers private keys that are archived on the certification authority. For more information, see Key archival and recovery. | Encryption | KRA | No | 2 |
| RAS and IAS Server | Enables RAS and IAS servers to authenticate their identity to other computers | Signature and Encryption | Computer | No | 2 |
| Root Certification Authority | Used to prove the identity of the root certification authority | Signature | CA | No | 1 |
| Router (Offline request) | Used by a router when requested through Simple Certificate Enrollment Protocol (SCEP) from a certification authority that holds a CEP Encryption certificate | Signature and encryption | Computer | No | 1 |
| Smartcard Logon | Allows the holder to authenticate using a smart card | Signature and encryption | User | No | 1 |
| Smartcard User | Allows the holder to authenticate and protect e-mail using a smart card | Signature and encryption | User | Yes | 1 |
| Subordinate Certification Authority | Used to prove the identity of the root certification authority. It is issued by the parent or root certification authority | Signature | CA | No | 1 |
| Trust List Signing | Allows the holder to digitally sign a trust list | Signature | User | No | 1 |
| User | Used by users for e-mail, EFS and client authentication | Signature and encryption | User | Yes | 1 |
| User Signature Only | Allows users to digitally sign data | Signature | User | No | 1 |
| Web Server | Proves the identity of a Web server | Signature and encryption | Computer | No | 1 |
| Workstation Authentication | Enables client computers to authenticate their identity to servers | Signature and encryption | Computer | No | 2 |

For more information on certificate templates, see Certificate Templates. For more information on key usage, see Key usage. For more information on template versions and publishing to Active Directory, see Using Certificate Templates.

# Controlling enrollment access to certificate templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Controlling enrollment access to certificate templates**

Certificate templates are published on a server. Each contains an access control list (ACL) which defines what specific operations a subject can do with the certificate.

| Setting | Description |
|---|---|
| Full Control | The selected group or user can perform any action on this template. |
| Read | The selected group or user can read this template. |
| Write | The selected group or user can modify this template. |
| Enroll | The selected group or user can submit a certificate issuance or renewal request based on this template. |
| Autoenroll | The selected group or user can submit a certificate request based on this template by way of autoenrollment. This option will not work unless the Enroll option is also selected. |

The most common use of certificates is for subject enrollment with autoenrollment permitted. In this case, the subject must be granted **Read**, **Enroll** and **Autoenroll** permissions. If autoenrollment is not wanted but manual or Web-based enrollment is, granting the **Read** and **Enroll** permissions is appropriate. When subjects already hold a certificate, they only need **Read** and **Enroll** permissions to renew that certificate, whether they use autoenrollment or not.

**Write** and **Full Control** permissions should be restricted to CA managers to ensure the templates are not improperly configured.

# Certificate templates and Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Certificate templates and Active Directory**

A Windows Server 2003 family certification authority can be installed as an enterprise server or a stand-alone server. When installed as an enterprise server, the certification authority is integrated into Active Directory. This allows the version 2 certificate templates to be replicated to all other enterprise certification authorities via the normal Active Directory replication process.

Certificate templates must be available from all certification authorities in the enterprise simultaneously in order to work correctly. As a result, creation or change of a certificate template must replicate completely before that certificate template can be used. This replication can take up to eight hours to complete, depending on your Active Directory implementation. Configuring and using certificates before replication is completed can have unwanted effects.

# Configuring a Certificate Template

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring a certificate template**
This section covers:

- Configuring the subject name
- Configuring the certificate purpose
- Configuring certificate publishing in Active Directory
- Establishing key options and key archival
- Establishing issuance policies
- Establishing application policies
- Establishing authentication and signature requirements for enrollment
- Allowing for autoenrollment
- Configuring key usage

# Configuring the subject name

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring the subject name**

When establishing a certificate template, the subject name must be defined. This is included in the issued certificate template and must uniquely identify the subject. The subject name can either be built automatically during the certificate request or explicitly defined by the subject and included in the certificate request.

There are a number of options that can be included with the subject name, as well as specific configuration settings for the subject name. The formats and options are:

**Subject name formats**

| Format | Description |
|---|---|
| None | Does not enforce any name format for this field |
| Common name | The certification authority creates the subject name from the common name (CN) obtained from Active Directory. These should be unique within a domain, but may not be unique within an enterprise. |
| Fully distinguished name | The certification authority creates the subject name from the fully distinguished name obtained from Active Directory. This guarantees that the name is unique within an enterprise. |
| Include e-mail name in subject name | If the e-mail name field is populated in the Active Directory user object, that e-mail name will be included with either the common name or fully distinguished name as part of the subject name. |

**Alternate subject name options**

| Field | Description | Useful for subject types |
|---|---|---|
| E-mail name | If the e-mail name field is populated in the Active Directory user object, that e-mail name will be used. | User |
| DNS name | The fully qualified domain name (FQDN) of the subject that requested the certificate. | Computer |
| User principal name (UPN) | The user principal name is part of the Active Directory user object and will be used. | User |
| Service principal name (SPN) | The service principal name is part of the Active Directory computer object and will be used. | Computer |

**Notes**

- If the Subject Name option is set to **Supply in the request**, one or more Issuance Requirements should be set for the template. If no Issuance Requirements are set, subjects are able to request and obtain certificates that contain any subject name. This would allow subjects to impersonate other subjects easily.

- A subject cannot request a certificate with a different subject name from the subject name of the requestor. That name is obtained through security authentication. The only subject that can request a certificate of this type is one who holds a certificate based on the Enrollment Agent template. That subject can request certificates on behalf of any other subject.

# Configuring the certificate purpose

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring the certificate purpose**

The certificate purpose defines the intended primary use of the certificate. The certificate purpose can be one of three settings:

| Purpose | Uses |
|---|---|
| Encryption | Used for encrypting data. A certificate with this purpose will contain cryptographic keys for encryption and decryption. |
| Signature | Used to digitally sign data. A certificate with this purpose will contain cryptographic keys for signing data only. |
| Signature and encryption | Used to either digitally sign data, digitally encrypt data, or both. This certificate purpose covers all primary uses of a certificate's cryptographic key. |
| Signature and smartcard logon | Used for initial logon with a smart card and to digitally sign data. A certificate with this purpose cannot be used for data encryption. |

# Configuring certificate publishing in Active Directory

Updated: November 14, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring certificate publishing in Active Directory**

A Microsoft certification authority (CA) can add certificates that have been issued to Active Directory subjects to the appropriate Active Directory object. This provides other users of Active Directory with the ability to easily locate and use the subject's certificate. There are two settings that affect the way this feature works:

- **Publish certificate in Active Directory**. When a subject obtains a certificate based on this template, the issued certificate will be added to that subject's Active Directory object.

| **Note** |
| --- |
| This setting indicates the certificate issued based on the certificate template should be published to the Active Directory Domain Services (AD DS) database. When this setting is enabled, the user or computer object in the AD DS database is updated with the certificate of the user or computer respectively. The private key is not published to the AD DS database. For both computer and user certificates, the userCertificate attribute of the AD DS object is updated with the certificate. The CA must have write permission to the AD DS database user and computer objects to make this update. The permission to write to the computer and user objects in the AD DS database is granted to CAs through their membership in the **Cert Publishers** group by default. This setting is typically only used with user certificates. When a user's certificate is published in the AD DS database, other users can search the AD DS database to find the certificate of that user. The certificate can then be used to encrypt email or files to the user whose certificate is published in the AD DS database. |

- **Do not automatically re-enroll if a duplicate certificate exists in Active Directory**. When the subject attempts to enroll for a certificate based on this template, computers running Windows XP or Windows Server 2003 will check to see if a duplicate certificate exists in Active Directory. If one does, autoenrollment will not submit a re-enrollment request. This allows certificates to be renewed but prevents multiple duplicate certificates from being issued.

# Establishing key options and key archival

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Establishing key options and key archival**

Windows Server 2003, Standard Edition, establishes public and private key options when issuing certificates to subjects. It also configures management and storage of the private key at that time. There are a number of settings that control the generation and management of certificate-based keys.

| Setting | Description |
|---|---|
| Archive subject's encryption private key | If the issuing Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, certification authority is configured for key archival, the subject's private key will be archived. |
| Include symmetric algorithms allowed by the subject | When the subject requests the certificate, they can supply a list of supported symmetric algorithms. This option allows the issuing certification authority to include those algorithms in the certificate, even if they are not recognized or supported by that server. The algorithms are commonly used by applications like Encrypting File System (EFS) or secure e-mail. |
| Minimum key size | This specifies the minimum size, in bits, of the key that will be generated for this certificate. |
| Cryptographic service providers | This is a list of cryptographic service providers (CSPs) that are installed on the certification authority. Selecting one or more CSPs configures the certificate to only work with those CSPs. If you do not select a CSP, the certificate works with any installed CSP. |
| Allow private key to be exported | When this option is specified, the subject can export their private key for backup or transportation. |

Note that some of these settings are not enforced by the issuing certification authority and may be ignored.

# Establishing issuance policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Establishing issuance policies**

An issuance policy describes the conditions under which a certificate is issued. This provides a level of assurance that the subject's certificate request was verified in a specific way.

One or more issuance policies may be selected for a certificate template. Because these issuance policies are simply text labels with an associated object identifier, there are no options associated with them. The only special issuance policy is **All issuance policies**, which indicates that this policy includes all others. This is normally reserved for certificates held by certification authorities.

# Establishing application policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Establishing application policies**

Application policies, which are called *enhanced key usage* in Windows 2000, define how a certificate can be used. Specifically, application policies are object identifiers that are included in the issued certificate. When a subject uses that certificate, Windows Server 2003, Standard Edition, reads the application policies to determine if this certificate can be used for the current intended purpose. If the intended purpose is included in the application policies, the operation continues. If not, the operation fails.

Because these application policies are simply text labels with an associated object identifier, there are no options associated with them. The only special application policy is **All application policies**, which indicates that this policy includes all others. This is normally reserved for certificates held by certification authorities.

# Establishing authentication and signature requirements for enrollment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Establishing authentication and signature requirements for enrollment**

When subjects submit certificate requests to a certification authority, the request can either be automatically approved or placed into a "pending" state. A pending state is normally used for certificates that require a higher level of assurance and consequently require more administration and further verification of the request. There are a number of settings that can configure the authentication and signature requirements for issuance certificates that are based on a template.

| Setting | Description |
|---|---|
| CA certificate manager approval | All certificates are placed into the pending container for a certificate manager to issue or deny. |
| This number of authorized signatures | This setting requires the certificate request to be digitally signed by one or more subjects before it can be issued. This enables several other configuration parameters. |
| Policy type required in signature | The signatures that are required for issuing a certificate must contain either a specific application policy, issuance policy, or both. This is how the certification authority determines whether the signature is appropriate for authorizing the issuance of the subject's certificate. This option is enabled when **This number of authorized signatures** is set. |
| Application policy | Specifies the application policy that is checked for when signing a certificate request. This option is enabled when **Policy type required in signature** is set to either **Application policy** or **Both application and issuance policy**. |
| Issuance policy | Specifies which issuance policies will be checked when signing a certificate request. This option is enabled when **Policy type required in signature** is set to either **Issuance policy** or **Both application and issuance policy**. |

# Allowing for autoenrollment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Allowing for autoenrollment**

You can use autoenrollment so that subjects automatically enroll for certificates, retrieve issued certificates, and renew expiring certificates without subject interaction. For certificate templates, the intended subjects must have Read, Enroll and Autoenroll permissions before the subjects can enroll. To ensure that unintended subjects cannot request a certificate based on this template, you must identify those unintended subjects and explicitly configure the Deny permission for them. This acts as a safeguard, further ensuring that they cannot even present an unacceptable request to the certification authority. Note that Read permission does not allow enrollment or autoenrollment, it only allows the subject to view the certificate template.

Renewal of existing certificates requires only the Enroll permission for the requesting subject. Certificates obtained in any way, including autoenrollment and manual requests, can be renewed automatically. These types of renewals do not require Autoenroll permission, even if they are renewed automatically.

For more information, see Planning for autoenrollment deployment.

# Configuring key usage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring key usage**

Windows Server 2003, Standard Edition, establishes public and private keys when it issues certificates to subjects. The usage of these keys is configured by key usage and application policy. The key usage configuration is a basic constraint on the broad types of operations that can be performed with this certificate. There are several options, depending on what purpose has been configured for this certificate, either Signature or Encryption.

**Signature**

| Setting | Description |
|---|---|
| Digital signature | Data can be digitally signed by this certificate. This is the most basic signature operation. |
| Signature is proof of origin (nonrepudiation) | Data signed by this certificate can be traced back to the subject that provided the digital signature. This provides nonrepudiation of signatures and is useful in certificate-based transactions. |
| Certificate signing | This certificate can be used to sign other certificates. This option is normally granted to certificate managers and certificates used by certification authorities. |
| Certificate revocation list signing | This certificate can be used to sign certificate revocation lists (CRLs). This option is normally granted to certificate managers and certificates used by certification authorities. |

**Encryption**

| Setting | Description |
|---|---|
| Allow key exchange without key encryption (key agreement) | This option configures the subject to use a key agreement protocol, such as Diffie-Hellman, to establish a symmetric key that can be used to encrypt and decrypt data between the subject and the intended target. |
| Allow key exchange only with key encryption (key encipherment) | This option will configure the subject to establish a symmetric key with a target by generating a symmetric key, encrypting it, and sending it to the target for decryption. |
| Allow encryption of user data | With this option, the subject can use the established symmetric key to encrypt and decrypt actual application data with the same key used for key establishment. This option is only available when **Allow key exchange only with key encryption (key encipherment)** is selected. |

For more information on application policy, see Establishing application policies.

# Certificate Templates Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The Certificate Templates Microsoft Management Console (MMC) does not list any templates after prompting to install new certificate templates.
- Certificates are not being issued to clients.
- Certificates are issued to subjects, but cryptographic operations with those certificates fail.
- Domain controllers are not obtaining a domain controller certificate.
- Clients are unable to obtain certificates via autoenrollment.
- Names of certificate templates in the snap-in are inconsistent between views or windows.
- The private key cannot be exported from smart card certificates, even whenAllow private key to be exportedis selected in the certificate template.
- The certificate template is modified, but some certification authorities (CAs) still have the unmodified version.
- The private key is not being archived even though I selected theArchive subject's encryption private keyoption and configured the CA to require key recovery.
- Autoenrollment is prompting me to renew a certificate that isn't mine, and I have certificates in my private certificate store that I didn't put there.

**The Certificate Templates Microsoft Management Console (MMC) does not list any templates after prompting to install new certificate templates.**
**Cause:** The certificate templates have not yet replicated to the certification authority (CA) that the computer is connected to. This replication is part of Active Directory replication.

**Solution:** Wait for the certificate templates to replicate and then reopen the Certificate Templates MMC.

**Certificates are not being issued to clients.**
**Cause:** The certification authority (CA) issuing certificate has a shorter remaining lifetime than the template overlap period configured for the request certificate template. This means the issued certificate would be immediately eligible for reenrollment. Instead of issuing and endlessly renewing this certificate the certificate request is not processed.

**Solution:** Renew the issuing certificate used by the CA.

**Certificates are issued to subjects, but cryptographic operations with those certificates fail.**
**Cause:** Cryptographic service provider does not match Key Usage settings.

**Solution:** Confirm that you set the cryptographic service provider in the template to one that supports the type of cryptographic operation that the certificate will be used for.

**See also:** Key type and cryptographic service provider type; Modify a Certificate Template

**Domain controllers are not obtaining a domain controller certificate.**
**Cause:** Autoenrollment is turned off by way of Group Policy on domain controllers. Domain controllers obtain their certificates through autoenrollment.

**Solution:** Enable autoenrollment for domain controllers.

**See also:** Modify a Certificate Template

**Cause:** The default Automatic Certificate Request setting for Domain Controllers has been removed from the Default Domain Controllers Policy.

**Solution:** Create a new Automatic Certificate Request in the Default Domain Controllers Policy for the Domain Controller certificate template.

**See also:** Automatic certificate request settings

**Clients are unable to obtain certificates via autoenrollement.**
**Cause:** Security permissions must be set to allow intended subjects to both enroll and autoenroll on the certificate template. Both permissions are required to enable autoenrollment.

**Solution:** Modify the access control list on the certificate template to grant **Read**, **Enroll** and **Autoenroll** permissions for the subjects that you want.

**See also:** Allow subjects to request a certificate that is based on the template

**Names of certificate templates in the snap-in are inconsistent between views or windows.**
**Cause:** Active Directory Sites and Services is being used to view the certificate templates. This tool may not provide as accurate a display as Certificate Templates.

**Solution:** Use the Certificate Templates snap-in to administer certificate templates.

**See also:** Modify a Certificate Template

**The private key cannot be exported from smart card certificates, even when Allow private key to be exported is selected in the certificate template.**
**Cause:** Smart cards do not allow private keys to be exported once they are written to the smart card.

**Solution:** None

**See also:** Smart Cards

**The certificate template is modified, but some certification authorities (CAs) still have the unmodified version.**
**Cause:** Certificate templates are replicated between CAs with the Active Directory replication process. Because this replication is not instantaneous, there may be a short delay before the new version of the template is available on all CAs.

**Solution:** Wait until the modified template is replicated to all CAs. To display the certificate templates that are available on the CA, use the Certutil.exe command.

**See also:** Understanding Sites and Replication and Certutil.

**The private key is not being archived even though I selected the Archive subject's encryption private key option and configured the CA to require key recovery.**
**Cause:** Private keys will not be archived when the key usage for the certificate template is set to **Signature**. This is because the digital signature usage requires the key to not be recoverable.

**Solution:** None

**See also:** Establishing key options and key archival and Key archival and recovery.

**Autoenrollment is prompting me to renew a certificate that isn't mine, and I have certificates in my private certificate store that I didn't put there.**
**Cause:** When using the smart card enrollment station on the administrator's computer to renew or change the certificate stored on the smart card, the certificate from the smart card is copied to the administrator's private certificate store. This certificate may be processed by autoenrollment and prompt you to begin the renewal process.

**Solution:** Click **Start** to begin the autoenrollment renewal process. Because the certificate is not yours, the autoenrollment process will disappear at that point. If you want to remove the certificates from your private store, they can be deleted manually.

**See also:** Delete a certificate.

# Internet Protocol Security (IPSec)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Protocol security (IPSec)**
Internet Protocol security (IPSec) is a framework of open standards for ensuring private, secure communications over Internet Protocol (IP) networks, through the use of cryptographic security services.

- For tips about using IPSec, see IPSec Best practices.
- For help with specific tasks, see IPSec How To....
- For general background information, see IPSec Concepts.
- For problem-solving instructions, see IPSec Troubleshooting.

### Note

- Portions of IPSec-related services were jointly developed by Microsoft® and Cisco Systems, Inc.

# IPSec Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Establish an IPSec deployment plan**.

  The deployment plan should address the following considerations: which deployment scenarios (such as server-to-server or remote access) require the use of IPSec, what level of security you require for each scenario, which types of data to secure, which computers to secure, which physical links to secure, who will manage IPSec policies, and how you will provide ongoing support and troubleshooting for end users after IPSec is deployed. The deployment plan should also address broader organizational security issues, such as the vulnerability of the network to specific types of attacks, the use of Active Directory, and how security is applied to Group Policy objects.

  For more information about IPSec security planning, see Establishing an IPSec security plan.

  For more information about Active Directory, see Active Directory Overview.

- **Create and test IPSec policies for each deployment scenario**.

  Before deploying IPSec in a production environment, test the IPSec policies in a realistic lab environment. To obtain realistic performance data, run standard workloads on programs. During initial tests, view packet contents with Network Monitor, or use Authentication Header (AH) or Encapsulating Security Payload (ESP) with null encryption to view packet contents for test environments.

- **Do not use preshared keys**.

  For enhanced security, the use of preshared key authentication is not recommended because it is a relatively weak authentication method. In addition, preshared keys are stored in plaintext. Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing and that you use certificates or Kerberos V5 instead in a production environment.

  For more information, see Preshared key authentication.

- **Do not use Diffie-Hellman Group 1 (low)**.

  For enhanced security, do not use Diffie-Hellman Group 1, which provides 768 bits of keying strength. For maximum security, use Group 2048 (high), which provides 2,048 bits of keying strength. Use Group 2 (medium), which provides 1,024 bits of keying strength when required for interoperability with Windows 2000 and Windows XP. Strong Diffie-Hellman groups combined with longer key lengths increase the computational difficulty of determining a secret key.

  For more information, see Key exchange methods.

  **Note**

  - Diffie-Hellman Group 2048 is provided only with the Windows Server 2003 family.

- **Use the Triple Data Encryption Standard (3DES) algorithm for stronger encryption**.

  For enhanced security, when configuring key exchange security methods for IPSec policies, use 3DES, which is a stronger encryption algorithm than DES.

  For information about how to configure key exchange security methods, see Create key exchange security methods.

  **Note**

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

- **Create and assign a persistent IPSec policy for failsafe security**.

  To enhance security, create and assign a persistent IPSec policy, so that computers can be secured if a local IPSec policy or an Active Directory-based IPSec policy cannot be applied. When you create and assign a persistent policy, it is applied before a local policy or an Active Directory-based policy, and it remains in effect regardless of whether the local policy or the Active Directory-based policy is applied (for example, an IPSec policy will not be applied if it is corrupted).

  **Note**

  - You cannot configure this feature in the IP Security Policy Management console. To configure this feature, you must use the Netsh IPSec command-line tool. For more information, see Netsh commands for Internet Protocol security.

- **For computers connected to the Internet, do not send the name of the certification authority (CA) with certificate requests**.

  When certificate authentication is used to establish trust between IPSec peers, each IPSec peer sends to the other peer a list of trusted root CAs from which it accepts a certificate for authentication. Each of these CA names is sent as a certificate request payload (CRP), and it must be sent before trust is established. Although transmitting this list aids in connectivity by facilitating the selection of a CA, it can expose sensitive information about the trust relationships of a computer, such as the name of the company that owns the computer and the domain membership of the computer (if an internal public key infrastructure is being used), to an attacker. Therefore, to secure computers that are connected to the Internet, enable the option to exclude the CA name from the certificate request.

- **For computers connected to the Internet, do not use Kerberos as an authentication method**.

  When Kerberos V5 authentication is used, during main mode negotiation, each IPSec peer sends its computer identity in unencrypted format to the other peer. The computer identity is unencrypted until encryption of the entire identity payload takes place during the authentication phase of the main mode negotiation. An attacker can send an Internet Key Exchange (IKE) packet that causes the responding IPSec peer to expose its computer identity and domain membership. To secure computers that are connected to the Internet, certificate authentication is recommended.

  For more information, see Authentication methods.

- **For computers that are connected to the Internet, do not allow unsecured communication**.

  If you configure a filter action to negotiate IPSec security, ensure that the following options are disabled in order to secure computers that are connected to the Internet:

  - **Accept unsecured communication, but always respond using IPSec**. This option allows initial incoming unsecured traffic (for example, TCP SYN packets) but requires outgoing traffic to be protected. This option should be disabled to prevent denial-of-service attacks.

  - **Allow unsecured communication with non-IPSec-aware computers**. This option allows unsecured communications with computers that cannot negotiate the use of IPSec or process IPSec-secured communications, and it is appropriate only in environments where IPSec-secured communication is not necessary.

    For more information, see Filter action.

- **Restrict the use of administrative credentials in your organization**.

  Members of the local Administrators group can view and modify the IPSec policy settings on their computers. For this reason, and as a general security best practice, ensure that end-users in your organization use the principle of least privilege.

  For information about general best practices for security, see Best practices for security for security.

- **When applying the same IPSec policy to computers running different versions of the Windows operating system, test the policy thoroughly**.

  Several features in the Windows Server 2003 family implementation of IPSec are not provided in Windows 2000 or in Windows XP. These new features include:

  - A stronger Diffie-Hellman group (2,048-bit Diffie-Hellman key exchange).
  - The ability for IPSec policy filters to allow logical addresses for local IP configuration.
  - The removal of default traffic exemptions from IPSec filtering (only Internet Key Exchange traffic is now exempt by default).
  - The ability to exclude the name of the certification authority (CA) from a certificate request.

  To ensure that the same IPSec policy functions as expected on computers running the Windows Server 2003 family and on computers running Windows XPor Windows 2000, test the policy thoroughly on all relevant operating systems before deployment.

  For more information about new features in IPSec, see New features for IPSec.

- **Use the** Windows Server 2003 **IP Security Policy Management console to manage the IPSec policies that use the new features that are available only in the** Windows Server 2003 **family implementation of IPSec**.

  If you plan to apply IPSec policies that use any of the new features that are available only in the Windows Server 2003 family implementation of IPSec, do not use the Windows XP or the Windows 2000 version of the IP Security Policy Management console to manage these policies. The settings in the earlier versions of the IP Security Policy Management console will override the settings in the Windows Server 2003 family IPSec policy, and the new features will not be functional.

- **Use Terminal Services to remotely manage and monitor IPSec on computers running different versions of the Windows operating system**.

  Remote management and monitoring of IPSec is supported only for computers running the same version of the Windows operating system. To remotely manage and monitor IPSec on a computer that is running a different version of Windows than the version of Windows that is running on your computer, use Terminal Services. For example, if your computer is running the Windows Server 2003 family, and you plan to remotely manage and monitor IPSec on computers running Windows 2000 or Windows XP, use Terminal Services to gain remote access to these computers.

  If your computer is running the Windows Server 2003 family, and you plan to manage and monitor IPSec on computers that are also running the Windows Server 2003 family, you can run the IPSec Policy Management console and IP Security Monitor, or you can use the Netsh command-line tool remotely.

# IPSec How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Start the IP Security Policy Management snap-in
- Define IPSec Policies
- Assign IPSec Policy
- Manage IPSec Policy
- Use Resultant Set of Policy (RSoP) to View IPSec Policy Assignments
- Monitor IPSec Activity

# Start the IP Security Policy Management snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start the IP Security Policy Management snap-in**

- To start the IP Security Policy Management snap-in from the Microsoft Management Console:

1. Click **Start**, click **Run**, type **MMC**, and then click **OK**.
2. Click **File**, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **IP Security Policy Management**, and then click **Add**.
4. Select the computer for which you want to manage IPSec policies:

| To | Do this |
|---|---|
| Manage only the computer on which this console is running | Click **Local computer** |
| Manage IPSec policies for any domain members | Click **The Active Directory domain of which this computer is a member**. |
| Manage IPSec policies for a domain of which the computer that is running this console is not a member | Click **Another Active Directory Domain**. |
| Manage a remote computer | Click **Another computer**. |

5. Click **Finish**, click **Close**, and then click **OK**.

- To access the IP Security Policy Management snap-in from Group Policy (Active Directory):

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

   **Where?**

   - Active Directory Users and Computers [*DomainControllerName.DomainName*]/*Domain*/*OrganizationalUnit*/*ChildOrganizationalUnit*...

3. Click **Properties**, and then click the **Group Policy** tab.
4. Click **Edit** to open the Group Policy object that you want to edit. Or, click **New** to create a new Group Policy object, and then click **Edit**.
5. In the Group Policy console tree, click **IP Security Policies on Active Directory**.

   **Where?**

   - *PolicyName* [*ComputerName*] Policy/Computer Configuration/Windows Settings/Security Settings/IP Security Policies on Active Directory

- To access the IP Security Policy Management snap-in from Local Computer Policy:

1. Click **Start**, click **Run**, type **MMC**, and then click **OK**.
2. Click **File**, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. Click **Finish**, click **Close**, and then click **OK**.
5. In the Group Policy console tree, click **IP Security Policies on Local Computer**.

   **Where?**

   - Local Computer Policy/Computer Configuration/Windows Settings/Security Settings/IP Security Policies on Local Computer

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To save console settings, on the **File** menu, click **Save**.
- To view the saved console, see Related Topics.
- You cannot administer Active Directory-based IPSec policy from a computer running Windows XP Home Edition.
- To manage policies in a remote domain, you must be using a computer that is a member of a domain that is trusted by the remote domain. You cannot configure policies in a remote domain from a computer that is a member of a workgroup (also known as a stand-alone computer).
- To revise your initial choice, you can start the Microsoft Management Console, add this snap-in again, and save the console again. If you require multiple configurations, you can save the console with another name.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define IPSec Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Define IPSec policies**

- Add, edit, or remove IPSec policies
- Define IPSec Rules
- Define IPSec Key Exchange Settings

# Add, edit, or remove IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove IPSec policies**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.

2. Choose whether to add a new policy, or edit or remove an existing one:

| To | Do this |
|---|---|
| Add a new policy | In the console tree, click **IP Security Policies on *Name***. Next, on the **Action** menu, click **Create IP Security Policy**. Follow the instructions in the IP Security Policy Wizard until the **Properties** dialog box for your new policy appears. |
| Modify an existing policy | Double-click the policy that you want to modify. |
| Remove a policy | Click the policy that you want to remove, and on the **Action** menu, click **Delete**. |

3. If you are adding or modifying a policy, click the **General** tab, and then in **Name**, type a unique name.

4. In **Description**, type a description of the security policy, such as which groups or domains it affects.

5. To specify how often the IPSec Policy Agent checks for updates, type a value in **Check for policy changes every numberminute(s)**.

6. If you have special requirements for the security of the key exchange, click **Settings**.

7. Click the **Rules** tab, and create or modify any necessary rules for the policy.

8. Activate or deactivate rules as needed.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

- For information about defining IPSec key exchange settings, see Related Topics.

- For information about configuring IPSec rules, see Related Topics.

- For information about how to activate or deactivate rules, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define IPSec Rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Define IPSec rules**

- Add, edit, or remove IPSec rules
- Activate or deactivate IPSec rules
- Define IPSec authentication methods
- Specify IPSec connection types
- Specify an IPSec tunnel
- Define IP Filter Lists
- Define Filter Actions

# Add, edit, or remove IPSec rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove IPSec rules**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. To add a rule, decide whether you want to use the Create IP Security Rule Wizard or add the rule manually:
   - To add a rule by using the Create IP Security Rule Wizard, confirm that the **Use Add Wizard** check box is selected, click **Add**, and then follow the instructions.
   - To add a rule manually, confirm that the **Use Add Wizard** check box is cleared, click **Add**, and then define settings on the **IP Filter List**, **Filter Action**, **Authentication Methods**, **Tunnel Setting**, and **Connection Type** tabs.
4. To edit a rule, select the rule that you want to edit, click **Edit**, and then modify the rule properties as needed.
5. To remove a rule, select the rule that you want to remove, and then click **Remove**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- New rules are automatically applied to the policy being edited or created.
- The rules for a policy are displayed in IP Security Policies in reverse alphabetical order, based on the name of the filter list selected for each rule. There is no method to specify an order in which to apply the rules in a policy. The IPSec driver automatically orders the rules based on the most specific filter list to the least specific filter list. For example, the IPSec driver places a rule containing a filter list that specifies individual IP addresses and TCP ports above a rule containing a filter list that specifies all addresses on a subnet.
- The default response rule is automatically added to every new IPSec policy. If you do not want this rule to be part of your policy, you can deactivate it by clearing the check box next to **<Dynamic>**. The default response rule cannot be removed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define IPSec authentication methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define IPSec authentication methods**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that you want to modify.
4. On the **Authentication Methods** tab, click **Add**. Or, if you are reconfiguring an existing method, click the authentication method, and then click **Edit**.
5. Select the authentication method that you want to add or modify:
   - To use the Kerberos V5 security protocol for authentication services, click **Active Directory default (Kerberos V5 protocol)** if this rule applies to computers that are validated by a Windows 2000 or Windows Server 2003 Active Directory domain or a trusted Active Directory domain.
   - To use a public key certificate for authentication services, click **Use a certificate from this certification authority (CA)**, and then click **Browse** to select a root CA.
   - To prevent the name of the CA from being sent with the certificate request, select the **Exclude the CA name from the certificate request** check box.
   - To enable certificate to account mapping, select the **Enable certificate to account mapping** check box.
   - To specify your own key that will be used for authentication, click **Use this string (preshared key)**.
6. To delete an authentication method or change its preference order, do one of the following:
   - To delete the selected method, click **Remove**.
   - To move the selected method up one level, click **Move up**. Repeat until the method is at the required preference level.
   - To move the selected method down one level, click **Move down**. Repeat until the method is at the required preference level.

**Important**

- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. Preshared key authentication creates a master key that is less secure (that might produce a weaker form of encryption) than certificates or the Kerberos V5 protocol. In addition, preshared keys are stored in plaintext. Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing and that you use certificates or Kerberos V5 instead in a production environment.

**Notes**

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a

computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

- The Kerberos V5 protocol authentication method is not supported on computers running Windows XP Home Edition.

- If you choose to use a certificate for authentication, you must select a CA (most commonly the root CA for your installed computer certificate). You cannot leave this field blank.

- For preshared key authentication, each IPSec peer must use the same preshared key, or authentication will fail.

- If filters in more than one rule apply to traffic between the same two IP addresses, then the authentication methods list should be identical in both rules. Otherwise, security requests that are initiated by one rule might match the filter of the other rule, but have a different authentication method. In this case, the negotiation will fail. After a rule has initiated a successful main mode security association between two IP addresses, other rules that are filtering different traffic will not renegotiate the authentication and master key (the main mode security association). Instead, these other rules will use the same main mode security association to negotiate security (algorithms and session keys) for traffic that matches their particular filter.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify IPSec connection types

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify IPSec connection types**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that you want to modify.
4. On the **Connection Type** tab, select the type of network connections to which this rule will apply:
   - To apply this rule to all network connections you have created on the computer, click **All network connections**.
   - To apply this rule to all LAN connections you have created on the computer, click **Local area network (LAN)**.
   - To apply this rule to any remote VPN or dial-up connections you have created on the computer, click **Remote access**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify an IPSec tunnel

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify an IPSec tunnel**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that you want to modify.
4. On the **Tunnel Setting** tab, specify the computer that will be the tunnel endpoint:

| To | Do this |
|---|---|
| Disable tunneling for this rule | Click **This rule does not specify an IPSec tunnel**. |
| Use tunneled communications to a specific tunnel endpoint | Click **The tunnel endpoint is specified by this IP address** and type the IP address of the tunnel endpoint. |

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- Because you cannot mirror filters for tunneled traffic, you must configure two rules. One rule is used for the outbound traffic and the other is used for inbound traffic. For the outbound traffic rule, the tunnel endpoint is the IP address of the IPSec peer on the other end of the tunnel. For the inbound traffic rule, the tunnel endpoint is an IP address configured on the local computer.
- IPSec tunnels are not supported for remote access VPN scenarios. L2TP/IPSec or PPTP should be used for remote access VPN connections. IPSec tunnels are used primarily for interoperability with other routers, gateways, or end-systems that do not support L2TP/IPSec or PPTP connections. IPSec tunnel mode is supported as an advanced feature, used only in gateway-to-gateway (also known as router-to-router) tunneling scenarios and for server-to-server or server-to-gateway configurations.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define IP Filter Lists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Define IP filter lists**

- Add, edit, or remove IP filter lists
- Add, edit, or remove IPSec filters
- Configure advanced IPSec filter settings
- Set an active IP filter list for a rule
- Manage multiple IP filter lists

# Add, edit, or remove IP filter lists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove IP filter lists**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that contains the IP filter list that you want to modify.
4. On the **IP Filter List** tab, do one of the following:
   - To add a new IP filter list, click **Add**.
   - To modify an existing IP filter list, click the filter list that you want to modify, and then click **Edit**.
   - To remove an IP filter list, click the filter list that you want to remove, and then click **Remove**.
5. If you are adding or modifying an IP filter list, type a unique name for the list.
6. Type a description to specify which computers and traffic types the IP filter list encompasses (for example, "Matches all TCP packets between this computer and any other computer").
7. Create or modify the filters as needed.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- For procedures on creating filters and advanced filter settings, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add, edit, or remove IPSec filters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove IPSec filters**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that contains the IP filter list you want to modify.
4. On the **IP Filter List** tab, double-click the IP filter list that contains the IPSec filter you want to modify.
5. In the **IP Filter List** dialog box, do one of the following:
   - To add a filter, click **Add**.
   - To modify an existing filter, select the filter that you want to modify, and then click **Edit**.
   - To remove an existing filter, select the filter that you want to remove, and then click **Remove**.
6. If you are adding or editing a filter, in **IP Filter Properties**, the **Addresses** tab, and then select the **Source Address**:

| Select | To secure packets from |
|---|---|
| **My IP Address** | All IP addresses on the computer for which you are configuring this filter. |
| **Any IP Address** | Any computer. |
| **A Specific DNS Name** | The Domain Name System (DNS) name that you specify in **Host name**. The DNS name is resolved to its IP addresses, and then filters are automatically created for the resolved IP addresses. This option is only available when creating new filters. |
| **A Specific IP Address** | The IP address that you specify in **IP Address**. |
| **A Specific IP Subnet** | The IP subnet, as defined by the IP address that you specify in **IP Address** and the subnet mask that you specify in **Subnet Mask**. |
| **DNS Servers <dynamic>** | The DNS server(s) for the computer for which you are configuring this filter. Changes in DNS server addresses are automatically detected, and the filter is updated as needed. |
| **WINS Servers <dynamic>** | The WINS server(s) for the computer for which you are configuring this filter. Changes in WINS server addresses are automatically detected, and the filter is updated as needed. |
| **DHCP Server <dynamic>** | The DHCP server for the computer for which you are configuring this filter. Changes in DHCP server addresses are automatically detected, and the filter is updated as needed. |
| **Default Gateway <dynamic>** | The default gateway for the computer for which you are configuring this filter. Changes in default gateway server addresses are automatically detected, and the filter is updated as needed. |

7. Click **Destination Address**, and repeat step 6 for the destination address.

8. Select the appropriate **Mirrored** setting:

| To | Do this |
|---|---|
| Automatically create two filters based on the filter settings, one for traffic to the destination and one for traffic from the destination | Select the **Mirrored** check box. |
| Create a single filter based on the filter settings | Clear the **Mirrored** check box. |
| Create a filter for an IPSec tunnel | Clear the **Mirrored** check box. For IPSec tunnels, you must create two filter lists: one list describes the traffic to be sent through the tunnel (outbound traffic) and another describes the traffic to be received through the tunnel (inbound). Then, create two rules that use the inbound and outbound filter lists in your policy. |

9. On the **Description** tab, in **Description**, type a description for this filter (for example, specify to what computers and traffic types it applies).

10. If you require additional IP filtering by a specific protocol or port number, on the **Protocol** tab, configure advanced filter settings.

**Caution**

Filters are the most important part of IPSec policy for a computer which is protected by IPSec. If you do not specify the proper filters in either client or server policies, or if the IP addresses change before the policy's filters are updated, security might not be provided.

- When adding a new static IP address to a protected computer:
    - Modify the IPSec policy filters on all clients and servers that make security requests to the protected computer. Ensure that those clients have updated their policy before adding the new address.
    - Inspect the policy being used on the protected computer. If the filters specify static IP addresses for local connections, after adding the new IP address to the interface, edit and save the new filter list to include the new static IP address. **My IP Address** filters will be automatically updated when the new static IP address is added.
- If the protected computer is a Web server and your clients use a proxy server, make sure that communications over all network paths are secured by IPSec:
    - Between the Web server and all clients that directly connect
    - Between the Web server and the proxy server
    - Between the proxy server and all clients of the proxy server
- The following filter is internally defined to permit (not secure) Internet Key Exchange (IKE) traffic:
    - Source Address = Any
    - Destination Address = Any
    - Protocol = UDP
    - Source port = 500

- Destination port = 500

**Important**

- In the Windows Server 2003 family, IPSec provides new source and destination address options for defining filters. In addition, the default behavior for traffic exemptions has changed. If you require previously exempted traffic types, you must create filters to permit this traffic. For instructions on how to configure permit filters for previously exempted traffic types and information about other IPSec special considerations, see Related Topics.

**Notes**

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

- To configure IP protocol, TCP port, or UDP port settings for a filter, see Related Topics.

- For IPSec tunnel rules, only address-based filters are supported. Protocol-specific and port-specific filters are not supported. Tunnel filters should not be mirrored.

- Filters are applied in the order of most-specific filters first. Filters are not applied in the order in which they appear in the list.

- If an outbound packet does not match any filter, it is sent unsecured.

- If an inbound packet does not match any filter, it is permitted.

- If an IKE security request is received, the source IP address of the request is used to find a matching filter. The security action and tunnel setting that is associated with that filter determines the IKE response.

- The **A specific DNS Name** option is used when creating filters to create IP address-based filters by resolving a DNS name to its IP addresses. The use of a computer name is for the one-time resolution of DNS names to IP addresses when creating the filter. The computer name is not used after the filters are created.

- All filters used in tunnel rules are matched first, before end-to-end transport filters are matched.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure advanced IPSec filter settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure advanced IPSec filter settings**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that contains the IP filter list you want to modify.
4. On the **IP Filter List** tab, double-click the IP filter list that contains the IPSec filter you want to modify.
5. In the **IP Filter List** dialog box, click the filter that you want to modify, and then click **Edit**.
6. In **IP Filter Properties**, click the **Protocol** tab, and then specify settings for **Select a protocol type**:

| To filter | Do this |
|---|---|
| Any packets sent on any protocol | Click **Any**. |
| Traffic sent on a specific protocol | Click the protocol. |
| Packets sent on a custom protocol | Click **Other**, and then type the protocol number. |

7. If you chose TCP or UDP, you can also filter packets by the source port.

   - To filter packets sent on any port used by the protocol type that you selected, click **From any port**.
   - To filter packets sent on a specific port used by the protocol type that you selected, click **From this port**, and then type the port number.

   If you chose TCP or UDP, you can also filter packets by the destination port.

   - To filter packets received on any port used by the protocol type that you selected, click **To any port**.
   - To only filter packets received on the port number that you specify, click **To this port**, and then type the port number.

**Caution**

- An erroneous port number might cause communication to be blocked or unsecured. If you are unsure of the correct value, see the Windows Resource Kits in Related Topics.

**Notes**

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

- For IPSec tunneling, only address-based filters are supported. Protocol-specific and port-specific filters are not supported.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set an active IP filter list for a rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set an active IP filter list for a rule**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that contains the IP filter list you want to modify.
4. On the **IP Filter List** tab, select the option that precedes the name of the IP filter list that you want to designate as the active filter list for this rule.

   The IP filter list you selected is now the active filter list for the rule.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- If the option preceding the name of an IP filter list is not selected, the IP filter list will not be set as active for the rule.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage multiple IP filter lists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage multiple IP filter lists**

1. In **IP Security Policies**, in the console tree, click **IP Security Policies on *Name***.
2. On the **Action** menu, click **Manage IP filter lists and filter actions**.
3. On the **Manage IP Filters Lists** tab, click **Add**. Or, if you are modifying an existing list, double-click that list.
4. Define the filters for the filter list.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define Filter Actions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Define filter actions**

- Add, edit, or remove filter actions
- Add, edit, or remove IPSec security methods
- Configure custom IPSec security methods
- Select a filter action for a rule
- Manage multiple filter actions

# Add, edit, or remove filter actions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove filter actions**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that you want to modify, and then click the **Filter Action** tab.
4. To add a filter action, decide whether you want to use the IP Security Filter Action Wizard or add the filter action manually:
   - To add a filter action by using the IP Security Filter Action Wizard, confirm that the **Use Add Wizard** check box is selected, click **Add**, and then follow the instructions.
   - To add a filter action manually, confirm that the **Use Add Wizard** check box is cleared, click **Add**, and then define settings on the **Security Methods** and **General** tabs.
5. To modify an existing filter action, select the filter action that you want to modify, and then click **Edit**.
6. To remove a filter action, select the filter action that you want to remove, and then click **Remove**.
7. If you are adding or modifying a filter action, choose a filter action type:
   - Click **Permit** to allow receiving or sending of packets in plaintext (unsecured traffic). Security will not be requested for these packets.
   - Click **Block** to discard packets. Security will not be requested for these packets.
   - Click **Negotiate security** to use the list of security methods in **Security method preference order** to provide security for packets that match this filter. Security requests will be accepted for these packets.
8. If you chose **Negotiate security**, add new security methods or edit the existing ones for the filter action.
9. If you do not want to block incoming, unsecured communications, but you want to ensure that all outgoing communications and subsequent two-way communications are secured, select the **Accept unsecured communication, but always respond using IPSec** check box.
10. To enable communication with other computers that do not support IPSec, and ensure that communication continues if there is no response to a request for IPSec negotiation, select the **Allow unsecured communication with non-IPSec-aware computers** check box. After the initial IPSec negotiation has failed, IPSec negotiation will be retried at five minute intervals.
11. To guarantee that no master keys or master keying material will be reused to generate the session key, select the **Use session key perfect forward secrecy (PFS)** check box.
12. On the **General** tab, in **Name**, type a unique name.
13. In **Description**, type a description. For example, you might type what security levels this filter action represents.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

- The filter action types **Permit** and **Block** and the options to **Allow unsecured communication with non-IPSec-aware computers** and **Accept unsecured communication, but always respond using IPSec** are not available in the default response rule.

- Session key perfect forward secrecy (PFS) renegotiates new master key keying material during every session rekey operation. This is the most secure setting. However, it adds overhead and increases the time required to complete a rekey operation. Both initiator and responder must be configured with the same setting for successful negotiation.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

Working with MMC console files

# Add, edit, or remove IPSec security methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove IPSec security methods**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that you want to modify, and then click the **Filter Action**tab.
4. Double-click the filter action that you want to modify.
5. On the **Security Methods** tab, click **Negotiate security**, and then do one of the following:
   - To add a new security method, click **Add**.
   - To modify an existing security method, click the security method that you want to modify, and then click **Edit**.
   - To remove a security method, click the security method that you want to remove, and then click **Remove**.
6. If you are adding or modifying a security method, on the **Security Method** tab, select the security level:
   - To use the ESP protocol to provide data confidentiality (encryption) with the triple Data Encryption Standard (3DES) algorithm, data integrity and authentication with the Secure Hash Algorithm 1 (SHA1) integrity algorithm, and default key lifetimes (100MB, 1 hour), click **Integrity and Encryption**.
   - To use the ESP protocol to provide data integrity and authentication with the SHA1 integrity algorithm and default key lifetimes (100MB, 1 hour), click **Integrity only**. ESP is not configured to provide data confidentiality (encryption).
   - Click **Custom**, and then click **Settings** to configure a custom security method or key lifetimes. For more information, see Related Topics.
7. Repeat this procedure to configure additional security methods for the filter action.

**Notes**

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should

only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 server operating system support 3DES and do not require installation of the High Encryption Pack.

- Click **Move up** to move the selected security method up one level. Repeat until the security method is at the required preference level.

- Click **Move down** to move the selected security method down one level. Repeat until the security method is at the required preference level.

- For information about how key lifetimes affect security, see **Filter action** in Related Topics.

- When negotiating security, the initiator proposes this list of security methods to the responder. The responder agrees to the first method (from the top down) that is found anywhere in its own security methods list. If none of the proposed security methods match an entry in the responder's list, then the responder fails the negotiation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure custom IPSec security methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure custom IPSec security methods**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that you want to modify, and then click the **Filter Action** tab.
4. Double-click the filter action that you want to modify.
5. On the **Security Methods** tab, do one of the following:
   - To add a new security method, click **Add**.
   - To modify an existing security method, click the security method that you want to modify, and then click **Edit**.
   - To remove a security method, click the security method that you want to remove, and then click **Remove.**
6. If you are adding or modifying a security method, on the **Security Method** tab, click **Custom**, and then click **Settings**.
7. To provide integrity for both the packet's addressing information (IP header) and the data, select the **Data and address integrity without encryption (AH)** check box, and then, in **Integrity algorithm**, click one of the following:
   - **MD5** to use the Message Digest 5 (MD5) integrity algorithm, which uses a 128-bit key.
   - **SHA1** to use the Secure Hash Algorithm 1 (SHA1) integrity algorithm, which uses a 160-bit key.
8. To provide both integrity and encryption (confidentiality) for the data, select the **Data integrity and encryption (ESP)** check box, and then, in **Integrity algorithm**, click one of the following:
   - **<None>** to use no data integrity.

     If you have enabled **AH**, you can click **None** for the ESP integrity algorithm to improve performance.
   - **MD5** to use the MD5 integrity algorithm, which uses a 128-bit key.
   - **SHA1** to use the SHA1 integrity algorithm, which uses a 160-bit key.
9. If you selected the **Data integrity and encryption (ESP)** check box, in **Encryption algorithm**, click one of the following:
   - **<None>** to use no encryption.
   - **DES** to use Data Encryption Standard (DES) with a 56-bit key.
   - **3DES** to use the triple DES (3DES) with three 56-bit keys.

10. To change the default session key lifetime settings, do one of the following:

    - To specify the number of kilobytes of data transferred before a new session key is generated, select the **Generate a new key every** check box, and then type a value in **Kbytes**.

    - To specify the number of seconds that elapse before a new session key is generated, select the **Generate a new key every** check box, and then type a value in **seconds**.

**Notes**

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

- You cannot choose **<None>** for both the ESP integrity and the encryption algorithm.

- Use caution when specifying lifetimes. The default internal lifetimes should work in most environments and be interoperable with other products. If your security requirements demand shorter lifetime values, you can explicitly set appropriate lifetime values in each security method. The lowest values that are explicitly set on initiator and responder will be used.

- Using shorter lifetime values does not increase the security with which data is protected. Short key lifetimes will only decrease the amount of data that is revealed if an attacker discovers one encryption key. Instead of adjusting the lifetime values lower, consider using a stronger encryption algorithm to protect data, such as 3DES.

- Before changing the default lifetimes, you should understand how lifetimes and rekeying work in detail. For more information, see **Filter action** in Related Topics.

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Select a filter action for a rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To select a filter action for a rule**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Double-click the rule that you want to modify.
4. On the **Filter Action** tab, select the option that precedes the name of the filter action that you want to designate as the active filter action for this rule.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- If the option preceding the name of a filter action is not selected, the filter action will not be set as active for the rule.
- If you have not removed them, you can activate one of the three predefined filter actions: **Permit**, **Request Security (Optional)**, or **Require Security**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage multiple filter actions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage multiple filter actions**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. In the console tree, click **IP Security Policies on *Name***.
3. Click **Action**, and then click **Manage IP filter lists and filter actions**.
4. On the **Manage Filter Actions** tab, do one of the following:
   - To add a new filter action, click **Add**.
   - To modify an existing filter action, click the filter action that you want to modify, and then click **Edit**.
   - To remove a filter action, click the filter action that you want to remove, and then click **Remove**.
5. If you are adding or modifying a filter action, define settings on the **Security Methods** and **General** tabs as needed.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- For more information about defining settings for filter actions, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define IPSec Key Exchange Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Define IPSec key exchange settings**

- Configure key exchange settings
- Create key exchange security methods

# Configure key exchange settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure key exchange settings**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Click the **General** tab, and then click **Settings**.
4. To force reauthentication and the negotiation of new master key keying material each time a new session key is required, click **Master key perfect forward secrecy (PFS)**.
5. If you require a different setting, type a value in **Authenticate and generate a new key after every number minutes**, which will cause a reauthentication and new master key generation at that interval.
6. If you require a different setting, type a value in **Authenticate and generate a new key after every number sessions** to set a maximum limit on the number of times a master key or its base keying material can be reused to generate the session key. This limit, when reached, will force a reauthentication and new master key generation. If you have enabled **Master key perfect forward secrecy (PFS)**, the number of sessions is set to 1 and is not configurable.
7. If you have special requirements for security methods on the master key exchange, click **Methods**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- Portions of IPSec-related services were jointly developed by Microsoft and Cisco Systems, Inc.
- Use **Master key perfect forward secrecy (PFS)** where it is required for interoperability. The default setting is disabled, which should work in most environments and be interoperable with most other products.
- A session limit of zero (0) will cause rekeys to be determined only by the time setting.
- Enabling master key perfect forward secrecy (PFS) might impact performance because each quick mode requires a new main mode negotiation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Start the IP Security Policy Management snap-in

Open MMC

Key exchange settings
Working with MMC console files

# Create key exchange security methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create key exchange security methods**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Double-click the policy that you want to modify.
3. Click the **General** tab, click **Settings**, and then click **Methods**.
4. In the **Key Exchange Security Methods** dialog box, do one of the following:
   - To add a new key exchange security method, click **Add**.
   - To modify an existing key exchange security method, click the security method that you want to modify, and then click **Edit**.
   - To remove a key exchange security method, click the security method that you want to remove, and then click **Remove**.
5. If you are adding or modifying a key exchange security method, in the **IKE Security Algorithms** dialog box, select an **Integrity algorithm**:
   - Click **MD5** to use a 128-bit key (faster).
   - Click **SHA1** to use a 160-bit key (stronger).
6. Select an **Encryption algorithm**:
   - Click **3DES** to use the triple Data Encryption Standard (3DES) algorithm and three unique 56-bit keys.
   - Click **DES** to use the DES algorithm and a single 56-bit key. Use this option if you are required to connect to computers that do not have 3DES or if you do not need the higher security and overhead of 3DES. For more information, see Notes.
7. Select a **Diffie-Hellman group** to set the length of base keying material used to generate the actual keys:
   - Click **Low (1)** to generate 768 bits of master key keying material.
   - Click **Medium (2)** to generate 1,024 bits of master key keying material (stronger).
   - Click **High (2048)** to generate 2,048 bits of master key keying material (strongest).

**Important**

- For enhanced security, do not use Diffie-Hellman Group 1 (low). For maximum security, use Group 2048 whenever possible. Use Group 2 when required for interoperability with Windows 2000 and Windows XP . When you use a stronger group, the secret key that is derived from the Diffie-Hellman exchange has greater strength. For more

information about Diffie-Hellman groups and key exchange methods, see Related Topics.

### Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

- Portions of IPSec-related services were jointly developed by Microsoft and Cisco Systems, Inc.

- A key exchange security method is a combination of three settings (integrity algorithm, encryption algorithm, and Diffie-Hellman group). The initiator and the responder must have a method in common (one that uses the same settings) for negotiations to succeed.

- Diffie-Hellman Group 2048 is provided only with the Windows Server 2003 family.

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

- Click **Move up** to move a selected security method up one level. Repeat until the security method is at the required preference level.

- Click **Move down** to move a selected security method down one level. Repeat until the security method is at the required preference level.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign IPSec Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Assign IPSec policy**

- Assign or unassign IPSec policy in Group Policy
- Assign or unassign IPSec policy on a computer

# Assign or unassign IPSec policy in Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign or unassign IPSec policy in Group Policy**

- For Active Directory-based Group Policy:

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

   **Where?**

   - Active Directory Users and Computers [*DomainControllerName.DomainName*]/*Domain/OrganizationalUnit/ChildOrganizationalUnit...*

3. Click **Properties**, and then click the **Group Policy** tab.
4. Click **Edit** to open the Group Policy object that you want to edit. Or, click **New** to create a new Group Policy object, and then click **Edit**.
5. In the Group Policy console tree, click **IP Security Policies on Active Directory**.

   **Where?**

   - *PolicyName* [*ComputerName*] Policy/Computer Configuration/Windows Settings/Security Settings/IP Security Policies on Active Directory

6. In the details pane, click the IPSec policy that you want to assign or unassign, and then do one of the following:

   a. To assign the policy, click the **Action** menu, and then click **Assign**.

   b. To unassign the policy, click the **Action** menu, and then click **Unassign**.

- For local computer policy:

1. Click **Start**, click **Run**, type **MMC**, and then click **OK**.
2. Click **File**, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. Click **Finish**, click **Close**, and then click **OK**.
5. In the Group Policy console tree, click **IP Security Policies on Local Computer**.

   **Where?**

   - Local Computer Policy/Computer Configuration/Windows Settings/Security Settings/IP Security Policies on Local

Computer

6. In the details pane, click the IPSec policy that you want to assign or unassign, and then do one of the following:

   a. To assign the policy, click the **Action** menu, and then click **Assign**.

   b. To unassign the policy, click the **Action** menu, and then click **Un-assign**.

**Important**

- An IPSec policy might remain active even after the IPSec policy or Group Policy object to which it is assigned has been deleted. Therefore, you should unassign the IPSec policy before you delete either the policy or the Group Policy object. To prevent problems, use the following procedure:

1. Unassign the IPSec policy in the Group Policy object.

2. Wait 24 hours to ensure that the change is propagated.

3. Delete the IPSec policy or Group Policy object.

   If you delete the IPSec policy or Group Policy object without following this procedure, computers in the Active Directory container to which the IPSec policy is assigned might treat the IPSec policy as if it cannot be located and continue to use a cached copy.

**Notes**

- To manage Active Directory-based IPSec policy, you must be a member of the Domain Admins group in Active Directory, or you must have permission to edit Group Policy objects (for information about Group Policy object editing, see Related Topics). To manage local or remote IPSec policy for a computer, you must be a member of the Administrators group on the local or remote computer. For more information, see Default local groups and Default groups.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- You cannot administer Active Directory-based IPSec policy from a computer running Windows XP Home Edition.

- The settings will take effect the next time Group Policy is refreshed.

- If a policy is currently assigned and you assign a new policy, the currently assigned policy is automatically unassigned.

- You cannot assign a policy from the IP Security Policies on Active Directory console; you can only configure policy. To assign policy for Active Directory containers, you must use **IP Security Policies on Active Directory** within the Group Policy console.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign or unassign IPSec policy on a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign or unassign IPSec policy on a computer**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. In the console tree, click **IP Security Policies on *Name***.
3. In the details pane, click the IPSec policy that you want to assign or unassign, and then do one of the following:
   - To assign the policy, click the **Action** menu, and then click **Assign**.
   - To unassign the policy, click the **Action** menu, and then click **Un-assign**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- If a policy is currently assigned and you assign a new policy, the currently assigned policy is automatically unassigned.
- If the computer is a member of a Windows 2000 or Windows Server 2003 domain and IPSec policy is assigned at the domain level, then the assigned local computer policy is not used.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage IPSec Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage IPSec policy**

- Restart the IPSec services
- Restore default IPSec policies
- Export IPSec policies
- Import IPSec policies
- Refresh the list of IPSec policies
- Delete an IPSec policy
- Rename an IPSec policy
- Export the list of IPSec policies

# Restart the IPSec services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To restart the IPSec service

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Services.
2. Right-click **IPSec services**.
3. Click **Restart**.

### Important

- Stopping and restarting the IPSec service can disconnect all computers that are using IPSec from the computer on which the IPSec service is stopped, and it can prevent further communication with that computer. For information about how to troubleshoot and resolve loss of connectivity in this situation, see Related Topics.

### Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
- You might need to restart the IPSec service in order to do any of the following:
    - Clear old security associations (SAs).
    - Clear soft SAs (unsecured negotiations).
    - Force an IPSec policy to download from Active Directory to domain clients.
- If the IPSec service does not start, then use Event Viewer to determine possible causes of failure. For more information, see Related Topics.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **net stop policyagent & net start policyagent**

**Important**

- Stopping and restarting the IPSec service can disconnect all computers that are using IPSec from the computer on which the IPSec service is stopped, and it can prevent further communication with that computer. For information about how to troubleshoot and resolve loss of connectivity in this situation, see Related Topics.

**Notes**

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.

- On a computer running the Routing and Remote Access service and either Windows 2000 Server or a Windows Server 2003 operating system, you must use the following sequence when restarting the IPSec service:

  1. Stop the Routing and Remote Access service using the **net stop remoteaccess** command.

  2. Stop and restart the IPSec service using the **net stop policyagent & net start policyagent** command.

  3. Start the Routing and Remote Access service using the **net start remoteaccess** command.

- You might need to restart the IPSec service in order to do any of the following:

  - Clear old security associations (SAs).

  - Clear soft SAs (unsecured negotiations).

  - Force an IPSec policy to download from Active Directory to domain clients.

- If the IPSec service does not start, then use Event Viewer to determine possible causes of failure. For more information, see Related Topics.

- For more information about the **net start** and **net stop** commands, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restore default IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore default IPSec policies**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. In the console tree, click **IP Security Policies on *Name***.
3. Click **Action**, point to **All Tasks**, and then click **Restore Default Policies**.
4. When prompted, click **Yes**.

### Important

- Restoring default IPSec policies will overwrite any changes to the original default policies, even when the names of the default policies have been changed. If you have modified the default policies and you do not want those modifications to be overwritten, do not restore the default policies.

### Notes

To perform this procedure, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- The option to restore default IPSec policies is only available for computer-based IPSec policy. You cannot restore the default IPSec policies for Active Directory-based IPSec policy.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

# Export IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export IPSec policies**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. In the console tree, click **IP Security Policies on *Name***.
3. Click **Action**, point to **All Tasks**, and then click **Export Policies**.
4. Type the path and the name of the file to which you want the policy information saved, and then click **Save**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- To enhance interoperablity in a mixed environment with computers running Windows 2000, limit the name of the file to which you want the policy information saved to 60 characters.
- To export IPSec policies, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import IPSec policies**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. In the console tree, click **IP Security Policies on *Name***.
3. Click **Action**, point to **All Tasks**, and then click **Import Policies**.
4. Type the path and the name of the file from which you are importing the IPSec policy information, and then click **Open**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- Importing IPSec policies replaces existing IPSec policies with the same name.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

Export the list of IPSec policies
Working with MMC console files

# Refresh the list of IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To refresh the list of IPSec policies**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. In the console tree, click **IP Security Policies on *Name***.
3. Click **Action**, and then click **Refresh**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- This procedure is only required to update the list of policies for any additions or deletions made by using another management tool.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete an IPSec policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete an IPSec policy**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Click the policy that you want to remove, click **Action**, and then click **Delete**.
3. When prompted, click **Yes**.

### Important

- For Active Directory-based IPSec policy, an IPSec policy might remain active even after the IPSec policy has been deleted. Therefore, you should unassign the IPSec policy before you delete the policy. To prevent problems, use the following procedure:

  1. Unassign the IPSec policy in the Group Policy object.
  2. Wait 24 hours to ensure that the change is propagated.
  3. Delete the IPSec policy.

  If you delete the IPSec policy without following this procedure, computers in the Active Directory container to which the IPSec policy is assigned might treat the IPSec policy as if it cannot be located and continue to use a cached copy.

### Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Rename an IPSec policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename an IPSec policy**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. Click the policy that you want to rename, click **Action**, and then click **Rename**.
3. Type a new name, and then press **Enter**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export the list of IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export the list of IPSec policies**

1. Create a console containing IP Security Policies. Or, open a saved console file containing IP Security Policies.
2. In the console tree, click **IP Security Policies on *Name***.
3. Click **Action**, and then click **Export List**.
4. Type the file name to which you want to save the selected IPSec policy or the displayed list of IPSec policies, and then click **Save**.

## Notes

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.
- To create a console containing IP Security Policies, start the IP Security Policies snap-in. To open a saved console file, open MMC. For more information, see Related Topics.
- This procedure does not export the IPSec policies, only a text list of the policies displayed in the details pane.
- To export IPSec policies, see Related Topics.

# Use Resultant Set of Policy (RSoP) to View IPSec Policy Assignments

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Resultant Set of Policy (RSoP) to view IPSec policy assignments**

- Use RSoP to view IPSec policy assignments for a computer
- Use RSoP to view IPSec policy assignments for members of a Group Policy container

# Use RSoP to view IPSec policy assignments for a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use RSoP to view IPSec policy assignments for a computer**

1. Open Resultant Set of Policy.

   An RSoP query runs in logging mode. For more information, see Related Topics.

2. In the console tree, click **IP Security Policies**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/IP Security Policies

   The list of all IPSec policies is displayed in the details pane.

3. To view detailed policy settings for the IPSec policy that is being applied, in the details pane, right-click the policy with the highest precedence, and then click **Properties**.

## Notes

- To open RSoP, click **Start**, click **Run**, type **rsop.msc**, and then click **OK**.
- To run an RSoP query in logging mode, see Related Topics.
- The RSoP console displays detailed IPSec policy settings for only the policy that is being applied. The detailed policy settings include the filter rules, filter actions, authentication methods, tunnel endpoints, and connection type.
- The details pane in the RSoP console provides two ways to indicate which IPSec policy is being applied:
  - The lower the number in the **Precedence** column, the higher the precedence of the IPSec policy. The IPSec policy with a precedence number of 1 is the policy that is being applied.
  - In the **Name** column, the folder icon that precedes the name of the IPSec policy that is being applied contains a green dot.
- The settings of the IPSec policy with the highest precedence apply in their entirety; they are not merged with the settings of IPSec policies that are assigned at higher levels of the Active Directory hierarchy. For more information about using RSoP to view IPSec policy assignments, see Related Topics.
- If a local user overrides domain-level IPSec policies with a local IPSec policy, RSoP does not detect the application of the local IPSec policy. As a result, no IPSec policies will be displayed in the RSoP console when a logging mode query is run.
- To hide or display columns in the RSoP console, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Using Resultant Set of Policy to view IPSec policy assignments

# Use RSoP to view IPSec policy assignments for members of a Group Policy container

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use RSoP to view IPSec policy assignments for members of a Group Policy container**

1. On a domain controller, open Resultant Set of Policy (RSoP) as a Microsoft Management Console (MMC). For more information, see Related Topics.

2. On the **Action** menu, click **Generate RSoP Data**.

3. On the **Welcome to the Resultant Set of Policy Wizard** page, click **Next**.

4. On the **Mode Selection** page, click **Planning mode**, and then follow the instructions in the wizard to run a planning mode query. For more information, see Related Topics.

5. In the console tree, click **IP Security Policies**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/IP Security Policies

   The list of all IPSec policies is displayed in the details pane.

6. To view detailed policy settings for the IPSec policy that is being applied, in the details pane, right-click the policy with the highest precedence, and then click **Properties**.

**Notes**

- The RSoP console displays detailed IPSec policy settings for only the policy that is being applied. The detailed policy settings include the filter rules, filter actions, authentication methods, tunnel endpoints, and connection type.

- The details pane in the RSoP console provides two ways to indicate which IPSec policy is being applied:

  - The lower the number in the **Precedence** column, the higher the precedence of the IPSec policy. The IPSec policy with a precedence number of 1 is the policy that is being applied.

  - In the **Name** column, the folder icon that precedes the name of the IPSec policy that is being applied contains a green dot.

- The settings of the IPSec policy with the highest precedence apply in their entirety; they are not merged with the settings of IPSec policies that are assigned at higher levels of the Active Directory hierarchy. For more information about using RSoP to view IPSec policy assignments, see Related Topics.

- You can run an RSoP planning mode query only on a domain controller (when you run a planning mode query, you must explicitly specify the domain controller name). However, you can specify any IPSec client as the target for the query, provided you have the appropriate permissions to do so.

- To hide or display columns in the RSoP console, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitor IPSec Activity

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitor IPSec activity**

- Add the IP Security Monitor snap-in
- Add a computer to the IP Security Monitor console
- View details about active IPSec policies
- View IP security statistics
- View main mode details
- View quick mode details
- Find a matching specific filter
- Change the automatic update refresh interval
- Enable DNS name resolution

# Add the IP Security Monitor snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add the IP Security Monitor snap-in**

1. Click **Start**, click **Run**, type **MMC**, and then click **OK**.
2. Click **File**, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **IP Security Monitor**, and then click **Add**.
4. Click **Close**, and then click **OK**.

## Notes

- To save the console settings, on the **File** menu, click **Save**.
- To view the saved console, see Related Topics.
- To revise your initial choice, you can start the Microsoft Management Console, add this snap-in again, and save the console again. If you require multiple configurations, you can save the console with another name.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a computer to the IP Security Monitor console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a computer to the IP Security Monitor console**

1. Create a console containing IP Security Monitor. Or, open a saved console file containing IP Security Monitor.
2. In the console tree, right-click **IP Security Monitor**, and then click **Add Computer**.
3. In the **Add Computer** dialog box:
   - For the local computer, click **This computer**.
   - For a remote computer, click **The following computer**, and then type the name of the remote computer. Or, click **Browse** to find it on the network.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- For information about adding the IP Security Monitor snap-in, see Related Topics.
- If the IPSec service is not started on the computer that is being monitored, the server icon is displayed as a stopped service. To refresh IP Security Monitor after the IPSec service on that computer have been restarted, right-click the computer and then click **Reconnect**.
- IP Security Monitor can be used to monitor IPSec only on computers running Windows XP or a Windows Server 2003 operating system. To monitor IPSec on a computer running Windows 2000, use the **IPSecmon** command at a Windows 2000 command prompt.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View main mode details

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view main mode details**

1. Create a console containing IP Security Monitor. Or, open a saved console file containing IP Security Monitor.
2. Double-click **Main Mode**.

   **Where?**

   - IP Security Monitor/*ServerName*/Main Mode

3. To view main mode details, do one of the following:

   - For generic filter details, in the console tree, click **Generic Filters**, and then in the details pane, double-click a filter.
   - For specific filter details, in the console tree, click **Specific Filters**. To find a specific main mode filter, right-click **Specific Filters**, and then click **Find matching filters**.
   - For IKE policy details, in the console tree, click **IKE Policies**, and then in the details pane, double-click a policy.
   - For statistical details, in the console tree, click **Statistics**.
   - For security association details, in the console tree, click **Security Associations**, and then in the details pane, double-click a security association.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- For information about adding the IP Security Monitor snap-in, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# View quick mode details

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view quick mode details**

1. Create a console containing IP Security Monitor. Or, open a saved console file containing IP Security Monitor.
2. Double-click **Quick Mode**.

   **Where?**

   - IP Security Monitor/*ServerName*/Quick Mode

3. To view quick mode details, do one of the following:

   - For generic filter details, in the console tree, click **Generic Filters**, and then in the details pane, double-click a filter.
   - For specific filter details, in the console tree, click **Specific Filters**. To find a specific quick mode filter, right-click **Specific Filters**, and then click **Find matching filters**.
   - For negotiation policy details, in the console tree, click **Negotiation Policies**, and then in the details pane, double-click a policy.
   - For statistical details, in the console tree, click **Statistics**.
   - For security association details, in the console tree, click **Security Associations**, and then in the details pane, double-click a security association.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- For information about adding the IP Security Monitor snap-in, see Related Topics.
- Quick mode details do not display **Block** or **Permit** filters.
- Although there are two separate quick mode SAs established (one for the inbound traffic and one for the outbound traffic), IP Security Monitor only displays a single quick mode SA.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Find a matching specific filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find a matching specific filter**

1. Create a console containing IP Security Monitor. Or, open a saved console file containing IP Security Monitor.
2. For a specific main mode filter:
   a. Double-click **Main Mode**.(console tree location is: IP Security Monitor/*ServerName*/Main Mode).
   b. In the console tree, right-click **Specific Filters**, and then click **Find matching filters**.
   c. In the **Find Matching Main Mode Filters** dialog box, configure the filter settings, and then click **Search**.
3. For a specific quick mode filter:
   a. Double-click **Quick Mode** (console tree location is: IP Security Monitor/*ServerName*/Quick Mode).
   b. In the console tree, right-click **Specific Filters**, and then click **Find matching filters**.
   c. In the **Find Matching Quick Mode Filters** dialog box, configure the filter settings, and then click **Search**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- For information about adding the IP Security Monitor snap-in, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the automatic update refresh interval

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the automatic update refresh interval**

1. Create a console containing IP Security Monitor. Or, open a saved console file containing IP Security Monitor.
2. Right-click a server name.

   **Where?**

   - IP Security Monitor/*ServerName*

3. Click **Properties**.
4. Configure the automatic update refresh interval, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- For information about adding the IP Security Monitor snap-in, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable DNS name resolution

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable DNS name resolution**

1. Create a console containing IP Security Monitor. Or, open a saved console file containing IP Security Monitor.
2. Right-click a server name.

   **Where?**

   - IP Security Monitor/*ServerName*

3. Click **Properties**.
4. Select the **Enable DNS name resolution** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- For information about adding the IP Security Monitor snap-in, see Related Topics.
- The **Enable DNS name resolution** check box specifies whether you want to use Domain Name System (DNS) reverse queries and NetBIOS Adapter Status messages to resolve the DNS or NetBIOS computer name that is associated with an IP address when displaying sources or destinations. To resolve the DNS computer name from its IP address, your DNS infrastructure must have the appropriate reverse domains and pointer records configured, either manually or with DNS dynamic update. To resolve the NetBIOS computer name from its IP address, NetBIOS over TCP/IP must be enabled on the computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# IPSec Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Internet Protocol security (IPSec):

- New features for IPSec
- Internet Protocol Security Overview
- Understanding Internet Protocol Security
- Using Internet Protocol Security
- IPSec Resources

# New features for IPSec

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features for IPSec**
Internet Protocol security (IPSec) provides the following new features for enhanced security, scalability, and availability, and ease of deployment and administration.

### Note

- Because several new IPSec features are available only in the Windows Server 2003 family, as a best practice, if you plan to apply the same IPSec policy to computers running the Windows Server 2003 family and to computers running Windows 2000 or Windows XP, test the policy thoroughly on all relevant operating systems before deployment. For additional best practices for using IPSec, see IPSec Best practices.

**IP Security Monitor**
In Windows 2000, IP Security Monitor was implemented as an executable program (IPSecmon.exe). In Windows XP and the Windows Server 2003 family, IP Security Monitor is implemented as a Microsoft Management Console (MMC) console and includes enhancements that allow you to:

- Monitor IPSec information for your local computer and for remote computers.
- View details about active IPSec policies, including the name, description, date last modified, store, path, organizational unit, and Group Policy object name.
- View main mode and quick mode generic filters and specific filters.
- View main mode and quick mode statistics. For information about the statistics displayed in IP Security Monitor, see Viewing main mode and quick mode statistics in IP Security Monitor.
- View main mode and quick mode security associations.
- Customize refresh rates, and use DNS name resolution for filter and security association output.
- Search for specific main mode or quick mode filters that match any source or destination IP address, a source or destination IP address on your local computer, or a specific source or destination IP address.

For information about adding the IP Security Monitor snap-in, see Add the IP Security Monitor snap-in. For information about additional IPSec troubleshooting tools, see IPSec troubleshooting tools.

**Stronger cryptographic master key (Diffie-Hellman)**
For enhanced security, IPSec now supports the use of a 2048-bit Diffie-Hellman key exchange. With a stronger Diffie-Hellman group, the secret key that is derived from the Diffie-Hellman exchange has greater strength. Strong Diffie-Hellman groups combined with longer key lengths increase the computational difficulty of determining a secret key.

This feature is provided only with the Windows Server 2003 family.

For more information about Diffie-Hellman groups and key exchange, see Key exchange methods and Key management and protection.

**Command-line management with Netsh**
Using commands in the Netsh IPSec context, you can configure static or dynamic IPSec main mode settings, quick mode settings, rules, and configuration parameters. To enter the Netsh IPSec context, type **netsh -c ipsec** at a command prompt. The Netsh IPSec context replaces the Ipsecpol.exe tool, which is provided with the Windows 2000 Server Resource Kit. You can use this feature to script and automate IPSec configuration. For more information, see IPSec troubleshooting tools.

This feature is provided only with the Windows Server 2003 family.

For more information about Netsh commands for IPSec, see Netsh commands for Internet Protocol security.

**Computer startup security**
For enhanced security, IPSec now provides stateful filtering of network traffic during computer startup. With stateful filtering, only the following traffic is permitted during computer startup: the outbound traffic that the computer initiates during startup, the inbound traffic that is sent in response to the outbound traffic, and DHCP traffic. As an alternative to stateful filtering, you can specify that all inbound and outbound traffic be blocked until an IPSec policy is applied. If you use stateful filtering, or if you specify that traffic be blocked during computer startup, you can also specify the traffic types that you want to exempt from IPSec filtering during computer startup.

### Note

- You cannot configure this feature in the IP Security Policy Management console. To configure this feature, you must use the Netsh IPSec command-line tool.

**Persistent policy for enhanced security**
You can now create and assign a persistent IPSec policy to secure a computer if a local IPSec policy or an Active Directory-based IPSec policy cannot be applied. When you create and assign a persistent policy, it is applied before the local policy or the Active Directory-based policy is applied, and it remains in effect regardless of whether the local policy or the Active Directory-based policy is applied (for example, an IPSec policy will not be applied if it is corrupted).

### Note

- You cannot configure this feature in the IP Security Policy Management console. To configure this feature, you must use the Netsh commands for IPSec.

**Removed default traffic exemptions**
In Windows 2000 and Windows XP, by default, all broadcast, multicast, Internet Key Exchange (IKE), Kerberos, and Resource Reservation Protocol (RSVP) traffic is exempt from IPSec filtering. To significantly improve security, in the Windows Server 2003 family, only IKE traffic (which is required for establishing IPSec-secured communication) is exempt from IPSec filtering. All other traffic types are now matched against IPSec filters, and you can configure, block, or permit filter actions specifically for multicast and broadcast traffic (IPSec does not negotiate security associations for multicast and broadcast traffic). For more information, see Special IPSec considerations.

**IPSec certificate to account mapping for network access control**
With the Windows Server 2003 family, if you use either Kerberos V5 or certificate authentication, you can set restrictions on which computers are allowed to connect. This functionality allows you to use IPSec to allow or deny any of the following access to a server running Windows Server 2003 :

- Computers that are members of a specific domain.
- Computers that have a certificate from a specific issuing certification authority.
- A specific group of computers.
- A specific computer.

When you enable certificate to account mapping in IPSec, the IKE protocol associates (maps) a computer certificate to a computer account in an Active Directory domain or forest, and then retrieves an access token, which includes the list of the user rights that are assigned to the computer. You can restrict access by configuring Group Policy security settings and assigning either the **Access this computer from the network** user right or the **Deny access to this computer from the network** user right to individual or multiple computers, as needed.

For more information about certificate to account mapping for IPSec, see Authentication methods.

For information about configuring security settings in Group Policy, see Security settings overview.

### Notes

- Certificate to account mapping for IPSec is provided only with the Windows Server 2003 family.

- Certificate mapping is not supported across forests.

**Ability to exclude the name of the certification authority (CA) from certificate requests**
For enhanced security, when you use certificate authentication to establish trust between IPSec peers, you can now exclude the name of the CA from the certificate request. When you exclude the name of the CA from the certificate request, you prevent the potential disclosure of sensitive information about the trust relationships of a computer, such as name of the company that owns the computer and the domain membership of the computer (if an internal public key infrastructure is being used), to an attacker.

**IPSec policy filters allow logical addresses for local IP configuration**
You can now use the IP Security Policy Management console to configure the source or the destination address fields that the local IPSec policy will interpret as the addresses for the DHCP server, the DNS servers, the WINS servers, and the default gateway. As a result, IPSec policies can now automatically accommodate changes in the IP configuration of the server, by using either DHCP or static IP configurations.

This feature is provided only with the Windows Server 2003 family.

**IPSec functionality over network address translation (NAT)**
IPSec Encapsulating Security Payload (ESP) packets can now pass through NATs that allow User Datagram Protocol (UDP) traffic. The IKE protocol automatically detects the presence of a NAT and uses UDP-ESP encapsulation to allow IPSec traffic to pass through the NAT. This functionality is an implementation of the Internet Engineering Task Force (IETF) IP Security Working Group standard for IPSec.

NATs are widely used for Internet Connection Sharing (ICS) and in locations that provide public Internet access (such as hotels and airports) and that are likely to be used by telecommuters. In addition, some Internet service providers (ISPs) use a centralized NAT to connect their clients to the Internet.

IPSec functionality over NAT enables IPSec-secured connections to be established in the following common deployment scenarios:

- Layer Two Tunneling Protocol (L2TP)/IPSec virtual private network (VPN) clients that are behind NATs can establish IPSec-secured connections over the Internet to their corporate network, using IPSec ESP transport mode.

- Servers running Routing and Remote Access can establish gateway-to-gateway IPSec tunnels when one of the servers running Routing and Remote Access is behind a NAT.

- Clients and servers can send IPSec-secured TCP and UDP packets to other clients or servers using IPSec ESP transport mode, when one or both of the computers are behind a NAT. For example, a program running on a server on a perimeter network can be IPSec-secured when it is used to make connections to the corporate network.

### Note

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

For more information about VPNs and IPSec, see Virtual private networking with IPSec. For more information about IPSec transport mode and tunnel mode, see Transport mode and Tunnel mode.

**Improved IPSec integration with Network Load Balancing**
Improved IPSec integration with Network Load Balancing allows a Network Load Balancing group of servers to provide highly available IPSec-based VPN services. Network Load Balancing can accurately track IPSec-secured sessions, and the IPSec IKE protocol can detect when an IPSec-secured session is being established with a cluster server and quickly recover from a failover. Additionally, Network Load Balancing can now maintain IPSec-secured connections to the correct Network Load Balancing host, even when the number of hosts in the cluster (and the algorithm used to map clients to hosts) changes. Because the IKE protocol automatically detects the Network Load Balancing service, no additional configuration is required to use this feature.

This feature is provided only with Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition.

For more information about Network Load Balancing, see Introduction to Network Load Balancing and How Network Load

Balancing works.

**IPSec support for RSoP**

To enhance IPSec deployment and troubleshooting, IPSec now provides an extension to the Resultant Set of Policy (RSoP) console. RSoP is an addition to Group Policy that you can use to view existing IPSec policy assignments for a computer or for members of a Group Policy container. To view IPSec policy assignments for a computer, run an RSoP logging mode query. To view IPSec policy assignments for members of a Group Policy container, run an RSoP planning mode query. For information about how to view IPSec policy assignments, see Use Resultant Set of Policy (RSoP) to View IPSec Policy Assignments.

After you run an RSoP logging mode query or an RSoP planning mode query, you can view detailed settings (the filter rules, filter actions, authentication methods, tunnel endpoints, and connection types that were specified when the IPSec policy was created) for the IPSec policy that is being applied.

For more information about using RSoP with IPSec, see Using Resultant Set of Policy to view IPSec policy assignments. For general information about RSoP, see RSoP overview.

# Internet Protocol Security Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Protocol security overview**

This section covers:

- Security information for IPSec
- Internet Protocol security defined
- Introducing IPSec
- Security issues with IP
- Protection against attacks
- Policy-based security
- Simplified deployment

# Security information for IPSec

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for IPSec**
Before deploying IPSec in your organization, consider the following security issues:

- 3DES and computers running Microsoft® Windows® 2000
- Authentication method
- Firewall packet filtering
- Protected traffic (using AH or ESP)
- Unprotected traffic (using the default response rule)
- Diffie-Hellman groups (using Diffie-Hellman Group 1, 2, or 2048)

**3DES and computers running Windows 2000**
IPSec policies allow the choice of a strong encryption algorithm, 3DES, which provides stronger encryption than DES for higher security. Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to perform the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, then the 3DES setting is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should use DES only as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP and the Windows Server 2003 family support 3DES and do not require installation of the High Encryption Pack.

**Authentication method**
If the computers in your organization are part of an Active Directory® domain, IPSec main mode authentication can be accomplished with the default authentication method (Kerberos V5). You do not have to deploy public key certificates for intranet communication. However, computers running Windows XP Home Edition do not support the Kerberos V5 authentication method. Also, if you have computers connected to the Internet, it is recommended that you do not use Kerberos V5 as an authentication method. When Kerberos authentication is used, during main mode negotiation, each IPSec peer sends its computer identity in unencrypted format to the other peer. The computer identity is unencrypted until encryption of the entire identity payload takes place during the authentication phase of the main mode negotiation. An attacker can send an Internet Key Exchange (IKE) packet that causes the responding IPSec peer to expose its computer identity and domain membership. To secure computers that are connected to the Internet, certificate authentication is therefore recommended.

For enhanced security, the use of preshared key authentication is not recommended because it is a relatively weak authentication method. In addition, preshared keys are stored in plaintext. Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing.

For more information, see Authentication methods and Preshared key authentication.

**Firewall packet filtering**
For a firewall, security gateway, router, or any other server or device that is connected to the Internet and providing packet filtering capabilities to computers on a perimeter network (also known as a demilitarized zone or DMZ), special filtering must be enabled on that computer to ensure that packets secured with IPSec are allowed to be forwarded to computers on the perimeter network. The firewall or other device should normally allow the following types of traffic to pass through it:

- IP Protocol ID of 50 (0x32) for IPSec Encapsulating Security Payload (ESP) traffic
- IP Protocol ID of 51 (0x33) for IPSec Authentication Header (AH) traffic
- UDP port 500 (0x1F4) for Internet Key Exchange (IKE) negotiation traffic

Most packet filtering software allows you to be more specific. You can define separate packet filters for inbound traffic (inbound filters), for outbound traffic (outbound filters), and for each interface. Additionally, you can specify IP addresses for the IPSec computers on the perimeter network. The most restrictive packet filters for IPSec traffic exchanged with a single IPSec computer on the perimeter network are outlined in the following sections.

**Filters on the Internet interface**

Configure the following inbound packet filters on the Internet interface of the firewall to allow the specific types of traffic:

- Destination IP address of the IPSec computer's perimeter network interface and UDP destination port of 500 (0x1F4)

  This filter allows IKE traffic to be sent to the IPSec computer on the perimeter network.

- Destination IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 50 (0x32)

  This filter allows IPSec ESP traffic to be sent to the IPSec computer on the perimeter network.

- Destination IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 51 (0x33)

  This filter allows IPSec AH traffic to be sent to the IPSec computer on the perimeter network.

Configure the following outbound packet filters on the Internet interface of the firewall to allow the specific types of traffic:

- Source IP address of the IPSec computer's perimeter network interface and UDP source port of 500 (0x1F4)

  This filter allows IKE traffic to be sent from the IPSec computer on the perimeter network.

- Source IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 50 (0x32)

  This filter allows IPSec ESP traffic to be sent from the IPSec computer on the perimeter network.

- Source IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 51 (0x33)

  This filter allows IPSec AH traffic to be sent from the IPSec computer on the perimeter network.

**Filters on the perimeter network interface**

Configure the following inbound packet filters on the perimeter network interface of the firewall to allow the specific types of traffic:

- Source IP address of the IPSec computer's perimeter network interface and UDP source port of 500 (0x1F4)

  This filter allows IKE traffic to be sent from the IPSec computer on the perimeter network.

- Source IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 50 (0x32)

  This filter allows IPSec ESP traffic to be sent from the IPSec computer on the perimeter network.

- Source IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 51 (0x33)

  This filter allows IPSec AH traffic to be sent from the IPSec computer on the perimeter network.

Configure the following outbound packet filters on the perimeter network interface of the firewall to allow the specific types of traffic:

- Destination IP address of the IPSec computer's perimeter network interface and UDP destination port of 500 (0x1F4)

  This filter allows IKE traffic to be sent to the IPSec computer on the perimeter network.

- Destination IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 50 (0x32)

This filter allows IPSec ESP traffic to be sent to the IPSec computer on the perimeter network.

- Destination IP address of the IPSec computer's perimeter network interface and IP Protocol ID of 51 (0x33)

  This filter allows IPSec AH traffic to be sent to the IPSec computer on the perimeter network.

**Protected traffic (using AH or ESP)**
When deciding whether to use AH or ESP to protect your IP traffic, consider the following:

- AH provides both data authentication and integrity services through the computation and inclusion of a keyed hash for each packet. With AH, the hash calculation includes the entire IP packet and header. Some fields that are allowed to change in transit are excluded. Packet replay protection services are provided through the inclusion of a sequence number for each packet.

- ESP provides data authentication and integrity services through the computation and inclusion of a keyed hash for each packet. With ESP, the hash calculation only includes the ESP header, trailer, and payload. The IP header is not protected with the hash. ESP provides data confidentiality services by encrypting the ESP payload with the DES (Data Encryption Standard) or 3DES (triple DES) encryption algorithms. Packet replay protection services are provided through the inclusion of a sequence number for each packet.

It is less CPU-intensive to verify the hash for each packet than it is to encrypt and decrypt each packet. If performance is a significant consideration, you can use AH to protect most of your traffic. When confidentiality is required, you can use ESP instead. For example, you can use AH to protect traffic on your intranet and ESP for traffic that is sent over the Internet.

**Note**

- This performance consideration assumes that you are not using IPSec offload network adapters in your organization. Offload network adapters perform cryptographic calculations, such as the calculation and verification of the hash and the encryption and decryption services, on the adapter itself, enhancing performance for IPSec-secured traffic.

**Unprotected traffic (using the default response rule)**
You can easily implement an IPSec deployment scenario that secures traffic from a specific set of servers, as follows:

1. Place the servers in an organizational unit and assign an IPSec policy to a Group Policy object of that organizational unit with a rule that requires secured traffic between the servers and any other computer. Within the filter action for the rule, enable the secure servers to accept unsecured communication but always respond using IPSec.

2. Place the client computers in an organizational unit and assign an IPSec policy to a Group Policy object of that organizational unit that uses only the default response rule. For more information, see IPSec Policy Rules.

In this configuration, the following traffic between the client computers and the secure servers is unsecured:

- The initial request (for example, a TCP SYN packet) sent by the client computer to establish communication is unsecured because the client does not have a rule in its policy to initiate secured communication with the secure server.

- Although ongoing communications are secured after secured communication is negotiated between the client and secure server computers, the quick mode security association (SA) that provides security settings for traffic can eventually time out and be removed from both the secure server and the client computer. This occurs when a TCP connection exists and no traffic is sent between the client computer and the secure server for an extended period of time. The dynamic filter created on the client computer by the default response rule is also removed after the dynamic filter has been timed out.

  If the secure server sends new data on the existing connection, it renegotiates the quick mode SA before sending this data to the client computer because a rule exists on the secure server to secure traffic between itself and all other computers. However, if the client computer sends new data after the quick mode SAs and dynamic filter time out, the new data is sent unsecured because the client does not have a rule to initiate secure communications with the secure

server. For TCP connections, one or multiple TCP segments can be sent unsecured by the client computer. To prevent client computers from sending unsecured data to secure servers, you must configure your client computer IPSec policy with additional rules that initiate secured communications to secure servers.

**Diffie-Hellman groups (using Diffie-Hellman group 1, 2, or 2048)**

Diffie-Hellman groups are used to determine the length of the base prime numbers that are used during the key exchange process. Group 2048 (high) is stronger (more secure) than Group 2 (medium), which is stronger than Group 1 (low). Group 1 provides 768 bits of keying strength, Group 2 provides 1,024 bits, and Group 2048 provides 2,048 bits.

Strong Diffie-Hellman groups combined with longer key lengths increase the computational difficulty of determining a secret key.

**Important**

- For enhanced security, do not use Diffie-Hellman Group 1. For maximum security, use Group 2048 whenever possible. Use Group 2 when required for interoperability with Windows 2000 and Windows XP.

**Note**

- Diffie-Hellman Group 2048 is provided only with the Windows Server 2003 family.

For more information about Diffie-Hellman groups and key exchange, see Key exchange methods and Key management and protection.

# Internet Protocol security defined

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Protocol security defined**

Internet Protocol security (IPSec) is a framework of open standards for ensuring private, secure communications over Internet Protocol (IP) networks, through the use of cryptographic security services. The Microsoft® Windows® 2000 , Windows XP, and the Windows Server 2003 family implementations of IPSec are based on standards developed by the Internet Engineering Task Force (IETF) IPSec working group.

IPSec is the long-term direction for secure networking. It provides aggressive protection against private network and Internet attacks through end-to-end security. The only computers that must know about IPSec protection are the sender and receiver in the communication. In Windows XP and the Windows Server 2003 family, IPSec provides the ability to protect communication between workgroups, local area network computers, domain clients and servers, branch offices (which might be physically remote), extranets, and roving clients.

# Introducing IPSec

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Introducing IPSec**

IPSec is the long-term direction for secure networking. It provides a key line of defense against private network and Internet attacks.

IPSec has two goals:

1. To protect the contents of IP packets.

2. To provide a defense against network attacks through packet filtering and the enforcement of trusted communication.

Both goals are met through the use of cryptography-based protection services, security protocols, and dynamic key management. This foundation provides both the strength and flexibility to protect communications between private network computers, domains, sites, remote sites, extranets, and dial-up clients. It can even be used to block receipt or transmission of specific traffic types.

IPSec is based on an end-to-end security model, establishing trust and security from a source IP to a destination IP address. The IP address itself does not necessarily have to be considered an identity, rather the system behind the IP address has an identity that is validated through an authentication process. The only computers that must know about the traffic being secured are the sending and receiving computers. Each computer handles security at its respective end, with the assumption that the medium over which the communication takes place is not secure. Any computers that only route data from source to destination are not required to support IPSec, unless firewall-type packet filtering or network address translation is being done between the two computers. This model allows IPSec to be successfully deployed for the following enterprise scenarios:

- Local area network (LAN): client/server and peer-to-peer

- Wide area network (WAN): router-to-router and gateway-to-gateway

- Remote access: dial-up clients and Internet access from private networks

Typically both sides require IPSec configuration (called an IPSec policy), to set options and security settings that will allow two systems to agree on how to secure traffic between them. The Microsoft® Windows® 2000 , Windows XP, and the Windows Server 2003 family implementations of IPSec is based on industry standards developed by the Internet Engineering Task Force (IETF) IPSec working group. Portions of IPSec-related services were jointly developed by Microsoft and Cisco Systems, Inc.

# Security issues with IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security issues with IP**
Without security, both public and private networks are susceptible to unauthorized monitoring and access. Internal attacks might be a result of minimal or nonexistent intranet security. Risks from outside the private network originate from connections to the Internet and extranets. Password-based user access controls alone do not protect data transmitted across a network.

**Common types of network attacks**
Without security measures and controls in place, your data might be subjected to an attack. Some attacks are passive in that information is only monitored. Other attacks are active and information is altered with intent to corrupt or destroy the data or the network itself. Your networks and data are vulnerable to any of the following types of attacks if you do not have a security plan in place.

**Eavesdropping**
In general, the majority of network communications occur in a plaintext (unencrypted) format, which allows an attacker who has gained access to data paths in a network to monitor and interpret (read) the traffic. When an attacker is eavesdropping on communications, it is referred to as sniffing or snooping. The ability of an eavesdropper to monitor the network is generally the biggest security problem that administrators face in an enterprise. Without strong encryption services that are based on cryptography, data can be read by others as it traverses the network.

**Data modification**
After an attacker has read data, the next logical step is often to modify it. An attacker can modify the data in the packet without the knowledge of the sender or receiver. Even if you do not require confidentiality for all communications, you do not want any of your messages to be modified in transit. For example, if you are exchanging purchase requisitions, you do not want the items, amounts, or billing information to be changed.

**Identity spoofing (IP address spoofing)**
Most networks and operating systems use the IP address to identify a computer as being valid on a network. In some cases, it is possible for an IP address to be falsely used. This is known as identity spoofing. An attacker might use special programs to construct IP packets that appear to originate from valid addresses inside an organization intranet.

After gaining access to the network with a valid IP address, the attacker can modify, reroute, or delete data. The attacker can also conduct other types of attacks, as described in the following sections.

**Password-based attacks**
A commonality among most operating systems and network security plans is password-based access control. Access to both a computer and network resources are determined by a user name and password.

Historically, many versions of operating system components have not always protected identity information as it was passed through the network for validation. This might allow an eavesdropper to determine a valid user name and password and use it to gain access to the network by posing as a valid user.

When an attacker finds and accesses a valid user account, the attacker has the same rights as the actual user. For example, if the user has administrative rights, the attacker can create additional accounts for access at a later time.

After gaining access to a network with a valid account, an attacker can do any of the following:

- Obtain lists of valid user and computer names and network information.
- Modify server and network configurations, including access controls and routing tables.
- Modify, reroute, or delete data.

**Denial-of-service attack**
Unlike a password-based attack, the denial-of-service attack prevents normal use of a computer or network by valid users.

After gaining access to a network, an attacker can do any of the following:

- Distract information systems staff so that they do not immediately detect the intrusion. This gives an attacker the opportunity to make additional attacks.
- Send invalid data to applications or network services, causing applications or services to close or operate abnormally.
- Send a flood of traffic until a computer or an entire network is shut down.
- Block traffic, which results in a loss of access to network resources by authorized users.

**Man-in-the-middle attack**
As the name indicates, a man-in-the-middle attack occurs when someone between two users who are communicating is actively monitoring, capturing, and controlling the communication without the knowledge of the users. For example, an attacker can negotiate encryption keys with both users. Each user then sends encrypted data to the attacker, who can decrypt the data. When computers are communicating at low levels of the network layer, the computers might not be able to determine with which computers they are exchanging data.

**Compromised-key attack**
A key is a secret code or number required to encrypt, decrypt, or validate secured information. Although determining a key is a difficult and resource-intensive process for an attacker, it is possible. After an attacker determines a key, that key is referred to as a compromised key.

An attacker uses the compromised key to gain access to a secured communication without the sender or receiver being aware of the attack. With the compromised key, the attacker can decrypt or modify data. The attacker can also attempt to use the compromised key to compute additional keys, which might allow access to other secured communications.

**Sniffer attack**
A sniffer is an application or device that can read, monitor, and capture network data exchanges and packets. If the packets are not encrypted, a sniffer provides a full view of the data that is inside of the packet. Even encapsulated (tunneled) packets can be opened and read if they are not encrypted.

Using a sniffer, an attacker can do the following:

- Analyze a network and access information, eventually causing the network to stop responding or become corrupted.
- Read private communications.

**Application-layer attack**
An application-layer attack targets application servers by causing a fault in a server's operating system or applications. This results in the attacker gaining the ability to bypass normal access controls. The attacker takes advantage of this situation, gaining control of an application, system, or network, and can do any of the following:

- Read, add, delete, or modify data or an operating system.
- Introduce a virus that uses computers and software applications to copy viruses throughout the network.
- Introduce a sniffer program to analyze the network and gain information that can eventually be used to cause the network to stop responding or become corrupted.
- Abnormally close data applications or operating systems.
- Disable other security controls to enable future attacks.

# Protection against attacks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protection against attacks**
IPSec protects data so that an attacker finds it extremely difficult or impossible to interpret it. The level of protection provided is determined by the strength of the security levels specified in your IPSec policy structure.

IPSec has a number of features that significantly reduce or prevent the following attacks:

- Sniffers (lack of confidentiality)

  The Encapsulating Security Payload (ESP) protocol in IPSec provides data confidentiality by encrypting the payload of IP packets.

- Data modification

  IPSec uses cryptography-based keys, shared only by the sending and receiving computers, to create a cryptographic checksum for each IP packet. Any modification to the packet data alters the checksum, which indicates to the receiving computer that the packet was modified in transit.

- Identity spoofing, password-based, and application-layer attacks

  IPSec allows the exchange and verification of identities without exposing that information to interpretation by an attacker. Mutual verification (authentication) is used to establish trust between the communicating systems and only trusted systems can communicate with each other. After identities are established, IPSec uses cryptography-based keys, shared only by the sending and receiving computers, to create a cryptographic checksum for each IP packet. The cryptographic checksum ensures that only the computers that have knowledge of the keys could have sent each packet.

- Man-in-the-middle attacks

  IPSec combines mutual authentication with shared, cryptography-based keys.

- Denial-of-service attacks

  IPSec uses IP packet filtering methodology as the basis for determining whether communication is allowed, secured, or blocked, according to the IP address ranges, IP protocols, or even specific TCP and UDP ports.

# Policy-based security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policy-based security**

Although stronger security methods based on cryptography have become necessary to fully protect communication, they can often greatly increase administrative overhead. To reduce overhead, IPSec uses policy-based administration.

IPSec policies, rather than application programming interfaces (APIs), are used to configure IPSec security services. The policies provide variable levels of protection for most traffic types in most existing networks.

You can configure IPSec policies to meet the security requirements of a computer, application, organizational unit, domain, site, or global corporation. You can use the IP Security Policy Management console provided in Microsoft® Windows® XP and the Windows Server 2003 family to define IPSec policies for computers through Active Directory® (for domain members) or on the local computer (for computers that do not belong to domains).

# Simplified deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Simplified deployment**
To achieve secure communications with a low cost of ownership, Microsoft® Windows® XP and the Windows Server 2003 family simplify the deployment of IPSec with the following features:

- Integration with the security framework in Windows 2000 and the Windows Server 2003 family.

  IPSec uses the secure domain in Windows 2000 and the Windows Server 2003 family as a trust model. By default, IPSec policies use the Active Directory® default authentication method (Kerberos V5 authentication) to identify and trust communicating computers. Computers that are members of a Windows 2000 or a Windows Server 2003 domain and are in trusted domains can easily establish IPSec-secured communications.

- Centralized IPSec policy administration through Active Directory

  IPSec policies can be assigned through Group Policy configuration of Active Directory domains and organizational units. This allows the IPSec policy to be assigned at the domain, site, or organizational unit level, eliminating the administrative overhead of configuring each computer separately.

- Transparency of IPSec to users and applications

  Integration at the IP layer (layer 3) provides security for any protocol in the TCP/IP suite of protocols. You do not need separate security for each protocol in the TCP/IP suite of protocols, because applications using TCP/IP pass the data to the IP protocol layer, where it is secured.

- Flexible security configuration

  The security services within each policy can be customized to meet the majority of security requirements for the network and data traffic.

- Automatic key management

  Internet Key Exchange (IKE) services dynamically exchange and manage cryptographic keys between communicating computers.

- Automatic security negotiation

  Internet Key Exchange (IKE) services dynamically negotiate a common set of security settings between communicating computers, eliminating the need for both computers to have identically configured policies.

- Public key infrastructure support

  Using public key certificates for authentication is supported. This allows trust and secure communication for computers that do not belong to a trusted Windows 2000 or Windows Server 2003 domain, non-Microsoft operating systems, computers that have membership in untrusted domains, and instances in which computer access must be restricted to a smaller group than domain authentication allows.

- Preshared key support

  If authentication using the Kerberos V5 protocol or public key certificates is not possible, a preshared authentication key can be configured.

**Important**

- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. Preshared key authentication creates a master key that is less secure (that might produce a weaker form of encryption) than certificates or the Kerberos V5 protocol. In addition, preshared keys are stored in plaintext. Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing and that you use certificates or Kerberos V5 instead in a production environment.

**Note**

- The integration with the security framework in Windows 2000 or the Windows Server 2003 family, centralized IPSec policy administration through Active Directory, and the use of the Kerberos V5 protocol as described here do not apply to computers running Windows XP Home Edition. You cannot administer Active Directory-based IPSec policy from computers running Windows XP Home Edition because these computers cannot join Active Directory domains.

# Understanding Internet Protocol Security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Internet Protocol security**

This section introduces the key concepts and terminology you should review before you deploy IPSec. This section covers:

- The IPSec process
- Virtual private networking with IPSec
- IPSec Security Services
- IPSec Protocol Types
- IPSec Components
- Description of an IPSec Policy

# The IPSec process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The IPSec process**

This topic provides an overview of IPSec concepts that are central to understanding the IPSec process, including IPSec policy configuration and the Internet Key Exchange (IKE) protocol. In addition, this topic describes how IPSec network traffic processing works, using two intranet computers as an example.

**IPSec Policy Configuration**

In Windows 2000, Windows XP, and the Windows Server 2003 family, IPSec is implemented primarily as an administrative tool that you can use to enforce security policies on IP network traffic. A security policy is a set of packet filters that define network traffic as it is recognized at the IP layer. A filter action defines the security requirements for the network traffic. A filter action can be configured to: **Permit**, **Block**, or **Negotiate security** (negotiate IPSec).

IPSec filters are inserted into the IP layer of the computer TCP/IP networking protocol stack so that they can examine (filter) all inbound or outbound IP packets. Except for a brief delay required to negotiate a security relationship between two computers, IPSec is transparent to end-user applications and operating system services.

A collective set of IPSec security settings is known as an IPSec policy. Windows 2000, Windows XP, and the Windows Server 2003 family provide a graphical user interface and several command-line tools that you can use to configure an IPSec policy, and then assign it to a computer.

To ensure that IPSec communication is successful and that IPSec meets the security requirements of your organization, you must carefully design, configure, coordinate, and manage IPSec policies. In many organizations, one administrator might be responsible for configuring and managing IPSec policies for many, if not all, computers.

**Internet Key Exchange (IKE) security associations**

The IKE protocol is designed to securely establish a trust relationship between each computer, to negotiate security options, and dynamically generate shared, secret cryptographic keying material. The agreement of security settings associated with keying material is called a security association, also known as an SA. These keys will provide authenticity, integrity, and optionally, encryption of IP packets that are sent using the security association. IKE negotiates two types of security associations:

- A main mode security association (the IKE security association that is used to protect the IKE negotiation itself).
- IPSec security associations (the security associations that are used to protect application traffic).

You can configure IPSec policy settings for both types of security associations.

The IPSec service interprets an IPSec policy, expanding it into the components that it needs to control the IKE negotiation. The IPSec policy contains one definition of a packet filter. The packet filter is interpreted in two ways: one uses only the address and identity information to allow IKE to establish a main mode SA (the IKE security association); the other allows IKE to establish the IPSec security associations (also known as quick mode security associations).

**IPSec network traffic processing**

The following illustration shows how IPSec works in terms of the IPSec components for two intranet computers.

For simplicity, this example is of an intranet in which two computers have an active IPSec policy.

1. Alice, using a data application on Computer A, sends an application IP packet to Bob on Computer B.
2. The IPSec driver on Computer A checks its outbound IP filter lists and determines that the packets should be secured.

3. The action is to negotiate security, so the IPSec driver notifies IKE to begin negotiations.

4. The IKE service on Computer A completes a policy lookup, using its own IP address as the source and the IP address of Computer B as the destination. The main mode filter match determines the main mode settings that Computer A proposes to Computer B. Computer A sends the first IKE message in main mode, using UDP source port 500, destination port 500. IKE packets receive special processing by the IPSec driver to bypass filters.

5. Computer B receives an IKE main mode message requesting secure negotiation. It uses the source IP address and the destination IP address of the UDP packet to perform a main mode policy lookup, to determine which security settings to agree to. Computer B has a main mode file that matches, and so replies to begin negotiation of the main mode SA.

6. Computer A and Computer B now negotiate options, exchange identities, verify trust in those identities (authentication), and generate a shared master key. They have now established an IKE main mode SA. Computer A and Computer B must mutually trust each other.

7. Computer A then performs an IKE quick mode policy lookup, using the full filter to which the IPSec driver matched the outbound packet. Computer A selects the quick mode security settings and proposes them, and the quick mode filter, to Computer B.

   Computer B also performs an IKE quick mode policy lookup, using the filter description offered by Computer A. Computer B selects the security settings required by its policy and compares those settings to those offered by computer A. Computer B accepts one set of options and completes the remainder of the IKE quick mode negotiation to create a pair of IPSec security associations.

8. One IPSec SA is inbound and one IPSec SA is outbound. The IPSec SAs are identified by a Security Parameter Index (SPI), which is inserted into the IPSec header of each packet sent.

9. The IPSec driver on Computer A uses the outbound SA to sign and, if required, encrypt the packets. If the network adapter can perform hardware offload of IPSec cryptographic functions, the IPSec driver formats the packets, but does not perform the IPSec cryptographic functions.

10. The IPSec driver passes the packets to the network adapter driver, indicating whether the adapter must perform the IPSec cryptographic functions. The network adapter transmits the packets into the network.

11. The network adapter driver at Computer B receives the encrypted packets from the network. The SPI is used by the receiver of an IPSec packet to find the corresponding IPSec security association, with the cryptographic keys required to verify and decrypt the packets. If the network adapter can decrypt the packets in hardware, it verifies whether it can recognize the SPI. If it cannot decrypt the packets in hardware, or if it cannot recognize the SPI, it passes the packets up to the IPSec driver.

12. The IPSec driver on Computer B uses the inbound SA SPI to retrieve the keys required to validate authentication and integrity and, if required, to decrypt the packets.

13. The IPSec driver converts the packets from IPSec format back to standard IP packet format. It passes the validated and decrypted IP packets to the TCP/IP driver, which passes them to the receiving application on Computer B.

14. The IPSec SAs continue to provide very strong, transparent protection for application data traffic. The IPSec SAs are automatically refreshed by an IKE quick mode negotiation for as long as the application sends and receives data. When the application stops sending and receiving data, the IPSec SAs become idle and are deleted.

15. Typically, the IKE main mode SA is not deleted. By default, the main mode SA has a lifetime of 8 hours. You can configure the main mode SA lifetime to as short as 5 minutes to a maximum of 48 hours. Whenever more traffic is sent, a new quick mode is negotiated automatically to create two new IPSec SAs to protect application traffic. This process is rapid, because the main mode SA already exists. If a main mode SA expires, it is automatically renegotiated as needed.

Any routers or switches in the path between the communicating computers simply forward the encrypted IP packets to their

destination. However, if there is a firewall, security router, or proxy server in the path, IPSec and IKE traffic might not be forwarded. These devices must be configured to allow IPSec and IKE protocol packets through. If the IPSec packets are not encrypted, the firewall or security router can still inspect the TCP or UDP ports or other content in the packets. If the contents of these packets are modified after they are sent, the receiving IPSec computer detects the modification and discards the packets.

However, the Windows Server 2003 family implementation of IPSec provides support for a new Internet specification that allows IPSec packets to be modified by a network address translator (NAT). IPSec Encapsulating Security Payload (ESP) packets can pass through NATs that allow UDP traffic. The IKE protocol automatically detects the presence of a NAT and uses User Datagram Protocol-ESP (UDP-ESP) encapsulation to allow IPSec traffic to pass through the NAT.

# Virtual private networking with IPSec

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private networking with IPSec**

Tunneling is the entire process of encapsulation, routing, and decapsulation. Tunneling wraps, or encapsulates, the original packet inside a new packet. This new packet might have new addressing and routing information, which enables it to travel through a network. When tunneling is combined with data confidentiality, the original packet data (as well as the original source and destination) is not revealed to those listening to traffic on the network. After the encapsulated packets reach their destination, the encapsulation is removed, and the original packet header is used to route the packet to its final destination.

The tunnel itself is the logical data path through which the encapsulated packets travel. To the original source and destination peer, the tunnel is usually transparent and appears as just another point-to-point connection in the network path. The peers are unaware of any routers, switches, proxy servers, or other security gateways between the tunnel's beginning point and the tunnel's end point. When tunneling is combined with data confidentiality, it can be used to provide a virtual private network (VPN).

The encapsulated packets travel through the network inside the tunnel. In this example, the network is the Internet. The gateway might be an edge gateway that stands between the outside Internet and the private network. The edge gateway can be a router, firewall, proxy server, or other security gateway. Also, two gateways can be used inside the private network to protect traffic across untrusted parts of the network.

**Tunnel types that use IPSec**

In Windows XP and the Windows Server 2003 family, two types of tunneling are provided that use IPSec:

- **The combination of the Layer Two Tunneling Protocol (L2TP) and IPSec (L2TP/IPSec)**

  L2TP is used to tunnel the data across a shared or public network such as the Internet, and IPSec Encapsulating Security Payload (ESP) is used to encrypt the data. L2TP/IPSec can be used to tunnel IP or Internetwork Packet Exchange (IPX) traffic.

- **IPSec in tunnel mode**

  When IPSec is used in tunnel mode, IPSec itself provides encapsulation for IP traffic only. The primary reason for using IPSec tunnel mode is interoperability with other routers, gateways, or end-systems that do not support L2TP/IPSec or PPTP VPN tunneling. IPSec tunnel mode is supported only in gateway-to-gateway tunneling scenarios and for certain server-to-server or server-to-gateway configurations as an advanced feature. IPSec tunnel mode is not supported for remote access VPN scenarios. L2TP/IPSec or PPTP should be used for remote access VPN connections.

  For information about IPSec tunnel mode and configuring IPSec tunnels, see Tunnel mode.

**How L2TP and IPSec work**

L2TP and IPSec are combined to provide both tunneling and security for IP, IPX, and other protocol packets across any IP network. IPSec can also perform tunneling without L2TP, but it is only recommended for interoperability, when one of the gateways does not support L2TP or PPTP.

L2TP encapsulates original packets first inside a PPP frame (performing compression when possible) and then inside a UDP message using port 1701. Because the UDP message is an IP payload, L2TP uses IPSec transport mode to secure the tunnel. This design supports RFC 3193 ("Securing L2TP Using IPSec"), and it is compatible with Windows XP and Windows 2000. The IPSec Internet Key Exchange (IKE) protocol negotiates security for the L2TP tunnel using certificate-based or preshared key authentication. If IPSec main mode and quick mode security associations are successfully established, L2TP negotiates the tunnel, including compression and user authentication options, and performs PPP-based user authentication.

The original packet, shown here as the **PPP payload**, includes the original and ultimate source and destination addresses used

on the private network. The outer IP header, shown as **IP header**, contains the source and destination addresses of the VPN client and server on the public network. The L2TP header includes L2TP tunnel control information. The PPP header identifies the protocol of the original packet (for example, IP or IPX).

### Note

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

#### Common L2TP/IPSec scenarios

Two common scenarios for L2TP/IPSec are securing communications between remote access clients and the corporate network across the Internet and securing communications between branch offices.

#### Remote access clients with L2TP/IPSec

A common requirement is securing communications between remote access clients and the corporate network across the Internet. Such a client might be a sales consultant who spends most of the time traveling, or an employee working from a home office.

In this figure, the remote gateway is a server that provides edge security for the corporate intranet. The remote client represents a roaming user who requires regular access to network resources and information. An ISP is used as an example to demonstrate the path of communication when the client uses an ISP to access the Internet. L2TP is combined with IPSec to provide a simple, efficient way to build the tunnel and protect the data across the Internet.

For more information about configuring L2TP-based client remote access VPN connections, see Setting Up Remote Access VPNs, Make a virtual private network (VPN) connection, and Virtual Private Network (VPN) Connections.

#### Connecting branch offices with L2TP/IPSec

A large corporation often has multiple sites that require communication--for example, a corporate office in New York and a sales office in Washington. In this case, L2TP is combined with IPSec to provide the VPN connection and protect the data between the sites.

In this figure, the router running the Windows Server 2003 family provides edge security. The routers might have a leased line, dial-up, or other type of Internet connection. The IPSec SA and L2TP tunnel runs between the routers only and provides protected communication through the Internet.

For more information about configuring L2TP-based router-to-router VPN connections, see Deploying Router-to-Router VPNs.

# IPSec Security Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPSec security services**

IPSec provides a high level of security by using cryptography-based services. Cryptography allows information to be transmitted securely by hashing (to provide integrity and authentication) and encrypting (to provide confidentiality) the information. IPSec provides or uses the following security services:

- Security properties
- Public key certificate-based authentication
- Preshared key authentication
- Data integrity with hash functions
- Data confidentiality with encryption
- Key management and protection

# Security properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security properties**

IPSec provides the following properties for secured communications:

- Anti-replay

  Ensures the uniqueness of each IP packet. Anti-replay is also called replay prevention. Anti-replay ensures that data captured by an attacker cannot be reused or replayed to establish a session or gain information illegally. This protects against attempts to intercept a message and then use the identical message to illegally gain access to resources, possibly months later.

- Integrity

  Protects data from unauthorized modification in transit, ensuring that the data received is exactly the same as the data sent. Hash functions sign each packet with a cryptographic checksum using a shared, secret key. Only the sender and receiver have the key that is used to calculate the checksum. If the packet contents have changed, the checksum verification fails and the packet is discarded.

- Confidentiality (encryption)

  Ensures that data is only disclosed to intended recipients. This is achieved by encrypting the data before transmission, ensuring that the data cannot be read during transmission, even if the packet is monitored or intercepted. Only the communicating computers with the shared, secret key are able to read the data after it has been decrypted. This property is optional and is dependent on IPSec policy settings.

- Authentication

  Verifies that a message could only have been sent from a computer that has knowledge of the shared, secret key. The sender includes (with the message) a message authentication code with a calculation that includes the shared, secret key. The receiver performs the same calculation and, if the receiver's calculation does not match the message authentication code that is included in the message, the message is discarded. The message authentication code is the same as the cryptographic checksum that is used for integrity.

# Public key certificate-based authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Public key certificate-based authentication**

An effectively implemented public key infrastructure, in which security credentials can be presented without compromising them in the process, resolves many security problems. IPSec works with your public key infrastructure to enable certificate-based authentication of computers.

A public key certificate is one type of authentication that reliably provides identity verification. Public key certificates are like digital passports. They are used to verify the identities of non-Microsoft operating system computers, stand-alone computers, clients that are not members of a trusted domain, or computers that are not running the Kerberos V5 authentication protocol (the default authentication method in Windows XP and Windows Server 2003 family) and Routing and Remote Access.

# Preshared key authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Preshared key authentication**

IPSec can use preshared keys for authentication. Preshared means that the parties agree on a shared, secret key that is used for authentication in an IPSec policy.

During security negotiation, information is encrypted before transmission by using a session key. The session key is created by using a Diffie-Hellman calculation and the shared, secret key. Information is decrypted on the receiving end using the same key. One IPSec peer authenticates the other peer's packet by decryption and verification of the hash inside the packet (the hash inside the packet is a hash of the preshared key). If authentication fails, the packet is discarded.

The use of preshared key authentication is not recommended because it is a relatively weak authentication method. Preshared key authentication creates a master key that is less secure (that might produce a weaker form of encryption) than certificates or the Kerberos V5 protocol. In addition, preshared keys are stored in plaintext in the registry. In Active Directory, preshared keys are stored in readable hexadecimal format.

Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing and that you use certificates or Kerberos V5 instead in a production environment. For more information about IPSec authentication methods, see Authentication methods and Public key certificate-based authentication.

# Data integrity with hash functions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data integrity with hash functions**

Hash message authentication codes (HMAC) sign packets to verify that the information received is exactly the same as the information sent. This is called integrity. HMACs provide integrity through a keyed hash, the result of a mathematical calculation on a message using a hash function (algorithm) combined with a shared, secret key. A hash is commonly described as a signature on the packet. However, a hash differs from a digital signature. A hash uses a secret, shared key, and a digital signature uses public key technology and the private key of the sending computer. A digital signature provides nonrepudiation, and a hash does not. Nonrepudiation ensures that a communication can be proven to have originated from a specific person whose identity can be verified. It also ensures that the communication actually occurred.

Hash functions are also called one-way functions because it is easy to determine the hash from the message but mathematically infeasible to determine the message from the hash. Conversely, in two-way functions, the original message can be determined from its converted form. Encryption and decryption schemes are examples of two-way functions.

The hash is a cryptographic checksum or message integrity code (MIC) that each party must compute to verify the message. For example, the sending computer uses a hash function and shared key to compute the checksum for the message, including it with the packet. The receiving computer must perform the same hash function on the received message and shared key and compare it to the original (included in the packet from the sender). If the message has changed in transit, the hash values are different and the packet is rejected.

For integrity, you can choose between two hash functions when setting policy:

- MD5

  Message Digest 5 (MD5) is based on RFC 1321. MD5 completes four passes over the data blocks, using a different numeric constant for each word in the message on each pass. The number of 32-bit constants used during the MD5 computation ultimately produces a 128-bit hash that is used for the integrity check.

- SHA1

  Secure Hash Algorithm 1 (SHA1) was developed by the National Institute of Standards and Technology as described in Federal Information Processing Standard (FIPS) PUB 180-1. The SHA process is closely modeled after MD5. The SHA1 computation results in a 160-bit hash that is used for the integrity check. Because longer hash lengths provide greater security, SHA is stronger than MD5.

# Data confidentiality with encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data confidentiality with encryption**
IPSec in Windows XP and the Windows Server 2003 family uses the US Data Encryption Standard (DES) to provide confidentiality (data encryption). The DES algorithm was published in 1977 by the US National Bureau of Standards.

DES is a block cipher that uses a 56-bit key. A block cipher is an encryption algorithm that operates on a fixed size block of data. DES encrypts data in 64-bit blocks using a 64-bit key. The key appears to be a 64-bit key, but one bit in each of the 8 bytes is used for error checking, resulting in 56 bits of usable key.

Cipher block chaining (CBC) is also used to hide patterns of identical blocks of data within a packet. An initialization vector (an initial random number) is used as the first random block to encrypt and decrypt a block of data. Different random blocks are used in conjunction with the secret key to encrypt each successive block. This ensures that identical sets of unsecured data (plaintext) result in unique, encrypted data blocks.

The Windows XP and the Windows Server 2003 family implementation of IPSec supports the use of:

- DES

  Used when the high security and overhead of 3DES are not necessary.

- 3DES

  Used when high security is required. 3DES processes each block three times, using a unique 56-bit key each time:

  1. Encryption on the block with key 1
  2. Decryption on the block with key 2
  3. Encryption on the block with key 3

     This process is reversed if the computer is decrypting a packet.

**Note**

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

# Key management and protection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Key management and protection**
A key is a secret code or number that is required to read, modify, or verify secured data. Keys are used in conjunction with algorithms (a mathematical process) to secure data.

**Key management**
Windows XP and the Windows Server 2003 family automatically handle key generation and implement the following keying properties:

- Variable key lengths

  With IPSec, you can select integrity and encryption algorithms that provide a range of key lengths. Every time the length of a key is increased by one bit, the number of possible keys doubles, making it exponentially more difficult to determine the key. Shorter key lengths are processed more quickly than longer key lengths. Longer key lengths provide a higher level of security, but are more resource-intensive to process.

- Key material generation: The Diffie-Hellman algorithm

  To enable secure communication, two computers must be able to gain the same shared key (session key), without sending the key across a network and compromising the secret.

  The Diffie-Hellman algorithm predates Rivest-Shamir-Adleman (RSA) cryptographic algorithms and offers better performance. It is one of the oldest and most secure algorithms used for key exchange. The two peers publicly exchange keying information, which Windows XP and the Windows Server 2003 family additionally protect with a hash function signature. Neither peer ever exchanges the actual key; however, after their exchange of keying material, each can generate the identical shared key.

  The Diffie-Hellman keying material that is exchanged by the two parties can be based on 768, 1,024, or 2,048 bits of keying material, known as Diffie-Hellman groups 1, 2, and 2048, respectively. The strength of the Diffie-Hellman group is proportional to the strength of the key that is computed from the Diffie-Hellman exchange. Strong Diffie-Hellman groups combined with longer key lengths increase the computational difficulty of determining a secret key.

  IPSec uses the Diffie-Hellman algorithm to provide the keying material for all other encryption keys. Diffie-Hellman does not provide authentication. In the Windows XP and the Windows Server 2003 family implementation of IPSec, identities are authenticated after the Diffie-Hellman exchange takes place, providing protection against man-in-the-middle attacks.

- Dynamic rekeying

  IPSec policy controls how often a new key is generated during communication, by using a method called dynamic rekeying. The communication is sent in blocks, and each block of data is secured with a different key. This prevents an attacker who has obtained part of a communication, and the corresponding session keys, from obtaining the remainder of the communication. This on-demand security negotiation and automatic key management service is provided using IKE, as defined in RFC 2409, "The Internet Key Exchange (IKE)."

  IPSec policy allows you to control how often a new key is generated. If no values are configured, keys are regenerated automatically at default intervals.

**Key protection**
The following features enhance the base prime numbers (keying material) and the strength of the keys for the master and session keys.

- Key lifetimes

  Key lifetimes determine when a new key is generated, rather than how it is generated. A key lifetime allows you to force

an automatic key regeneration after a specific interval of either kilobytes (KB) or seconds, whichever occurs first. This ensures that even if an attacker is able to decipher part of a communication protected by one key, new keys protect the remainder of the communication. Whenever a key lifetime is reached, the security association (SA) is also renegotiated and the key is refreshed or regenerated. For this reason, key lifetimes are also referred to as SA lifetimes. You can specify key lifetimes for the master key and for session keys.

The master key lifetime corresponds to the IKE SA lifetime created by the IKE main mode (phase I) negotiation. It is configured in terms of time and number of quick mode negotiations, and it applies to all security rules in the IPSec policy. The IKE SA and master key typically have a long lifetime (the default value is eight hours). Master keys are much more resource-intensive to generate than session keys, due to the fact that reauthentication and additional Diffie-Hellman exchanges are required.

The session keys correspond to the IPSec SAs that are used to protect program traffic. The session keys and IPSec SAs are quickly derived from the master key by the IKE quick mode (phase II) negotiation. Thus the session keys are used to protect the data, and they have lifetimes based on the amount of data sent and the amount of time elapsed since the key started being used. Typically, session keys have shorter lifetimes than master keys. The default values are 100,000 KB (approximately 100 megabytes) or one hour. When the session keys are refreshed, new IPSec SAs replace the old ones. The IPSec SA session keys must be refreshed before either the data or time lifetime expires, or traffic is discarded. A session key will be deleted if the IPSec SAs become idle (by default, SAs become idle after five minutes). Because the master key lives longer than the session key, it allows new IPSec SAs and session keys to be established quickly. To prevent data loss, the quick mode SA session key is generated shortly before the main mode SA expires. The IKE SA and corresponding master key are not deleted when session keys and IPSec SAs are deleted, unless the specified number of quick mode SA negotiations has elapsed.

For example, if a communication takes one hour (3,600 seconds), and if you specify the minimum session key lifetime of five minutes (300 seconds), more than 12 keys are generated to complete the communication. If a 100 megabytes (MB) file is transferred over a fast corporate LAN using an IPSec security association with a 100 MB and one hour lifetime, at least one, if not two, session rekeys occur.

**Notes**

- To provide maximum protection against cryptographic attacks, the amount of data encrypted using Data Encryption Standard (DES) or Triple DES (3DES) by a single session key should not exceed 100 MB. In a high-security environment, consider using session key lifetimes for MD5 or Secure Hash Algorithm (SHA-1) that are shorter then the default values, to provide stronger protection against future cryptographic attacks.

- In certain scenarios, there might be practical operational limits on key lifetimes. The shorter the key lifetimes, the more CPU cycles are spent refreshing keys. This might limit either the number of active IPSec SAs that a computer can maintain or the throughput performance of IPSec-secured traffic.

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

- Session key refresh limit

  Repeated rekeying off of a session key can compromise the Diffie-Hellman shared secret. Because of this, you might want to set a limit to the number of quick mode session keys that can be derived from a main mode negotiation.

  If you have enabled master key perfect forward secrecy (PFS), the session key limit is not used. Setting a session key limit to 1 is identical to enabling master key PFS. If both a master key lifetime and a session limit are specified, whichever limit is reached first causes a new main mode negotiation. By default, IPSec policy does not specify a session limit.

- Diffie-Hellman groups

Diffie-Hellman groups are used to determine the length of the base prime numbers (key material) for the Diffie-Hellman exchange. The cryptographic strength of any key derived from a Diffie-Hellman exchange depends, in part, on the strength of the Diffie-Hellman group on which the prime numbers are based.

Diffie-Hellman Group 2048 (high) is stronger than Group 2 (medium), which is stronger than Group 1 (low). When a stronger group is used, the key that is derived from a Diffie-Hellman exchange is stronger and more difficult for an attacker to break.

IKE negotiates which specific group to use, ensuring that there are not any negotiation failures that result from a mismatched Diffie-Hellman group between the two peers.

If session key PFS is enabled, a new Diffie-Hellman key is negotiated during the first quick mode SA negotiation. This new key removes the dependency of the session key on the Diffie-Hellman exchange that is performed for the master key.

Both the initiator and responder must have session key PFS enabled, or negotiation fails.

The Diffie-Hellman group is the same for both the main mode and quick mode SA negotiations. When session key PFS is enabled, even though the Diffie-Hellman group is set as part of the main mode SA negotiation, it affects any rekeys during session key establishment.

**Important**

- For enhanced security, do not use Diffie-Hellman Group 1. For maximum security, use Group 2048 whenever possible. Use Group 2 when required for interoperability with Windows 2000 and Windows XP.

  For more information about Diffie-Hellman groups and key exchange, see Key exchange methods.

**Note**

- Diffie-Hellman Group 2048 is provided only with the Windows Server 2003 family.

- Perfect forward secrecy

  Unlike key lifetimes, PFS determines how a new key is generated, rather than when it is generated. Specifically, PFS ensures that the compromise of a single key permits access only to data that is protected by it, not necessarily to the entire communication. To achieve this, PFS ensures that a key used to protect a transmission cannot be used to generate additional keys. In addition, if the key that was used was derived from specific keying material, that material cannot be used to generate other keys.

  Master key PFS requires a reauthentication and is resource intensive. When it is enabled, IKE must reauthenticate identities, increasing overhead for domain controllers when Kerberos V5 is used for authentication. It requires a new main mode negotiation for every quick mode negotiation that occurs.

  Session key PFS can be used without a reauthentication and is less resource intensive. Session key PFS results in a Diffie-Hellman exchange to generate new keying material. It requires only four messages and no authentication.

  Unlike session key PFS, master key PFS does not have to be enabled on both peers. This is because master key PFS is not part of the SA negotiation. If the responder requires PFS, and the quick mode SA of the initiator expires, the responder rejects the message from the initiator and requires a new main mode negotiation. The initiator expires the main mode SA and renegotiates. PFS can be individually set for both the master and session keys.

# IPSec Protocol Types

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPSec protocol types**
IPSec protocols provide data and identity protection for each IP packet by adding their own security protocol header to each packet.

For information about AH and ESP when used in transport and tunnel mode, see the following topics:

- Transport mode
- Tunnel mode

# Transport mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Transport mode**
Transport mode is the default mode for IPSec, and it is used for end-to-end communications (for example, for communications between a client and a server). When transport mode is used, IPSec encrypts only the IP payload. Transport mode provides the protection of an IP payload through an AH or ESP header. Typical IP payloads are TCP segments (containing a TCP header and TCP segment data), a UDP message (containing a UDP header and UDP message data), or an ICMP message (containing an ICMP header and ICMP message data).

**Authentication Header transport mode**
Authentication Header (AH) provides authentication, integrity, and anti-replay protection for the entire packet (both the IP header and the data payload carried in the packet). It does not provide confidentiality, which means that it does not encrypt the data. The data is readable, but protected from modification. AH uses keyed hash algorithms to sign the packet for integrity. For more information, see Data integrity with hash functions.

For example, Alice on Computer A sends data to Bob on Computer B. The IP header, the AH header, and the data are protected with integrity. This means Bob can be certain it was really Alice who sent the data and that the data was unmodified.

Integrity and authentication are provided by the placement of the AH header between the IP header and the IP payload, as shown in the following illustration.

AH is identified in the IP header with an IP protocol ID of 51. AH can be used alone or combined with the Encapsulating Security Payload (ESP) protocol.

The AH header contains the following fields:

- Next Header

  Identifies the IP payload by using the IP protocol ID. For example, a value of 6 represents TCP.

- Length

  Indicates the length of the AH header.

- Security Parameters Index (SPI)

  Used in combination with the destination address and the security protocol (AH or ESP) to identify the correct security association for the communication. The receiver uses this value to determine with which security association the packet is identified.

- Sequence Number

  Provides anti-replay protection for the packet. The sequence number is a 32-bit, incrementally increasing number (starting from 1) that indicates the packet number sent over the security association for the communication. The sequence number cannot repeat for the life of the quick mode security association. The receiver checks this field to verify that a packet for a security association with this number has not already been received. If one has been received, the packet is rejected.

- Authentication Data

  Contains the integrity check value (ICV), also known as the message authentication code, which is used to verify both message authentication and integrity. The receiver calculates the ICV value and checks it against this value (which is calculated by the sender) to verify integrity. The ICV is calculated over the IP header, the AH header, and the IP payload.

**Packet signature with the AH header**
AH signs the entire packet for integrity, with the exception of some fields in the IP header which might change in transit (for example, the Time to Live and Type of Service fields). If another IPSec header is being used in addition to AH, the AH header is inserted before any other IPSec headers. The AH packet signature is shown in the following illustration.

**Encapsulating Security Payload transport mode**
Encapsulating Security Payload (ESP) provides confidentiality (in addition to authentication, integrity, and anti-replay protection) for the IP payload. ESP in transport mode does not sign the entire packet. Only the IP payload (not the IP header) is protected. ESP can be used alone or in combination with AH.

For example, Alice on Computer A sends data to Bob on Computer B. The IP payload is encrypted and signed for integrity. Upon receipt, after the integrity verification process is complete, the data payload in the packet is decrypted. Bob can be certain that it was Alice who sent the data, the data is unmodified, and no one else was able to read it.

ESP is identified in the IP header with the IP protocol ID of 50. As shown in the following illustration, the ESP header is placed before the IP payload, and an ESP trailer and ESP authentication trailer is placed after the IP payload.

The ESP header contains the following fields:

- Security Parameters Index

  Identifies the correct security association for the communication when used in combination with the destination address and the security protocol (AH or ESP). The receiver uses this value to determine the security association with which this packet should be identified.

- Sequence Number

  Provides anti-replay protection for the packet. The sequence number is a 32-bit, incrementally increasing number (starting from 1) that indicates the packet number sent over the quick mode security association for the communication. The sequence number cannot repeat for the life of the quick mode security association. The receiver checks this field to verify that a packet for a security association with this number has not already been received. If one has been received, the packet is rejected.

The ESP trailer contains the following fields:

- Padding

  Padding of 0 to 255 bytes is used to ensure that the encrypted payload with the padding bytes are on byte boundaries required by encryption algorithms.

- Padding Length

  Indicates the length of the Padding field in bytes. The receiver uses this field to remove padding bytes after the encrypted payload with the padding bytes has been decrypted.

- Next Header

  Identifies the type of data in the payload, such as TCP or UDP.

The ESP authentication trailer contains the following field:

- Authentication Data

  Contains the integrity check value (ICV), also known as the message authentication code, which is used to verify both

message authentication and integrity. The receiver calculates the ICV value and checks it against this value (which is calculated by the sender) to verify integrity. The ICV is calculated over the ESP header, the payload data, and the ESP trailer.

**Packet signature and encryption**

As shown in the following illustration, ESP provides protection for IP payloads. The signed portion of the packet indicates where the packet has been signed for integrity and authentication. The encrypted portion of the packet indicates what information is protected with confidentiality.

The IP header is not signed and is not necessarily protected from modification. To provide data integrity and authentication for the IP header, use ESP and AH.

# Tunnel mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tunnel mode**

When IPSec tunnel mode is used, IPSec encrypts the IP header and the payload, whereas transport mode only encrypts the IP payload. Tunnel mode provides the protection of an entire IP packet by treating it as an AH or ESP payload. With tunnel mode, an entire IP packet is encapsulated with an AH or ESP header and an additional IP header. The IP addresses of the outer IP header are the tunnel endpoints, and the IP addresses of the encapsulated IP header are the ultimate source and destination addresses.

IPSec tunnel mode is useful for protecting traffic between different networks, when traffic must pass through an intermediate, untrusted network. Tunnel mode is primarily used for interoperability with gateways, or end-systems that do not support L2TP/IPSec or PPTP connections. You can use tunnel mode in the following configurations:

- Gateway-to-gateway
- Server-to-gateway
- Server-to-server

**AH tunnel mode**

As shown in the following illustration, AH tunnel mode encapsulates an IP packet with an AH and IP header and signs the entire packet for integrity and authentication.

**ESP tunnel mode**

As shown in the following illustration, ESP tunnel mode encapsulates an IP packet with both an ESP and IP header and an ESP authentication trailer.

The signed portion of the packet indicates where the packet has been signed for integrity and authentication. The encrypted portion of the packet indicates what information is protected with confidentiality.

Because a new header for tunneling is added to the packet, everything that comes after the ESP header is signed (except for the ESP authentication trailer) because it is now encapsulated in the tunneled packet. The original header is placed after the ESP header. The entire packet is appended with an ESP trailer before encryption occurs. Everything that follows the ESP header, except for the ESP authentication trailer, is encrypted. This includes the original header which is now considered to be part of the data portion of the packet.

The entire ESP payload is then encapsulated within the new tunnel header, which is not encrypted. The information in the new tunnel header is used only to route the packet from origin to tunnel endpoint.

If the packet is being sent across a public network, it is routed to the IP address of the gateway for the receiving intranet. The gateway decrypts the packet, discards the ESP header, and uses the original IP header to route the packet to the intranet computer.

ESP and AH can be combined when tunneling, providing both confidentiality for the tunneled IP packet and integrity and authentication for the entire packet.

**Using IPSec tunnels**

IPSec tunnels provide security for IP traffic only. The tunnel is configured to protect traffic between either two IP addresses or two IP subnets. If the tunnel is used between two computers instead of two gateways, the IP address outside the AH or ESP payload is the same as the IP address inside the AH or ESP payload. In Windows XP and the Windows Server 2003 family, IPSec does not support protocol-specific or port-specific tunnels. You can configure tunnels by using the IP Security Policy Management and Group Policy consoles to configure and enable two rules:

1. A rule for the outbound traffic for the tunnel.

   The rule for the outbound traffic is configured with a filter list that describes the traffic to be sent through the tunnel and a tunnel endpoint of an IP address configured on the IPSec tunnel peer (the computer or router on the other side of the tunnel).

2. A rule for the inbound traffic for the tunnel.

   The rule for the inbound traffic is configured with a filter list that describes the traffic to be received through the tunnel and a tunnel endpoint of a local IP address (the computer or router on the local side of the tunnel).

Additionally, filter actions, authentication methods, and other settings need to be specified for each rule.

For conceptual information about IPSec policy tunnel settings, see Tunnel endpoint. For information about configuring an IPSec tunnel, see Specify an IPSec tunnel. For information about how tunneling is used for virtual private networking, see Virtual private networking with IPSec.

# IPSec Components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPSec components**

The following topics describe IPSec components that are installed with Windows XP and the Windows Server 2003 family:

- IPSec Policy Agent service
- Internet Key Exchange
- IPSec driver

# IPSec Policy Agent service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPSec Policy Agent service**

The purpose of the IPSec Policy Agent is to retrieve policy information and pass it to other IPSec components that require this information to perform security services, as shown in the following illustration.

The IPSec Policy Agent is a service that resides on each computer running a Windows Server 2003 operating system, appearing as **IPSec services** in the list of system services in the Services console. The IPSec Policy Agent:

- Retrieves the appropriate IPSec policy (if one has been assigned) from Active Directory, if the computer is a domain member, or from the local registry, if the computer is not a member of a domain.
- Polls for changes in policy configuration.
- Sends the assigned IPSec policy information to the IPSec driver.

If the computer is a member of a domain, policy retrieval occurs when the system starts, at the interval specified in the IPSec policy, and at the default Winlogon polling interval. You can also manually poll Active Directory for policy using the **gpupdate /target:computer** command.

The following are additional aspects of IPSec policy behavior for a computer that is a member of a domain:

- If IPSec policy information is centrally configured for computers that are domain members, the IPSec policy information is stored in Active Directory and cached in the local registry of the computer to which it applies.
- If the computer is temporarily not connected to the domain and policy is cached, new policy information for that computer replaces old, cached information when the computer reconnects to the domain.
- If the computer is a stand-alone computer or a member of a domain that is not using Active Directory for policy storage, IPSec policy is stored in the local registry.

The IPSec Policy Agent starts automatically at system start time. If there are no IPSec policies in Active Directory or the registry, or if the IPSec Policy Agent cannot connect to Active Directory, the IPSec Policy Agent waits for policy to be assigned or activated.

# Internet Key Exchange

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Key Exchange**
Before secured data can be exchanged, a security agreement between the two computers must be established. In this security agreement, called a security association (SA), both agree on how to exchange and protect information, as shown in the following illustration.

To build this agreement between the two computers, the IETF has established a standard method of security association and key exchange resolution named Internet Key Exchange (IKE) which:

- Centralizes security association management, reducing connection time.
- Generates and manages shared, secret keys that are used to secure the information.

This process not only protects communication between computers, it also protects remote computers that request secure access to a corporate network. In addition, this process works whenever the negotiation for the final destination computer (endpoint) is performed by a security gateway.

**Security association (SA) defined**
A security association (SA) is the combination of a negotiated key, security protocol, and security parameters index (SPI), which together define the security used to protect the communication from sender to receiver. The SPI is a unique, identifying value in the SA that is used to distinguish among multiple security associations that exist at the receiving computer. For example, multiple associations might exist if a computer is securely communicating with multiple computers at the same time. This is a common occurrence when the computer is a file server or a remote access server that serves multiple clients. In these situations, the receiving computer uses the SPI to determine which SA is used to process the incoming packets.

**Phase I or main mode SA**
In order to ensure successful and secure communication, IKE performs a two-phase operation. Confidentiality and authentication are ensured during each phase by the use of encryption and authentication algorithms that are agreed upon by the two computers during security negotiations. With the duties split between two phases, key creation can be rapidly accomplished.

During the first phase, the two computers establish a secure, authenticated channel. This is called the phase I or main mode SA. IKE automatically provides necessary identity protection during this exchange.

**Phase I or main mode negotiation**
The following are the steps that comprise a main mode negotiation.

1. Policy negotiation

   The following four mandatory parameters are negotiated as part of the main mode SA:

   - The encryption algorithm (DES or 3DES)
   - The integrity algorithm (MD5 or SHA1)
   - The Diffie-Hellman group to be used for the base keying material: Group 1 (768 bits of keying material) Group 2 (1,024 bits), or Group 2048 (2,048 bits)
   - The authentication method (Kerberos V5, certificate, or preshared key authentication)

     If certificates or preshared keys are used for authentication, the computer identity is protected. If Kerberos V5 authentication is used, the computer identity is unencrypted until encryption of the entire identity payload takes

place during authentication.

**Important**

For enhanced security, do not use Diffie-Hellman Group 1. For maximum security, use Group 2048 whenever possible. Use Group 2 when required for interoperability with Windows 2000 and Windows XP.

For more information about Diffie-Hellman groups, see Key exchange methods. For more information about preshared key authentication, see Preshared key authentication.

2. Diffie-Hellman exchange (of public values)

   At no time are actual keys exchanged. Only the base information required by the Diffie-Hellman key determination algorithm to generate the shared, secret key is exchanged. After this exchange, the IKE service on each computer generates the master key that is used to protect authentication.

3. Authentication

   To prevent a successful man-in-the-middle attack, the computers attempt to authenticate the Diffie-Hellman key exchange. Without successful authentication, communication will not proceed. The master key is used, in conjunction with the negotiation algorithms and methods, to authenticate identities. The entire identity payload is hashed and encrypted using the keys generated from the Diffie-Hellman exchange in the second step. The payload includes the identity type (for authentication), port, and protocol. IPSec uses the following identity types for authentication: For certificate authentication, the certificate distinguished name and general name; for Kerberos V5 and preshared key authentication, IPv4 addresses, the fully qualified domain name (FQDN) of the computer, and FQDN of the user. The identity payload, regardless of which authentication method is used, is protected from both modification and interpretation.

The sender presents an offer for a potential security association to the receiver. The responder cannot modify the offer. Should the offer be modified, the initiator rejects the responder's message. The responder sends either a reply accepting the offer or a reply with alternatives.

Messages sent during this phase have an automatic retry cycle that is repeated five times. If a response is received before the retry cycle ends, standard SA negotiation begins. If allowed by IPSec policy, unsecured communications will begin after a brief interval. If unsecured communications begin, after five minutes of idle time (during which no messages are sent), secured communication negotiation is attempted the next time messages are sent. If messages are sent continuously, the communication remains unsecured during the lifetime set for the main mode policy. After the policy time has elapsed, a new secured communication negotiation attempt is made.

There is no preset limit to the number of exchanges that can take place. The number of SAs established is only limited by system resources. When estimating the number of SAs that can be established without significantly degrading computer performance, consider the CPU processing strength and RAM of the computer, the lifetime of the SA, and how much traffic is being sent over the SAs.

For more information about unsecured communications, see Filter action.

**Phase II or quick mode SA**
In this phase, SAs are negotiated on behalf of the IPSec driver.

**Phase II or quick mode negotiation**
The following are the steps that comprise a quick mode negotiation.

1. Policy negotiation occurs.

   The IPSec computers exchange the following requirements for securing the data transfer:

   - The IPSec protocol (AH or ESP)
   - The hash algorithm for integrity and authentication (MD5 or SHA1)

- The algorithm for encryption, if requested (3DES or DES)

  A common agreement is reached, and two SAs are established. One SA is for inbound communication and the other is for outbound communication.

2. Session key material is refreshed or exchanged.

   IKE refreshes the keying material and new shared keys are generated for packet integrity, authentication, and encryption (if negotiated). If rekeying is required, either a second Diffie-Hellman exchange (as described in main mode negotiation) occurs, or a refresh of the original Diffie-Hellman key is used.

3. The SAs and keys, along with the SPI, are passed to the IPSec driver.

The second negotiation of security settings and keying material (for the purpose of securing data) is protected by the main mode SA. As the first phase provided identity protection, the second phase provides protection by refreshing the keying material prior to sending data. IKE can accommodate a key exchange payload for an additional Diffie-Hellman exchange if a rekey is necessary--that is, master key perfect forward secrecy (PFS) is enabled. Otherwise, IKE refreshes the keying material from the Diffie-Hellman exchange completed in main mode.

Quick mode results in a pair of security associations, each with its own SPI and key. One SA is used for inbound communication, and the other for outbound communication.

**Notes**

- Although there are two separate quick mode SAs established, IP Security Monitor only displays a single quick mode SA.

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

The retry algorithm for a message is similar to the process described in main mode negotiation. However, if this process times out for any reason during the second or higher negotiation off of the same main mode SA, a renegotiation of the main mode SA is attempted. If a message for this phase is received without an established main mode SA, it is rejected.

Using a single main mode SA for multiple quick mode SA negotiations increases the speed of the process. As long as the main mode SA does not expire, renegotiation and reauthentication are not necessary. The number of quick mode SA negotiations that can be performed is determined by IPSec policy settings.

**Note**

- Excessive rekeying off of the same main mode SA might make the shared, secret key vulnerable to a known plaintext attack. A known plaintext attack is a sniffer attack in which the attacker attempts to determine the encryption key from encrypted data based on known plaintext.

**SA lifetimes**

The main mode SA is cached to allow multiple quick mode SA negotiations (unless master key PFS is enabled). When a key lifetime is reached for the master or session key, the SA is renegotiated. In addition, the key is refreshed or regenerated.

When the default time-out period elapses for the main mode SA, or the master or session key lifetime is reached, a delete message is sent to the responder. The IKE delete message tells the responder to expire the main mode SA. This prevents additional new quick mode SAs from being created from the expired main mode SA. IKE does not expire the quick mode SA, because only the IPSec driver contains the number of seconds or bytes that have passed to reach the key lifetime.

Use caution when setting very different key lifetimes for master and session keys. For example, setting a master key lifetime of

eight hours and a session key lifetime of two hours might leave a quick mode SA in place for almost two hours after the main mode SA has expired. This occurs when the quick mode SA is generated shortly before main mode SA expiration.

It is generally recommended that all of the IKE settings (for example, master key PFS and key lifetime) and security methods remain at their defaults to avoid unnecessary administrative overhead. This provides a standard (medium) level of security. If your security plan calls for a high level of security, you should consider modifying the default security methods.

# IPSec driver

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPSec driver**

The IPSec driver receives the active IP filter list from the IPSec Policy Agent, as shown in the following illustration, and then attempts to match every inbound and outbound packet against the filters in the list.

When a packet matches a filter, it applies the filter action. When a packet does not match any filters, the packet is passed back without modification to the TCP/IP driver to be received or transmitted.

If the filter action permits transmission, the packet is received or sent with no modifications. If the action blocks transmission, the packet is discarded. If the action requires the negotiation of security, main mode and quick mode SAs are negotiated.

The negotiated quick mode security association (SA) and keys are used with both outbound and inbound processing. The IPSec driver stores all current quick mode SAs in a database. The IPSec driver uses the Security Parameters Index (SPI) field to match the correct SA with the correct packet.

When an outbound IP packet matches the IP filter list with an action to negotiate security, the IPSec driver queues the packet and then notifies Internet Key Exchange (IKE), which begins security negotiations with the destination IP address of that packet. If several outbound packets are going to the same destination and match the same filter before IKE has finished the negotiation, then only the last packet sent is saved.

After a successful negotiation is completed, the IPSec driver on the sending computer:

1. Receives the SA containing the session key from IKE.
2. Locates the outbound SA in its database, and inserts the SPI from the SA into the AH or ESP header.
3. Signs the packets (and encrypts them if confidentiality is required).
4. Sends the packets to the IP layer to be forwarded to the destination computer.

If the negotiation failed, the IPSec driver discards the packet.

When an IPSec-secured inbound packet matches a filter in the IP filter list, the IPSec driver:

1. Receives the session key, SA, and SPI from IKE.
2. Locates the inbound SA in its database by destination address and SPI.
3. Checks the signature and, if required, decrypts the packets.
4. Matches the IP packet searches for a matching filter in the filter list to ensure that no traffic, other than what was agreed upon during the negotiation, is received.
5. Sends packets to the TCP/IP driver to pass to the receiving application.

When an unsecured IP packet is received, the IPSec driver searches for a matching filter in the filter list. If a match occurs and the filter action for that filter either requires IP security or blocks the packet, then the packet is discarded.

**Note**

- The IPSec driver matches all inbound unsecured packets with the list of filters that specify IPSec tunnels first, and then matches the packet with all filters that specify end-to-end (transport) filters. The IPSec driver does not filter certain types of IP packets. For more information, see Add, edit, or remove IPSec filters.

# Description of an IPSec Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Description of an IPSec policy**
An IPSec policy consists of:

- General IPSec Policy Settings

  Settings that apply regardless of which rules are configured. These settings determine the name of the policy, its description for administrative purposes, key exchange settings, and key exchange methods.

- IPSec Policy Rules

  One or more IPSec rules that determine which types of traffic IPSec must examine, how traffic is treated, how to authenticate an IPSec peer, and other settings.

After the policies are created, they can be assigned and applied at the domain, site, organizational unit, and local level. For more information, see Creating, modifying, and assigning IPSec policies.

# General IPSec Policy Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**General IPSec policy settings**

The general settings for an IPSec policy consist of the following types:

- Name

  The name for the policy.

- Description

  Optional text that describes the purpose of the IPSec policy. It is recommended that you complete and update this description to provide a summary of the settings and rules for the policy.

- Policy change poll interval

  The number of minutes between consecutive polls for changes in Active Directory-based IPSec policies. This polling does not detect a change in domain or organizational unit membership, or the assigning or unassigning of a new policy. These events are detected when the Winlogon service polls for changes in Group Policy, which occurs by default every 90 minutes.

- Key exchange settings

  The way in which new keys are derived and how often they are renewed.

- Key exchange methods

  The ways in which identities are protected during the key exchange.

The default key exchange settings and methods are configured to work for most IPSec deployments. Unless there are special security requirements, default settings should not have to be changed.

# Key exchange settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Key exchange settings**
The strength of the keys which protect the key exchange phase is enhanced by the following features:

**Key lifetimes**
Lifetime settings determine when a new key is generated. Any time a key lifetime is reached, the associated SA is also renegotiated. The process of generating new keys at intervals is called dynamic rekeying or key regeneration. Lifetimes allow you to force the generation of a new key after a specific interval. For example, if the communication takes 100 minutes and you specify the key lifetime as 10 minutes, 10 keys will be generated (one every 10 minutes) during the exchange. Using multiple keys ensures that if an attacker manages to gain the key to one part of a communication, the entire communication is not compromised. Automatic key regeneration is provided by default. You can override the defaults and either specify a master key lifetime in minutes or by the number of session keys, or enable master key perfect forward secrecy (PFS).

Caution should be taken when setting very different key lifetimes, since they also determine the lifetime of the SA. For example, setting a master key lifetime of 8 hours (480 minutes) and a session key lifetime (set within a filter action) of 2 hours might result in a quick mode SA that is in place for almost 2 hours after the main mode SA has expired. This has the potential to occur if the new quick mode SA is generated just before the main mode SA expires.

- **Session key limit**

  Repeated rekeying off of the same master key might eventually compromise the key. For example, if Alice on Computer A sends a message to Bob on Computer B, and then a few minutes later sends another message to Bob, the same master key material can be reused since an SA was recently established with that computer. If you want to limit the number of times this reuse occurs, you can specify a session key limit.

  If you decide to enable master key perfect forward secrecy (PFS), the session key limit will be set to 1. Master key PFS forces key regeneration each time. If you specify both a master key lifetime in minutes, and a session key limit, whichever interval is reached first will start a new key.

- **Master key perfect forward secrecy (PFS)**

  Master key PFS determines how a new session key is generated. Enabling master key PFS ensures that the master key keying material cannot be used to generate more than one session key.

  Master key PFS should be used with caution because it requires reauthentication and might impact performance. It is not required to be enabled on both peers.

For information about how to configure key exchange settings and methods, see Configure key exchange settings and Create key exchange security methods.

# Key exchange methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Key exchange methods**
In addition to key properties, you can set security methods for main mode IKE negotiation. For example, you can specify which algorithms are used for integrity and confidentiality. The same algorithms that are available for quick mode security methods are available for main mode IKE negotiation: MD5 and SHA1 for integrity; DES and 3DES for confidentiality.

**Diffie-Hellman groups**
In addition to setting integrity and confidentiality algorithms, you can specify which Diffie-Hellman groups to use. Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based.

Group 2048 (high) is stronger (more secure) than Group 2 (medium), which is stronger than Group 1 (low). Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, and Group 2048 provides 2048 bits. If mismatched groups are specified on each peer, negotiation fails. The group cannot be switched during the negotiation.

The Diffie-Hellman group is configured as part of the main mode key exchange settings. New session keys generated during quick mode are derived from the Diffie-Hellman main mode master key material, unless master key or session key perfect forward secrecy (PFS) is enabled. If either master key or session key PFS is enabled, a new Diffie-Hellman exchange is performed to obtain new master key keying material for each new session key that is required. The difference between master key PFS and session key PFS is that master key PFS requires a reauthentication of the main mode SA in addition to the Diffie-Hellman exchange.

**Important**

- For enhanced security, do not use Diffie-Hellman Group 1. For maximum security, use Group 2048 whenever possible. Use Group 2 when required for interoperability with Windows 2000 and Windows XP.

**Notes**

- Diffie-Hellman Group 2048 is provided only with the Windows Server 2003 family.
- For a standard level of security, it is generally recommended that all of the IKE settings (for example, master key PFS and key lifetime) and security methods remain at their defaults. For more information about IKE settings, see Internet Key Exchange.
- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

For information about how to configure key exchange settings and methods, see Configure key exchange settings and Create key exchange security methods.

# IPSec Policy Rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPSec policy rules**

An IPSec policy consists of one or more rules that determine IPSec behavior. IPSec rules are configured on the **Rules** tab in the properties of an IPSec policy. Each IPSec rule contains the following configuration items:

- Filter list

  A single filter list is selected that contains one or more predefined packet filters that describe the types of traffic to which the configured filter action for this rule is applied. The filter list is configured on the **IP Filter List** tab in the properties of an IPSec rule within an IPSec policy.

- Filter action

  A single filter action is selected that includes the type of action required (Permit, Block, or Negotiate Security) for packets that match the filter list. For the Negotiate Security filter action, the negotiation data contains one or more security methods that are used (in order of preference) during IKE negotiations and other IPSec settings. Each security method determines the security protocol (such as AH or ESP), the specific cryptographic and hashing algorithms, and session key regeneration settings used. The filter action is configured on the **Filter Action** tab in the properties of an IPSec rule within an IPSec policy.

- Authentication methods

  One or more authentication methods are configured (in order of preference) and used for authentication of IPSec peers during main mode negotiations. The available authentication methods are the Kerberos V5 protocol, use of a certificate issued from a specified certification authority, or a preshared key. The negotiation data is configured on the **Authentication Methods** tab in the properties of an IPSec rule within an IPSec policy.

  **Important**

  - The use of preshared key authentication is not recommended because it is a relatively weak authentication method. Preshared key authentication creates a master key that is less secure (that might produce a weaker form of encryption) than certificates or the Kerberos V5 protocol. In addition, preshared keys are stored in plaintext. Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing and that you use certificates or Kerberos V5 instead in a production environment.

- Tunnel endpoint

  Specifies whether the traffic is tunneled and, if it is, the IP address of the tunnel endpoint. For outbound traffic, the tunnel endpoint is the IP address of the IPSec tunnel peer. For inbound traffic, the tunnel endpoint is a local IP address. The tunnel endpoint is configured on the **Tunnel Setting** tab in the properties of an IPSec rule within an IPSec policy. For more information, see Tunnel mode.

- Connection type

  Specifies whether the rule applies to local area network (LAN) connections, dial-up connections, or both. The connection type is configured on the **Connection Type** tab in the properties of an IPSec rule within an IPSec policy.

The rules for a policy are displayed in IP Security Policies in reverse alphabetical order based on the name of the filter list selected for each rule. There is no method for specifying an order in which to apply the rules in a policy. The IPSec driver automatically orders the rules based on the most specific to the least specific filter list. For example, the IPSec driver would apply a rule containing a filter list that specified individual IP addresses and TCP ports before a rule containing a filter list that specified all addresses on a subnet.

**Default response rule**

The default response rule, which can be used for all policies, has the IP filter list of **<Dynamic>** and the filter action of **Default Response** when the list of rules is viewed with the IP Security Policy Management console. The default response rule cannot be deleted, but it can be deactivated. It is activated by default for all policies.

The default response rule is used to ensure that the computer responds to requests for secure communication. If an active policy does not have a rule defined for a computer that is requesting secure communication, then the default response rule is applied and security is negotiated. For example, when Computer A communicates securely with Computer B, and Computer B does not have an inbound filter defined for Computer A, the default response rule is used.

Security methods and authentication methods can be configured for the default response rule. The filter list of **<Dynamic>** indicates that the filter list is not configured, but that filters are created automatically based on the receipt of IKE negotiation packets. The filter action of **Default Response** indicates that the action of the filter (Permit, Block, or Negotiate security) cannot be configured. Negotiate Security will be used. However, you can configure:

- The security methods and their preference order on the **Security Methods** tab.
- The authentication methods and their preference order on the **Authentication Methods** tab.

# Filter list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Filter list**

When traffic matches a source, destination, and type of IP traffic in a filter, security negotiations are initiated. This type of IP packet filtering enables a network administrator to precisely define what IP traffic is secured. Each IP filter list contains one or multiple filters, which define IP addresses and traffic types. One IP filter list can be used for multiple communication scenarios.

IPSec requires both an inbound and outbound filter between the computers specified in the filter list. Inbound filters apply to incoming traffic. Outbound filters apply to traffic leaving a computer towards a destination. For example, if Computer A wants to securely exchange data with Computer B:

- The active IPSec policy on Computer A must have a filter for any outbound packets to Computer B. Source=A and Destination=B.
- The active IPSec policy on Computer A must have a filter for any inbound packets from Computer B. Source=B and Destination=A.

Each peer must also have the reverse filter:

- The active IPSec policy on Computer B must have a filter for any inbound packets from Computer A. Source=A and Destination=B.
- The active IPSec policy on Computer B must have a filter for any outbound packets to Computer A. Source=B and Destination=A.

**Filter settings**

Each filter defines a particular subset of inbound or outbound network traffic that should be secured. You must have a filter to cover any traffic to which the associated rule applies. A filter contains the following settings:

- **The source and destination address of the IP packet.** You can specify any IP address assigned to the IPSec peer, a single IP address, IP addresses by DNS name, or groups of addresses to specify IP subnets.
- **The protocol over which the packet is being transferred.** By default, all protocols in the TCP/IP protocol suite are selected. However, you can specify an individual protocol for this filter to meet special requirements, including custom protocols.
- **The source and destination port for TCP and UDP.** By default, all TCP and UDP ports are selected, but you can select a specific TCP or UDP port.

For information about how to configure IP filter lists, see Add, edit, or remove IP filter lists.

Special filters might be required for certain types of traffic, such as SNMP traffic or security gateways. For more information, see Special IPSec considerations.

# Filter action

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Filter action**

A filter action defines the security requirements for the data transmission. A filter action can be configured to:

- Permit traffic (**Permit**)

  IPSec passes this traffic without modification or the requirement for security. This is appropriate for traffic from specific computers that are not IPSec-capable. Be sure to limit the IP filter list to a minimal scope when using this type of filter action, so you do not let traffic through which should be secured.

- Block traffic (**Block**)

  IPSec silently discards this traffic. Be sure to use an IP filter list that appropriately defines the scope of traffic when using a blocking filter action so that you do not block valid computers from communicating.

- Negotiate IPSec (**Negotiate security**)

  IPSec requires the negotiation of security associations and the sending or receiving of IPSec-secured traffic. After you choose to negotiate IPSec, you can also configure the following:

  - Security methods and their order

    For more information, see IPSec security methods.

  - Allowance of initial incoming unsecured traffic (**Accept unsecured communication, but always respond using IPSec**)

    IPSec allows an incoming packet that matches the configured filter list to be unsecured (not protected by IPSec). However, the outgoing response to the incoming packet must be protected. This setting is useful when you are using the default response rule for clients. When a group of servers are configured with a rule that secures communications with any IP address and accepts unsecured communication, responding with only secured communications, enabling the default response rule on client computers ensures that the clients will respond to the server request to negotiate security. This option should be disabled for secure computers connected to the Internet to prevent denial of service attacks.

  - Enabling of communication with non-IPSec-enabled computers (**Allow unsecured communication with non-IPSec-aware computer**)

    IPSec falls back to unsecured communication, if necessary. Again, you might need to limit the IP filter list to a minimal scope. Otherwise, if negotiation fails for any reason, any communications affected by the rule in which this filter action resides could result in data being sent without security. If you are concerned about unsecured communication, you might consider disabling this setting. However, communication with computers that cannot initiate IPSec, such as legacy systems, might be blocked. This option should be disabled for secure computers connected to the Internet.

  - Generation of session keys from new keying material (**Use session key perfect forward secrecy (PFS)**)

    This determines whether existing master key keying material can be used to derive a new session key. Enabling session key perfect forward secrecy (PFS) ensures that master key keying material cannot be used to derive more than one session key. When session key PFS is enabled, a new Diffie-Hellman key exchange is performed to generate new master key keying material before the new session key is created. Session key PFS does not require main mode reauthentication and uses less resources than master key PFS.

For information about how to configure filter actions, see Add, edit, or remove filter actions.

**IPSec security methods**

Each security method defines the security requirements of any communications to which the associated rule applies. Creating multiple security methods increases the chance that a common method can be found between two computers. The IKE component reads the list of security methods in descending order and sends a list of allowed security methods to the other peer. The first method in common is selected. Typically, the most secure methods are placed at the top of the list and the least secure methods are placed at the bottom of the list.

**Predefined security methods**

The following security methods are predefined:

- Encryption and Integrity

  Uses the ESP protocol to provide data confidentiality (encryption) with the triple Data Encryption Standard (3DES) algorithm, data integrity and authentication with the Secure Hash Algorithm 1 (SHA1) integrity algorithm, and default key lifetimes (100MB, 1 hour). If you require both data and addressing (IP header) protection, you can create a custom security method. If you do not require encryption, use **Integrity only**.

- Integrity only

  Uses the ESP protocol to provide data integrity and authentication with the SHA1 integrity algorithm and default key lifetimes (100MB, 1 hour). In this configuration, ESP does not provide data confidentiality (encryption). This is appropriate when your security plan calls for standard levels of security.

**Custom security methods**

If the predefined **Encryption and Integrity** or **Integrity only** settings do not meet your security requirements, you can specify custom security methods. For example, you can use custom methods when encryption and address integrity, stronger algorithms, or key lifetimes need to be specified. When configuring a custom security method, you can configure the following:

- Security protocols

  Both AH (**Data and address integrity without encryption**) and ESP (**Data integrity and encryption**) can be enabled in a custom security method when you require IP header integrity and data encryption. If you chose to enable both, you do not need to specify an integrity algorithm for ESP. The algorithm that you select for AH provides integrity.

- Integrity algorithm

  - Message Digest 5 (MD5), which uses a 128-bit key.
  - Secure Hash Algorithm 1 (SHA1), which uses a 160-bit key.

- Encryption algorithm

  - 3DES is the most secure of the DES combinations, and somewhat slower in performance. 3DES processes each block three times, using three unique 56-bit keys.
  - DES is used when the higher security and overhead of 3DES is not necessary. DES uses a single 56-bit key.

- Session key settings

  Session key settings determine when a new key is generated, rather than how it is generated. You can specify a lifetime in kilobytes, seconds, or both. For example, if the communication takes 10,000 seconds and you specify the key lifetime as 1000 seconds, 10 keys will be generated to complete the transfer. This ensures that, even if an attacker manages to determine one session key and decipher part of a communication, deciphering the entire communication is not possible. By default, new session keys are generated for every 100 MB of data or every hour. Note that any time a key lifetime is reached, the quick mode SA is also renegotiated in addition to the key refresh or regeneration.

**Note**

- When IPSec provides data confidentiality between a Windows XP or Windows Server 2003 family-based computer (or a Windows 2000-based computer that has the High Encryption Pack or Service Pack 2 or higher installed) and another computer that does not use 3DES, your list of security methods must include DES. Otherwise, the computer that you are trying to communicate with might not be able to reach a common security agreement with your computer. If confidentiality of the data is not required, you can select ESP format with an integrity algorithm only and set the encryption to **<None>**. Alternately, you can select an AH format with an integrity algorithm.

For information about how to configure security methods, see Add, edit, or remove IPSec security methods.

# Authentication methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication methods**
Each rule defines a list of authentication methods. Each authentication method defines the requirements for how identities are verified in communications to which the associated rule applies. The two peers must have at least one common authentication method or communication will fail. Creating multiple authentication methods increases the chance that a common method between two computers can be found.

Only one authentication method can be used between a pair of computers, regardless of how many are configured. If you have multiple rules that apply to the same pair of computers, you must configure the authentication methods list in those rules to enable the pair to use the same method. For example, if a rule between a pair of computers specifies only Kerberos for authentication and filters only TCP data and, in another rule, specifies only certificates for authentication and filters only UDP data, authentication will fail.

**Overview of authentication methods**
For authentication, IPSec allows you to use the Kerberos V5 protocol, certificate-based authentication, or preshared key authentication.

- The Kerberos V5 security protocol is the default authentication technology. This method can be used for any clients running the Kerberos V5 protocol (whether or not the clients are running Windows 2000, Windows XP Professional, or a Windows Server 2003 operating system) that are members of the same or trusted domains.

- A public key certificate should be used in situations that include Internet access, remote access to corporate resources, external business partner communications, or computers that do not run the Kerberos V5 security protocol. This requires that at least one trusted certification authority (CA) and associated certificate have been configured. Computers running Windows 2000, Windows XP, or a Windows Server 2003 operating system support X.509 Version 3 certificates, including computer certificates generated by commercial CAs.

- A preshared secret key can be specified. It is simple to use and does not require the client to run the Kerberos V5 protocol or have a public key certificate. Both parties must manually configure IPSec to use this preshared key.

  **Important**

  - The use of preshared key authentication is not recommended because it is a relatively weak authentication method. Preshared key authentication creates a master key that is less secure (that might produce a weaker form of encryption) than certificates or the Kerberos V5 protocol. In addition, preshared keys are stored in plaintext. Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing and that you use certificates or Kerberos V5 instead in a production environment.

## Notes

- The ability to authenticate using Kerberos V5 is not supported on computers running Windows XP Home Edition or computers running any other version of Windows 2000, Windows XP, or a Windows Server 2003 operating system that are not a member of an Active Directory domain.

- For information about how to configure authentication methods, see Define IPSec authentication methods.

**IPSec certificate to account mapping**
When you use either Kerberos V5 or certificate authentication, you can set restrictions on which computers are allowed to connect. When you enable IPSec certificate to account mapping, the IKE protocol associates (maps) a computer certificate to a computer account in an Active Directory domain or forest, and then retrieves an access token, which includes the list of user rights assigned to the computer. You can restrict access by configuring Group Policy security settings and assigning either the **Access this computer from the network** user right or the **Deny access to this computer from the network** user right to individual or multiple computers as needed.

When a Windows 2000 or a Windows Server 2003 family certification authority is used for computer certificate autoenrollment, the certificates are automatically stored in Active Directory as a property of the computer account. Alternatively, you can use a non-Microsoft certification authority in which to enroll computers. If you do not use computer certificate autoenrollment, you must manage certificate to account mapping manually.

**Notes**

- If you use the Kerberos V5 protocol for authentication, the IKE protocol verifies access controls, but only if IKE is a responder. Therefore, for access controls to be applied, you must configure the IPSec policy on the client computer to initiate IKE to the server. If you use certificate authentication, access controls are applied if either the server or the client computer initiates IKE to the server.

- For information about configuring security settings in Group Policy, see Security settings overview.

# Tunnel endpoint

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tunnel endpoint**

As discussed in Virtual private networking with IPSec, IPSec can perform layer 3 tunneling for scenarios in which Layer Two Tunneling Protocol (L2TP) cannot be used. If you are using L2TP for remote communications, no tunnel configuration is needed because the client and server VPN components of Windows XP and the Windows Server 2003 family automatically create the appropriate rules to secure L2TP traffic.

To create a layer 3 tunnel using IPSec, use the IP Security Policy Management or Group Policy consoles to configure and enable the following two rules for the appropriate policy:

1. A rule for the outbound traffic for the tunnel.

   The rule for the outbound traffic is configured with both a filter list that describes the traffic to be sent across the tunnel and a tunnel endpoint of an IP address configured on the IPSec tunnel peer (the computer or router on the other side of the tunnel).

2. A rule for the inbound traffic for the tunnel.

   The rule for the inbound traffic is configured with both a filter list that describes the traffic to be received across the tunnel and a tunnel endpoint of a local IP address (the computer or router on this side of the tunnel).

For each rule, you must also specify filter actions, authentication methods, and other settings.

For information about how to configure IPSec tunnel endpoints, see Specify an IPSec tunnel. For more information about IPSec tunnel mode, see Tunnel mode.

For advanced information about configuring IPSec tunnels, see article Q252735, "How to Configure IPSec Tunneling in Windows 2000," in the Microsoft Knowledge Base.

# Connection type

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection type**
For each IPSec rule, you can define which connection types on your computer are affected. The connection types apply to all connections in Network Connections on the computer for which you are configuring IPSec policy.

Each rule has one connection type setting:

- **All Network Connections**. The rule applies to communications sent through any of the network connections that you have configured on the computer.
- **Local Area Network (LAN)**. The rule only applies to communications sent through LAN connections that you have configured on the computer.
- **Remote Access**. The rule only applies to communications sent through any virtual private network (VPN) or dial-up connections that you have configured on the computer.

For information about how to configure connection types, see Specify IPSec connection types.

For information about configuring network connections on a computer, see Configuring a network or dial-up connection.

# Using Internet Protocol Security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Internet Protocol security**

This section covers:

- Managing IPSec from the command line
- Designing and Planning IPSec Policies
- Viewing IPSec Statistics and Details About Active IPSec Policies

# Managing IPSec from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing IPSec from the command line**
The Netsh commands for Internet Protocol security (IPSec) provide a fully equivalent alternative to the console-based management and diagnostic capabilities provided by the IP Security Policy Management and IP Security Monitor consoles. You can use Netsh commands for IPSec to script IPSec policy creation, display details about IPSec policies, and change the IPSec configuration for troubleshooting. In addition, administering IPSec from the command line is useful when you want to extend the security and manageability of IPSec. For example, you can use Netsh commands for IPSec to enable IPSec driver event logging, set default traffic exemptions, and configure computer startup security.

For a comprehensive **netsh ipsec** command reference (including syntax and parameters), see Netsh commands for Internet Protocol security.

### Notes

- For information about how to use Netsh commands for IPSec to change the IPSec configuration for troubleshooting, see the section "Using Netsh to change the IPSec configuration on computers running the Windows Server 2003 family" in IPSec troubleshooting tools.

- You can use the Netsh commands for IPSec to configure IPSec policies only on computers running members of the Windows Server 2003 family. To use the command line to configure IPSec policies on computers running Windows XP, use Ipseccmd.exe. To use the command line to configure IPSec policies on computers running Windows 2000, use Ipsecpol.exe, which is provided with the Windows 2000 Server Resource Kit. For more information, see IPSec troubleshooting tools.

# Designing and Planning IPSec Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Designing and planning IPSec policies**
This section provides information about planning and deploying IPSec in your organization. You should also review IPSec Best practices for general information about IPSec deployment.

For information on specific topics, see:

- Establishing an IPSec security plan
- Default IPSec policies
- Creating, modifying, and assigning IPSec policies
- Special IPSec considerations
- IPSec troubleshooting tools

# Establishing an IPSec security plan

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Establishing an IPSec security plan**

Whether for a large domain or a small workgroup, implementing IPSec means finding a balance between making information easily available to the largest number of users, and protecting sensitive information from unauthorized access.

Finding the proper balance requires:

- Assessing the risk and determining the appropriate level of security for your organization.
- Identifying valuable information.
- Defining security policies that use your risk management criteria and protect the identified information.
- Determining how the policies can best be implemented within the existing organization.
- Ensuring that management and technology requirements are in place.
- Providing all users with both secure and efficient access to the appropriate resources, according to their needs.

Security considerations are also influenced by the way the computer will be used. For example, the required security might differ, depending on whether the computer is a domain controller, Web server, remote access server, file server, database server, or intranet or remote client. The security framework in Windows 2000, Windows XP, and Windows Server 2003 family is designed to fulfill the most stringent security requirements. However, software alone might be less effective without careful planning and assessment, effective security guidelines, enforcement, auditing, and sensible security policy design and assignment.

There is no exact definition of the measures that define standard security. These can vary widely, depending on an organization's policies and infrastructures. The following security levels can be considered a general basis for planning your IPSec deployment:

- Minimal security

  Computers do not exchange sensitive data. IPSec is not active by default. No administrative action to disable IPSec is required.

- Standard security

  Computers, especially file servers, are used to store valuable data. Security must be balanced so it does not become a barrier to users trying to perform their tasks. Windows XP and the Windows Server 2003 family provide example IPSec policies that secure data, but do not necessarily require the highest level of security: **Client (Respond Only)** and **Server (Request Security)**. Use these as a basis for your IPSec policies. These, or similar custom policies, optimize efficiency without compromising security.

- High security

  Computers that contain highly sensitive data are at risk for data theft, accidental or malicious disruption of the system (especially in remote dial-up scenarios), or any public network communications. **Secure Server (Require Security)**, a default policy, requires IPSec protection for all traffic being sent or received (except initial inbound communication) with stronger security methods. Unsecured communication with a non-IPSec-aware computer is not allowed.

**From planning to policy configuration**

After you have identified the types of traffic that need to be secured and the level of security required, you can begin policy configuration. Windows XP and Windows Server 2003 IPSec policy configuration is the translation of your security

requirements to one or more IPSec policies, only one of which can be assigned at each of the following levels: domain, site, organizational unit, or local levels. Each IPSec policy consists of one or more IPSec rules. Each IPSec rule consists of:

- A selected filter list.
- A selected filter action.
- Selected authentication methods.
- A selected connection type.
- A selected tunnel setting.

You can configure IPSec policy in the following ways:

- Create a new policy and define the set of rules for the policy, adding filter lists and filter actions as required.

  In this method, an IPSec policy is created first and then rules are added and configured. Filter lists (specifying traffic types) and filter actions (specifying how the traffic is treated) are added during rule creation.

  For more information, see Add, edit, or remove IPSec policies and Add, edit, or remove IPSec rules.

- Create the set of filter lists and filter actions, and then create the policies and add rules that combine the filter lists with filter actions.

  In this method, the filter lists and the filter actions are configured first. Next, IPSec policies are created and rules are added that combine the appropriate filter list with the appropriate filter action. Additionally, authentication methods, connection types, and tunnel settings are specified.

  For information about how to individually configure IP filter lists and filter actions, see Manage multiple IP filter lists and Manage multiple filter actions.

For either configuration method, after the IPSec policies have been created, they must be assigned. For more information, see Creating, modifying, and assigning IPSec policies.

**Notes**

- To manage Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. To manage local or remote IPSec policies for a computer, you must be a member of the Administrators group on the local or remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups and Default groups.

- The integration of IPSec policies with Active Directory described here does not apply to computers running Windows XP Home Edition. You cannot administer Active Directory-based IPSec policy from a computer running Windows XP Home Edition because these computers cannot join Active Directory domains.

# Default IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Default IPSec policies**

Windows XP and the Windows Server 2003 family provide a set of predefined IPSec filter lists and filter actions and default policies. This is only intended to provide an example. It is not designed for operational use without modification. A knowledgeable IPSec network administrator or advanced user should design new, custom polices for operational use.

Computers that are connected to the Internet must be carefully protected from network attacks with custom policies. The default policies are defined as examples for intranets because they allow a computer to receive unsecured traffic. The default policies are designed for computers that are members of an Active Directory domain.

**Predefined filter lists**

The following predefined filter lists are provided as examples for use in the default policies:

- **All ICMP Traffic**

  A filter list for all ICMP traffic (IP protocol 1) sent and received between this computer and all other computers.

- **All IP Traffic**

  A filter list for all IP traffic sent and received between this computer and all other computers. By default, all Internet Key Exchange (IKE) traffic is excluded. All other traffic types are matched against IPSec filters, however, and you can configure, block, or permit filter actions specifically for multicast and broadcast traffic (IPSec does not negotiate security associations for multicast and broadcast traffic).

**Predefined filter actions**

The following predefined filter actions are provided as examples for use in the default policies:

- **Permit**

  Traffic is permitted (the security method is set to **Permit**).

- **Request Security (Optional)**

  Traffic is secured (the security method is set to **Negotiate security**), however, the following exceptions apply:

  - Initial incoming unsecured communication is allowed. This behavior is known as inbound passthrough.

  - If security negotiation fails after 3 seconds, unsecured communication to a non-IPSec-aware computer is allowed. This filter action secures traffic to IPSec-aware computers, but allows unsecured communication if it is required. This behavior is known as fallback to clear.

  In order to avoid the potential for denial-of-service attacks, this filter action must not be used on the Internet.

  The following table lists the security methods (in preference order) for the **Request Security (Optional)** predefined filter action.

| Type | AH integrity | ESP confidentiality | ESP integrity | Key lifetimes (KB/sec) |
|---|---|---|---|---|
| Custom | None | 3DES | SHA1 | 100000/900 |
| Custom | None | DES | SHA1 | 100000/900 |
| Custom | SHA1 | None | None | 100000/300 |

| | | | | |
|---|---|---|---|---|
| Custom | MD5 | None | None | 100000/300 |

The security negotiation for traffic using this filter action attempts ESP encryption (first 3DES, and then DES) with SHA1 integrity. If those security methods cannot be negotiated with the peer, AH integrity (first SHA1, and then MD5) only is attempted.

- **Require Security**

  Traffic is secured (the security method is set to **Negotiate security**), however, initial incoming unsecured communication is allowed (inbound passthrough is enabled). Unsecured communication with non-IPSec-aware computers is not allowed (fallback to clear is disabled). For example, an incoming connection request packet is allowed. The computer's reply to the connection request matches the outbound filter, causing a request for security to be sent to the sender of the unsecured traffic. If security negotiation is successful, traffic in both directions is required to be secure. If security negotiation is not successful, outgoing traffic is not allowed. The computer might continue to receive incoming unsecured traffic and will continue to attempt to negotiate security.

  In order to avoid the potential for denial-of-service attacks, this filter action must not be used on the Internet.

  The following table lists the security methods (in preference order) for the **Require Security** predefined filter action.

| Type | AH integrity | ESP confidentiality | ESP integrity | Key lifetimes (KB/sec) |
|---|---|---|---|---|
| Custom | None | 3DES | SHA1 | 100000/900 |
| Custom | None | 3DES | MD5 | 100000/900 |
| Custom | None | DES | SHA1 | 100000/900 |
| Custom | None | DES | MD5 | 100000/900 |

The security negotiation for traffic using this filter action will only attempt to negotiate ESP encryption (first 3DES, and then DES) with differing ESP authentication methods (first SHA1, and then MD5).

The most secure filter action is one that negotiates security and neither receives unsecured traffic (inbound passthrough is disabled) nor allows communication with non-IPSec-aware computers (fallback to clear is disabled). This is known as a lockdown filter action. When a server is using this filter action, clients must initiate secured communication before sending any IP traffic. The IPSec policy for client computers must be configured with additional rules that force the client to negotiate security with the server. A client configured with policy that consists of only the default response rule is not able to communicate with a locked down server.

**Predefined rules**

The only predefined rule that is available on all policies is the default response rule. The default response rule is automatically created in a new policy and cannot be created manually. It is used to respond to security requests when no other rule applies. For example, a client policy that enables a client to respond to security requests but does not secure any traffic by default, would have only the default response rule active. In some cases, it is enabled by default. You can disable the default response rule on the **Rules** tab in properties for a policy. You can also modify the authentication method and security methods of the default response rule for specific needs. For more information, see the section "Default response rule" in IPSec Policy Rules.

**Default policies**

The following are provided as examples for use as default policies:

- **Client (Respond Only)**

  This is an example policy for computers that secure communication on request. For example, intranet clients might not require IPSec except when requested by another computer. This policy enables the computer on which it is active to respond to requests for secured communications. This policy contains the default response rule, which creates dynamic IPSec filters for inbound and outbound traffic based on the requested protocol and port traffic for the communication that is being secured.

  This policy has the following settings:

**First rule (default response rule)**

- IP Filter List: <Dynamic>
- Filter Action: Default Response
- Authentication: Kerberos
- Tunnel Setting: None
- Connection Type: All

- **Server (Request Security)**

  This is an example policy for computers that should secure communications in most cases, allowing unsecured communication with non-IPSec-aware computers. With this policy, the computer accepts unsecured traffic, but always attempts to secure additional communications by requesting security from the original sender. This policy allows the entire communication to be unsecured if the other computer is not IPSec-enabled. For example, communication to specific servers can be secure while allowing the server to communicate in an unsecured manner to accommodate a mixture of clients (some of which support IPSec and some of which do not).

  This policy has a rule to request security for all IP traffic, a rule to permit ICMP traffic, and the default response rule to respond to requests for security from other computers.

  This policy has the following settings:

  **First rule**

  - IP Filter List: All IP Traffic
  - Filter Action: Request Security (Optional)
  - Authentication: Kerberos
  - Tunnel Setting: None
  - Connection Type: All

  **Second rule**

  - IP Filter List: All ICMP Traffic
  - Filter Action: Permit
  - Authentication: N/A
  - Tunnel Setting: None
  - Connection Type: All

  **Third rule (default response rule)**

  - IP Filter List: <Dynamic>
  - Filter Action: Default Response

- Authentication: Kerberos
- Tunnel Setting: None
- Connection Type: All

- **Secure Server (Require Security)**

  This is an example policy for computers on an intranet that require secure communications, such as a server that transmits highly sensitive data. Administrators can use this IPSec policy as an example to create their own custom IPSec policy for production use. The filters used in this policy require all outbound communication to be secured, allowing only the initial inbound communication request to be unsecured.

  This policy has a rule to require security for all IP traffic, a rule to permit ICMP traffic, and the default response rule to respond to requests for security from other computers.

  **First rule**

  - IP Filter List: All IP Traffic
  - Filter Action: Require Security
  - Authentication: N/A
  - Tunnel Setting: None
  - Connection Type: All

  **Second rule**

  - IP Filter List: All ICMP Traffic
  - Filter Action: Permit
  - Authentication: Kerberos
  - Tunnel Setting: None
  - Connection Type: All

  **Third rule (default response rule)**

  - IP Filter List: <Dynamic>
  - Filter Action: Default Response
  - Authentication: Kerberos
  - Tunnel Setting: None
  - Connection Type: All

**Notes**

- In the Windows Server 2003 family, IPSec provides new source and destination address options for defining filters. In addition, the default behavior for traffic exemptions has changed. If you require previously exempted traffic types, you

must create filters to permit this traffic. For more information about the new source and destination options provided by IPSec and for instructions on how to configure permit filters for several previously exempted traffic types, see Special IPSec considerations.

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

# Creating, modifying, and assigning IPSec policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating, modifying, and assigning IPSec policies**

IPSec policies can be applied to local computers, domains, sites, organizational units, or any Group Policy object in Active Directory. You can create, modify, and assign IPSec policies by using the IP Security Policy Management console that is available in Microsoft Management Console (MMC) or by using the Netsh commands for IPSec that are available at the command line.

Your organization's IPSec policies should be based on your written guidelines for secure operations. Policies can store multiple rules, so that one policy can be used to affect multiple types of traffic.

The Windows 2000, Windows XP, and Windows Server 2003 family include example IPSec policies. These examples are provided only to show how policies can be designed. They are not designed as default policies for securing a client or a server in a production environment. Instead, you should design and create custom IPSec policies that apply to the specific scenarios in your security plan.

### Notes

- For information about how to use the IP Security Policy Management console, see Define IPSec Policies.
- For information about how to use Netsh, see Netsh commands for Internet Protocol security.
- Although you can assign local IPSec policies for a computer by using the IP Security Policy Management console, you must use Group Policy to assign IPSec policies for groups of computers in Active Directory domains. For more information, see Assign or unassign IPSec policy in Group Policy.

**IPSec driver modes**

To understand how IPSec policies are processed and applied, it is important to understand the modes in which the IPSec driver operates. The IPSec driver operates in computer startup mode and operational mode and, optionally, in a diagnostics mode for troubleshooting.

### Computer startup mode

During computer startup, the Windows operating system loads the IPSec driver to perform in computer startup mode. Computer startup mode is used until the IPSec Policy Agent sets the IPSec driver into an operational mode. The IPSec driver can perform in any one of the following computer startup modes:

- **Permit.** When the IPSec driver operates in permit mode, it does not process any IP packets, and, therefore, no IPSec security is provided. If an IPSec policy has never been assigned to a computer, permit mode is the default mode for the IPSec driver.
- **Stateful.** When the IPSec driver operates in stateful mode, it allows all outbound traffic, and it automatically creates inbound permit filters in response to the outbound traffic. All other inbound unicast, broadcast, and multicast packets are dropped. If an IPSec policy has been assigned to a computer, the IPSec Policy Agent sets the stateful mode for the IPSec driver by default.
- **Block.** When the IPSec driver operates in block mode, it discards all inbound and outbound IP packets, except for those that match specific filters that you can configure to be used during block mode. By default, all inbound and outbound DHCP traffic is permitted so that an IP address can be obtained. You can configure filters for block mode by using the **netsh ipsec dynamic set config bootexemptions** command.

To change the default mode for the IPSec driver during computer startup, use the **netsh ipsec static set config bootmode** command.

### Operational mode

After the IPSec service starts, the IPSec Policy Agent can set the IPSec driver to any one of the following operational modes. The operational mode that is chosen does not change the mode that the IPSec driver uses during computer startup.

- **Secure.** When the IPSec driver operates in secure mode, IPSec policy filters are enforced for standard IPSec operation. The IPSec Policy Agent sets the driver into secure mode after it applies persistent policy (if a persistent policy has been configured) and before it applies the Active Directory-based policy or the local policy. If no persistent policy has been configured and assigned, secure mode does not provide IPSec protection until either the assigned Active Directory-based policy or the local policy is applied. When the Active Directory-based policy or the local policy changes, the IPSec Policy Agent updates the IPSec filter list in the IPSec driver. If no IPSec policy is assigned, the IPSec Policy Agent deletes the filters from the IPSec driver and no IPSec protection is provided in this mode.

- **Permit.** When the IPSec driver operates in permit mode, it does not process any IP packets, and, therefore, no IPSec protection is provided. Permit mode is used when the IPSec service is manually stopped.

- **Block.** When the IPSec driver operates in this mode, the exemptions that might apply during computer startup are not applied. Instead, all inbound and outbound traffic is blocked. This mode is used to enhance security, in the event that the IPSec Policy Agent fails to apply a persistent policy, if a persistent policy has been configured.

The operational mode can be configured only by the IPSec Policy Agent. You cannotuse the Netsh commands for IPSec to configure this mode.

### Diagnostic mode

To record all inbound and outbound dropped packets and other packet processing errors in the Event Viewer System log for troubleshooting, you can enable IPSec driver event logging and specify the level of logging to provide. The types of packet processing errors that the IPSec driver records in the System log depend on the level of logging that is provided. IPSec driver logs can record inbound and outbound per-packet drop events during computer startup mode and operational mode.

IPSec driver event logging is disabled by default, and it should not be used for extended periods. Depending on the logging level that you set, many events might be generated that fill the System log very quickly. For more information, see the section "Using Netsh to change the IPSec configuration on computers running the Windows Server 2003 family" in IPSec troubleshooting tools.

#### Application methods for IPSec policy

IPSec policies are provided in six ways, in the order described in the following sections.

#### IPSec startup policy

When a computer loads the Windows operating system during startup, the IPSec driveris loaded at the same time as the TCP/IP driver. The following table describes thebehavior of the IPSec driver based on the startup type of the IPSec service.

| IPSec service startup type | IPSec driver behavior |
|---|---|
| Disabled | The IPSec driver loads in permit mode, meaning that no IPSec security is applied. In this mode, the IPSec driver does not filter any traffic. |
| Manual | The IPSec driver loads in permit mode, meaning that no IPSec security is applied. In this mode, the IPSec driver does not filter any traffic. |
| Automatic | The IPSec driver loads in a startup mode configured by the IPSec Policy Agent. If no IPSec policy is assigned, by default the IPSec driver loads in permit mode. If IPSec policy is assigned, the IPSec Policy Agent configures the IPSec driver to load in stateful mode.<br><br>After the IPSec service starts, persistent policy (if it has been configured) is applied, and the IPSec driver is set to secure mode (normal operation). |

When the IPSec driver is loaded, it reads the registry to determine the actions that it must perform during computer startup. These actions include:

- Whether to apply stateful filtering, permit all traffic, or block all traffic.

- Whether to exempt specific traffic types from filtering during computer startup.
- Whether to enable IPSec diagnostic logging and, if so, which level of logging to provide.
- Whether to modify the default IPSec traffic exemption. By default, in the Windows Server 2003 family, RSVP, Kerberos, multicast, and broadcast traffic are not exempt from IPSec filtering. Only IKE traffic is exempt.

The IPSec driver remains in a startup mode until the IPSec Policy Agent sets it to an operational mode. After the IPSec driver is set to secure operation mode, the startup stateful mode settings are discarded. You can use the Netsh commands for IPSec to configure IPSec driver settings. For more information, see the **netsh ipsec dynamic set config** section in Netsh commands for Internet Protocol security.

**Persistent policy**

In the Windows Server 2003 family, you can use the Netsh commands for IPSec to add, modify, and maintain IPSec policy settings permanently, after you run the appropriate commands. This type of policy is known as a persistent policy. You can configure persistent policies to extend existing Active Directory-based or local IPSec policies, override Active Directory-based or local IPSec policies, and enhance security during computer startup. Persistent policies enhance security by providing a secure transition from computer startup to Active Directory-based IPsec policy enforcement.

Persistent policies provide the following two key benefits:

- You can configure a persistent policy as your most restrictive IPSec policy. For example, the persistent policy can block all inbound traffic to the Internet IP address of a computer, except for ICMP traffic and communication with a particular management station. To complement the persistent policy, you can design an Active Directory-based policy or a local policy with additional rules that include more specific filters to allow additional communication types.
- You can selectively enforce security rules that are required only for specific servers, due to unique network adapter configurations or program needs. For example, you can enforce security rules specifying that:
    - A specific port always be blocked.
    - Traffic that uses a specific network adapter be permitted without IPSec security, or only with IPSec security.
    - Unsecured traffic to a specific monitoring station be permitted.

Persistent policies, if configured, are stored in the local registry. The persistent store is loaded by the IPSec Policy Agent during service startup. After a persistent policy is successfully applied, the IPSec Policy Agent sets the IPSec driver to secure mode. If an error occurs when a persistent policy is applied, the IPSec Policy Agent removes the persistent policy settings from the IPSec driver and sets the IPSec driver to block operation mode for security. You can update a persistent policy at any time, as long as the IPSec service is running. However, changes in persistent policy are not active immediately. You must restart the IPSec service to load the new persistent policy settings.

If you have configured Active Directory-based policies, you can use a persistent policy as a tool to require that traffic to Active Directory always be secured by IPSec, including the retrieval of Active Directory-based IPSec policies. When an Active Directory-based or local policy is applied, those policy settings are added to the persistent policy settings.

To configure persistent policies, you must use the **netsh ipsec static set store location=persistent** command. To view the IPSec policy that is currently being applied, you can use either IP Security Monitor or the **netsh ipsec dynamic show** commands. For information about how to use Netsh, see Netsh commands for Internet Protocol security.

**Important**

- To provide maximum protection against attacks during computer startup, it is highly recommended that you configure and assign a persistent policy. If you do not configure a persistent policy, no policy can be enforced by the IPSec driver until the IPSec Policy Agent retrieves and applies the assigned Active Directory-based or local IPSec policy.

**Active Directory-based policy**

A Group Policy object defines access, configuration, and usage settings for accounts and resources. IPSec policies can be assigned to the Group Policy object of a site, domain, or organizational unit. When the IPSec policy is applied to one of the

Group Policy objects for the Active Directory object, the IPSec policy is propagated to all of the computer accounts that are affected by that Group Policy object.

You can manage Active Directory-based policy by using the IP Security Policy Management console or by using the **netsh ipsec static set store location=domain** command. IPSec policies that are configured and assigned for the domain take precedence over the local, active IPSec policy on a computer, when that computer is a member of the domain. Active Directory-based policy overrides any local IPSec policy that is assigned, and it adds to the persistent IPSec policy that has already been applied by the IPSec Policy Agent, if a persistent policy has been configured.

**Important**

- Several features in the Windows Server 2003 family implementation of IPSec are not provided in Windows 2000 or in Windows XP. To ensure that the same IPSec policy functions as expected on computers running the Windows Server 2003 family and on computers running Windows 2000 or Windows XP, test the policy thoroughly on all relevant operating systems before deployment. For more information about new features in IPSec, see New features for IPSec.

- If you plan to apply IPSec policies that use the new features that are available only in the Windows Server 2003 family implementation of IPSec, do not use the Windows 2000 or the Windows XP version of the IP Security Policy Management console to manage these policies. The settings in the earlier versions of the IP Security Policy Management console will override the settings in the Windows Server 2003 family IPSec policy, and the new features will not be functional.

When assigning an IPSec policy in Active Directory, consider the following:

- The list of all IPSec policies is available to assign at any level in the Active Directory hierarchy. However, only a single IPSec policy can be assigned at a specific level in Active Directory.

- An IPSec policy that is assigned to an organizational unit in Active Directory takes precedence over a domain-level policy for members of that organizational unit.

- An IPSec policy that is assigned to the lowest-level organizational unit in the domain hierarchy overrides an IPSec policy that is assigned to a higher-level organizational unit, for member computers of that organizational unit.

- An organizational unit inherits the policy of its parent organizational unit unless either policy inheritance is explicitly blocked or policy is explicitly assigned.

- IPSec policies from different organizational units are never merged.

- The highest possible level of the Active Directory hierarchy should be used to assign policies to reduce the amount of configuration and administration required.

- An IPSec policy might remain active even after the Group Policy object to which it is assigned has been deleted. Because of this, you should unassign the IPSec policy before you delete the policy object. To prevent problems, use the following procedure:

  1. Unassign the IPSec policy in the Group Policy object.

  2. Wait 24 hours to ensure that the change is propagated.

  3. Delete the Group Policy object.

     If you delete the Group Policy object without following this procedure, computers in the Active Directory container to which the IPSec policy is assigned treat the IPSec policy as if it cannot be located and continue to use a cached copy.

- You can use Group Policy backup and restore tools to store information about which policy is assigned to a Group Policy

object. To ensure consistency, when you use these tools, make sure that you include IPSec policies. Because these tools do not store the IPSec policies themselves, however, you cannot use them to back up and restore the IPSec policies themselves. You can only back up and restore information about whether the IPSec policies are assigned to Group Policy objects and, if so, to which Group Policy objects. To back up and restore all of the IPSec policies in the IPSec container in Active Directory, use the Export Policies and Import Policies commands in the IP Security Policy Management console. For more information, see Export IPSec policies and Import IPSec policies.

- Before assigning an IPSec policy to a Group Policy object, verify the Group Policy settings that are required for the IPSec policy. For example, if an IPSec policy requires certificate authentication, assign the Group Policy settings that allow computers to enroll for certificates (usually one or two days before you assign the IPSec policy that requires use of the computer certificate). In addition, you should test the certificate enrollment process and resolve any errors before assigning the IPSec policy.

The IPSec Policy Agent on a computer running Windows XP Professional or a Windows Server 2003 operating system polls Active Directory for updates to the assigned IPSec policy. This polling does not detect a change in domain or organizational unit membership or the assigning or unassigning of a new IPSec policy. These events are detected when the Winlogon service polls for changes in Group Policy, which occurs by default every 90 minutes. The Winlogon service discovers these changes, notifies the IPSec Policy Agent, and the IPSec policy changes are applied.

For more information about Group Policy, see Group Policy overview.

### Notes

- The integration of IPSec policies with Active Directory described here does not apply to computers running Windows XP Home Edition because you cannot administer Active Directory-based IPSec policy from a computer running Windows XP Home Edition.

- Careful planning is required when you design Active Directory-based IPSec policies for computers that are used the internal network and on other public or partner networks.

- By default, IPSec policies are read from Active Directory when the connection to Active Directory is interpreted by Group Policy to be a slow link.

#### Directory cache policy

If you assign an Active Directory-based IPSec policy, a copy of the current policy is maintained in a cache in the local registry. If the computer to which the policy is assigned cannot connect to the domain, the cached copy of the Active Directory-based policy is applied. This cached policy adds to the settings of the persistent policy, if a persistent policy has been configured. Note that you cannot configure or manage the cached copy of an Active Directory-based IPsec policy.

#### Local computer policy

Each computer running Windows XP or a Windows Server 2003 operating system has exactly one local Group Policy object, often called the local computer policy. In using this local Group Policy object, Group Policy settings can be stored on individual computers regardless of whether they are members of an Active Directory domain. The local Group Policy object can be overwritten by Group Policy objects associated with sites, domains, or organizational units in an Active Directory environment. On a network without an Active Directory domain (a network that lacks a Windows 2000 or a Windows Server 2003 domain controller), the local Group Policy object settings determine IPSec behavior because they are not overwritten by other Group Policy objects.

You can manage local IPSec policies by using the IP Security Policy Management console or by using the **netsh ipsec static set store location=local** command. The settings of a local IPSec policy are added to the persistent policy, if a persistent policy has been configured. If an Active Directory-based IPSec policy is assigned, and if the computer is connected to an Active Directory domain, the settings of the Active Directory-based policy are applied instead.

For information about how to assign IPSec policy locally, see Assign or unassign IPSec policy on a computer.

#### Netsh dynamic mode policy

You can use the **netsh ipsec dynamic** commands to create, modify, and assign IPSec rules that take effect immediately and are not stored. If the IPSec service is stopped, either administratively or when the computer is restarted, these rules are lost. However, if you use the **netsh ipsec dynamic set config** commands to change the IPSec configuration, those settings are not lost.

# Special IPSec considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Special IPSec considerations**
The following special IPSec considerations can help simplify the administration of IPSec policies.

**Recommended IPSec scenarios and IPSec scenarios that are not recommended**
Following are recommended scenarios and scenarios that are not recommended for the Windows Server 2003 family implementation of IPSec.

**Recommended IPSec scenarios**
The Windows Server 2003 family implementation of IPSec is recommended for use as follows:

- Packet filtering. IPSec provides limited firewall capabilities for end-systems. You can also use IPSec with Internet Connection Firewall, Windows Firewall, and Routing and Remote Access to permit or block inbound or outbound traffic.

- Securing host-to-host traffic on specific paths. You can use IPSec to provide mutual authentication and cryptographic protection for traffic between servers or other static IP addresses or subnets. For example, IPSec can secure traffic between domain controller sites or forests, or between Web servers and database servers.

- Securing traffic to servers. You can use IPSec to require mutual authentication for all client computers that access a server. In addition, you can set restrictions on which computers are allowed to connect to a server running Windows Server 2003 family.

- Using L2TP/IPSec tunneling for VPN connections. You can use the combination of the Layer Two Tunneling Protocol (L2TP) and IPSec (L2TP/IPSec) for all virtual private network VPN scenarios.

- Using IPSec in tunnel mode for gateway-to-gateway tunnels. For interoperability with other routers, gateways, or end-systems that do not support L2TP/IPSec or PPTP VPN tunneling, you can use IPSec in tunnel mode for gateway-to-gateway tunnels.

### Notes

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**IPSec scenarios that are not recommended**
When using IPSec authentication and data protection features, the policy management model in Windows 2000, Windows XP, and Windows Server 2003 family lends itself best to server-to-server and client-to-server scenarios where one end-point has a static address. In large network deployments, when policy involves dynamic addresses at both end–systems, and in some mobility cases, policy management complexity can make IPSec deployment difficult. Because of this, IPSec is not recommended for use as follows:

- Securing communication between domain members and their domain controllers. Because of the complexity of the IPSec policy configuration and management required for this scenario, using IPSec to secure communication between domain members and their domain controllers is not recommended.

- Securing all traffic in a network. Configuring IPSec communications between all client computers and all servers in order to secure many or all computers in a network is difficult. IPSec cannot negotiate security for multicast and broadcast traffic. Traffic from real-time communications, applications that require ICMP, and peer-to-peer applications might be incompatible with IPSec. For these reasons, using IPSec to secure all traffic in a network is not recommended.

Additionally, the IPSec protocol and implementation has characteristics that require special consideration in other scenarios:

- Securing traffic over wireless 802.11 networks. IPSec policies are not optimized for configuration for mobile clients. Because of this, IPSec is not recommended as the only method to secure traffic sent over wireless 802.11 networks. Instead, it is recommended that you use IEEE 802.1X authentication. 802.1X enhances security and ease of deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. In cases where clients roam between access points on the same network, IPSec can be used in combination with 802.11 and 802.1x. In cases where roaming causes the client IP address to change, IPSec security associations become not valid and new security associations are renegotiated.

- Using IPSec in tunnel mode for remote access VPN connections. Using IPSec in tunnel mode is not recommended for remote access VPN scenarios. Instead, use L2TP/IPSec or PPTP for remote access VPN connections.

**Managing policies that use new features available only in the Windows Server 2003 family**
The following features are available only in the Windows Server 2003 family implementation of IPSec:

- Support for new source and destination address options for defining filters. For example, you can now create:

    - Filters with a source address and destination address of **Any IP Address**.

    - Filters that use a non-standard subnet class as a source address or a destination address.

    - Filters that use a multicast or a broadcast address as a destination address.

    - Filters with a source address or a destination address that corresponds to the local IP configuration for the DNS servers, WINS servers, and the DHCP server and default gateway for the computer to which the filter applies.

- The ability to exclude the name of the certification authority (CA) from certificate requests.

- Certificate-to-account mapping for network access control.

- Support for root CA names that are represented in extended ASCII character sets.

- A stronger Diffie-Hellman group (2048-bit Diffie-Hellman key exchange).

Computers running Windows XP and Windows 2000 cannot use these new policy settings. If you plan to apply Active Directory-based IPSec policies that use features that are only available in the Windows Server 2003 family, use the Windows Server 2003 family version of the IP Security Policy Management console to manage them. If you use the Windows XP or Windows 2000 version of the IP Security Policy Management console to manage these policies, the earlier versions of the IP Security Policy Management console will delete the new feature settings.

In addition, if you want to apply the same IPSec policy to computers running different versions of Windows, test the policy to ensure that it functions as expected on both servers running Windows Server 2003 and computers running Windows XP or Windows 2000.

For information about new features available with the Windows Server 2003 family implementation of IPSec, see New features for IPSec. For more information about best practices for using IPSec, see IPSec Best practices.

**IP filters**
Consider the following when configuring IP filters:

- Use general filters when you want a single filter to apply to a group of computers. For example, when configuring the filter, use **My IP address**, **Any IP Address**, or a subnet address instead of specifying a specific computer's source and destination IP addresses.

- Define filters that allow you to group and secure traffic from logically associated segments or subnets within your network.

- Be aware that when you are viewing the IPSec policy, the order in which the filters apply is not in the order displayed. When the IPSec Policy Agent reads an IPSec policy, filters are processed into one ordered list, sorted from most to least

specific. You can use the IP Security Monitor console to view filters sorted by weight. Filters that have the same weight might appear in any order relative to each other.

During policy updates, the IPSec Policy Agent recalculates the sorted order and updates the IPSec driver with the changes only. If a filter is deleted, or if the filter action is changed for a filter, all security associations related to that filter are deleted. As a result, some packets are lost when a new security association is negotiated. TCP connections, however, should immediately recover by retransmitting the lost packets.

- If you are configuring an IPSec policy to secure Kerberos traffic, IPSec can only negotiate security associations if your authentication method does not use Kerberos. If Kerberos is required for authentication between domain members, special consideration must be given to the traffic required by Kerberos between domain members and domain controllers, and the following requirements must be met:

  - If a domain member and a domain controller are members of different domains, a two-way trust must exist between the domains or Internet Key Exchange (IKE) rekeys will fail.

  - If a client computer or a server in the domain uses Kerberos authentication to negotiate IPSec with all peers, you must create mirrored permit filters for all Kerberos-dependent traffic to all domain controllers. It is recommended that you create permit filters to exempt all traffic to each domain controller IP address in the domain member's domain. You do not need to create permit filters to exempt all traffic to all trusted domain controller IP addresses. Instead, create permit filters to exempt only Kerberos traffic and domain controller site location (LDAP) queries to all domain controller IP addresses in the trust path between the computers. If DNS service is not provided by the domain controller (for which you already permit all traffic), you might also need to exempt DNS traffic to the DNS server IP addresses so that DNS can be used for domain controller discovery.

    To exempt these traffic types in the IPSec policy, create the following filters, each with a permit filter action:

| **Filter** | **Filter Action** |
|---|---|
| All traffic to my domain controllers | • Mirrored<br>• Source Address = My IP Address<br>• Destination Address = **A specific IP Address** (where **A specific IP Address** is the static IP address of each domain controller in the domain)<br>• Protocol = **Any**<br>• This filter permits LDAP site location queries and ICMP, DNS, and Kerberos traffic. In addition, it permits the remote procedure call (RPC) traffic and Group Policy downloads required to manage Active Directory-based IPSec policies. |
| Kerberos | • Mirrored<br>• Source Address = My IP Address<br>• Destination Address = **A specific IP Address** (where **A specific IP Address** is the static IP address of each domain controller in the domain)<br>• Protocol = **Any**<br>• This filter permits LDAP site location queries and ICMP, DNS, and Kerberos traffic. In addition, it permits the remote procedure call (RPC) traffic and Group Policy downloads required to manage Active Directory-based IPSec policies. |

| | |
|---|---|
| Domain controller site location (LDAP) queries | • Mirrored<br>• Source Address = **My IP Address**<br>• Destination Address = **A specific IP Address** (where **A specific IP Address** is the static IP address of each domain controller in trusted domains)<br>• Protocol = **UDP**<br>• Source port = **Any**<br>• Destination port = **88**<br>• After you create this filter, create another filter with the same settings, but specify **TCP** for the protocol. |
| DNS client queries | • Mirrored<br>• Source Address = **My IP Address**<br>• Destination Address = **DNS Servers <dynamic>** (or **A specific IP Address**, where the IP address is the static IP address of each DNS server in the network)<br>• Protocol = **UDP**<br>• Source port = **Any**<br>• Destination port = **53**<br>• After you create this filter, create another filter with the same settings, but specify **TCP** for the protocol. |

**Caution**

- To minimize the security issues, you should allow these exemptions only for the specific IP addresses of the domain controllers and the DNS servers.

When designing an IPSec policy to secure or block ICMP traffic, ensure that you plan carefully and test the policy before implementing it in a production environment. Be aware that ICMP is required for the following scenarios:

- Outbound TCP connections that traverse networks with different link frame sizes require path maximum transmission unit (PMTU) discovery. For PMTU discovery to function correctly, inbound ICMP traffic from routers and other gateways must be received.

- The **tracert** command requires ICMP traffic to determine the path taken to a destination. If IPSec protects ICMP traffic, however, **tracert** output shows only the destination computer--not the path of intermediate routers.

- File sharing and other applications use ICMP traffic to determine whether a destination IP address can be reached.

- Network logon and Group Policy measure ICMP response times to each domain controller IP address. This measurement is performed to both aid in the selection of a domain controller to service a network logon and determine whether to apply Group Policy settings over slow links.

In some cases, even the three-second delay before a soft SA (an unsecured connection) is established might impact upper-

layer communication that requires fast ICMP responses.

- In Windows 2000 and Windows XP, by default, broadcast, multicast, Kerberos, Internet Key Exchange (IKE), and Resource Reservation Protocol (RSVP) traffic are exempt from filter matches. In the Windows Server 2003 family, broadcast, multicast, and Kerberos, are not exempt from filter matches by default (only IKE traffic is exempt). In additon, Resource Reservation Protocol (RSVP) has been turned off. Broadcast and multicast packets will be dropped if they match a filter with a filter action to negotiate security. By default, the Windows Server 2003 family provides limited support for filtering broadcast and multicast traffic. A filter with a source address of **Any IP Address** will match multicast and broadcast addresses. A filter with a source address of **Any IP Address** and a destination address of **Any IP Address** will match inbound and outbound multicast addresses. You can use such a filter to block all traffic. One-way filters that would be used to block or permit specific multicast or broadcast traffic, however, are not supported.

  As a result of the change in default exemption behavior for the Windows Server 2003 family implementation of IPSec, you should verify the behavior of IPSec policies designed for Windows 2000 or Windows XP, and determine whether to configure explicit permit filters to permit specific traffic types. To restore the default Windows 2000 and Windows XP behavior for IPSec policies, you can use the **netsh ipsec dynamic set config command**, or you can modify the registry. For more information, see the section "Using Netsh to change the IPSec configuration on computers running the Windows Server 2003 family" in IPSec troubleshooting tools.

  **Caution**

  - The Windows 2000 and Windows XP default exemption settings for IPSec are designed for corporate LAN environments with a low risk of attack. For this reason, you should only use the Windows 2000 and Windows XP default exemption settings when necessary for troubleshooting, in low-risk environments, or when you cannot solve program compatibility issues by configuring explicit filters in IPSec policies.

**Safe Mode with Networking**

If you start a computer in Safe Mode with Networking, consider the following:

- The IPSec service cannot apply filters from an IPSec policy or negotiate IP security when the computer is in Safe Mode with Networking. As a result, when Directory Services Restore Mode operations are in progress, communication does not occur with remote domain controllers or network backup devices that enforce an IPSec policy to require IPSec.

- When a computer loads the Windows operating system during startup, the IPSec driver is loaded at the same time as the TCP/IP driver. If an IPSec policy is assigned to the computer and the IPSec service is configured for automatic startup, by default, the IPSec driver startup mode is changed to perform stateful filtering. When stateful filtering is performed, all outbound traffic is permitted, but all inbound traffic is blocked, except for DHCP traffic and traffic that is sent in response to the outbound traffic initiated during computer startup. (The IPSec driver automatically creates inbound filters to permit responses to outbound traffic.) The IPSec service itself, however, does not start. As a result, no persistent, local, or Active Directory-based IPSec policies can be applied.

- When the computer is in Safe Mode with Networking, you can allow the IPSec driver to continue to provide stateful filtering protection by configuring inbound exemptions for specific traffic. Or, you can force the IPSec driver to permit all traffic.

- To configure inbound exemptions for specific traffic, restart the computer normally (not in Safe Mode), use the **netsh ipsec dynamic set config bootexemptions** command to specify the traffic types to exempt during computer startup, and then restart the computer. The new exemptions will take effect when the computer is restarted and will remain in effect until they are deleted or changed.

- If you allow the IPSec driver to configure inbound exemptions for specific traffic, keep in mind that unless you configure the appropriate exemptions, the following will occur:

  - Inbound connections will be blocked to network services, such as Remote Desktop Connection and Remote Assistance, which open ports for receiving connections. To allow clients to use Remote Desktop Connection or Remote Assistance, you must configure an exemption to allow inbound traffic to TCP port 3389. To configure this exemption, use the following Netsh command:

**netsh ipsec dynamic set config bootexemptions TCP:any:3389:inbound**

- Some outbound TCP connections, such as those requiring PMTU discovery, might not work. To enable TCP PMTU discovery, you must configure an exemption to allow inbound ICMP traffic. To configure this exemption, use the following Netsh command:

  **netsh ipsec dynamic set config bootexemptions ICMP:inbound**

  **Important**

- Modifying IPSec traffic exemptions from startup security (that is, modifying the **bootexemptions=** parameter) will overwrite all previous exemptions from startup security.

For more information about how to specify traffic types to exempt during computer startup, see Netsh commands for Internet Protocol security.

To force the IPsec driver to permit all inbound traffic while the computer is in Safe Mode with Networking, you must either configure the IPSec service for manual startup or disable it, and then restart the computer in Safe Mode with Networking.

**Filter actions**
Consider the following special requirements when configuring IP filter actions:

- If there is specific traffic that you always want to block, such as traffic to and from either not valid addresses or specific TCP ports, create a blocking filter action with the **Security Method** set to **Block**.

- If there is specific traffic that you always want to be unsecured, create a permit filter action with the **Security Method** set to **Permit**.

- When you are configuring custom security methods for encrypted traffic, you should only set the ESP confidentiality selection to **<None>** when a higher layer protocol provides data encryption.

- When you are planning Internet scenarios, such as IPSec tunneling between branch offices, consider using a list of security methods that specifies high levels of security (for example, 3DES only), short key lifetimes (less than 50 MB), and perfect forward secrecy (PFS) for the session keys. This helps protect against known key attacks.

**Note**

- Computers running Windows 2000 must have the High Encryption Pack or Service Pack 2 (or later) installed in order to use the 3DES algorithm. If a computer running Windows 2000 receives a 3DES setting, but does not have the High Encryption Pack or Service Pack 2 (or later) installed, the 3DES setting in the security method is set to the weaker DES, to provide some level of confidentiality for communication, rather than blocking all communication. However, you should only use DES as a fallback option if not all computers in your environment support the use of 3DES. Computers running Windows XP or a Windows Server 2003 operating system support 3DES and do not require installation of the High Encryption Pack.

**VPN connections using L2TP**
When you are using Layer Two Tunneling Protocol (L2TP) for your remote access or router-to-router VPN connections, certificates are the default authentication method for main mode security associations. Computer certificates must be installed either on both the VPN server and remote access client (for remote access connections), or on both the calling router and answering router (for router-to-router VPN connections). The simplest method for installing computer certificates is to configure your Windows 2000 and Windows Server 2003 domains to auto-enroll computer certificates for domain members. For more information, see Computer certificates for L2TP/IPSec VPN connections.

When you are using the certificate authentication method for L2TP connections, the list of certification authorities (CAs) is not configurable. Instead, each computer in the L2TP connection sends a list of root CAs to its IPSec peer from which it accepts a certificate for authentication. The root CAs in this list correspond to the root CAs that issued computer certificates to the computer. For example, if Computer A was issued computer certificates by root CAs CertAuth1 and CertAuth2, it notifies its IPSec peer during main mode negotiation that it will accept certificates for authentication from only CertAuth1 and CertAuth2. If the IPSec peer, Computer B, does not have a valid computer certificate issued from either CertAuth1 or CertAuth2, IPSec

main mode negotiation fails. Therefore, ensure one of the following before attempting an L2TP connection:

- Both the VPN client and VPN server were issued computer certificates from the same CA.
- Both the VPN client and VPN server were issued computer certificates from CAs that follow a certificate chain up to the same root CA.

In general, the VPN client must have a valid computer certificate installed that was issued by a CA that follows a valid certificate chain from the issuing CA up to a root CA that the VPN server trusts. Additionally, the VPN server must have a valid computer certificate installed that was issued by a CA that follows a valid certificate chain from the issuing CA up to a root CA that the VPN client trusts.

For example, if the VPN client was issued computer certificates by root CAs CertAuth1 and CertAuth2, it notifies the VPN server during main mode negotiation that it will accept certificates for authentication from only CertAuth1 and CertAuth2. If the VPN server does not have a valid computer certificate issued from a CA that follows a certificate chain to either CertAuth1 or CertAuth2, IPSec main mode negotiation fails.

A single CA commonly issues computer certificates to all computers in an organization. Because of this, all computers within the organization both have computer certificates from a single CA and request certificates for authentication from the same single CA.

Windows XP and Windows Server 2003 family VPN clients also support the use of preshared key authentication to create L2TP/IPSec connections.

**Important**

- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. Preshared key authentication creates a master key that is less secure (that might produce a weaker form of encryption) than certificates or the Kerberos V5 protocol. In addition, preshared keys are stored in plaintext. Preshared key authentication is provided for interoperability purposes and to adhere to IPSec standards. It is recommended that you use preshared keys only for testing or as an interim measure in a production environment, when your public key infrastructure (PKI) is being deployed to obtain computer certificates, or when preshared key authentication is required by your VPN server. For long-term use in production environment, it is recommended instead that you use certificates or Kerberos V5.

For a remote access VPN client running Windows XP or a Windows Server 2003 operating system, you can enable preshared key authentication and configure a preshared key in **IPSec settings** on the **Security** tab in the properties of a VPN connection in Network Connections.

**Domain controllers and DHCP, DNS, or WINS servers**
Before enabling IPSec for a computer that functions as a domain controller or DHCP, DNS, or WINS server, determine whether all of the clients are IPSec-enabled. If the IPSec policy assigned to the domain controller or DHCP, DNS, or WINS server is not configured to allow fall back to clear, which permits unsecured communication with non-IPSec-capable clients, secure negotiation will fail and access to these network services will be blocked.

**SNMP**
If you are using Simple Network Management Protocol (SNMP) and your SNMP management systems or agents include computers running Windows 2000, Windows XP, or a Windows Server 2003 operating system that are configured with IPSec policy, you can add a rule to the appropriate IPSec policy to prevent SNMP messages from being secured. The filter list must specify the source and destination addresses of the SNMP management systems and agents for all UDP traffic that uses ports 161 and 162. The filter action should be set to **Permit**, which passes through any traffic that matches the IP filter list.

# IPSec troubleshooting tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting tools**

This topic provides information about the following IPSec troubleshooting tasks and the troubleshooting tools that you can use to perform each of these tasks:

- Viewing IPSec policy assignment information
- Viewing details about the active IPSec policy and IPSec statistics
- Viewing details about the active IPSec policy and IPSec statistics in IP Security Monitor
- Verifying that security auditing is enabled
- Viewing IPSec-related events in Event Viewer
- Enabling detailed tracing for Internet Key Exchange (IKE) negotiations
- Viewing IPSec and other network communication with Network Monitor
- Using Netsh to change the IPSec configuration on computers running the Windows Server 2003 family
- Using Ipseccmd.exe to manage and monitor IPSec on computers running Windows XP
- Using Netdiag.exe to display IPSec information and to test and view network configuration
- Disabling TCP/IP and IPSec hardware acceleration

Details about each of these subjects are provided in the following sections.

**Notes**

- For general recommended practices that can help you enhance security and minimize the potential for problems when deploying IPSec, see IPSec Best practices.
- For the Windows Server 2003 family, the Netsh commands for IPSec replace and enhance the functionality provided by Netdiag.exe and Ipseccmd.exe. For information about how to use Netsh to script IPSec policy creation and to monitor IPSec activity, see Netsh commands for Internet Protocol security.
- Ipseccmd.exe is a support tool that is provided only on the Windows XP CD. To install this tool, run the Setup.exe file from the Support\Tools folder. You can use this tool to manage and monitor IPSec policies only on computers running Windows XP. For more information about Ipseccmd.exe, see the Microsoft Tech Net Web site.

Netdiag.exe is available in the Windows Server 2003 family, Windows XP, and in Windows 2000, as follows:

- In the Windows Server 2003 family, run the Suptools.msi file from the \Support\Tools folder on the Windows Server 2003 family CD (select the **Complete** setup option). Although you can still use this version of Netdiag.exe to obtain basic networking information that is not IPSec-specific, the Netsh commands for IPSec replace all IPSec-specific functionality.
- In Windows XP, run the Setup.exe file from the \Support\Tools folder on the Windows XP CD (select the **Complete** setup option).

- For Windows 2000, an updated version of Netdiag.exe is available for download from the Web. For more information, see "Windows 2000 Resource Kits," at the Microsoft Windows Resource Kits Web site.

For more information about Netdiag.exe, see Using Netdiag.exe to display IPSec information and to test and view network configuration in this topic.

**Viewing IPSec policy assignment information**

Viewing the name of an active IPSec policy and the name of the Group Policy object to which the active IPSec policy is assigned can be useful for troubleshooting policy precedence issues. The following table summarizes the tools that you can use to view this information for the Windows Server 2003 family, Windows XP, and Windows 2000.

| On computers running | Use these tools to view the name of the active IPSec policy | Use these tools to view the name of the Group Policy object to which the active IPSec policy is assigned |
|---|---|---|
| Windows Server 2003 family | • IP Security Monitor console.<br><br>For more information, see View details about active IPSec policies.<br><br>• Netsh, **netsh ipsec static show gpoassignedpolicy** command.<br><br>For more information, see Netsh commands for Internet Protocol security. | • Resultant Set of Policy (RSoP) console.<br><br>For more information, see Use Resultant Set of Policy (RSoP) to View IPSec Policy Assignments.<br><br>• Netsh, **netsh ipsec static show gpoassignedpolicy** command. |
| Windows XP | • IP Security Policy Management console (for local policies only).<br><br>• Network Connectivity Tester (Netdiag.exe), **netdiag /test:ipsec** command.<br><br>For more information, see Using Netdiag.exe to display IPSec information and to test and view network configuration in this topic. | • Netdiag.exe, **netdiag /test:ipsec** command. |
| Windows 2000 | • Netdiag.exe, **netdiag /test:ipsec** command.<br><br>• In the properties for the relevant network connection, **TCP/IP Properties/Advanced/Options/IPSec**.<br><br>The assigned IPSec policy that is displayed in **TCP/IP Properties** is global. It is not specific to the connection. | • Netdiag.exe, **netdiag /test:ipsec** command.<br><br>• Gpresult.exe (Group Policy Results).<br><br>• Gpotool.exe (Group Policy Verification Tool).<br><br>Gpresult.exe and Gpotool.exe are both available for download from the Web. For more information, see "Windows 2000 Resource Kits," at the Microsoft Windows Resource Kits Web site. |

**Notes**

- To view all IPSec policies that are available (but not necessarily assigned or applied) to computers, use the IP Security Policy Management console. For information about policy precedence and IPSec policy behavior in an Active Directory environment, see the section "Active Directory-based policy" in Creating, modifying, and assigning IPSec policies.

- For the Windows Server 2003 family, to determine which IPSec policies are assigned but are not being applied to IPSec clients, use the RSoP console.

- The Windows XP implementation of the RSoP console does not support the display of IPSec policies. In addition, the **gpresult /scope computer** command does not display the Group Policy object that contains an IPSec policy assignment. For these reasons, you should use Netdiag.exe to view IPSec policy assignment information on computers running Windows 2000 or Windows XP. The **netdiag /test:ipsec** command displays the Group Policy object that contains the IPSec policy assignment, and the organizational unit to which the Group Policy object is assigned.

- Gpotool.exe allows you to monitor the health of Group Policy objects on domain controllers. You can use this tool to check the consistency and replication of Group Policy objects and to display Group Policy object properties. Gpotool.exe is available only for computers running Windows 2000.

**Viewing details about the active IPSec policy and IPSec statistics**

The IP Security Policy Management console, Netdiag.exe, Gpresult.exe, and Gpotool.exe allow you to determine which IPSec policy has been assigned through Group Policy. After you verify this information, you might need to view details about the assigned IPSec policy and IPSec statistics (for example, filters, filter actions, and active security associations). The following table summarizes the tools that you can use to view an active IPSec policy and IPSec statistics for the Windows Server 2003 family, Windows XP, and Windows 2000.

| **On computers running** | **Use these tools to display the active IPSec policy, IPSec statistics, or both** | **Notes** |
|---|---|---|
| Windows Server 2003 family | • IP Security Monitor console.<br><br>For more information, see View IP security statistics<br><br>• Netsh, **netsh ipsec dynamic show all** command. | • To view details about the active IPSec policy and IPSec statistics on a local or remote computer, you must be a member of the Administrators group on that computer. |
| Windows XP | • IP Security Monitor console.<br><br>• IPseccmd.exe, **ipseccmd show all** command. | • To view details about the active IPSec policy and IPSec statistics for a local or remote computer, you must be a member of the Administrators group on that computer. |
| Windows 2000 | • Netdiag.exe, **netdiag /test:ipsec /v /debug** command.<br><br>• Ipsecmon.exe. | • To use the **/debug** option, you must be logged on as a member of the Administrators group on that computer. In addition, to view details about Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory.<br><br>• Ipsecmon.exe only displays active outbound quick mode security associations (SAs). |

**Note**

- To remotely monitor IPSec on a computer that is running a different version of Windows than your computer, use Remote Desktop Connection. For example, if your computer is running the Windows Server 2003 family and you plan to

remotely monitor IPSec on computers running Windows 2000 or Windows XP, use Remote Desktop Connection to gain remote access to these computers. For information about Remote Desktop Connection, see Remote Desktop Connection.

**Viewing details about the active IPSec policy and IPSec statistics in IP Security Monitor**

In Windows XP and the Windows Server 2003 family, IP Security Monitor is implemented as a Microsoft Management Console (MMC) snap-in, and it includes enhancements that allow you to view details about an active IPSec policy that is applied by the domain or locally, as well as quick mode and main mode statistics, and active IPSec SAs. IP Security Monitor also enables you to search for specific main mode or quick mode filters. To troubleshoot complex IPSec policy designs, you can use IP Security Monitor to search for all matches for filters of a specific traffic type.

- For procedures on how to use IP Security Monitor, see Monitor IPSec Activity.
- For detailed information about IP security statistics, see Viewing main mode and quick mode statistics in IP Security Monitor.

### Notes

- You can use IP Security Monitor to monitor only computers that are running Windows XP or the Windows Server 2003 family. In addition, the computer that is being monitored must run the same version of the Windows operating system as the computer on which IP Security Monitor is running. To monitor IPSec on a computer that is running Windows 2000, use the **ipsecmon** command at the Windows 2000 command prompt on the computer that is being monitored.
- For remote monitoring, you can use IP Security Monitor only to monitor computers that are running the same version of the Windows operating system. To remotely monitor IPSec on a computer that is running a different version of Windows than your computer, use Remote Desktop Connection. For information about Remote Desktop Connection, see Remote Desktop Connection.
- If your computer is running the Windows Server 2003 family, and you plan to monitor IPSec on computers that are also running the Windows Server 2003 family, you can run IP Security Monitor or use the Netsh command-line tool remotely.

**Verifying that security auditing is enabled**

You can use Local Security Policy settings (for a local computer) or Group Policy Object Editor (for a domain) to verify that security auditing is enabled, so you can ensure that the success and failure of IKE negotiations is recorded. Auditing for IKE is supported in Windows 2000, Windows XP, and the Windows Server 2003 family (IKE uses the Logon Events category). In the Windows Server 2003 family, you can also enable auditing for the security policy database (SPD). SPD uses the Policy Change category. For more information, see Define or modify auditing policy settings for an event category.

**Viewing IPSec-related events in Event Viewer**

You can use Event Viewer to view the following IPSec-related events:

**IKE events (negotiation success and failure) in the security log.**

To view these events, enable success or failure auditing for the **Audit logon events** audit policy for your domain or local computer. The IKE event category is also used for auditing user logon events in services other than IPSec. For more information, see Define or modify auditing policy settings for an event category.

When you enable success or failure auditing for the **Audit logon events** audit policy, IPSec records the success or failure of each main mode and quick mode negotiation and the establishment and termination of each negotiation as separate events. However, enabling this type of auditing can cause the security log to fill with IKE events. For example, for servers that are connected to the Internet, attacks on the IKE protocol can cause the security log to fill with IKE events. IKE events can also fill the security log for servers that use IPSec to secure traffic to many clients. To avoid this, you can disable auditing for IKE events in the security log by modifying the registry.

- To disable auditing of IKE events in the security log, do the following:

  1. Set the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Lsa\Audit\DisableIKEAudits** registry setting to a value of **1**.

     The **DisableIKEAudits** key does not exist by default and must be created.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

1. Restart the computer, or stop and then restart the IPSec service by running the **net stop policyagent** and **net start policyagent** commands at the command prompt.

**Note**

- Stopping and restarting the IPSec service can disconnect all of the computers that are using IPSec from the computer on which the IPSec service is stopped, and it can prevent further communication with that computer. If you restart the IPSec service immediately, TCP-based communication might resume, due to the retransmit behavior of TCP, after new IKE and IPSec SAs are established. For more information, see "Stopping and restarting the IPSec service," later in this topic.

**IPSec policy change events in the Security log.**

To view these events, enable success or failure auditing for the **Audit policy change** audit policy for your domain or local computer. For more information, see Define or modify auditing policy settings for an event category.

**IPSec driver per-packet drop events in the System log.**

In Windows 2000, Windows XP, and the Windows Server 2003 family, you can enable packet event logging for the IPSec driver by modifying the registry. The IPSec driver reads the registry during computer startup. In the Windows Server 2003 family, you can enable packet event logging for the IPSec driver by using the **Netsh ipsec** command-line tool. To enable logging of dropped inbound and outbound packets, specify a value of **7**. For information about the other levels of IPSec driver event logging, see Notes.

- To enable IPSec driver logging of dropped inbound and outbound packets by modifying the registry, do the following:

  1. Set the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\IPSec\EnableDiagnostics DWORD** registry setting to a value of **7**.

  **Caution**

  - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

  1. Restart the computer.

- To enable IPSec driver logging of dropped inbound and outbound packets by using the Netsh IPSec command-line tool in the Windows Server 2003 family, do the following:

  1. At the command prompt, type: **netsh ipsec dynamic set config ipsecdiagnostics 7**

  2. Restart the computer.

You can also change the interval for writing IPSec driver packet events to the System log. By default, the IPSec driver writes events to the System log once an hour or after a threshold for the number of events has been reached. For troubleshooting, you should set this interval to the minimum value, 60 seconds.

- To change the interval for writing IPSec driver packet events by modifying the registry, do the following:

1. Set the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\IPSec\LogInterval DWORD** registry setting to **60 decimal**.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

1. Restart the computer.

- To change the interval for writing IPSec driver packet events by using the **Netsh ipsec** command-line tool in the Windows Server 2003 family, do the following:

  1. At the command prompt, type **netsh ipsec dynamic set config ipseclogginterval 60**

  2. Restart the computer.

The IPSec driver reads the registry during computer startup.

By default, packet event logging for the IPSec driver is disabled (that is, the value is set to **0**). When you enable packet event logging for the IPSec driver, you can specify any of the following values, to enable different levels of logging:

| Logging Level | Description |
|---|---|
| **1** | When **1** is specified, bad SPI packets (the total number of packets for which the Security Parameters Index or SPI was incorrect), IKE negotiation failures, IPSec processing failures, packets received with invalid packet syntax, and other errors are recorded in the System log. Unauthenticated hashes (with the exception of the "Clear text received when should have been secured" event) are logged as well. |
| **2** | When **2** is specified, inbound per-packet drop events are recorded in the System log. |
| **3** | When **3** is specified, level 1 and level 2 logging are performed. In addition, unexpected clear text events (packets that are sent or received in plaintext) are also recorded. |
| **4** | When **4** is specified, outbound per-packet drop events are recorded in the System log. |
| **5** | When **5** is specified, level 1 and level 4 logging are performed. |
| **6** | When **6**is specified, level 2 and level 4 logging are performed. |
| **7** | When **7** is specified, all levels of logging are performed. |

For more information about IPSec driver event logging, see the Microsoft Windows Resource Kits Web site.

You cannot configure audit policies on a computer running Windows XP Home Edition. However, success and failure auditing for the **Audit logon events** and **Audit policy change** audit policies for the local computer are enabled by default.

Enabling auditing in the security log or IPSec driver diagnostics in the system log can cause these logs to fill with events quickly. Before you perform either of these tasks, you should do the following:

- Ensure that the size of the log is at least 10 megabytes (MB).

- Save the existing log to a file.

- Clear all events in the log so that the log is empty.

- Consider disabling auditing of IKE events in the security log by modifying the registry, if your computer hosts many simultaneous network connections.

**Enabling detailed tracing for Internet Key Exchange (IKE) negotiations**

Enabling audit logging for IKE events and viewing the events in Event Viewer is the fastest and simplest way to troubleshoot failed main mode or quick mode negotiations. However, some scenarios might require a more detailed analysis of the IKE main mode negotiation and quick mode negotiations for troubleshooting. You can enable tracing for IKE negotiations if the audit failure events do not provide enough information. The IKE tracing log is a very detailed log intended for troubleshooting IKE interoperability under controlled circumstances. Expert knowledge of the ISAKMP RFC 2408 and IKE RFC 2409 is required to interpret this log.

The IKE tracing log appears as the *systemroot*\Debug\Oakley.log file. The log has a fixed size of 50,000 lines and will overwrite as necessary. A new Oakley.log file is created each time the IPSec service is started and the previous version of the Oakley.log file is saved as Oakley.log.sav. When the Oakley.log file becomes full, the current file is saved as Oakley.log.bak, and a new Oakley.log file is created.

Because many IKE negotiations can occur simultaneously, you should minimize the number of negotiations and log for as short a period of time as possible to capture a more easily interpreted log.

**Enabling and disabling the IKE tracing log in the** Windows Server 2003 **family**

In the Windows Server 2003 family, you can enable or disable the IKE tracing log dynamically while the IPSec service is running by doing the following:

- To enable the IKE tracing log, type the following at the command prompt:

  **netsh ipsec dynamic set config ikelogging 1**

  This command creates the IKE tracing log file if it does not exist. If the file does exist, it appends logging information to the existing file.

- To disable the IKE tracing log, type the following at the command prompt:

  **netsh ipsec dynamic set config ikelogging 0**

**Enabling the IKE tracing log in Windows 2000 and** Windows XP

In Windows 2000 and Windows XP, you must enable IKE tracing by modifying the registry. For the changes to take effect, you must also stop and restart the IPSec service:

- To enable the IKE tracing log in Windows XP and Windows 2000, do the following:

  1. Set the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\PolicyAgent\Oakley\EnableLoggingDWORD** registry setting to a value of **1**.

     The Oakley key does not exist by default and must be created.

  **Caution**

  - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

  1. Stop and start the IPSec service by running the **net stop policyagent** and **net start policyagent** commands at the command prompt.

**Stopping and restarting the IPSec service**

Stopping and restarting the IPSec service can disconnect all of the computers that are using IPSec from the computer on which the IPSec service is stopped, and it can prevent further communication with that computer. However, if you restart the IPSec service immediately, TCP-based communication might resume, due to the retransmit behavior of TCP, after new IKE and IPSec SAs are established. If you leave the IPSec service stopped, any clients that used the default response rule to establish security will be unable to communicate with this computer for two hours.

To avoid losing Terminal Services connectivity for computers that are using IPSec over a Terminal Server session, you must stop and restart the IPSec service by using a single command line:

- To stop and restart the IPSec service for computers over a Terminal Server session

    - At the command prompt, type the following:

      **net stop policyagent & net start policyagent**

If you are restarting the IPSec service while an L2TP/IPSec VPN tunnel is connected, the tunnel will lose connectivity and must be reconnected when the IPSec service is restarted. A PPTP tunnel, however, does not use IPSec and therefore will stay connected if you stop the IPSec service.

If you are restarting the IPSec service on a computer that is running the Windows Server 2003 family or the Windows Server 2003 family and that is also running the Routing and Remote Access service, any IPSec configuration for L2TP will be lost and the L2TP tunnels will be disconnected. Therefore, you must stop and restart the Routing and Remote Access service, as well as the IPSec service.

- To stop and restart the IPSec service and the Routing and Remote Access service, do the following:

    1. Stop the Routing and Remote Access service using the **net stop remoteaccess** command.
    2. Stop the IPSec service by using the **net stop policyagent** command.
    3. Start the IPSec service by using the **net start policyagent** command.
    4. Start the Routing and Remote Access service using the **net start remoteaccess** command.

**Viewing IPSec and other network communication with Network Monitor**

You can install and use Network Monitor to view IPSec and other network communication. Note that the version of Network Monitor that is provided with the Windows Server 2003 family can be used only to view the network traffic that is sent to or from the computer on which it is installed. To view network traffic that is sent to or from another computer and is routed through your computer (using the Routing and Remote Access service), you must use the Network Monitor component that is provided with Microsoft Systems Management Server.

The Network Monitor component that is provided with the Windows Server 2003 family includes parsers for the ISAKMP (IKE), AH, and ESP protocols. The Network Monitor parsers for ESP can parse inside the ESP packet only if null-encryption is being used and the full ESP packet is captured. Network Monitor cannot parse the encrypted portions of IPSec-secured ESP traffic when encryption is performed in software. However, if encryption is being performed by an IPSec hardware offload network adapter, the ESP packets are decrypted when Network Monitor captures them and as a result, can be parsed and interpreted into the upper-layer protocols. If you need to diagnose ESP software-encrypted communication, you must disable ESP encryption and use ESP-null encryption by changing the IPSec policy on both computers.

### Notes

- For information about how to install the version of Network Monitor that is provided with the Windows Server 2003 family, see Install Network Monitor.

- For information about Systems Management Server, go to the Microsoft Web site.

**Using Netsh to change the IPSec configuration on computers running the Windows Server 2003 family**

For computers running the Windows Server 2003 family, you can use the Netsh commands for IPSec to script IPSec policy creation, display details about IPSec policies, and change the IPSec configuration for troubleshooting.

For troubleshooting, you can use the Netsh commands for IPSec to change the following settings:

#### Disable Internet Key Exchange (IKE) certificate revocation list (CRL) checking

By default, in Windows 2000 CRLs are not checked during IKE certificate authentication. In Windows XP and the Windows Server 2003 family, CRLs are checked during IKE certificate authentication, but a fully successful check is not required for the certificate to be accepted. In some cases, failures during CRL processing might cause IKE to not accept the certificate. Or, the delay required for CRL checking might delay IKE negotiation enough to cause the connection attempt to time-out. To determine whether certificate authentication will be successful without CRL checking, you can disable IKE CRL checking. To do this, type the following at the command prompt:

**netsh ipsec dynamic set config strongcrlcheck 0**

This setting takes effect immediately. It does not require a restart.

#### Enable IPSec driver event logging

To record all inbound and outbound dropped packets and other packet processing errors in the Event Viewer System log, you can set the IPSec driver event logging level to **7**. To do this, type the following at the command prompt:

**netsh ipsec dynamic set config ipsecdiagnostics 7**

This setting will not take effect until you restart your computer.

### Notes

- If you configured an IPSec filter action on a computer to block traffic, setting the IPSec driver event logging level to **7** on that computer might generate many events that fill the System log very quickly. Accordingly, you should set the IPSec driver event logging level to **7** only for testing.

- All packets that are dropped by IPSec contribute to the **Datagrams Received Discarded** or **Datagrams Outbound Discarded** System Monitor counters for the IP object. IPSec itself does not provide a counter object. You can monitor IPSec performance counters manually by using IP Security Monitor.

#### Permit inbound and outbound traffic during computer startup

To permit inbound and outbound traffic during computer startup (before the IPSec service starts), you can use the following Netsh command:

**netsh ipsec dynamic set config bootmode permit**

This setting will not take effect until you restart your computer.

### Note

- If you start the computer in Safe Mode with Networking, the IPSec service will not start and cannot retrieve IPSec policy settings from Active Directory or the local registry, and persistent policy cannot be applied. As a result, inbound and outbound traffic will continue to be permitted until the computer is no longer in Safe Mode.

#### Exempt all broadcast, multicast, IKE, Kerberos, and RSVP traffic from IPSec filtering

In Windows 2000 and Windows XP, by default, the IPSec driver exempts all broadcast, multicast, IKE, Kerberos, and RSVP traffic from IPSec filtering. In the Windows Server 2003 family, only IKE traffic is exempt from IPSec filtering, and you can configure, block, or permit filter actions specifically for multicast and broadcast traffic (IPSec does not negotiate SAs for multicast and broadcast traffic). To restore the IPSec driver to the default Windows 2000 and Windows XP filtering behavior, you can use the following Netsh command:

**netsh ipsec dynamic set config ipsecexempt 0**

This setting will not take effect until you restart your computer.

### Caution

- The Windows 2000 and Windows XP default exemption settings for IPSec are designed for corporate LAN environments with a low risk of attack. For this reason, you should use only the Windows 2000 and Windows XP default exemption settings when necessary for troubleshooting, in low-risk environments, or when you cannot solve program compatibility issues by configuring explicit filters in IPSec policies.

You can also exempt all broadcast, multicast, IKE, Kerberos, and RSVP traffic from IPSec filtering by modifying the registry as follows:

1. Set the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\IPSEC\NoDefaultExempt DWORD** registry setting to a value of **0**.

2. The **NoDefaultExempt** key does not exist by default and must be created.

   **Caution**

   - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer

3. Restart the computer.

#### Using Ipseccmd.exe to manage and monitor IPSec on computers running Windows XP

For computers running Windows XP, you can use the Ipseccmd.exe command-line tool to script IPSec policy creation and to display IPSec policy assignments, active SAs, and detailed IPSec policy settings, including filters, filter actions, and authentication methods. Ipseccmd.exe replaces and enhances the functionality provided by the Ipsecpol.exe (used in Windows 2000 for scripting IPSec policy creation) and the Netdiag.exe **/test:ipsec /v /debug** command (used in Windows 2000 to display configuration information and SAs for an active IPSec policy).

To install Ipseccmd.exe on a computer running Windows XP, run the Setup.exe file from the \Support\Tools folder on the Windows XP CD.

**Notes**

- Ipseccmd.exe is provided only with Windows XP, and you can use this tool to manage and monitor IPSec policies only on computers running Windows XP.

- To display all IPSec policy settings and statistics for diagnostics, use the **ipseccmd show all** command.

#### Using Netdiag.exe to display IPSec information and to test and view network configuration

You can use the Netdiag.exe command-line tool to display information about IPSec policies and statistics, report network configuration, and test basic networking capabilities and domain-based functionality. The following table describes how to install Netdiag.exe and provides information about functional changes relevant to IPSec for each version of this tool.

| On computers running | Use this method to install | Notes |
|---|---|---|
| Windows Server 2003 family | For the Windows Server 2003 family, Netdiag.exe is available for installation from the Windows Server 2003 family CD (run the Suptools.msi file from the \Support\Tools folder, and choose the **Complete** setup option. | • Although you can still use Netdiag.exe to obtain basic networking information that is not IPSec-specific, for the Windows Server 2003 family, the **netdiag /test:ipsec** option has been removed, and the Netsh commands for IPSec replace all IPSec-specific functionality. To view details about IPSec policies, use either the **netsh ipsec static show** command or the **netsh ipsec dynamic show** command. |

| | | |
|---|---|---|
| Windows XP | For Windows XP, Netdiag.exe is available for installation from the Windows XP CD (run the Setup.exe file from the \Support\Tools folder, and choose the **Complete** setup option). | • Displays information about IPSec policy assignments, including the name of the active IPSec policy, the name of the Group Policy object that assigned the policy, and the policy path.<br><br>• The display of detailed IPSec policy information and IPSec statistics (provided by the **/debug** and **/v** options in Windows 2000) is not supported in Windows XP. Instead, to view details about IPSec policies, use the Ipseccmd.exe **show** command. |
| Windows 2000 | For Windows 2000, an updated version of Netdiag.exe is available for download from the Web. For information, see "Windows 2000 Resource Kits," at the Microsoft Windows Resource Kits Web site. | • Netdiag.exe was enhanced in Windows 2000 Service Pack 1 to display the number of bytes offloaded by the IPSec driver to a network adapter that is capable of IPSec hardware offload. The hardware offload statistics are Offloaded Bytes Sent and Offloaded Bytes Received.<br><br>• To use the **/debug** option to view details about Active Directory-based IPSec policies, you must be a member of the Domain Admins group in Active Directory. |

You can use the **netdiag /v /l** command to obtain networking information that is not IPSec-specific, for any platform. Typical uses of these options include:

- Reporting the IP configuration and routing configuration for a computer with one command.
- Testing WINS and DNS name resolution and consistency.
- Reporting the build version of a computer and the hotfixes that are installed on that computer.
- Testing the validity of domain membership, whether domain members can successfully contact domain controllers, and trust relationships.

The **/l** option generates a Netdiag.log file. This file is written to the folder in which Netdiag.exe is run.

**Notes**

- To run all Netdiag.exe commands, you must be a member of the Administrators group on the local computer.
- Each version of Netdiag.exe is customized to run on a different version of the Windows operating system (that is, Windows 2000, Windows XP, or the Windows Server 2003 family). You can only run Netdiag.exe on a computer that is running the Windows operating system for which Netdiag.exe has been specifically designed.
- If you are running a version of Netdiag.exe that is designed for Windows 2000 or Windows XP in a Windows Server 2003 domain, Netdiag.exe might not report the correct operating system version of the domain.
- If you run Netdiag.exe on a computer that is assigned an IPSec policy that affects most inbound and outbound IP traffic on that computer, Netdiag.exe might not report results correctly the first time it is run. This is because it might take a few seconds for IPSec to establish SAs to the many remote computers for which Netdiag.exe tests connectivity. If this occurs, wait five seconds, and then run Netdiag.exe again.

**Disabling TCP/IP and IPSec hardware acceleration**

Network adapters can accelerate IPSec processing by performing hardware offload of IPSec cryptographic functions (IPSec offload) and the calculation of TCP checksums (checksum offload). Such adapters might also process large TCP segments for very fast transmission (large-send offload). By default, when a network adapter driver that can perform hardware offload is enabled during the Plug and Play initialization process, the driver advertises this capability to TCP/IP and IPSec. TCP/IP and

IPSec then offload tasks to the network adapter driver as appropriate.

If you use network adapters to perform hardware offload of IPSec cryptographic functions, you might need to verify that hardware acceleration is not causing problems with the packet processing that is performed by the network adapter. To do so, you can:

- Disable hardware offload functions in the network adapter driver (if this function is supported by the driver). This task does not require you to restart the computer.
- Disable TCP/IP and IPSec hardware acceleration. This task requires you to restart the computer.
- Disable only IPSec hardware acceleration. This task requires you to restart the computer.

**Disabling hardware offload functions in the network adapter driver**

To determine whether you can disable hardware offload functions in the network adapter driver, do one of the following:

- Open Device Manager, click **Network Adapters**, right-click the network adapter whose properties you want to view, and then click **Properties**. For more information, see Change network adapter settings
- Open Network Connections, right-click the network adapter that you want to view, click **Properties**, and then, on the **General** tab, click **Configure**.

**Disabling TCP/IP and IPSec hardware acceleration**

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

To disable both TCP/IP and IPSec hardware acceleration by modifying the registry, do the following:

1. Set the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\DisableTaskOffload** DWORD registry setting to a value of **1**.

   **Caution**

   - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

2. Restart the computer.

If the **DisableTaskOffload** DWORD registry setting is set to a value of **0**, and if the network adapter advertises hardware offload capabilities, IPSec and TCP/IP will attempt to offload the appropriate functions to the network adapter.

**Disable only IPSec hardware acceleration**

To disable only IPSec hardware acceleration by modifying the registry, do the following:

1. Set the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\IPSEC\EnableOffload** DWORD registry setting to a value of **0**.

   **Caution**

   - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

2. Restart the computer.

**Note**

- To help minimize the potential for hardware acceleration to cause problems with packet processing performed by the network adapter, make sure that you use the latest network adapter driver available from the vendor.

# Viewing IPSec Statistics and Details About Active IPSec Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing IPSec statistics and details about active IPSec policies**
This section covers:

- Viewing main mode and quick mode statistics in IP Security Monitor
- Viewing details about active IPSec policies in IP Security Monitor
- Using Resultant Set of Policy to view IPSec policy assignments

# Viewing main mode and quick mode statistics in IP Security Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing main mode and quick mode statistics in IP Security Monitor**

**Main Mode (IKE) Statistics**
The following table describes the items in the list of main mode (IKE) statistics in IP Security Monitor.

For information about how to view these statistics, see View IP security statistics.

| Main Mode (IKE) Statistic | Description |
|---|---|
| Active Acquire | The number of pending requests to initiate an Internet Key Exchange (IKE) negotiation in order to establish a security association (SA) between IPSec peers. The Active Acquire statistic includes the outstanding request and the number of any queued requests. Under a heavy load, the number of active acquires is 1 plus the number of requests that are queued by IKE for processing. |
| Active Receive | The number of IKE messages received that are queued for processing. |
| Acquire Failures | The total number of acquire outbound requests that have failed since the IPSec service was last started. Acquires are requests to establish SAs between IPSec peers. |
| Receive Failures | The total number of errors that have occurred during the process of receiving IKE messages since the IPSec service was last started. |
| Send Failures | The total number of errors that have occurred during the process of sending IKE messages since the IPSec service was last started. The number of Send Failures typically increases for computers that establish SAs over temporary network connections, such as dial-up connections, virtual private network tunnels, and wireless connections. |
| Acquire Heap Size | The number of entries in the acquire heap. The acquire heap stores successful acquires. Acquires are outbound requests to establish SAs between IPSec peers. |
| Receive Heap Size | The number of entries in the IKE receive buffers. The receive buffers store incoming IKE messages. |
| Authentication Failures | The total number of identity authentication (Kerberos, certificate, and preshared key) failures that have occurred during main mode negotiation since the IPSec service was last started. If you are having difficulty communicating securely, attempt the communication and determine whether the number of Authentication Failures increases. If it does, check your authentication settings for either an unmatched authentication method or an incorrect authentication method configuration (for example, the use of preshared keys that do not match). |
| Negotiation Failures | The total number of negotiation failures that have occurred during main mode or quick mode negotiation since the IPSec service was last started. If you are having difficulty communicating securely, attempt the communication and determine whether the number of Negotiation Failures increases. If it does, check your authentication and security method settings for an unmatched authentication method, an incorrect authentication method configuration (for example, the use of preshared keys that do not match), or unmatched security methods or settings. |
| Invalid Cookies Received | The total number of cookies that could not be matched with an active main mode SA since the IPSec service was last started. A cookie is a value contained in a received IKE message that is used to help identify the corresponding main mode SA. |
| Total Acquire | The total number of requests that have been submitted to IKE since the IPSec service was last started to establish an SA. This number includes acquires that result in soft SAs. |

| | |
|---|---|
| Total Get SPI | The total number of requests that have been submitted by IKE to the IPSec driver to obtain a unique Security Parameters Index (SPI) since the IPSec service was last started. The SPI matches inbound packets with SAs. |
| Key Additions | The total number of outbound quick mode SAs that have been added by IKE to the IPSec driver since the IPSec service was last started. |
| Key Updates | The total number of inbound quick mode SAs that have been added by IKE to the IPSec driver since the IPSec service was last started. |
| Get SPI Failures | The total number of failed requests that have been submitted by IKE to the IPSec driver to obtain a unique SPI since the IPSec service was last started. |
| Key Addition Failures | The total number of failed outbound quick mode SA addition requests that have been submitted by IKE to the IPSec driver since the IPSec service was last started. |
| Key Update Failures | The total number of failed inbound quick mode SA addition requests that have been submitted by IKE to the IPSec driver since the IPSec service was last started. |
| ISADB List Size | The number of main mode state entries. This number includes successfully negotiated main modes, main mode negotiations in progress, and main mode negotiations that failed or expired and have not yet been deleted. |
| Connection List Size | The number of quick mode negotiations that are in progress. |
| IKE Main Mode | The total number of successful SAs that have been created during main mode negotiations since the IPSec service was last started. |
| IKE Quick Mode | The total number of successful SAs that have been created during quick mode negotiations since the IPSec service was last started. |
| Soft Associations | The total number of SAs formed with computers that have not responded to main mode negotiation attempts since the IPSec service was last started. Although these computers did not respond to main mode negotiation attempts, IPSec policy allowed communications with the computers. Soft SAs are not secured by IPSec. |
| Invalid Packets Received | The total number of invalid IKE messages that have been received since the IPSec service was last started. This number includes IKE messages with invalid header fields, incorrect payload lengths, and incorrect values for the responder cookie. Invalid IKE messages are commonly caused by retransmitted IKE messages or an unmatched preshared key between the IPSec peers. |

**Quick Mode (IPSec) Statistics**

The following table describes the items in the list of quick mode (IPSec) statistics in IP Security Monitor.

| **Quick Mode (IPSec) Statistic** | **Description** |
|---|---|
| Active Security Associations | The number of active quick mode SAs. |
| Offloaded Security Associations | The number of active quick mode SAs offloaded to hardware. Certain network adapters can accelerate IPSec processing by performing hardware offload of IPSec cryptographic functions. |
| Pending Key Operations | The number of IPSec key exchange operations that are in progress but are not yet completed. |
| Key Additions | The total number of keys for quick mode SA negotiations that have been successfully added since the computer was last started. |
| Key Deletions | The total number of keys for quick mode SAs that have been successfully deleted since the computer was last started. |

| | |
|---|---|
| Rekeys | The total number of successful rekey operations for quick mode SAs since the computer was last started. |
| Active Tunnels | The number of active IPSec tunnels. |
| Bad SPI Packets | The total number of packets for which the SPI has been incorrect since the computer was last started. If the SPI is incorrect, it might mean that the inbound SA has expired and a packet using the old SPI has recently arrived. This number is likely to increase if rekey intervals are short and there are a large number of SAs. A large number of packets with bad SPIs that are received within a short amount of time might indicate a packet spoofing attack. |
| Packets Not Decrypted | The total number of packets that could not be decrypted since the computer was last started. A packet might not be decrypted if it fails a validation check. |
| Packets Not Authenticated | The total number of packets for which data could not be verified (for which the integrity hash verification failed) since the computer was last started. Increases in this number might indicate an IPSec packet spoofing or modification attack or packet corruption by network devices. |
| Packets With Replay Detection | The total number of packets that have contained an invalid sequence number since the computer was last started. Increases in this number might indicate a network problem or replay attack. |
| Confidential Bytes Sent | The total number of bytes that have been sent using the Encapsulating Security Payload (ESP) protocol (excluding non-encrypted ESP) since the computer was last started. |
| Confidential Bytes Received | The total number of bytes that have been received using the ESP protocol (excluding non-encrypted ESP) since the computer was last started. |
| Authenticated Bytes Sent | The total number of authenticated bytes that have been sent using the Authentication Header (AH) protocol or the ESP protocol since the computer was last started. |
| Authenticated Bytes Received | The total number of authenticated bytes that have been received using the AH protocol or the ESP protocol since the computer was last started. |
| Transport Bytes Sent | The total number of bytes that have been sent using IPSec transport mode since the computer was last started. |
| Transport Bytes Received | The total number of bytes that have been received using IPSec transport mode since the computer was last started. |
| Bytes Sent in Tunnels | The total number of bytes that have been sent using IPSec tunnel mode since the computer was last started. |
| Bytes Received in Tunnels | The total number of bytes that have been received using IPSec tunnel mode since the computer was last started. |
| Offloaded Bytes Sent | The total number of bytes that have been sent using IPSec hardware offload since the computer was last started. |
| Offloaded Bytes Received | The total number of bytes that have been received using IPSec hardware offload since the computer was last started. |

# Viewing details about active IPSec policies in IP Security Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing details about active IPSec policies in IP Security Monitor**

IP Security Monitor allows you to view details about the active IPSec policies that are applied to the domain, the local computer, or a remote computer. This topic describes the type of details that IP Security Monitor displays.

For information about how to view details about active IPSec policies, see View details about active IPSec policies. For information about creating, assigning, and assigning IPSec policies, see Creating, modifying, and assigning IPSec policies.

**Active IPSec policies that are applied by the domain**

The following table describes the items that are displayed when you use IP Security Monitor to view details about an active IPSec policy that is applied by the domain.

| Active IPSec policy item | Description |
|---|---|
| **Policy Name** | Specifies the name of the active IPSec policy. |
| **Description** | Optional text that describes the purpose of the active IPSec policy. |
| **Policy Last Modified** | Not applicable (this information is displayed only for active IPSec policies that are applied to a computer). |
| **Policy Store** | Specifies the storage location for the active IPSec policy. For active IPSec policies that are applied by the domain, this location appears as "Domain Store." |
| **Policy Path** | Specifies the LDAP path to the active IPSec policy. |
| **Organizational Unit** | Specifies the organizational unit to which the Group Policy object is applied. |
| **Group Policy Object Name** | Specifies the Group Policy object to which the active IPSec policy is applied. |

**Active IPSec policies that are applied to a computer**

The following table describes the items that are displayed when you use IP Security Monitor to view details about active IPSec policies that are applied to a computer.

| Active IPSec policy item | Description |
|---|---|
| **Policy Name** | Specifies the name of the active IPSec policy. |
| **Description** | Optional text that describes the purpose of the active IPSec policy. |
| **Policy Last Modified** | Specifies the date and the time that the active IPSec policy was last modified. |
| **Policy Store** | Specifies the storage location of the active IPSec policy. For active IPSec policies that are applied to a computer, this location appears as "Local Store." |
| **Policy Path** | Not applicable (this information is only displayed for active IPSec policies that are applied by the domain). |
| **Organizational Unit** | Not applicable (this information is only displayed for active IPSec policies that are applied by the domain). |

| | |
|---|---|
| **Group Policy Object Name** | Not applicable (this information is only displayed for active IPSec policies that are applied to the domain). |

**Note**

- You cannot use IP Security Monitor to add, edit, or remove IPSec policies. For information about how to add, edit, or remove IPSec policies, see Add, edit, or remove IPSec policies.

# Using Resultant Set of Policy to view IPSec policy assignments

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Resultant Set of Policy to view IPSec policy assignments**
Resultant Set of Policy (RSoP) is an addition to Group Policy that you can use to view IPSec policy assignments for a computer or for members of a Group Policy container. This information can help you troubleshoot policy precedence issues and plan your deployment.

To view IPSec policy assignments in RSoP, you must first open the RSoP MMC console, and then run a query. RSoP provides two types of queries: logging mode queries (for viewing IPSec policy assignments for a computer) and planning mode queries (for viewing IPSec policy assignments for members of a Group Policy container).

**Logging mode queries**
You can run an RSoP logging mode query to view all of the IPSec policies that are assigned to an IPSec client. The query results display the precedence of each IPSec policy assignment, so that you can quickly determine which IPSec policies are assigned but are not being applied and which IPSec policy is being applied. The RSoP console also displays detailed settings (that is, the filter rules, filter actions, authentication methods, tunnel endpoints, and connection type) for the IPSec policy that is being applied.

When you run a logging mode query, RSoP retrieves policy information from the Windows Management Instrumentation (WMI) repository on the target computer, and then displays this information in the RSoP console. In this way, RSoP provides a view of the policy settings that are being applied to a computer at a given time.

For information about how to run RSoP logging mode queries for IPSec policies, see Use RSoP to view IPSec policy assignments for a computer. For general information about RSoP logging mode queries, see RSoP logging mode. For general information about RSoP, see RSoP overview.

**Planning mode queries**
You can run an RSoP planning mode query to view all of the IPSec policies that are assigned to members of a Group Policy container. For example, a planning mode query can be useful if you are planning a company reorganization and you want to move computers from one organizational unit to a new organizational unit. By supplying the appropriate information and then running a planning mode query, you can determine which IPSec policies are assigned but are not being applied to the new organizational unit and which IPSec policy is being applied. In this way, you can identify which policy would be applied if you were to move the computers to the new organizational unit. As with logging mode queries, when you run a planning mode query, the RSoP console displays detailed policy settings for the IPSec policy that is being applied.

When you run a planning mode query, RSoP retrieves the names of the target user, computer, and domain controller from the WMI repository on the domain controller. WMI then uses the Group Policy Data Access Service (GPDAS) to create the policy settings that would be applied to the target computer, based on the RSoP query settings that you entered. RSoP reads the policy settings from the WMI repository on the domain controller, and then displays this information in the RSoP console user interface.

For information about how to run RSoP planning mode queries for IPSec policies, see Use RSoP to view IPSec policy assignments for members of a Group Policy container. For general information about RSoP planning mode queries, see RSoP planning mode.

### Note

- You can run an RSoP planning mode query only on a domain controller (when you run a planning mode query, you must explicitly specify the domain controller name). However, you can specify any IPSec client as the target for the query, provided you have the appropriate permissions to do so.

**Assigning and processing IPSec policy in Group Policy**
IPSec policies can be assigned from and stored in Active Directory, as part of Group Policy, or they can be assigned and stored locally, on a computer. When a computer is joined to an Active Directory domain, the domain-level IPSec policy applies. If a computer is not joined to an Active Directory domain, the local IPSec policy applies.

Group Policy settings are contained in Group Policy objects, which are linked with specific Active Directory objects (sites, domains, and organizational units). When an IPSec policy is assigned to a Group Policy object for an Active Directory object (such as an organizational unit), that IPSec policy is propagated to any computer accounts that are affected by the Group Policy

object.

Multiple Group Policy objects, each of which can contain an IPSec policy, can be assigned to a computer account. When multiple IPSec policies are assigned, the last policy that is processed is the policy that is applied (that is, the last policy takes the highest precedence and overrides the settings of any IPSec policy assignments that were processed earlier).

Policy precedence is based on the Group Policy inheritance model. The policy used is the policy assigned at the lowest level of the domain hierarchy for the domain container of which the computer is a member. For example, if there are IPSec policies that are configured for both the domain and for an organizational unit within the domain, the computers that are members of the domain use the domain IPSec policies. The computers that are members of the organizational unit within the domain use the organizational unit IPSec policies. If there are multiple organizational units, members of each organizational unit use the IPSec policy assigned to the organizational unit that is closest in level to their container in the Active Directory hierarchy. If no IPSec policies are configured for Active Directory, or if a computer is not connected to an Active Directory domain, the local IPSec policy is used.

**IPSec policy information displayed in the RSoP console**
The RSoP console simplifies the task of determining which IPSec policy is being applied by displaying the following information for each Group Policy object that contains an IPSec policy assignment: the name of the IPSec policy, the name of the Group Policy object that the IPSec policy is assigned to, the IPSec policy precedence (the lower the number, the higher the precedence), and the name of the site, domain, and organizational unit to which the Group Policy object containing the IPSec policy applies (that is, the scope of management for the Group Policy object).

For information about policy precedence and IPSec policy behavior in an Active Directory environment, see the section "Active Directory-based policy" in Creating, modifying, and assigning IPSec policies. For general information about Group Policy, see Group Policy overview.

### Note

- The settings of the IPSec policy with the highest precedence apply in their entirety; they are not merged with the settings of IPSec policies that are applied at higher levels of the Active Directory hierarchy.

# IPSec Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

**Windows Resource Kits**
The Windows Resource Kits contain extensive technical information on TCP/IP and IPSec. For more information, see Using the Windows Deployment and Resource Kits.

**IPSec-related Web sites**
The following Web sites contain links that relate to IPSec:

- The IPSec Working Group page contains links to RFCs, Internet Drafts, and other IPSec-related links at the Internet Engineering Task Force Web site.
- For information and the latest recommendations on security, see Microsoft Security at the Microsoft Web site.
- For information about the standards and technology for IPSec, as well as other computer security topics, see the National Institute of Standards and Technology Web site.

**Note**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# IPSec Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Traffic is not being secured.
- IPSec SA negotiation is failing.
- IPSec SA negotiation is failing when using certificate authentication.
- Some computers are unable to communicate with secure computers.
- Local computer IPSec policy is not being used.
- Unable to assign or unassign an IP Security policy.
- DES is being used when 3DES is needed.
- Unsecured traffic is being sent to a secure server.
- Event Viewer is displaying error messages related to IPSec.
- A policy location error message is displayed.
- Event Viewer is displaying "Bad SPI" error message.
- IP Security Monitor displays the error message "The IPSec server is unavailable or incompatible with the IPSec monitor."

**Traffic is not being secured.**
**Cause:** An IPSec security association (SA) that secures traffic (also known as a hard SA) is not being established.

**Solution:** This might be caused by either filter list misconfiguration or the enabling of unsecured communication with non-IPSec-aware computers. Examine the policies that are assigned to both IPSec peers and determine, based on the rules, filter lists, and filter action settings, whether IPSec requires traffic to be secured. Check to determine whether the **Allow unsecured communication with non-IPSec-aware computer** option on the **Security Methods** tab of the appropriate filter action is enabled. Use audit logging to determine the cause of the failed negotiation.

**See also:** IPSec troubleshooting tools; Add, edit, or remove IPSec security methods

**IPSec SA negotiation is failing.**
**Cause:** An IPSec security association (SA) that secures traffic (also known as a hard SA) is not being established. If unsecured communication with non-IPSec-aware computers is enabled, the negotiation failure is expected.

Negotiation failure between two IPSec-aware computers commonly occurs when the default policies are used on two IPSec peers and one or both are not members of an Active Directory domain. Computers running Windows XP Home Edition do not support Active Directory domain membership or the Kerberos V5 authentication method. Default policies use the Kerberos V5 authentication method, which does not work for computers that are not Active Directory domain members.

**Solution:** A negotiation failure between two IPSec-aware computers is most often caused by a mismatched key exchange method, authentication method, or security method. Examine the policies that are assigned to both IPSec peers and determine, based on the advanced settings, rules, filter lists, and filter action settings, whether IPSec should be securing the traffic. If it should, determine whether there is a mismatched key exchange, authentication method, or security method that is preventing a successful negotiation of a hard SA. Use audit logging to determine the cause of the failed negotiation.

**See also:** IPSec troubleshooting tools; Add, edit, or remove IPSec security methods; Define IPSec authentication methods;

Create key exchange security methods

**IPSec SA negotiation is failing when using certificate authentication.**
**Cause:** The correct computer certificates are not installed on the IPSec peers.

**Solution:** Install the correct computer certificates on the IPSec peers.

**Cause:** An incorrect certification authority (CA) is selected in the authentication method.

**Solution:** For the rules of each IPSec peer, select the CA that issued the computer certificate that is installed on the other IPSec peer.

**Cause:** The certificate chain from the issuing CA to the root CA is broken.

**Solution:** Install a computer certificate on each IPSec peer that follows a valid certificate chain up to a trusted root CA.

**Cause:** The computer certificate on one or both of the IPSec peers has expired.

**Solution:** Install a current computer certificate on each IPSec peer.

**See also:** IPSec troubleshooting tools; Authentication methods; Define IPSec authentication methods; Special IPSec considerations; Using Certificates

**Some computers are unable to communicate with secure computers.**
**Cause:** Secure computers are using a lockdown policy that requires client computers to initiate secure communications. The computers that are unable to communicate are not configured with a rule to initiate secure communication.

**Solution:** Either allow unsecured incoming connection requests on the secure servers or configure additional rules for the computers that are unable to communicate so that they can initiate secure communication with the secure computers.

**Cause:** Client computers are not IPSec-capable and secure computers are not allowing unsecured communications.

**Solution:** Either install client computers that are IPSec-capable or reconfigure the secure computers to allow communication with computers that are not IPSec-capable.

**Cause:** Some computers are configured with a policy that has a key exchange, authentication method, or security method that is mismatched with the policy configured for the secure computers.

**Solution:** Examine the policies that are assigned to both IPSec peers and determine, based on the advanced settings, rules, filter lists, and filter action settings, whether IPSec should be securing the traffic. If it should, determine whether there is a mismatched key exchange, authentication method, or security method that is preventing a successful SA negotiation. Use audit logging to determine the cause of the failed negotiation.

**See also:** Add, edit, or remove filter actions; IPSec troubleshooting tools; Add, edit, or remove IPSec security methods; Define IPSec authentication methods; Create key exchange security methods

**Local computer IPSec policy is not being used.**
**Cause:** The computer is a member of an Active Directory domain and is receiving Active Directory-based IPSec policy.

**Solution:** All domain members receive Active Directory-based IPSec policy, which overrides local IPSec policy settings. To prevent this, remove the computer from the domain.

**Cause:** The IPSec service is not started.

**Solution:** Start or restart the IPSec service.

**See also:** Restart the IPSec services

**Unable to assign or unassign an IP Security policy.**
**Cause:** You cannot assign or unassign policies when IP Security Policies are used for Active Directory.

**Solution:** To assign Active Directory-based policies, use IP Security Policies within Group Policy.

**See also:** Assign or unassign IPSec policy in Group Policy

**DES is being used when 3DES is needed.**
**Cause:** The IPSec peer is a computer running Windows 2000 without either the Windows 2000 High Encryption Pack or Windows 2000 Service Pack 2 (or later) installed.

**Solution:** Install either the Windows 2000 High Encryption Pack or Windows 2000 Service Pack 2 (or later) on the computer

running Windows 2000.

**Unsecured traffic is being sent to a secure server.**
**Cause:** The client computer is using the default response rule.

**Solution:** When the client computer is configured with the default response rule, it sends unsecured packets when it either initiates communication or restarts communication after a delay long enough for the quick mode SA and dynamic filter list to time out. To prevent this, configure additional rules for client computers that always initiate secure communication to secure servers.

**See also:** Security information for IPSec

**Event Viewer is displaying error messages related to IPSec.**
**Cause:** There might be a problem with either the IPSec Policy Agent or the Oakley service.

**Solution:** View the system and security event logs for messages that might help in determining the origin of the problem.

**A policy location error message is displayed.**
**Cause:** This error might occur if the IPSec Policy Agent is attempting to retrieve policy from an incorrect storage location.

**Solution:** Examine both the IPSec Policy Agent events in Event Viewer and the IPSec Policy Agent log for messages that indicate from what location policy is being retrieved (the local registry or the domain). If **HKLM\SOFTWARE\Policies\Microsoft\Windows\IPSec\GPTIPSecPolicy\DSIPSecPolicyFlags** is set to 1, then IPSec policy is obtained from Active Directory. Otherwise, it is obtained from the registry. The local computer warns a user that domain policy is in effect when it starts. If the policy is supposed to be Active Directory-based, but cannot be obtained, you can delete **HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Group Policy\History** and then restart the computer.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**See also:** View Event Logs.

**Event Viewer is displaying "Bad SPI" error message.**
**Cause:** This error might occur if a key lifetime value is set too low, or if the SA has expired but the sender continues to transmit data to the receiver.

**Solution:** To determine and correct the problem, use IP Security Monitor to examine the number of rekeys. If the number of rekeys is very large compared to the amount of time the connections have been active, set the key lifetimes in the policy to be longer. Good values for high-traffic Ethernet connections are greater than both 50 megabytes and five minutes. This event is usually logged when an SA has been deleted on one IPSec peer, and the other IPSec peer sends secure traffic on the SA. This is usually a temporary situation that occurs on systems that are busy and fixes itself.

**IP Security Monitor displays the error message "The IPSec server is unavailable or incompatible with the IPSec monitor."**
**Cause:** You are using the IP Security Monitor console to monitor IPSec on a computer running Windows 2000.

**Solution:** The IP Security Monitor console can only be used to monitor IPSec on computers running Windows XP or a Windows Server 2003 operating system. To monitor IPSec on a computer running Windows 2000, use the **IPSecmon** command at the Windows 2000 command prompt on the computer that is being monitored.

# Windows Time Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Time Service**
Windows Time Service is a component of Windows XP and the Windows Server 2003 family that automates the synchronization of computers on a network.

- For tips about using Windows Time Service, see Windows Time Service Best practices.
- For help with specific tasks, see Windows Time Service How To....
- For general background information, see Windows Time Service Concepts.
- For problem-solving instructions, see Windows Time Service Troubleshooting.

# Windows Time Service Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Synchronize your domain with an accurate external time source**

  Synchronized clocks are necessary on all computers on the network for the proper operation of many services. You must also ensure that the synchronized time is correct. By default, the computers on the network obtain the time from their authenticating domain controller. The domain controllers on a network obtain their time from their domain's primary domain controller (PDC) operations master or an explicitly configured time source. Because of this, you must ensure that the PDC operations master in each domain is set to the correct time.

  There are many computers on the Internet that provide accurate time information. One such source is the National Institute of Standards and Technology (NIST), which provides the NIST Network Time Service.

- **Check Event Viewer**

  When Windows Time Service encounters errors, it writes events to the system log, so check Event Viewer periodically for messages regarding Windows Time Service. For more information, see Event Viewer.

# Windows Time Service How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Synchronize the client time with a time server
- Synchronize an internal time server with an external time source

# Synchronize the client time with a time server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To synchronize the client time with a time server**

1. Open Command Prompt.
2. Type:

   **w32tm /resync**

## Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- This procedure only works on computers that are joined to a domain. For information about synchronizing computers that are not joined to a domain, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Synchronize an internal time server with an external time source

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To synchronize an internal time server with an external time source**

1. Open Command Prompt.

2. Type the following, where *PeerList* is a comma-separated list of Domain Name System (DNS) names or Internet protocol (IP) addresses of the desired time sources:

   **w32tm /config /syncfromflags:manual /manualpeerlist:***PeerList*

3. Type:

   **w32tm /config /update**

## Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- The most common use of this procedure is to synchronize the internal network's authoritative time source with a very precise external time source. However, this procedure can be run on any computer running Windows XP or a member of the Windows Server 2003 family.

- If the computer cannot reach the servers, the procedure fails and an entry is written to the Event Log.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**

This section provides general background information about Windows Time Service:

- Windows Time Service overview

# Windows Time Service overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Time Service overview**

Computers keep the time on their internal clocks, which allows them to perform any function that requires the date or time. However, for scheduling purposes, the clocks must be set to the correct date and time, and they must be synchronized with the other clocks in the network. Without some other method in place, these clocks must be set manually.

With time synchronization, computers set their clocks automatically to match another computer's clock. One computer maintains very accurate time, and then all other computers set their clocks to match that computer. In this way, you can set accurate time on all computers.

**How Windows Time Service works**

In the Windows Server 2003 family, Windows Time Service automatically synchronizes the local computer's time with other computers on the network. The time source for this synchronization varies, depending on whether the computer is joined to an Active Directory® domain or a workgroup.

When the computers are part of a workgroup, you must manually configure the time synchronization settings. One or more computers might be identified as a locally reliable time source by configuring Windows Time Service on those computers to use a known accurate time source, either by using special hardware or a time source available on the Internet. Then, all other workgroup computers can be configured manually to synchronize their time with these local time sources.

When the computers belong to an family Active Directory domain, Windows Time Service configures itself automatically, using Windows Time Service that is available on domain controllers. Windows Time Service configures a domain controller within its domain as a reliable time source and synchronizes itself periodically with this source. These settings can be modified or overwritten, depending on specific needs.

**Benefits of Windows Time Service**

To function correctly, a number of Windows Server 2003 family components rely on accurate and synchronized time. For example, without clocks that are synchronized to the correct time on all computers, the Kerberos V5 authentication protocol might falsely interpret logon requests as intrusion attempts and deny access to users.

Another important benefit of time synchronization is the ability to correlate events on different computers in an enterprise. With synchronized clocks on all of your computers, you ensure that you can correctly analyze events that happen in sequence on multiple computers for success or failure.

# Windows Time Service Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Clients are not synchronized with servers.
- Windows Time service generates event ID 7023 after upgrading to Windows Server 2003 with Service Pack 1 (SP1).

**Clients are not synchronized with servers.**
**Cause:** Windows Time Service has been stopped manually.

**Solution:** Start Windows Time Service. To start Windows Time Service, follow these steps:

1. Open Command Prompt.
2. Type:

   **net start w32time**

**See also:** Start, stop, pause, resume, or restart a service; Configure how a service is started

**Windows Time service generates event ID 7023 after upgrading to Windows Server 2003 with Service Pack 1 (SP1).**
**Cause:** The LocalService account has not been granted "Change the system time" permissions. Windows Server 2003 with SP1 changes the startup configuration of the Windows Time service from LocalSystem to LocalService. Therefore, the startup account that the Windows Time service uses must have "Change the system time" permissions.

**Solution:** Use Domain Controller Security Policy to grant "Change the system time" permissions to the LocalService account. Alternatively, change the logon account of the Windows Time Service. For more information about performing these solutions, see article Q892501 "The Windows Time service may generate event ID 7023 after you upgrade to Windows Server 2003 Service Pack 1," in the Microsoft Knowledge Base.

# Security Configuration Wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Security Configuration Wizard (SCW) is an attack surface reduction tool for members of the Microsoft® Windows® Server 2003 family with Service Pack 1 (SP1). SCW determines the minimum functionality required for a server's role or roles, and disables functionality that is not required.

For the latest information about SCW, see "Security Configuration Wizard for Windows Server 2003" at the Microsoft Windows Server 2003 Web site. (http://go.microsoft.com/fwlink/?LinkID=42434)

SCW does the following:

- Disables unneeded services.
- Blocks unused ports.
- Allows further address or security restrictions for ports that are left open.
- Prohibits unnecessary IIS web extensions, if applicable.
- Reduces protocol exposure to server message block (SMB), LanMan, and Lightweight Directory Access Protocol (LDAP).
- Defines a high signal-to-noise audit policy.

SCW guides you through the process of creating, editing, applying, or rolling back a security policy based on the selected roles of the server. The security policies that are created with SCW are XML files that, when applied, configure services, network security, specific registry values, audit policy, and if applicable, Internet Information Services (IIS).

**Note**

- In some cases, you must be connected to the Internet to use the links in SCW Help. If your computer is not connected to the Internet, you can find the same topic in Help and Support Center by searching for the link text. To open Help and Support Center, click **Start**, and then click **Help and Support Center**.

You can install SCW on computers running a member of the Windows Server 2003 family with SP1.

- For recommendations about how to get the most out of SCW, see Security Configuration Wizard Best Practices.
- For information about how to perform certain tasks, see Security Configuration Wizard How To.
- For general background information, see Security Configuration Wizard Concepts.

You do not need to run SCW to help secure your computer running Windows Small Business Server 2003. Instead, Windows Small Business Server 2003 uses the default settings in Setup and in the Configure E-mail and Internet Connection Wizard to help secure your server.

If you have not already run the Configure E-mail and Internet Connection Wizard, you should run it to help secure your server.

To start the Configure E-mail and Internet Connection Wizard on the computer running Windows Small Business Server 2003:

- Click **Start** and then click **Server Management**.
- In the console tree, click **Internet and E-mail**.
- In the details pane, click **Connect to the Internet**.

# Security Configuration Wizard Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best Practices**
This section tells how to get the most out of Security Configuration Wizard (SCW).

**Identify and target similar servers**
SCW helps to reduce the attack surface of servers by creating a security policy that is specifically designed for their specific roles. Administrators can simplify policy authoring and distribution by identifying groups of servers that perform the same, or similar, tasks. Here are ways you can do this:

- **Author one policy for a group of servers**. SCW authors a security policy based on the roles, tasks, and functions performed by a server. Others servers that perform the same, or very similar, functions can be configured with the same security policy. Administrators can use SCW once to author a security policy, save it, and apply it to all servers that perform the job function.

- **Group similar servers in one organizational unit (OU)**. The SCW transform operation can apply a security policy to a domain or OU by using Group Policy. To simplify policy distribution, an administrator could group servers that perform similar job functions, and use the same security policy, into a single OU. A new security policy can be distributed quickly and easily to the server OU by using the SCW transform operation.

- **Create policies for similar platforms**. For services or ports specific to 64-bit computers, create the policies on a 64-bit computer. Then deploy these policies to other 64-bit computers only (not 32-bit computers) to ensure the services are properly identified and configured.

It is highly recommended that the prototype server from which the security policy will be created matches the target servers to be configured at the service level. The security policy disables any service on the server that is contained in the Security Configuration Database but was not present on the prototype server when the policy was created. For example, if the DCOM Server Process Launcher service is listed in the Security Configuration Database, but is not present on the prototype server, the security policy created based on the prototype server will set the DCOM Server Process Launcher state to disabled. When you apply the security policy to other servers, the DCOM Server Process Launcher service will be disabled on those servers. You can configure unnecessary services in SCW (you can disable the service or leave the startup mode of the service unchanged), but only services that are not in the Security Configuration Database, and therefore are not defined in the security policy that you create with SCW.

**Test new security policies offline before deployment**

- The settings configured in the new security policies may cause compatibility issues with applications or services. Therefore, thoroughly test new security policies in a test environment before applying the policies to production servers.

**Create one complete security policy**

- SCW should be used to author a single security policy that contains all desired security settings for a server. This will simplify configuration, rollback, and analysis. For simple configuration and rollback, a single security policy for a machine, or set of machines, is much easier to understand and update than a series of policies. If a security policy defines all the desired settings for a server, a compliance report can be generated by executing one scan. This makes analysis using the scwcmd /analyze command easy. For more information about scwcmd, see Security Configuration Wizard command-line tool.

**Organize similar servers into organizational units (OUs) in Active Directory**

- Grouping servers by OUs in Active Directory domains facilitates the application of security policy through Group Policy.

# Security Configuration Wizard How To

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Install Security Configuration Wizard

Install Security Configuration Wizard unattended

Start Security Configuration Wizard

Create, edit, apply, or roll back a security policy

Remove Security Configuration Wizard from a computer

# Install Security Configuration Wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

1. Open **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. Select the **Security Configuration Wizard** check box, click **Next**, and then click **Finish**.

**Notes**

- Security Configuration Wizard (SCW) is an optional component in Windows Server 2003 SP1. To install SCW, you must first install Service Pack 1 for Windows Server 2003.
- To perform this procedure, you must be a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open **Add or Remove Programs**, click **Start**, click **Control Panel**, and then double-click **Add or Remove Programs**.

# Install Security Configuration Wizard unattended

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

1. Before initiating the unattended installation, add the following entry to the **[Components]** section of Unattend.txt: **SCW=On**

To apply an SCW policy during the unattended installation, also carry out the following steps.

1. Create the policy file on a server that already has SCW installed.
2. Either create a Cmdlines.txt file (or modify the existing one) so that it has a **[Commands]** section containing the following line: **scwcmd configure /p:SCWPolicy.xml**
3. Copy the Cmdlines.txt file and the previously created policy file to the **$OEM$** directory. The **$OEM$** directory is specified by the OEMFILESPATH entry in the **[Unattended]** section of Unattend.txt.

**Note**

- For detailed instructions about running unattended installation, see Automating and Customizing Installations on the Microsoft Web Site.

# Start Security Configuration Wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

1. Open **Administrative Tools**.
2. Double-click **Security Configuration Wizard.**

### Notes

- To open Administrative Tools, click **Start**, click **Control Panel**, and then click **Administrative Tools**.
- Security Configuration Wizard (SCW) can be used to author policy and to perform configuration or rollback for one server at a time. The SCW executable is called SCW.exe. To start SCW from the command prompt, type **SCW**.
- The SCW command-line tool can be used for multi-machine configuration, analysis, rollback, and Group Policy object (GPO) policy management. The SCW command-line tool is called scwcmd.exe. To start SCW from the command prompt, type **SCWcmd**. To see SCW command-line help, type scwcmd.exe /?

# Create, edit, apply, or roll back a security policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

1. Start the Security Configuration Wizard.
2. On the **Welcome to the Security Configuration Wizard** page, click **Next**.
3. On the **Configuration Action** page, do one of the following:
   - To create a security policy, click **Create a new security policy**.
   - To edit a security policy, click **Edit an existing security policy**.
   - To apply a security policy, click **Apply an existing security policy**.
   - To roll back a security policy, click **Rollback the last applied security policy**.
4. If you chose to edit or apply an existing security policy, in Existing security policy file, enter the security policy path and file name, or browse to the security policy, and click Next.
5. Complete the Security Configuration Wizard.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- For information about how to open Security Configuration Wizard (SCW), see Related Topics.
- To apply or roll back a security policy that you have created with SCW, SCW must be installed on the selected server. When creating or editing a security policy, you can select a server that does not have SCW installed. In either case, the selected server must always be a computer running a member of the Windows Server 2003 family with Service Pack 1.
- Do not end the SCW task while policy configuration is in progress as this can leave the server in a partially configured state. A policy should instead be rolled back after it has been applied to the system.

# View Change Logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

- At the command prompt, type scwcmd view /x:file_name.xml, where file_name is the name of the change log. Example: scwcmd view /x:AnalysisLog10.xml

**Note**

- When you use Security Configuration Wizard (SCW) to apply a policy, SCW creates a change log file to document the changes. Change logs are stored in the following directory:

  %windir%\security\msscw\ChangeConfigurationLogs

# Remove Security Configuration Wizard from a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

1. Open **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. Clear the **Security Configuration Wizard** check box, click **Next**, and then click **Finish**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open **Add or Remove Programs**, click **Start**, click **Control Panel**, and then double-click **Add or Remove Programs**.
- When Security Configuration Wizard (SCW) is uninstalled, all files contained in the %Windir%\Security\Msscw folder are removed. This includes all policy files, log files, and rollback files that were created after SCW was installed.

Understanding Security Configuration Wizard

# Security Configuration Wizard Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Security Configuration Wizard (SCW) is an attack surface reduction tool for computers running a member of the Windows Server 2003 family with Service Pack 1 (SP1). SCW guides you through the process of creating a security policy, based on the roles performed by a given server. Once a policy is created, it can be edited or applied to one or more similarly configured servers. Applied policies can be rolled back in order to undo changes that have caused problems. To edit, apply, or roll back a security policy, the policy must have been created with SCW.

SCW can only be installed on computers running a member of the Windows Server 2003 family with SP1. Also, the server that you are configuring must be running a member of the Windows Server 2003 family with SP1.

SCW is composed of the following sections:

- Role-based service configuration
- Network security
- Registry settings
- Audit policy
- Internet Information Services (IIS)

You will not see the IIS section if you have not selected the Web Server role on the Select Server Roles page of SCW.

SCW helps reduce the attack surface of a configured server, and you can use other security features to further secure your computers. For more information, see Security on the Microsoft Web Site.

The security policy that you create is based on the roles that are installed on the selected server. The selected server can be a server to which you want to apply the security policy, or you can use the selected server to create a security policy, and then apply the security policy to a group of servers that perform similar roles as the selected server. For example, if you want to create a security policy for all of the file servers in your organization, you can choose one representative file server as the selected server, use that server to create the security policy, and then apply the security policy to each file server in your organization. For more information about selecting a server, see Select Server Roles.

While using SCW to configure a policy, if you are not sure of the correct selection for your environment, it is recommended that you skip the associated sections by clicking Next and then configure the rest of the security policy. You can configure the skipped sections later, once you are familiar with the technology. SCW does not configure skipped sections. These sections are left undefined until you edit the policy and configure those sections. However, you cannot skip the Role-Based Service Configuration section.

**Deploying SCW security policies by means of Group Policy**

SCW policies are XML files that can contain settings for services, Windows Firewall, Internet Protocol security (IPsec), registry values, audit policy, IIS, and other settings that are imported from existing security templates. These SCW XML policy files are not natively supported by the Group Policy infrastructure. Instead, SCW XML policy files must be transformed into formats that the various Group Policy extensions understand. The SCW command line tool, Scwcmd.exe, provides the Transform operation. For help with this tool, at a command prompt, type **scwcmd transform**. In short, the administrator provides the Transform operation with the name of the SCW policy file to be transformed, along with the name of a Group Policy object (GPO) to be created. The Transform operation then creates the GPO and defines the settings for these Group Policy extensions:

- **Security Settings** contains service settings, registry values, audit policy and security template settings that were imported into the SCW XML policy.
- **IP Security Policies** contains the IPsec configuration that is defined in the SCW policy.
- **Windows Firewall** contains Windows Firewall settings that are defined in the SCW policy.

After the GPO is created, the administrator must manually link the GPO to the target organizational unit (OU) by using Active Directory Users and Computers, or by using the Group Policy Management Console.

**Notes**

- For more information about Group Policy, see Configure Group Policy. For more information about scwcmd.exe, see Security Configuration Wizard command-line tool. For more information about OUs, see Organizational units. For the latest information about Windows Firewall performance considerations, see Windows Firewall on the Microsoft Web Site.
- You must be logged on with an account that is a member of the Domain Admins group in order to perform the Transform operation.
- The Transform operation must be performed from a server that is joined to the domain where the Group Policy object will apply.
- Any IIS settings that are defined in the SCW policy will be lost during the Transform operation because Group Policy does not have an IIS extension.
- The OU hierarchy in Active Directory must be organized along server roles in order to take advantage of SCW-generated policies. There should be a separate OU for each server role supported by your organization.
- Applying SCW-generated policies to servers running versions of Windows earlier than Windows Server 2003 with SP1 is not supported. Use the WMI filtering capabilities of Group Policy to ensure that SCW-generated policies do not apply to servers running versions of Windows earlier than Windows Server 2003 with SP1. Alternatively, place only servers running Windows Server 2003 with SP1 into the OUs where the transformed SCW policies will apply.

**Roles**

*Server roles* are the main functions performed by the servers in your organization. Examples of server roles are file server, domain controller, and Web server roles. *Client features* use services provided by other servers. Examples of client features are the domain member and Dynamic Host Configuration Protocol (DHCP) client.

A role is defined by the services, ports, and IIS requirements that are necessary to perform the role. The specific services, inbound ports, and settings that are required vary for each role. As a result, security policies created by SCW are specific to servers that perform the same roles as the selected server. If you apply a file server security policy to a Web server, the services, inbound ports, and settings that are required to perform the Web server role are disabled and the file server security policy settings are enabled. In some cases, security policies are specific to the selected server and must be modified before applying them to other servers.

To determine which services are required for a server to perform a certain role, on the **Select Server Roles, Select Client Features**, and **Select Administration and Other Options pages**, click the triangle between the check box and the role name. Information about the role appears below its name, including a brief description and the required services.

SCW analyzes the selected server to determine which roles it performs. The scanning and analysis process is guided by the *Security Configuration Database*. The Security Configuration Database also contains information about services that are required to perform a role, as well as ports that must be open, if applicable.

For more information about the Security Configuration Database, see Security Configuration Database.

By using the information in the Security Configuration Database, SCW determines which roles the selected server is capable of performing with the software that is currently installed and which roles the server is currently configured to perform. If a server is currently configured to perform a specific role, that role is automatically selected by default, and the role appears in the **Installed server roles** view on the **Select Server Roles** page, and the same is true for the **Select Client Features** and **Select Administration and Other Options** pages. If a server is likely performing a specific role, then that installed role is automatically selected by default.

Selecting roles from the **All roles** view will have no effect on the selected server with the software that is currently installed. These views are useful if you plan to install other roles on the selected server or if you plan to apply the security policy to multiple servers that perform similar roles, but have slight differences.

For more information, see Security Configuration Wizard.

# Security Configuration Wizard command-line tool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Security Configuration Wizard (SCW) includes the Scwcmd.exe command-line tool. You can use Scwcmd for the following tasks:

- Configure one or many servers with an SCW-generated policy.
- Analyze one or many servers with an SCW-generated policy.
- View analysis results in HTML format.
- Roll back SCW policies.
- Transform an SCW-generated policy into native files that are supported by Group Policy.
- Register a Security Configuration Database extension with SCW.

When you use scwcmd to configure, analyze, or roll back a policy on a remote server, SCW is required to be installed on the remote server.

**Getting command-line help for Scwcmd**
To get basic help on the Scwcmd tool, at a command prompt, type **scwcmd**.

**Viewing formatted analysis results with the scwcmd /view command**
The directory %windir%\security\msscw\transformfiles contains .xsl transform files. These are applied to the .xml policy file for the rendering process when you view analysis results through the scwcmd /view command.

# Extending the Security Configuration Database

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This is an advanced topic for developers with XML expertise and for IT professionals.

You can create a new Security Configuration Database file or custom applications in your environment.

**Caution**

- When customizing the Security Configuration Database, do not make changes to W2K3.xml or to any other XML files that are included with Security Configuration Wizard (SCW).

You can create a new Security Configuration Database so that it is customized for your environment. For example, you may be creating a security policy and your organization uses custom applications that require specific services to be enabled or ports to be open. You can customize the Security Configuration Database to contain this information. For more information about the Security Configuration Database, see Security Configuration Database.

**Caution**

- When customizing the Security Configuration Database, do not make changes to W2K3.xml.

Create your own XML file and save it to **%Systemroot%\Security\Msscw\KBs**. To customize an existing role, in your custom Security Configuration Database, create a new role with the same role type and name as the role in W2K3.xml. For example, if you want to customize the file server role, in your custom XML file, you would create a role with Server and File. You can customize the entries for <Selected>, <Services>, and <Ports>. Then, open KBReg.xml and replace <**Custom** /> with <**Custom**>Custom_KB_Name.**xml** </**Custom**>.

For more information about the Security Configuration Database, see Security Configuration Database.

# Rolling back a security policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use Security Configuration Wizard (SCW) to roll back a security policy after it is applied.

You are not limited to one rollback. However, to avoid administrative overhead, do not roll back a policy more often than you must. Make multiple changes during each SCW session, rather than running through SCW several times and creating a separate policy each time.

If, after you roll back a security policy, some services do not behave as expected, check whether services that were started manually were stopped. If you apply a security policy that disables manually-started services and then roll back this policy, those services might need to be restarted manually.

# Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Active Directory**
Active Directory® is a directory service that stores information about objects on a network and makes this information available to users and network administrators.

- Before deploying Active Directory, see Active Directory Checklists.
- To find administrative tool equivalents that have changed from Windows NT® 4.0 Server, see New ways to do familiar Active Directory tasks.
- For tips about using Active Directory, see Active Directory Best practices.
- For help with specific tasks, see Active Directory How To....
- For general background information, see Active Directory Concepts
- For problem-solving instructions, see Active Directory Troubleshooting.

# Active Directory Checklists

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

- Checklist: Creating a new forest
- Checklist: Creating a new child domain
- Checklist: Creating a new domain tree
- Checklist: Creating an additional domain controller in an existing domain
- Checklist: Creating a group
- Checklist: Configuring a site
- Checklist: Optimizing intersite replication
- Checklist: Creating a forest trust

# Checklist: Creating a new forest

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Creating a new forest**

| Step | Reference |
|---|---|
| (Optional) Review concepts and key DNS implications to consider before setting up a new forest. | Creating a new forest |
| (Optional) Review concepts about security and other options available when using the Active Directory Installation Wizard. | Using the Active Directory Installation Wizard |
| Verify that the server on which you will be installing Active Directory has an NTFS partition. | Reformatting or converting a partition to use NTFS |
| (Optional) Review the role of a domain controller. | Domain controllers |
| (Optional) Review concepts on Domain Name System (DNS) namespace planning and how Active Directory is integrated with DNS. | Namespace planning for DNS; Configure a DNS server for use with Active Directory; DNS integration |
| Verify that you are a member of the Administrators group on the server on which you will be installing Active Directory. | Default groups |
| Verify that DNS is properly configured before installing Active Directory. | Checklist: Verifying DNS before installing Active Directory |
| Create the domain controller. | Create a new forest |

# Checklist: Creating a new child domain

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Creating a new child domain**

| Step | Reference |
| --- | --- |
| (Optional) Review concepts about adding new child domains. | Creating a new child domain |
| (Optional) Review concepts about security and other options available when using the Active Directory Installation Wizard. | Using the Active Directory Installation Wizard |
| Verify that the server on which you will be installing Active Directory has an NTFS partition. | Reformatting or converting a partition to use NTFS |
| Verify that you are a member of the Enterprise Admins group or the Domain Admins group of the parent domain. | Default groups |
| Verify that DNS is properly configured before installing Active Directory. | Checklist: Verifying DNS before installing Active Directory |
| Create the domain controller. | Create a new child domain |

# Checklist: Creating a new domain tree

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Creating a new domain tree**

| Step | Reference |
|---|---|
| (Optional) Review concepts about adding new domain trees. | Creating a new domain tree |
| (Optional) Review concepts about security and other options available when using the Active Directory Installation Wizard. | Using the Active Directory Installation Wizard |
| Verify that the server on which you will be installing Active Directory has an NTFS partition. | Reformatting or converting a partition to use NTFS |
| Verify that you are a member of the Enterprise Admins group or the Domain Admins group in the forest root domain. | Default groups |
| Verify that DNS is properly configured before installing Active Directory. | Checklist: Verifying DNS before installing Active Directory |
| Create the domain controller. | Create a new domain tree |

# Checklist: Creating an additional domain controller in an existing domain

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Creating an additional domain controller in an existing domain**

| Step | Reference |
|---|---|
| (Optional) Review concepts about creating additional domain controllers over the network or by using backup media. | Creating an additional domain controller |
| (Optional) Review concepts about security and other options available when using the Active Directory Installation Wizard. | Using the Active Directory Installation Wizard |
| Verify that the server on which you will be installing Active Directory has an NTFS partition. | Reformatting or converting a partition to use NTFS |
| (Optional) Review the role of a domain controller. | Domain controllers |

# Checklist: Creating a forest trust

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Creating a forest trust**

| Task | Reference |
|---|---|
| (Optional) Review the various trust types and understand forest trust concepts. | Trust types; Forest trusts; When to create a forest trust; Accessing resources across forests; Routing name suffixes across forests |
| Ensure that Domain Name System (DNS) is properly set up.<br><br>If there is a root DNS server that can be made the root DNS server for both of the forest DNS namespaces, make it the root server by ensuring that the root zone contains delegations for each of the DNS namespaces. Also, update the root hints of all DNS servers with the new root DNS server.<br><br>If there is no shared root DNS server and the root DNS servers for each forest DNS namespace are running a member of the Windows Server 2003 family, configure DNS conditional forwarders in each DNS namespace to route queries for names in the other namespace.<br><br>If there is no shared root DNS server, and the root DNS servers for each forest DNS namespace are not running a member of the Windows Server 2003 family, configure DNS secondary zones in each DNS namespace to route queries for names in the other namespace. | Verify a zone delegation using the nslookup command; Update root hints on the DNS server; Configure a DNS server to use forwarders; Add a secondary server for an existing zone; Namespace planning for DNS |
| Set the forest functional level in both forests to Windows Server 2003. | Raise the forest functional level |
| Create a forest trust. | Create a forest trust |

# New ways to do familiar Active Directory tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**
The following table lists common tasks for configuring Active Directory. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

### Note

- There are no significant user interface differences between Windows 2000 and the Windows Server 2003 family of products for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Install a domain controller | Windows Setup | The Active Directory Installation Wizard.<br><br>For more information, see Using the Active Directory Installation Wizard;Create a new forest;Create a new domain tree;Create a new child domain;Create an additional domain controller. |
| Manage users | User Manager | Active Directory Users and Computers.<br><br>For more information, see Manage Users. |
| Manage groups | User Manager | Active Directory Users and Computers. For more information, see Manage Groups. |
| Manage computer accounts | Server Manager | Active Directory Users and Computers. For more information, see Manage Computers. |
| Add a computer to a domain | Server Manager | Active Directory Users and Computers.<br><br>For more information, see Manage Computers. |
| Create or manage trust relationships | User Manager | Active Directory Domains and Trusts. For more information, see Manage Trusts. |
| Manage account policy | User Manager | Active Directory Users and Computers.<br><br>For more information, see Account and local policies. |
| Manage user rights | User Manager | Active Directory Users and Computers. Edit the Group Policy object for the domain or organizational unit containing the computers to which the user rights apply. For more information, see Edit security settings on a Group Policy object. |
| Manage audit policy | User Manager | Active Directory Users and Computers.<br><br>Edit the Group Policy object assigned to the Domain Controllers organizational unit. For more information, see Edit security settings on a Group Policy object. |

# Active Directory Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **As a security best practice, it is recommended that you do not log on to your computer with administrative credentials.**

  When you are logged on to your computer without administrative credentials, you can use Run as to accomplish administrative tasks.

  For more information, see Why you should not run your computer as an administrator and Using Run as.

- **To further secure Active Directory, it is recommended that you implement the following security guidelines:**

  - Rename or disable the Administrator account (and guest account) in each domain to prevent attacks on your domains. For more information, see User and computer accounts.

  - Physically secure all domain controllers in a locked room. For more information, see Domain controllers and Securing Active Directory.

  - Manage the security relationship between two forests and simplify security administration and authentication across forests. For more information, see Forest trusts.

  - To provide additional protection for the Active Directory schema, remove all users from the Schema Admins group, and add a user to the group only when schema changes need to be made. Once the change has been made remove the user from the group.

  - Restrict user, group, and computer access to shared resources and to filter Group Policy settings. For more information, see Group types.

  - Avoid disabling the use of signed or encrypted LDAP traffic for Active Directory administrative tools. For more information, see Connecting to domain controllers running Windows 2000.

  - Some default user rights assigned to specific default groups may allow members of those groups to gain additional rights in the domain, including administrative rights. Therefore, your organization must equally trust all personnel that are members of the Enterprise Admins, Domain Admins, Account Operators, Server Operators, Print Operators and Backup Operators groups. For more information about these groups, see Default groups.

  - Use global groups or universal groups instead of domain local groups when specifying permissions on domain directory objects replicated to the global catalog. For more information, see Global catalog replication.

    For general security information about Active Directory, see Security information for Active Directory and Securing Active Directory.

- **Establish as a site every geographic area that requires fast access to the latest directory information.**

  Establishing areas that require immediate access to up-to-date Active Directory information as separate sites will provide the resources required to meet your needs.

  For more information, see Create a site.

- **Place at least one domain controller in every site, and make at least one domain controller in each site a global catalog.**

Sites that do not have their own domain controllers and at least one global catalog are dependent on other sites for directory information and are less efficient.

For more information, see Enable or disable a global catalog.

- **Perform regular backups of domain controllers in order to preserve all trust relationships within that domain.**

  For more information, see Domain controllers.

# Active Directory How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Manage Users, Groups, and Computers
- Publish Resources
- Manage Domains
- Manage Operations Master Roles
- Manage Trusts
- Manage Forests
- Manage Sites
- Manage COM+ Partitions and Partition Sets
- Search Active Directory

# Manage Users, Groups, and Computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage users, groups, and computers**

- Manage Users
- Manage Groups
- Manage Computers

# Manage Users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage users**

- Create a new user account
- Reset a user password
- Copy a user account
- Move a user account
- Set logon hours
- Disable or enable a user account
- Map a certificate to a user account
- Change a user's primary group
- Delete a user account
- Rename a user account

# Create a new user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new user account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the folder in which you want to add a user account.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder*

3. Point to **New**, and then click **User**.
4. In **First name**, type the user's first name.
5. In **Initials**, type the user's initials.
6. In **Last name**, type the user's last name.
7. Modify **Full name** to add initials or reverse order of first and last names.
8. In **User logon name**, type the user logon name, click the UPN suffix in the drop-down list, and then click **Next**.

   If the user will use a different name to log on to computers running Windows 95, Windows 98, or Windows NT, then you can change the user logon name as it appears in **User logon name (pre-Windows 2000)** to the different name.

9. In **Password** and **Confirm password**, type the user's password, and then select the appropriate password options.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To add a user, you can also click

  on the toolbar.

- To add a user, you can also copy any previously created user account. For more information, see Related Topics.

- A new user account with the same name as a previously deleted user account does not automatically assume the permissions and group memberships of the previously deleted account because the security ID (SID) for each account is unique. To duplicate a deleted user account, all permissions and memberships must be manually recreated.

- For interoperability with other directory services, you can create an InetOrgPerson user object. To create a new inetOrgPerson, in step three, click **InetOrgPerson** instead of **User**. For more information about InetOrgPerson, see User and computer accounts in Related Topics.

- When creating a new user, the full name attribute is created in the *FirstNameLastName* format by default. The full name attribute also governs the display name format that is shown in the global address list. You can change the display name format by using ADSI Edit. If you do so, this will also change the full name format. For more information, see article Q250455, "How to Change Display Names of Active Directory Users" in the Microsoft Knowledge Base.

- Windows NT 4.0 and earlier domains allow the use of a period (.) at the end of a user logon name as long as the user logon name does not consist solely of period characters. Windows Server 2003 domains do not allow the use of a period or multiple periods at the end of a user logon name.

#### Using a command line

1. Open Command Prompt.

2. Type:

   **dsadd user***UserDN* [**-samid***SAMName*] **-pwd** {*Password*|*****}

| Value | Description |
|---|---|
| *UserDN* | Specifies the distinguished name of the user object to be added. |
| *SAMName* | Specifies the Security Accounts Manager (SAM) name as the unique SAM account name for this user (for example, Linda). If not specified, dsadd will attempt to create the SAM account name using up to the first 20 characters from the common name (CN) value of UserDN. |
| *Pwd* | Specifies the password to be used for the user account. If set to *, you are prompted for a user password. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To add a user, you can also copy any previously created user account. For more information, see Related Topics.

- A new user account with the same name as a previously deleted user account does not automatically assume the permissions and group memberships of the previously deleted account because the security ID (SID) for each account is unique. To duplicate a deleted user account, all permissions and memberships must be manually recreated.

- To view the complete syntax for this command, and for information on entering more user account information, at a command prompt, type:

  **dsadd user /?**

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reset a user password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reset a user password**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. In the details pane, right-click the user whose password you want to reset, and then click **Reset Password**.
4. Type and confirm the password.
5. If you want to require the user to change this password at the next logon process, select the **User must change password at next logon** check box.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Services that are authenticated with a user account must be reset if the password for the service's user account is changed.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod user***UserDN***-pwd***NewPassword*
3. If you want to require the user to change this password at the next logon process, Type:

   **dsmod user***UserDN***-mustchpwd** {**yes**|**no**}

| Value | Description |
| --- | --- |
| *UserDN* | Specifies the distinguished name of the user for which the password will be reset. |
| *NewPassword* | Specifies the password that will replace the current user password. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If a password is not assigned, then the first time the user tries to log on (using a blank password), a logon message will appear that says "You are required to change your password at first logon" and after user has changed the password, the logon process continues.

- Services that are authenticated with a user account must be reset if the password for the service's user account is changed.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod user /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Copy a user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a user account**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. In the details pane, right-click the user account that you want to copy, and then click **Copy**.
4. In **First name**, type the user's first name.
5. In **Last name**, type the user's last name.
6. Modify **Full name** to add initials or reverse order of first and last names.
7. In **User logon name**, type the user logon name, click the UPN suffix in the drop-down list, and then click **Next**.

   If the user will use a different name to log on to computers running Windows 95, Windows 98, or Windows NT, then you can change the user logon name as it appears in **User logon name (pre-Windows 2000)** to the different name.
8. In **Password** and **Confirm password**, type the user's password, and then select the appropriate password options.

   If the user account from which the new user account was copied was disabled, click **Account is disabled** to enable the new account.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- After creating the user account, edit the user account properties to enter additional user account information.
- Only the most commonly used attributes, such as logon hours, workstation restrictions, and account expiration restrictions are transferred to the copied user by default.
- You can modify which default attributes are carried over to a newly copied user or specify additional attributes that will be copied to the new user. To do this, open the Active Directory Schema snap-in, view the desired attribute properties, and select (or clear) the **Attribute is copied when duplicating user** check box. You can only modify or add attributes that are instances of the user class. If the Active Directory Schema snap-in is not installed, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Move a user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To move a user account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. In the details pane, right-click the user you want to move, and then click **Move**.
4. In the **Move** dialog box, click the folder to which you want to move the user account.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- You cannot use Active Directory Users and Computers to move user accounts between domains. To move a user account between domains, use Movetree, one of the Active Directory support tools. For more information, see Related Topics.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmove***UserDN* [**-newparent** ParentDN]

| Value | Description |
|---|---|
| *UserDN* | Specifies the distinguished name of the user object to be moved. |

| | |
|---|---|
| *ParentDN* | Specifies the new location to which you want to move the user object. The new location is specified as the distinguished name of the new parent node. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, and for information on entering more user account information, at a command prompt, type:

  **dsmove /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set logon hours

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set logon hours**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. Right-click the user account, and then click **Properties**.
4. On the **Account** tab, click **Logon Hours**, and then set the permitted or denied logon hours for the user.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To modify the logon hours for multiple users, press and hold down CTRL, and then click each user. Right-click the selected users, and then click **Properties**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable or enable a user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable or enable a user account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. In the details pane, right-click the user.
4. Depending on the status of the account, do one of the following:

   - To disable, click **Disable Account**.
   - To enable, click **Enable Account**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To prevent a particular user from logging on for security reasons, you can disable user accounts rather than deleting user accounts.
- By creating disabled user accounts with common group memberships, you can use disabled user accounts as account templates to simplify user account creation. For more information, see Related Topics.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod user***UserDN***-disabled** {**yes**|**no**}

| Value | Description |
| --- | --- |
| *UserDN* | Specifies the distinguished name of the user object to be disabled or enabled. |
| {**yes**\|**no**} | Specifies whether the user account is disabled for log on (**yes**) or not (**no**). |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod user /?**

- To prevent a particular user from logging on for security reasons, you can disable user accounts rather than deleting user accounts.

- By creating disabled user accounts with common group memberships, you can use disabled user accounts as account templates to simplify user account creation. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Map a certificate to a user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To map a certificate to a user account**

1. Open Active Directory Users and Computers.
2. On the **View** menu, select **Advanced Features**.
3. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers\domain node\Users

   Or, click the folder that contains the user account.
4. In the details pane, click the user account to which you want to map a certificate.
5. On the **Action** menu, click **Name Mappings**.
6. In the **Security Identity Mapping** dialog box, on the **X.509 Certificates** tab, click **Add**.
7. Type the name and path of the .cer file that contains the certificate you want to map to this user account, and then click **Open**.
8. Do one of the following:

| To | Do this |
|---|---|
| Map the certificate to one account (one-to-one mapping) | Confirm that both the **Use Issuer for alternate security identity** and the **Use Subject for alternate security identity** check boxes are selected. |
| Map any certificate that has the same subject to the user account, regardless of the issuer of the certificate (many-to-one mapping) | Clear the **Use Issuer for alternate security identity** check box, and confirm that the **Use Subject for alternate security identity** check box is selected. |
| Map any certificate that has the same issuer to the user account, regardless of the subject of the certificate (many-to-one mapping) | Clear the **Use Subject for alternate security identity** check box, and confirm that the **Use Issuer for alternate security identity** check box is selected. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- The certificate you are mapping to a user account must be in Distinguished Encoding Rules (DER) or Base64 encoded binary format. For instructions on exporting an existing certificate to a .cer file, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change a user's primary group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a user's primary group**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. In the details pane, right-click the user you want to change, and then click **Properties**.
4. On the **Member of** tab, click the group that you want to set as the user's primary group, and then click **Set Primary Group**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- The user's primary group applies only to users who log on to the network through Services for Macintosh or to who run POSIX-compliant applications. Unless you are using these services, there is no need to change the primary group from Domain Users, which is the default value.
- Setting the user's primary group membership to a value other than Domain Users may adversely impact performance as all users in the domain are members of Domain Users. If the user's primary group is set to another group, it may cause the group membership to exceed the supported maximum number of members.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a user account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. In the details pane, right-click the user account, and then click **Delete**.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Once a user account has been deleted, all permissions and memberships associated with that user account are permanently deleted. Because the security ID (SID) for each account is unique, a new user account with the same name as a previously deleted user account does not automatically assume the permissions and memberships of the previously deleted account. To duplicate a deleted user account, all permissions and memberships must be manually recreated.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsrm***ObjectDN*

| Value | Description |
|---|---|
| *ObjectDN* | Specifies the distinguished name of the user object to be deleted. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the

Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Once a user account has been deleted, all permissions and memberships associated with that user account are permanently deleted. Because the security ID (SID) for each account is unique, a new user account with the same name as a previously deleted user account does not automatically assume the permissions and memberships of the previously deleted account. To duplicate a deleted user account, all permissions and memberships must be manually recreated.

- To view the complete syntax for this command, at a command prompt, type:

  **dsrm /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage groups**

- Create a new group
- Add a member to a group
- Allow anonymous users to be members of the Everyone security group on a domain controller
- Convert a group to another group type
- Change group scope
- Delete a group
- Find groups in which a user is a member
- Assign user rights to a group in Active Directory

# Create a new group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the folder in which you want to add a new group.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder*

3. Point to **New**, and then click **Group**.
4. Type the name of the new group.

   By default, the name you type is also entered as the pre–Windows 2000 name of the new group.

5. In **Group scope**, click one of the options.
6. In **Group type**, click one of the options.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To add a group, you can also click the folder in which you want to add the group, and then click

  on the toolbar.

- If the domain in which you are creating the group is set to the domain functional level of Windows 2000 mixed, you can select only the **Security** group type with **Domain local** or **Global** scopes. For more information, see Related Topics.
- In Active Directory Users and Computers, by default, the name that you type is also entered as the pre–Windows 2000 name of the new group.
- A group name cannot be identical to any other group name in the domain.
- A group name (CN) can contain up to 64 uppercase or lowercase characters.

- A group name (CN) cannot consist solely of spaces.
- A group name (pre–Windows 2000) (**samAccountName** object attribute) can contain up to 256 uppercase of lowercase characters except for the following:

  " / \ [ ] : ; | = , + * ? < >

- A group name (pre–Windows 2000) (**samAccountName** object attribute) cannot consist solely of periods or spaces.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsadd group** *GroupDN* **–samid** *SAMName* **–secgrp** *yes* | *no* **–scope** *l* | *g* | *u*

| Value | Description |
|---|---|
| *GroupDN* | Specifies the distinguished name of the group object that you want to add. |
| *SAMName* | Specifies to use the Security Accounts Manager (SAM) name as the unique SAM account name for this group (for example, operators). |
| *yes* \| *no* | Specifies whether the group you want to add is a security group (yes) or a distribution group (no). |
| *l* \| *g* \| *u* | Specifies whether the scope of the group you want to add is domain local (l), global (g), or universal (u). |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- If the domain in which you are creating the group is set to the domain functional level of Windows 2000 mixed, you can select only the **Security** group type with **Domain local** or **Global** scopes. For more information, see Related Topics.
- To view the complete syntax for this command, at a command prompt, type:

  **dsadd group /?**

- A group name cannot be identical to any other group name in the domain.
- A group name (CN) can contain up to 64 uppercase or lowercase characters.
- A group name (CN) cannot consist solely of spaces.
- A group name (pre–Windows 2000) (**samAccountName** object attribute) can contain up to 256 uppercase of lowercase characters except for the following:

  " / \ [ ] : ; | = , + * ? < >

- A group name (pre–Windows 2000) (**samAccountName** object attribute) cannot consist solely of periods or spaces.

| Note |
| --- |
| When you use **net group** to create a new group account (**net group <group_name> /add /domain**, for example, **net group Group1 /add /domain**), if you specify a group name that is longer than 64 characters, the directory service sets the group's CN to the automatically generated **objectSID** of the newly created group account and the **samAccountName** object attribute assumes the name that you specify in the **net group** command. For more information about **net group** name restrictions, see NetGroupAdd (http://go.microsoft.com/fwlink/?LinkID=159751). |

**Information about functional differences**

# Add a member to a group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a member to a group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click the folder that contains the group to which you want to add a member.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder that contains the group*

3. In the details pane, right-click the group, and then click **Properties**.
4. On the **Members** tab, click **Add**.
5. In **Enter the object names to select**, type the name of the user, group, or computer that you want to add to the group, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- In addition to users and computers, membership in a particular group can include contacts and other groups.
- To add members to a group, you can click the members you want to add, click

  on the toolbar, and then type the name of the group into which they will be added. You can also drag a member object to a group, or right-click the object, and then click **Add to a group**.

- When you administer a domain, security principals in the parent domain or other trusted domains are not visible on the **Member Of** tab of a domain users properties. The only domain accounts that you can add or view are the present domain groups. Only domain groups in the present domain are shown, even if the member belongs to other trusted domain groups.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **dsmod group***GroupDN***-addmbr***MemberDN*

| Value | Description |
|---|---|
| *GroupDN* | Specifies the distinguished name of the group object to which you want to add the object. |
| *MemberDN* | Specifies the distinguished name of the object that you want to add to the group. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- In addition to users and computers, a group can contain contacts and other groups.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod group /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow anonymous users to be members of the Everyone security group on a domain controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow members of the Anonymous Logon group to be members of the Everyone group on a domain controller**

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Domain Security Policy**.
2. In the console tree, click **Security Options**.

   **Where?**

   - Security Settings/Local Policies/Security Options

3. In the details pane, right-click **Network access: Let Everyone permissions apply to anonymous users**, and then click **Properties**.
4. Select the **Define this policy setting** check box, and then click **Enabled**.

**Note**

- By default, members of the Anonymous Logon group are not included in the Everyone group.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Convert a group to another group type

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To convert a group to another group type**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click the folder that contains the group that you want to convert to another group type.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder that contains the group*

3. In the details pane, right-click the group, and then click **Properties**.
4. On the **General** tab, under **Group type**, click the group type.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To convert a group, the domain functional level must be set to Windows 2000 native or higher. Groups cannot be converted when the domain functional level is set to Windows 2000 mixed.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod group** *GroupDN* **-secgrp** {**yes**|**no**}

| Value | Description |
|---|---|
| *GroupDN* | Specifies the distinguished name of the group object for which you want to change the group type. |
| {**yes**\|**no**} | Specifies that the group type is set to security group (**yes**) or distribution group (**no**). |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the

Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To convert a group, the domain functional level must be set to Windows 2000 native or higher. Groups cannot be converted when the domain functional level is set to Windows 2000 mixed.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod group /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change group scope

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change group scope**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click the folder that contains the group for which you want to change the group scope.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder that contains the group*

3. In the details pane, right-click the group, and then click **Properties**.
4. On the **General** tab, under **Group scope**, click the group scope.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- You can only change group scopes when the domain functional level is set to Windows 2000 native or higher.
- Changing the scope of a group from universal to domain local can only be done on a global catalog server. An error is returned if the domain controller is not a global catalog server.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod group***GroupDN***-scope***L*|*G*|*U*

| Value | Description |
|---|---|
| *GroupDN* | Specifies the distinguished names (DNs) of the group object to which the scope will be changed. |

| | |
|---|---|
| *L\|G\|U* | Specifies that the scope of the group be set to local, global or universal. If the domain is still in Windows 2000 mixed, then the universal scope will not be supported. Also, it is not possible to convert a domain local group to global group or vice versa. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can only change group scopes when domain functional level is set to Windows 2000 native or higher.

- Changing the scope of a group from universal to domain local can only be done on a global catalog server. An error is returned if the domain controller is not a global catalog server.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod group /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click the folder that contains the group you want to delete.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder that contains the group*

3. In the details pane, right-click the group, and then click **Delete**.

### Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Deleting a group is a permanent operation.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsrm***GroupDN*

| Value | Description |
|---|---|
| *GroupDN* | Specifies the distinguished name of the group object to be deleted. |

### Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command**

**prompt**.

- Deleting a group is a permanent operation.
- To view the complete syntax for this command, at a command prompt, type:

  **dsrm /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Find groups in which a user is a member

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find groups in which a user is a member**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
3. In the details pane, right-click a user account, and then click **Properties**.
4. Click the **Member Of** tab.

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- The **Member Of** tab for a user displays a list of groups in the domain where the user's account is located. Active Directory does not display groups that reside in trusted domains where the user is a member.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsget user***UserDN***-memberof**

| Value | Description |
|---|---|
| *UserDN* | Specifies the distinguished name of the user object for which you want to display group membership. |

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **dsget user /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign user rights to a group in Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign user rights to a group in Active Directory**

1. Open Domain Controller Security Policy.
2. In the console tree, click **User Rights Assignment**.

   **Where?**

   - Security Settings/Local Policies/User Rights Assignment

3. In the details pane, double-click the user right that you want to assign.
4. Click **Add User or Group**.

   If the button appears dimmed, select the **Define these policy settings** check box.

5. Type the name of the group to which you want to assign this right.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Domain Controller Security Policy, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage computers**

- Create a new computer account
- Add a computer account to a group
- Delete a computer account
- Manage a remote computer
- Move a computer account
- Reset a computer account
- Disable or enable a computer account

# Create a new computer account

Updated: June 5, 2013

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012

**To create a new computer account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click **Computers**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Computers

   Or, right-click the folder in which you want to add the computer.
3. Point to **New**, and then click **Computer**.
4. Type the computer name.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- By default, members of the Account Operators group can create computer accounts in the Computers container and in new organizational units.
- By default, Authenticated Users in a domain are assigned the **Add workstations to a domain** user right and can create up to 10 computer accounts in the domain. For more information, see Related Topics.
- There are two additional ways to give a user or group permission to add a computer to the domain: Use a Group Policy object to assign the Add Computer User permission, or, on the organizational unit, assign the user or group the Create Computer Objects permission.
- To view or change a computer name and to modify the domain in which it belongs, click **Start**, right-click **My Computer**, click **properties**, click the **Computer Name** tab, and then click **Change**.
- If the computer using the account you are creating is a pre-Windows 2000 computer, select the **Assign this computer account as a pre-Windows 2000 computer** check box.

- If the computer using the account you are creating is a Windows NT backup domain controller, select **Assign this computer account as a backup domain controller** check box.

- By default, a newly created computer account is assigned an "Account Ops-FC" access control entry (ACE) that gives members of the Account Operators group full control over that computer account. If a server that is represented by this computer account is promoted to a domain controller, the computer account retains this "Account Ops-FC" ACE, and therefore, members of the Account Operators group will have full control on this domain controller, which is not a recommended configuration. For example, members of Account Operators group will be able to reset this domain controller's password. Because the Account Operators group has significant power in the domain, we recommend that you add members to it with caution. For a detailed description of the Account Operators group, see Default groups (http://go.microsoft.com/fwlink/?LinkID=131422). To modify permissions for Account Operators on a computer account, you can use Active Directory Users and Computers snap-in and complete the following steps:

  1. To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

  2. In the console tree, right-click the computer account that represents the server that you want to promote to a domain controller status, and then click **Properties**.

  3. On the **Security** tab, select **Account Operators** in the **Group or user names** list, and then modify permissions according to the specifications of your environment.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **dsadd computer** *ComputerDN*

| Value | Description |
|---|---|
| *ComputerDN* | Specifies the distinguished name of the computer you want to add. The distinguished name specifies the directory location. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- By default, members of the Account Operators group can create computer accounts in the Computers container and in new organizational units.

- By default, Authenticated Users in a domain are assigned the **Add workstations to a domain** user right and can create up to 10 computer accounts in the domain. For more information, see Related Topics.

- There are two additional ways to give a user or group permission to add a computer to the domain: Use a Group Policy object to assign the Add Computer User permission, or, on the organizational unit, assign the user or group the Create Computer Objects permission.

- To view the complete syntax for this command, at a command prompt, type:

**dsadd computer /?**

- To modify the properties of a computer account, use the **dsmod computer** command.

- By default, a newly created computer account is assigned an "Account Ops-FC" access control entry (ACE) that gives members of the Account Operators group full control over that computer account. If a server that is represented by this computer account is promoted to a domain controller, the computer account retains this "Account Ops-FC" ACE, and therefore, members of the Account Operators group will have full control on this domain controller, which is not a recommended configuration. For example, members of Account Operators group will be able to reset this domain controller's password. Because the Account Operators group has significant power in the domain, we recommend that you add members to it with caution. For a detailed description of the Account Operators group, see Default groups (http://go.microsoft.com/fwlink/?LinkID=131422). To modify permissions for Account Operators on a computer account, you can use Active Directory Users and Computers snap-in and complete the following steps:

  1. To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

  2. In the console tree, right-click the computer account that represents the server that you want to promote to a domain controller status, and then click **Properties**.

  3. On the **Security** tab, select **Account Operators** in the **Group or user names** list, and then modify permissions according to the specifications of your environment.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a computer account to a group

Updated: June 5, 2013

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012

**To add a computer account to a group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Computers

   Or, click the folder in which the computer is located.
3. In the details pane, right-click the computer, and then click **Properties**.
4. On the **Member Of** tab, click **Add**.
5. In **Enter the object names to select**, type the name of a group that you want this computer to be a member of, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- When viewing users, computers, and groups as containers, you can add a computer to a group by dragging it onto the desired group. For more information about view options in Active Directory Users and Computers, see Related Topics.
- By adding a computer to a group, you can assign permissions to all of the computer accounts in that group and filter Group Policy settings on all accounts in that group.

**Using a command line**

1. Open Command Prompt.
2. Type:

```
Dsmod group GroupDN -addmbr ComputerDN
```

For example, to add computer1 to Group A in the Contoso domain, type

```
Dsmod "CN=Group A,OU=Domain Groups,DC=Contoso,DC=com" -addmbr
"CN=Computer1,OU=Domain Computers,DC=Contoso,DC=com"
```

| Value | Description |
|---|---|
| *GroupDN* | Specifies the distinguished names of the group object to which you want to add the computer object. |
| *ComputerDN* | Specifies the distinguished name of the computer object to be added to the group. The distinguished name specifies the directory location. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- By adding a computer to a group, you can assign permissions to all of the computer accounts in that group and filter Group Policy settings on all accounts in that group.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod group /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a computer account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a computer account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Computers

   Or, click the folder in which the computer is located.

3. In the details pane, right-click the computer, and then click **Delete**.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Once a computer account has been deleted, all permissions and memberships associated with that computer account are permanently deleted. Because the security ID (SID) for each account is unique, a new computer account with the same name as a previously deleted computer account does not inherit the permissions and memberships of the previously deleted account. To duplicate a deleted computer account, all permissions and memberships must be manually recreated.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsrm computer***ComputerDN*

| Value | Description |
|---|---|
| *ComputerDN* | Specifies the distinguished name of the computer you want to add. The distinguished name specifies the directory location. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Once a computer account has been deleted, all permissions and memberships associated with that computer account are permanently deleted. Because the security ID (SID) for each account is unique, a new computer account with the same name as a previously deleted computer account does not inherit the permissions and memberships of the previously deleted account. To duplicate a deleted computer account, all permissions and memberships must be manually recreated.

- To view the complete syntax for this command, at a command prompt, type:

  **dsrm computer /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage a remote computer**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Computers

   Or, click the folder that contains the computer you want to manage.
3. In the details pane, right-click the computer, and then click **Manage**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Clicking **Manage** starts Computer Management from which you can administer remote computers. You must have administrative credentials on the local computer to view certain information or to modify computer properties using Computer Management.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Move a computer account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To move a computer account**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Computers

   Or, click the folder that contains the computer that you want to move.
3. In the details pane, right-click the computer, and then click **Move**.
4. In the **Move** dialog box, click the domain node.
5. Click the folder to which you want to move the computer, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- You cannot use Active Directory Users and Computers to move computer accounts between domains. To move a computer account between domains, use Movetree, one of the Active Directory support tools. For more information, see Related Topics.
- Members of the Account Operators group can move computer accounts to organizational units but not to default containers, such as Builtin or Computers. However, Account Operators cannot move computer accounts into the Domain Controllers organizational unit but can move computer accounts from the Domain Controllers organizational unit.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reset a computer account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reset a computer account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Computers

   Or, click the folder that contains the computer that you want to reset.
3. In the details pane, right-click the computer, and then click **Reset Account**.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod computer***ComputerDN***-reset**

| Value | Description |
|---|---|
| *ComputerDN* | Specifies the distinguished names of one or more computer objects that you want to reset. |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command**

**prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod computer /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable or enable a computer account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable or enable a computer account**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

   **Where?**

   - Active Directory Users and Computers/*domain node*/Computers

   Or, click the folder that contains the computer that you want to enable or disable.
3. In the details pane, right-click the desired computer, and then do one of the following:

   - To disable, click **Disable Account**.
   - To enable, click **Enable Account**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- When you disable a computer account, the computer cannot authenticate to the domain until it has been enabled.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod computer***ComputerDN***-disabled** {**yes**|**no**}

| Value | Description |
|---|---|
| *ComputerDN* | Specifies the distinguished names of the computer object that you want to disable or enable. |

| | |
|---|---|
| {**yes**\|**no**} | Specifies whether the computer is disabled for log on (**yes**) or not (**no**). |

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- When you disable a computer account, the computer cannot authenticate to the domain until it has been enabled.

- To view the complete syntax for this command, at a command prompt, type:

  **dsmod computer /?**

**Information about functional differences**

# Publish Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Publish resources**

- Publish a shared folder
- Manually publish a printer in Active Directory

# Publish a shared folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To publish a shared folder**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the folder in which you want to add a shared folder.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder*

3. Point to **New**, and then click **Shared Folder**.
4. Type the name of the folder and the network path.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

# Manually publish a printer in Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manually publish a printer in Active Directory**

1. Open **Active Directory Users and Computers**.
2. In **Name**, right-click the container object folder in which you want to publish the printer.
3. Point to **New**, and then click **Printer**.
4. Type the UNC name of the printer that you want to publish in the directory.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To perform this procedure, you must be a member of the Print Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- Group Policy settings for printers determine whether printers published with a print server running Windows NT 4.0 or an earlier operating system should be pruned if the print server becomes unavailable.
- You can also use the **Pubprn.vbs** script, provided in the System32 folder, to publish printers with print servers running Windows NT 4.0 or an older operating system.
- The printer you want to publish must be shared.
- You must have directory service administration rights to publish printers.
- You must have the Manage Printers permission for the printer you want to share or to publish.
- You can create printer names that contain spaces, special characters, and more than eight characters. However, some clients do not recognize or correctly handle such names. The entire qualified name of a shared printer (for example, \\PRINTER2\PSCRIPT) must contain 32 or fewer characters.

Publish a printer in Active Directory

# Manage Domains

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage domains**

- Create a new forest
- Create a new domain tree
- Create a new child domain
- Manage a different domain
- Remove a domain
- Manage the domain using a different domain controller
- Add user principal name suffixes
- Delete extinct domain metadata
- Raise the domain functional level
- Assign, change, or remove permissions on Active Directory objects or attributes
- Modify the AdminSDHolder container
- Manage Organizational Units
- Manage Domain Controllers

# Create a new forest

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new forest**

1. Click **Start**, click **Run**, and then type **dcpromo** to start the Active Directory Installation Wizard.
2. On the **Operating System Compatibility** page, read the information and then click **Next**.

   If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.
3. On the **Domain Controller Type** page, click **Domain controller for a new domain**, and then click **Next**.
4. On the **Create New Domain** page, click **Domain in a new forest**, and then click **Next**.
5. On the **New Domain Name** page, type the full DNS name for the new domain, and then click **Next**.
6. On the **NetBIOS Domain Name** page, verify the NetBIOS name, and then click **Next**.
7. On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location, and then click **Next**.
8. On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next**.
9. On the **DNS Registration Diagnostics** page, verify if an existing DNS server will be authoritative for this forest or, if necessary, choose to install and configure DNS on this server by clicking **Install and configure the DNS server on this computer, and set this computer to use this DNS server as its preferred DNS server**, and then click **Next**.
10. On the **Permissions** page, select one of the following:

    - **Permissions compatible with pre-Windows 2000 Server operating systems**
    - **Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems**
11. Review the **Summary** page, and then click **Next** to begin the installation.
12. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- The server on which you install Active Directory using this procedure will be the first domain controller in the forest root domain.
- Before installing Active Directory, you will need to consider pre-Windows 2000 compatible security levels and identify the DNS name of the domain. For more information, see the checklist in Related Topics.

- The wizard options on the **Permissions** page affect application compatibility with computers running pre-Windows 2000 and Windows Server 2003 operating systems and are not related to domain functionality. For more information about permissions, see Related Topics.

- The Active Directory Installation Wizard allows Active Directory domain names up to 64 characters or up to 155 bytes. Although the limit of 64 characters is usually reached before the limit of 155 bytes, the opposite could be true if the name contains Unicode characters consuming three bytes. These limits do not apply to computer names.

- You cannot install Active Directory on a computer running Windows Server 2003, Web Edition, but you can join the computer to an Active Directory domain as a member server. For more information about Windows Server 2003, Web Edition, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a new domain tree

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new domain tree**

1. Click **Start**, click **Run**, and then type **dcpromo** to start the Active Directory Installation Wizard.

2. On the **Operating System Compatibility** page, read the information and then click **Next**.

   If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.

3. On the **Domain Controller Type** page, click **Domain controller for a new domain**, and then click **Next**.

4. On the **Create New Domain** page, click **Domain tree in an existing forest**.

5. On the **Network Credentials** page, type the user name, password, and user domain of the user account you want to use for this operation, and then click **Next**.

   The user account must be a member of the Enterprise Admins group.

6. On the **New Domain Tree** page, type the full DNS name for the new domain, and then click **Next**.

7. On the **NetBIOS Domain Name** page, verify the NetBIOS name, and then click **Next**.

8. On the **Database and Log Folders** page, type the location in which to install the database and log folders, or click **Browse** to choose a location, and then click **Next**.

9. On the **Shared System Volume** page, type the location in which to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next**.

10. On the **DNS Registration Diagnostics** page, verify if an existing DNS server will be authoritative for this forest or, if necessary, choose to install and configure DNS on this server by clicking **Install and configure the DNS server on this computer, and set this computer to use this DNS server as its preferred DNS server**, and then click **Next**.

11. On the **Permissions** page, select one of the following:

    - **Permissions compatible with pre-Windows 2000 Server operating systems**

    - **Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems**

12. On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password that you want to assign to the Administrator account for this server, and then click **Next**.

    Use this password when starting the computer in Directory Services Restore Mode.

13. Review the **Summary** page, and then click **Next** to begin the installation.

14. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Before installing Active Directory, you will need to consider pre-Windows 2000 compatible security levels and identify the DNS name of the domain. For more information, see the checklist in Related Topics.

- When a new domain tree is created in an existing forest, a two-way, transitive tree root trust is established by default.

- The wizard options on the **Permissions** page affect application compatibility with computers running pre-Windows 2000 and Windows Server 2003 operating systems and are not related to domain functionality. For more information about permissions, see Related Topics.

- You can also use a smart card to verify administrative credentials. For more information about smart cards, see Related Topics.

- The Active Directory Installation Wizard allows Active Directory domain names up to 64 characters or up to 155 bytes. Although the limit of 64 characters is usually reached before the limit of 155 bytes, the opposite could be true if the name contains Unicode characters consuming three bytes. These limits do not apply to computer names.

- You cannot install Active Directory on a computer running Windows Server 2003, Web Edition, but you can join the computer to an Active Directory domain as a member server. For more information about Windows Server 2003, Web Edition, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a new child domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new child domain**

1. Click **Start**, click **Run**, and then type **dcpromo** to start the Active Directory Installation Wizard.

2. On the **Operating System Compatibility** page, read the information and then click **Next**.

   If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.

3. On the **Domain Controller Type** page, click **Domain controller for a new domain**, and then click **Next**.

4. On the **Create New Domain** page, click **Child domain in an existing domain tree**, and then click **Next**.

5. On the **Network Credentials** page, type the user name, password, and user domain of the user account you want to use for this operation, and then click **Next**.

   The user account must be a member of the Enterprise Admins group.

6. On the **Child Domain Installation** page, verify the parent domain and type the new child domain name, and then click **Next**.

7. On the **NetBIOS Domain Name** page, verify the NetBIOS name, and click **Next**.

8. On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location, and then click **Next**.

9. On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next**.

10. On the **DNS Registration Diagnostics** page, verify the DNS configuration settings are accurate, and then click **Next**.

11. On the **Permissions** page, select one of the following:

    - **Permissions compatible with pre-Windows 2000 server operating systems**

    - **Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems**

12. On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password that you want to assign to the Administrator account for this server, and then click **Next**.

    Use this password when starting the computer in Directory Services Restore Mode.

13. Review the **Summary** page, and then click **Next** to begin the installation.

14. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in

Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- The server on which you install Active Directory using this procedure will be the first domain controller in a new child domain.

- Before installing Active Directory, you will need to consider pre-Windows 2000 compatible security levels and identify the DNS name of the domain. For more information, see the checklist in Related Topics.

- When a child domain is added to an existing tree domain, a two-way, transitive parent and child trust is established by default.

- The wizard options on the **Permissions** page affect application compatibility with computers running pre-Windows 2000 and Windows Server 2003 operating systems and are not related to domain functionality. For more information about permissions, see Related Topics.

- You can also use a smart card to verify administrative credentials. For more information about smart cards, see Related Topics.

- The Active Directory Installation Wizard allows Active Directory domain names up to 64 characters or up to 155 bytes. Although the limit of 64 characters is usually reached before the limit of 155 bytes, the opposite could be true if the name contains Unicode characters consuming three bytes. These limits do not apply to computer names.

- You cannot install Active Directory on a computer running Windows Server 2003, Web Edition, but you can join the computer to an Active Directory domain as a member server. For more information about Windows Server 2003, Web Edition, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage a different domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage a different domain**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click **Active Directory Users and Computers**, and then click **Connect to Domain**.
3. Type the domain name.

   Or, click **Browse**, and then select a domain from the list.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials. However, you must have the appropriate administrative credentials to manage the domain you select.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- If you select the **Save this domain setting for the current console** option, Active Directory Users and Computers will attempt to connect to the domain each time it is opened.
- The domain name includes all of the domain's parent domains. For example, the domain *widgets* could have a full name of *widgets.microsoft.com*.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a domain**

1. On the last domain controller in the domain, click **Start**, and then click **Run**.
2. In **Open**, type **dcpromo** to open the Active Directory Installation Wizard, and then click **Next**.
3. On the **Remove Active Directory** page, select the **This server is the last domain controller in the domain** check box, and then continue to follow the wizard.

## Caution

- Removing a domain will result in the permanent loss of any data contained in that domain. This includes all user, group, and computer accounts.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To remove an Active Directory domain, you must first demote all other domain controllers associated with the domain. For information about demoting domain controllers, see Related Topics.
- If the domain has child domains, it cannot be deleted.
- If this is the last domain in the forest, demoting this domain controller will also delete the forest.
- If the domain controller currently holds the domain naming master or schema master operations roles, transfer the role to domain controller in a different domain before removing the domain. For information about locating operations masters and transferring operations master roles, see Related Topics.
- If the domain controller holds the last replica of one or more application directory partitions, you must first remove the last application directory partition replicas from the domain controller before you can delete the domain. You can use the Active Directory Installation Wizard to remove all application directory partition replicas from the domain controller or you can manually remove the partitions using the Ntdsutil command-line tool. For information about application directory partitions, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage the domain using a different domain controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage the domain using a different domain controller**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click **Active Directory Users and Computers**, and then click **Connect to Domain Controller**.
3. Click a domain controller in the list.

   Or, in **Enter the name of another domain controller**, type the name of a domain controller.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials. However, you must have the appropriate administrative credentials to manage the domain you select.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- By default, domain controllers are created in the Domain Controllers organizational unit when they are first configured.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add user principal name suffixes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding user principal name suffixes**
**To add user principal name suffixes**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click **Active Directory Domains and Trusts**, and then click **Properties**.
3. On the **UPN Suffixes** tab, type an alternative user principal name (UPN) suffix for the forest, and then click **Add**.
4. Repeat step 3 to add additional alternative UPN suffixes.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- UPN suffixes should conform to DNS conventions for valid characters and syntax.
- UPN suffixes are stored in the uPNSuffixes property of the following LDAP leaf: LDAP://cn=partitions,cn=configuration,dc=<*domain*>,dc=<*domainsuffix*>.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete extinct domain metadata

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete extinct domain metadata**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command, type:

   **metadata cleanup**
4. At the metadata cleanup command, type:

   **connection**
5. At the connection command, type:

   **connect to server***Server*
6. At the connection command, type:

   **quit**
7. At the metadata cleanup command, type:

   **select operation target**
8. At the select operation target command, type:

   **list sites**
9. A numbered list of sites will be displayed, type:

   **select site***SiteNumber*
10. At the select operation target command, type:

    **list domains in site**
11. A numbered list of domains in the selected site will be displayed, type:

    **select domain***DomainNumber*

    **quit**
12. At the metadata cleanup command, type:

    **remove selected domain**

| Value | Description |
| --- | --- |
| *Server* | The DNS name of a domain controller. |
| *SiteNumber* | The number in the displayed list that corresponds to the site that you want to connect to. |
| *DomainNumber* | The number in the displayed list that corresponds to the domain that you want to clean up. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To clean metadata you must first select the operation target. When selecting the operation target for a server, you must first select the site and then the domain.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Raise the domain functional level

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To raise the domain functional level**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain for which you want to raise functionality, and then click **Raise Domain Functional Level**.
3. In **Select an available domain functional level**, do one of the following:
   - To raise the domain functional level to Windows 2000 native, click **Windows 2000 native**, and then click **Raise**.
   - To raise domain functional level to Windows Server 2003, click Windows Server 2003, and then click **Raise**.

**Caution**

- If you have or will have any domain controllers running Windows NT 4.0 and earlier, then do not raise the domain functional level to Windows 2000 native. Once the domain functional level is set to Windows 2000 native, it cannot be changed back to Windows 2000 mixed.
- If you have or will have any domain controllers running Windows NT 4.0 and earlier or Windows 2000, then do not raise the domain functional level to Windows Server 2003. Once the domain functional level is set to Windows Server 2003, it cannot be changed back to Windows 2000 mixed or Windows 2000 native.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group in the domain for which you want to raise functionality or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- You can also raise the domain functional level by right-clicking a domain displayed in Active Directory Users and Computers, and then clicking **Raise Domain Functional Level**.
- The current domain functional level is displayed under **Current domain functional level** in the **Raise Domain Functional Level** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign, change, or remove permissions on Active Directory objects or attributes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign, change, or remove permissions on Active Directory objects or attributes**

1. Open Active Directory Users and Computers.
2. On the **View** menu, select **Advanced Features**.
3. Right-click the object for which you want to assign, change, or remove permissions, and then click **Properties**.
4. On the **Security** tab, click **Advanced** to view all of the permission entries that exist for the object.
5. Do one or more of the following:
   - To assign new permissions on an object or attribute, click **Add**. Type the name of the group, computer, or user that you want to add, and then click **OK**. In the **Permission Entry for *ObjectName*** dialog box, on the **Object** and **Properties** tabs, select or clear the **Allow** or **Deny** check boxes, as appropriate.
   - To change existing permissions on an object or attribute, click a permission entry, and then click **Edit**. On the **Object** and **Properties** tabs, select or clear the **Allow** or **Deny** check boxes, as appropriate.
   - To remove existing permissions from an object or attribute, click a permission entry, and then click **Remove**.

### Important

- Before adding access control permissions on Active Directory objects or properties, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify the AdminSDHolder container

Updated: April 17, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure provides steps for modifying the AdminSDHolder container object, which is a built-in container object for each Active Directory domain that has a specific access control list (ACL) set on it. You can use the Dsacls tool to help prevent administrators from making unauthorized changes to the membership of administrative groups in an Active Directory domain.

| **Important** |
| --- |
| This procedure will not completely prevent unauthorized changes to membership of administrative groups in an Active Directory domain. It is always recommended that you have auditing in place that alerts you when any changes are made to the membership of administrative groups in your Active Directory domain. For more information, see "Additional references." |

**To modify the AdminSDHolder container**

1. Download and install the Windows Server 2003 Service Pack 1 (SP1) Support Tools.

   Dsacls.exe is available as part of the Windows Support Tools. For more information, see article 89277 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkID=44321).

2. In the domain that you want to modify, create a new domain local group, for example, AdminDenyGrp.

   For more information about creating a new domain local group, see Create a new group.

3. For each administrator that you want to help prevent from making changes to administrative groups in the domain, add the administrator's name to the group that you created.

   For more information about adding a member to a group, see Add a member to a group.

4. Open a command prompt with your administrative credentials.

5. At the command prompt, type the following, and then press ENTER:

   ```
   dsacls <AdmSDHolderDN> /D <DomName>\<AdminDenyGrp>:WP;"<Attribute>"
   ```

6. Apply the parameters in the following table as appropriate for your deployment.

| Parameter | Description |
| --- | --- |
| <AdmSDHolderDN> | Specifies the distinguished name of the AdminSDHolder object for the domain. For example, where the domain is CORPHQ, as in corphq.contoso.com, the distinguished name is the following:<br><br>CN=AdminSDHolder,CN=System,DC=corphq,C=contoso,DC=com |
| <DomName> | Specifies the name of the trusting domain. For example, where the full distinguished name is corphq.contoso.com, the domain name is specified as "CORPHQ" here. |
| <AdminDenyGrp> | Specifies the actual name of the group that you created in step 2 in this procedure. |
| <Attribute> | Specifies the attribute on the AdminSDHolder container that will be modified when the command is run. For this procedure, specify the value as "member" (including the quotation marks). This is the name of the attribute that Active Directory uses to store the membership data that is associated with a group. |

When you run this command, it modifies the AdminSDHolder container for the domain that you specified to deny the specified group the ability to write the **member** attribute for group objects.

For example, the following command line uses actual values that might appear in the **dsacls** command in which **/D** indicates that you are adding a DENY access control entry (ACE), and **WP** indicates the **Write** property for the **member** attribute.

```
dsacls CN=AdminSDHolder,CN=System,DC=corphq,C=contoso,DC=com /D
CORPHQ\AdminDenyGrp:WP;"member"
```

To view the complete syntax for this command, and for information about entering user account information, at a command prompt, type the following, and then press ENTER:

```
dsacls /?
```

**Additional considerations**

| **Important** |
| --- |
| Before you add access control permissions on Active Directory objects or properties, see "Additional references." |

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To complete this procedure, you must have the Dsacls command-line tool installed.

- You can use this procedure to put other restrictions in place for protected objects. For example, the following command puts DENY-Delete & DENY-Modify Permissions ACEs on protected objects for the specified user or group object (ServiceAccount):

  ```
  DSACLS DNofAdminSDHolderContainer /D CONTOSO\ServiceAccount:SDWD
  ```

  The following command puts a DENY-Reset Password ACE on protected objects for the specified user or group object (ServiceAccount):

  ```
  DSACLS DNofAdminSDHolderContainer /D CONTOSO\ServiceAccount:CA;"Reset Password"
  ```

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Organizational Units

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage organizational units**

- Create a new organizational unit
- Delegate control of an organizational unit
- Delete an organizational unit
- Move an organizational unit

# Create a new organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new organizational unit**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the folder in which you want to add an organizational unit.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder*

3. Point to **New**, and then click **Organizational Unit**.
4. Type the name of the organizational unit.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To add an organizational unit, you can also click the domain node or folder in which you want to add the organizational unit, and then click

  on the toolbar.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsadd ou***OrganizationalUnitDN*

| Value | Description |
|---|---|
| *OrganizationalUnitDN* | Specifies the distinguished name of the organizational unit to be added. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using

Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **dsadd ou /?**

- To modify the properties of an organizational unit, use the **dsmod ou** command.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate control of an organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate control of an organizational unit**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the organizational unit for which you want to delegate control.

   **Where?**

   - Active Directory Users and Computers/*domain node/organizational unit*

3. Click **Delegate control** to start the Delegation of Control Wizard, and then follow the instructions.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete an organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete an organizational unit**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the organizational unit in which you want to delete.

   **Where?**

   - Active Directory Users and Computers/*domain node*/*organizational unit*

3. Click **Delete**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- If the selected organizational unit contains other objects, Active Directory Users and Computers prompts you to either continue or cancel the deletion. If you continue the deletion, all objects within the organizational unit will also be deleted.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsrm***OrganizationalUnitDN*

| Value | Description |
|---|---|
| *OrganizationalUnitDN* | Specifies the distinguished name of the organizational unit to be deleted. |

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Attempting to delete an organizational unit containing other objects will result in an error, unless the **-subtree** option is used. With the **-subtree** option, **dsrm** deletes both the selected organizational unit and any objects it contains.

- To view the complete syntax for this command, at a command prompt, type:

  **dsrm /?**

  or see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Move an organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To move an organizational unit**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the organizational unit that you want to move.

   **Where?**

   - Active Directory Users and Computers/*domain node/organizational unit*

3. Click **Move**, and then click the folder to which you want to move the organizational unit.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Active Directory Users and Computers can only move organizational units within the same domain. To move organizational units between domains, use Movetree. For more information about Movetree and other Active Directory support tools, see Related Topics.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmov***OuDN* [**-newparent** ParentDN] **-pwd** {*Password*|*****}

| Value | Description |
|---|---|
| *OuDN* | Specifies the distinguished name of the organizational unit object to be moved. |
| *ParentDN* | Specifies the new location to which you want to move the organizational unit object. The new location is specified as the distinguished name of the new parent node. |
| *Pwd* | Specifies to use either a password or a * to log on to a remote server. If you type *, then you are prompted for a password. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Active Directory Users and Computers can only move organizational units within the same domain. To move organizational units between domains, use Movetree. For more information about Movetree and other Active Directory support tools, see Related Topics.

# Manage Domain Controllers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage domain controllers**

- Create an additional domain controller
- Demote a domain controller
- Rename a domain controller
- Disable signed or encrypted LDAP traffic

# Create an additional domain controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an additional domain controller**

1. Click **Start**, click **Run**, and then type **dcpromo /adv** to open the Active Directory Installation Wizard with the option to create an additional domain controller from restored backup files.

2. On the **Operating System Compatibility** page, read the information and then click **Next**.

   If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.

3. On the **Domain Controller Type** page, click **Additional domain controller for an existing domain**, and then click **Next**.

4. On the **Copying Domain Information** page, do one of the following:

   - Click **Over the network**, and then click **Next**.

   - Click **From these restored backup files**, and type the location of the restored backup files, or click **Browse** to locate the restored files, and then click **Next**.

5. On the **Network Credentials** page, type the user name, password, and user domain of the user account you want to use for this operation, and then click **Next**.

   The user account must be a member of the Domain Admins group for the target domain.

6. On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location, and then click **Next**.

7. On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next**.

8. On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password that you want to assign to the Administrator account for this server, and then click **Next**.

   Use this password when starting the computer in Directory Services Restore Mode.

9. Review the **Summary** page, and then click **Next** to begin the installation.

10. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- The **/adv** switch is only necessary when you want to create a domain controller from restored backup files. It is not required when creating an additional domain controller over the network.

- In step 3, when choosing the option to copy domain information over the network, all directory data for the domain in

which this domain controller will be a member will be copied over your network connection. You will have the option to cancel non-critical replication, if necessary.

- In step 3, when choosing the option to copy domain information from restored backup files, you will need to first back up the System State data of a domain controller running Windows Server 2003 from the domain in which this member server will become an additional domain controller. Then, the System State backup must be restored locally on the server on which you are installing Active Directory. To do this using Backup, choose the option **Restore files to: Alternate location**. For more information about restoring backups, see Related Topics.

- If a domain controller that was backed up contained an application directory partition, the application directory partition will not be restored on the new domain controller. For information about how to manually create an application directory partition on a new domain controller, see Related Topics.

- If the domain controller from which you restored the System State data was a global catalog, you will have the option to make this new domain controller a global catalog.

- You can also use a smart card to verify administrative credentials. For more information about smart cards, see Related Topics.

- You cannot install Active Directory on a computer running Windows Server 2003, Web Edition, but you can join the computer to an Active Directory domain as a member server. For more information about Windows Server 2003, Web Edition, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Demote a domain controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To demote a domain controller**

1. On a domain controller, click **Start**, and then click **Run**.
2. In **Open**, type **dcpromo** to open the Active Directory Installation Wizard, and then click **Next**.
3. On the **Remove Active Directory** page, click **Next**, and then continue to follow the wizard.

### Caution

- Before you complete this procedure, verify that this domain controller is not the only global catalog and that it does not hold an operations master role.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If this domain controller is a global catalog, ensure that another global catalog is available to users before demoting it. For information about configuring domain controllers to host the global catalog, see Related Topics.
- If this domain controller currently holds one or more operations master roles, transfer the operations master roles to another domain controller before demoting it. For information about locating operations masters and transferring operations master roles, see Related Topics.
- If this domain controller is the last domain controller in the domain, demoting this domain controller will remove this domain from the forest. If this is the last domain in the forest, demoting this domain controller will also delete the forest. For information about removing domains and forests, see Related Topics.
- If this domain controller holds the last replica of one or more application directory partitions, you must first remove the last application directory partition replicas from this domain controller before you can demote it. You can use the Active Directory Installation Wizard to remove all application directory partition replicas from this domain controller or you can manually remove them using the Ntdsutil command-line tool. For information about application directory partitions, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Rename a domain controller

Updated: April 23, 2013

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To rename a domain controller

To rename a domain controller in a domain that contains a single domain controller

**To rename a domain controller**

1. Open Command Prompt.

2. Type:

   **netdom computername** *CurrentComputerName***/add:***NewComputerName*

   This command will update the service principal name (SPN) attributes in Active Directory for this computer account and register DNS resource records for the new computer name. The SPN value of the computer account must be replicated to all domain controllers for the domain and the DNS resource records for the new computer name must be distributed to all the authoritative DNS servers for the domain name. If the updates and registrations have not occurred prior to removing the old computer name, then some clients may be unable to locate this computer using the new or old name.

3. Ensure the computer account updates and DNS registrations are completed, then type:

   **netdom computername** *CurrentComputerName* **/makeprimary:***NewComputerName*

4. Restart the computer.

5. From the command prompt, type:

   **netdom computername** *NewComputerName* **/remove:***OldComputerName*

| Value | Description |
|---|---|
| *CurrentComputerName* | The current, or primary, computer name or IP address of the computer you are renaming. |
| *NewComputerName* | The new name for the computer. The *NewComputerName* must be a fully qualified domain name (FQDN). The primary DNS suffix specified in the FQDN for *NewComputerName* must be the same as the primary DNS suffix of *CurrentComputerName* or it must be contained in the list of allowed DNS suffixes specified in the **msDS-AllowedDNSSuffixes** attribute of the **domainDns** object. |
| *OldComputerName* | The old name of renamed computer. The *OldComputerName* must be a fully qualified domain name (FQDN). |

**Important**

- To rename a domain controller using the Netdom tool, the domain functional level must be set to Windows Server 2003. For more information, see Related Topics.

- Renaming a domain controller requires that you first provide a FQDN as a new computer name for the domain controller. All of the computer accounts for the domain controller must contain the updated SPN attribute and all the authoritative DNS servers for the domain name must contain the host (A) resource record for the new computer name. Both the old and new computer names are maintained until you remove the old computer name. This ensures that there will be no interruption in the ability of clients to locate or authenticate to the renamed domain controller, except when the domain controller is restarted.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- This command-line method requires the Netdom Windows support tool. For information about installing Windows support tools, see Related Topics.

- The corresponding nTFRSMember or msDFSR-Member object is not renamed automatically, but the reference attributes are correctly set so SYSVOL replication is not impacted. The only potential problem with not renaming these objects is that if another domain controller is created at a later date with the same NetBIOS name of the old domain controller, then a conflict can occur as described in KB article 316826. After the rename is complete, you can optionally rename the nTFRSMember or msDFSR-Member object as part of cleanup.

- If the domain controller belongs to a group with a Group Policy enabled on its primary DNS suffix, the string specified in the Group Policy is used as the primary DNS suffix. The local setting is used only if the Group Policy is disabled or unspecified.

- By default, the primary DNS suffix portion of a computer's FQDN is the same as the name of the Active Directory domain to which the computer is joined. To allow different primary DNS suffixes, a domain administrator can create a restricted list of allowed suffixes by creating the **msDS-AllowedDNSSuffixes** attribute in the domain object container. This attribute is managed by the domain administrator using Active Directory Service Interfaces (ADSI) or Lightweight Directory Access Protocol (LDAP). For more information about programming interfaces and directory access protocol, see Related Topics.

- Domain controller locator (Locator) DNS resource records are registered by the domain controller after the renamed domain controller has been restarted. The records that are registered are available on the domain controller in the systemroot\System32\Config\Netlogon.dns file.

- To enumerate the names with which the computer is currently configured, at a command prompt, type:

  **netdom computername** *ComputerName***/enumerate:***{AlternateNames | PrimaryName | AllNames}*

- You can also specify a parameter that will use administrator credentials required to modify the computer account in Active Directory. If this parameter is not specified, Netdom uses the credentials of the user currently logged on. For more information, see the Netdom command-line help.

- If you rename a domain controller through the **System Properties** dialog box instead of using the Netdom tool, DNS and Active Directory replication latency may delay the ability of clients to locate or authenticate to the renamed domain controller. The length of this latency depends on your network design and the replication topology of your organization.

**To rename a domain controller in a domain that contains a single domain controller**

1. Install a Windows Server 2003 member server in the domain.

2. On the new server, create an additional domain controller by installing Active Directory.

3. After Active Directory is installed, enable the global catalog on the new domain controller.

4. Transfer the operations master roles from the domain controller that you want to rename to the new domain controller. Note that you must transfer the roles, do not seize them.

5. Verify that the new domain controller is functioning correctly by doing the following:

a. Verify authentications and global catalog searches.

b. Run Dcdiag.exe against the domain controller.

c. Perform any other appropriate tests to verify that the new domain controller can provide all of the domain functions of the first domain controller.

6. Verify that the \sysvol and \netlogon drives are shared on the new domain controller by doing the following:

   a. On the new domain controller, open Command Prompt.

   b. Type:

   **Net share**

   a. In the list that is generated, verify the existence of Sysvol and Netlogon.

7. Uninstall Active Directory from the domain controller that you want to rename to be a member server.

8. Rename the member server.

9. Install Active Directory on the renamed server to create an additional domain controller.

10. Transfer the operations master roles back to the renamed domain controller.

11. Enable the global catalog on the renamed domain controller.

For information about performing the individual steps in this procedure, see the topics under "See Also."

**Note**

- You can also rename a domain controller in a domain that contains a single domain controller by using My Computer. However, doing so will result in a service interruption to clients. Always perform a system state backup before you rename a domain controller. For more information about backing up system state data, see the topics under "See Also."

# Disable signed or encrypted LDAP traffic

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To disable signed or encrypted LDAP traffic

1. Open Registry Editor.

   **Caution**

   - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. You can also use the Last Known Good Configuration startup option if you encounter problems after manual changes have been applied.

2. In Registry Editor, navigate to the following registry key:

   **Where?**

   - HKEY_LOCAL_MACHINE/SOFTWARE/Microsoft/Windows/CurrentVersion/AdminDebug

3. Click **Edit**, point to **New**, and then click **DWORD Value**.

4. In the text box that appears, type **ADsOpenObjectFlags**, and then press ENTER.

5. Double-click the **ADsOpenObjectFlags** registry key you just created, and then change the **Value Data** to one of the following values below:

| Value data (Hexadecimal) | Disables |
|---|---|
| 1 | Signing |
| 2 | Encryption |
| 3 | Encryption and Signing |

### Caution

- This procedure will disable the use of signed or encrypted LDAP traffic for some Active Directory administrative tools. It is recommended that you avoid disabling this feature. For more information, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Operations Master Roles

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage operations master roles**

- Identify operations master roles
- Transfer operations master roles
- Seize operations master roles

# Identify operations master roles

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Identify operations master roles**

- Identify the RID master
- Identify the PDC emulator
- Identify the infrastructure master
- Identify the domain naming master
- Identify the schema master

# Identify the RID master

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To identify the RID master

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Active Directory Users and Computers.
2. Right-click the domain node, and then click **Operations Masters**.
3. On the **RID** tab, under **Operations masters**, view the current RID master.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Every domain has only one RID master. To identify the RID master in a different domain, target the appropriate domain before clicking **Operations Masters**.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **dsquery server -hasfsmo rid**

| Value | Description |
|---|---|
| **-hasfsmo** | Finds the domain controller (server object) that currently holds the requested operations masters role. |
| **rid** | Requests the RID master of the current domain. |

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Identify the PDC emulator

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To identify the PDC emulator

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Active Directory Users and Computers.
2. Right-click the domain node, and then click **Operations Masters**.
3. On the **PDC** tab, under **Operations masters**, view the operations masters that will serve as the PDC emulator.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Every domain has only one PDC emulator master. To identify the PDC emulator in a different domain, target the appropriate domain before clicking **Operations Masters**.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **dsquery server -hasfsmo pdc**

| Value | Description |
|---|---|
| **-hasfsmo** | Finds the domain controller (server object) that currently holds the requested operations masters role. |
| **pdc** | Requests the PDC emulator master of the current domain. |

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Identify the infrastructure master

Updated: October 13, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To identify the infrastructure master**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. Right-click the domain node, and then click **Operations Masters**.
3. On the **Infrastructure** tab, under **Operations masters**, view the name of the current infrastructure master.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Every domain has only one infrastructure master. To identify the infrastructure master in a different domain, target the appropriate domain before clicking **Operations Masters**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsquery server –hasfsmo infr**

| Value | Description |
|---|---|
| **-hasfsmo** | Finds the domain controller (server object) that currently holds the requested operations masters role. |
| **infr** | Requests the infrastructure master of the forest. |

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

**Information about functional differences**

# Identify the domain naming master

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To identify the domain naming master**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. Right-click **Active Directory Domains and Trusts**, and then click **Operations Master**.
3. Under **Domain naming operations master**, view the current domain naming operations master.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- Every forest has only one domain naming master. To identify the domain naming master in a different forest, target the appropriate forest before clicking **Operations Master**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsquery server -hasfsmo name**

| Value | Description |
|---|---|
| **-hasfsmo** | Finds the domain controller (server object) that currently holds the requested operations master role. |
| **name** | Requests the domain naming master of the forest. |

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

**Information about functional differences**

# Identify the schema master

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To identify the schema master**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open the Active Directory Schema snap-in.
2. In the console tree, right-click **Active Directory Schema**, and then click **Operations Master**.
3. Under **Current Schema Master**, view the current schema operations master.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open the Active Directory Schema snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Schema**.
- Each forest has only one schema master. To identify the schema master in a different forest, target the appropriate forest before clicking **Operations Master**.
- If the Active Directory Schema snap-in is not installed, see Related Topics.

**Using a command line**

1. Open Command Prompt.
2. Type:

```
dsquery server -hasfsmo schema
```

| Value | Description |
|---|---|
| -hasfsmo | Finds the domain controller (server object) that currently holds the requested operations master role. |
| schema | Requests the schema master of the forest. |

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Transfer operations master roles

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Transfer operations master roles**

- Transfer the RID master role
- Transfer the PDC emulator role
- Transfer the infrastructure master role
- Transfer the domain naming master role
- Transfer the schema master role

# Transfer the RID master role

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To transfer the RID master role

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Active Directory Users and Computers.
2. In the console tree, right-click **Active Directory Users and Computers**, and then click **Connect to Domain Controller**.
3. In **Enter the name of another domain controller**, type the name of the domain controller you want to hold the RID master role.

   Or, click the domain controller in the list of available domain controllers.
4. In the console tree, right-click **Active Directory Users and Computers**, point to **All Tasks**, and then click **Operations Masters**.
5. Click the **RID** tab, and then click **Change**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To transfer a role to another domain controller, you may first need to change the focus of Active Directory Users and Computers to the target domain controller. To do this, right-click **Active Directory Users and Computers**, click **Connect to Domain Controller**, and then click the target domain controller.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **roles**
4. At the fsmo maintenance command prompt, type:

   **connection**

5. At the server connections command prompt, type:

   **connect to server***DomainController*

6. At the server connections command prompt, type:

   **quit**

7. At the fsmo maintenance command prompt, type:

   **transfer RID master**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to assign the new operations master role. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the **ntdsutil** command prompt, type:

  **roles** ENTER

  **?** ENTER

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Transfer the PDC emulator role

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To transfer the PDC emulator role**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click **Active Directory Users and Computers**, and then click **Connect to Domain Controller**.
3. In **Enter the name of another domain controller**, type the name of the domain controller you want to hold the PDC emulator role.

   Or, click the domain controller in the list of available domain controllers.
4. In the console tree, right-click **Active Directory Users and Computers**, point to **All Tasks**, and then click **Operations Masters**.
5. Click the **PDC** tab, and then click **Change**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To transfer a role to another domain controller, you may first need to change the focus of Active Directory Users and Computers to the target domain controller. To do this, right-click **Active Directory Users and Computers**, click **Connect to Domain Controller**, and then click the target domain controller.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **roles**
4. At the fsmo maintenance command prompt, type:

   **connection**

5. At the server connections command prompt, type:

   **connect to server***DomainController*

6. At the server connections command prompt, type:

   **quit**

7. At the fsmo maintenance command prompt, type:

   **transfer PDC**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to assign the new operations master role. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the **ntdsutil** command prompt, type:

  **roles** ENTER

  **?** ENTER

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Transfer the infrastructure master role

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To transfer the infrastructure master role

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Active Directory Users and Computers.
2. In the console tree, right-click **Active Directory Users and Computers**, and then click **Connect to Domain Controller**.
3. In **Enter the name of another domain controller**, type the name of the domain controller you want to hold the infrastructure master role.

   Or, click the domain controller in the list of available domain controllers.
4. In the console tree, right-click **Active Directory Users and Computers**, point to **All Tasks**, and then click **Operations Masters**.
5. On the **Infrastructure** tab, click **Change**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To transfer a role to another domain controller, you may first need to change the focus of Active Directory Users and Computers to the target domain controller. To do this, right-click **Active Directory Users and Computers**, click **Connect to Domain Controller**, and then click the target domain controller.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **roles**
4. At the fsmo maintenance command prompt, type:

   **connection**

5. At the server connections command prompt, type:

   **connect to server***DomainController*

6. At the server connections command prompt, type:

   **quit**

7. At the fsmo maintenance command prompt, type:

   **transfer infrastructure master**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to assign the new operations master role. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the **ntdsutil** command prompt, type:

  **roles** ENTER

  **?** ENTER

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Transfer the domain naming master role

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To transfer the domain naming master role

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click **Active Directory Domains and Trusts**, and then click **Connect to Domain Controller**.
3. In **Enter the name of another domain controller**, type the name of the domain controller you want to hold the domain naming master role.

   Or, click the domain controller in the list of available domain controllers.
4. In the console tree, right-click **Active Directory Domains and Trusts**, and then click **Operations Master**.
5. Click **Change**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- To transfer a role to another domain controller, you may first need to change the focus of Active Directory Domains and Trusts to the target domain controller. To do this, right-click **Active Directory Domains and Trusts**, click **Connect to Domain Controller**, and then click the target domain controller.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **roles**
4. At the fsmo maintenance command prompt, type:

   **connection**

5. At the server connection command prompt, type:

   **connect to server***DomainController*

6. At the server connection command prompt, type:

   **quit**

7. At the fsmo maintenance command prompt, type:

   **transfer domain naming master**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to assign the new operations master role. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the **ntdsutil** command prompt, type:

  **roles** ENTER

  **?** ENTER

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Transfer the schema master role

Updated: January 20, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To transfer the schema master role

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open the **Active Directory Schema** snap-in.

   If you have not already installed the Active Directory Schema snap-in, please see Install the Active Directory Schema snap-in (http://go.microsoft.com/fwlink/?LinkID=209652).

2. In the console tree, right-click **Active Directory Schema** and then click **Change Domain Controller**.

3. Click **Specify Name** and type the name of the domain controller that you want to hold the schema master role.

4. In the console tree, right-click **Active Directory Schema**, and then click **Operations Master**.

5. Click **Change**.

### Notes

- To perform this procedure, you must be a member of the Schema Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- The Active Directory Schema snap-in must be connected to the schema master to perform this procedure. The Active Directory Schema snap-in connects to the schema master by default when it is started.
- If the Active Directory Schema snap-in is not installed, see Related Topics.

#### Using a command line

1. Open Command Prompt.

2. Type:

   **ntdsutil**

3. At the ntdsutil command prompt, type:

   **roles**

4. At the fsmo maintenance command prompt, type:

   **connection**

5. At the server connections command prompt, type:

**connect to server***DomainController*

6. At the server connections command prompt, type:

   **quit**

7. At the fsmo maintenance command prompt, type:

   **transfer schema master**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to transfer the role. |

**Notes**

- To perform this procedure, you must be a member of the Schema Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open the Active Directory Schema snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Schema**.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the **ntdsutil** command prompt, type:

  **roles** ENTER

  **?** ENTER

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Seize operations master roles

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Seize operations master roles**

- Seize the RID master role
- Seize the PDC emulator role
- Seize the infrastructure master role
- Seize the domain naming master role
- Seize the schema master role

# Seize the RID master role

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To seize the RID master role**

1. Open Command Prompt.
2. Type:

   **ntdsutil**

3. At the ntdsutil command prompt, type:

   **roles**

4. At the fsmo maintenance command prompt, type:

   **connections**

5. At the server connections command prompt, type:

   **connect to server***DomainController*

6. At the server connections prompt, type:

   **quit**

7. At the fsmo maintenance command prompt, type:

   **seize RID master**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to assign the new operations master role. Use only for recovery purposes. |

**Caution**

- Do not seize the RID master role if you can transfer it instead. Seizing the RID master is a drastic step that should be considered only if the current operations master will never be available again. For more information about transferring operations master roles, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Before seizing the RID master, use the **repadmin** command-line tool to verify whether the new operations master has received any updates performed by the previous role holder, and then remove the current operations master from the network. For more information about operations master roles and the Active Directory command-line tools, see Related

Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Seize the PDC emulator role

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To seize the PDC emulator role**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **roles**
4. At the fsmo maintenance command prompt, type:

   **connections**
5. At the server connections command prompt, type:

   **connect to server***DomainController*
6. At the server connections prompt, type:

   **quit**
7. At the fsmo maintenance command prompt, type:

   **seize PDC**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to assign the new operations master role. Use only for recovery purposes. |

**Caution**

- Do not seize the PDC emulator role if you can transfer it instead. Seizing the PDC emulator is a drastic step that should be considered only if the current operations master will never be available again. For more information about transferring operations master roles, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Before seizing the PDC emulator role, use the **repadmin** command-line tool to verify whether the new operations master has received any updates performed by the previous role holder, and then remove the current operations master from the network. For more information about operations master roles and the Active Directory command-line tools, see

Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Seize the domain naming master role

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To seize the domain naming master role**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **roles**
4. At the fsmo maintenance command prompt, type:

   **connections**
5. At the server connections command prompt, type:

   **connect to server** *DomainController*
6. At the server connections prompt, type:

   **quit**
7. At the fsmo maintenance command prompt, type:

   **seize domain naming master**

| Value | Description |
|---|---|
| *DomainController* | The domain controller to which you want to assign the new operations master role. Use only for recovery purposes. |

**Caution**

- Do not seize the domain naming master role if you can transfer it instead. Seizing the domain naming master role is a drastic step that should be considered only if the current operations master will never be available again. For more information about transferring operations master roles, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Before seizing the domain naming master role, use the **repadmin** command-line tool to verify whether the new operations master has received any updates performed by the previous role holder, and then remove the current operations master from the network. For more information about operations master roles and the Active Directory

command-line tools, see Related Topics.

# Manage Trusts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage trusts**

- Verify a trust
- Remove a trust
- Create a shortcut trust
- Create an external trust
- Create a realm trust
- Select the scope of authentication for users
- Manage Forest Trusts

# Verify a trust

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To verify a trust**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that contains the trust you want to verify, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the trust to be verified, and then click **Properties**.
4. Click **Validate**.
5. Do one of the following, and then click **OK**:

   - Click **No, do not validate the incoming trust**.

     If you choose this option, it is recommended that you repeat this procedure for the reciprocal domain.

   - Click **Yes, validate the incoming trust**.

     If you choose this option, you must type a user account and password with administrative credentials for the reciprocal domain.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- You can verify trusts for shortcut, external, and forest trusts but not realm trusts.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/verify**

| Value | Description |
|---|---|

| | |
|---|---|
| *TrustingDomainName* | Specifies the DNS name of the trusting domain in the trust that is being verified. |
| *TrustedDomainName* | Specifies the DNS name of the domain that is trusted in the trust that is being verified. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can verify trusts for shortcut, external, and forest trusts but not realm trusts.

- This command-line method requires the Netdom Windows support tool. For information about installing Windows support tools, see Related Topics.

- To view the complete syntax for this command, at a command prompt, type:

  **netdom trust | more**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a trust

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a trust**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that contains the trust you want to remove, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the trust to be removed, and then click **Remove**.
4. Do one of the following, and then click **OK**:

   - Click **No, remove the trust from the local domain only**.

     If you choose this option, it is recommended that you repeat this procedure for the reciprocal domain.

   - Click **Yes, remove the trust from both the local domain and the other domain**.

     If you choose this option, you must type a user account and password with administrative credentials for the reciprocal domain.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- It is not possible to revoke the default two-way, transitive trusts between domains in a forest. Explicitly created shortcut trusts can be deleted.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/remove/UserD:***User***/PasswordD:****

| Value | Description |
|---|---|
| *TrustingDomainName* | Specifies the DNS name of the trusting domain in the trust that is being removed. |

| | |
|---|---|
| *TrustedDomainName* | Specifies the DNS name of the domain that is trusted in the trust that is being removed. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- This command-line method requires the Netdom Windows support tool. For information about installing Windows support tools, see Related Topics.

- To view the complete syntax for this command, at a command prompt, type:

  **netdom trust | more**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a shortcut trust

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a shortcut trust**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain you want to establish a shortcut trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the DNS name (or NetBIOS name) of the domain, and then click **Next**.
5. On the **Direction of Trust** page, do one of the following:

   - To create a two-way, shortcut trust, click **Two-way**.

     Users in this domain and users in the specified domain can can use this trust path.

   - To create a one-way, incoming shortcut trust, click **One-way:incoming**.

     Users in the specified domain will not be able to use this trust path.

   - To create a one-way, outgoing shortcut trust, click **One-way:outgoing**.

     Users in this domain will not be able to use this trust path.

6. Continue to follow the wizard.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- If you have the appropriate administrative credentials for each domain, you can create both sides of a shortcut trust at the same time by clicking **Both this domain and the specified domain** on the **Sides of Trust** page. For more information, see Related Topics.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/add**

| Value | Description |
|---|---|
| *TrustingDomainName* | Specifies the DNS name (or NetBIOS name) of the trusting domain in the trust being created. |
| *TrustedDomainName* | Specifies the DNS name (or NetBIOS name) of the domain that will be trusted in the trust being created. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- This command-line method requires the Netdom Windows support tool. For information about installing Windows support tools, see Related Topics.

- Other switches can be used to assign a password or determine the direction of the trust. For example, to make the above trust a two-way, transitive trust you would use the following syntax:

  **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/add/twoway**

- To view the complete syntax for this command, at a command prompt, type:

  **netdom trust | more**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create an external trust

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an external trust**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the DNS name (or NetBIOS name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, do one of the following:

   - To create a two-way, external trust, click **Two-way**.

     Users in this domain and users in the specified domain can access resources in either domain.

   - To create a one-way, incoming external trust, click **One-way:incoming**.

     Users in the specified domain will not be able to access any resources in this domain.

   - To create a one-way, outgoing external trust, click **One-way:outgoing**.

     Users in this domain will not be able to access any resources in the specified domain.

7. Continue to follow the wizard.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- If you have the appropriate administrative credentials for each domain, you can create both sides of an external trust at the same time by clicking **Both this domain and the specified domain** on the **Sides of Trust** page. For more information, see Related Topics.
- If you want to allow users from the specified domain to obtain access to all the resources in this domain, click **Allow**

**authentication for all resources in the local domain** on the **Outgoing Trust Properties** page. This option should be used when both domains belong to the same organization.

- If you want to restrict users in the specified domain from obtaining access to any of the resources in this domain, click **Allow authentication only for selected resources in the local domain** on the **Outgoing Trust Properties** page. This option should be used when each domain belongs to a separate organization.

#### Using a command line

1. Open Command Prompt.

2. Type:

   **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/add**

| Value | Description |
|---|---|
| *TrustingDomainName* | Specifies the DNS name (or NetBIOS name) of the trusting domain in the trust being created. |
| *TrustedDomainName* | Specifies the DNS name (or NetBIOS name) of the domain that will be trusted in the trust being created. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- This command-line method requires the Netdom Windows support tool. For information about installing Windows support tools, see Related Topics.

- Other switches can be used to assign a password or determine the direction of the trust. For example, to make a two-way, transitive trust, you can use the following syntax:

  **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/add/twoway**

- To view the complete syntax for this command, at a command prompt, type:

  **netdom trust | more**

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a realm trust

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a realm trust**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain you want to administer, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the realm name for the target realm, and then click **Next**.
5. On the **Trust Type** page, select the **Realm trust** option, and then click **Next**.
6. On the **Transitivity of Trust** page, do one of the following:
   - To form a trust relationship with the domain and the specified realm, click **Nontransitive**, and then click **Next**.
   - To form a trust relationship with the domain and the specified realm and all trusted realms, click **Transitive**, and then click **Next**.
7. On the **Direction of Trust** page, do one of the following:
   - To create a two-way, realm trust, click **Two-way**.

     Users in this domain and users in the specified realm can access resources in either domain or realm.
   - To create a one-way, incoming realm trust, click **One-way:incoming**.

     Users in the specified realm will not be able to access any resources in this domain.
   - To create a one-way, outgoing realm trust, click **One-way:outgoing**.

     Users in this domain will not be able to access any resources in the specified realm.
8. Continue to follow the wizard.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and

then double-click **Active Directory Domains and Trusts**.

#### Using a command line

1. Open Command Prompt.

2. Type:

   **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/add/realm/PasswordT:***NewRealmTrustPassword*

| Value | Description |
|---|---|
| *TrustingDomainName* | Specifies the DNS name of the trusting domain in the new realm trust. |
| *TrustedDomainName* | Specifies the DNS name of the domain that will be trusted in the new realm trust. |
| *NewRealmTrustPassword* | Specifies the trust password for the new realm trust. This password must match the one used in the Kerberos realm. |

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- This command-line method requires the Netdom Windows support tool. For information about installing Windows support tools, see Related Topics.

- Other switches can be used to assign a password or determine the direction of the trust. For example, to make the above trust a two-way, transitive trust you would use the following syntax:

  **netdom trust***TrustingDomainName***/d:***TrustedDomainName***/add/realm/twoway**

- To view the complete syntax for this command, at a command prompt, type:

  **netdom trust | more**

#### Information about functional differences

# Select the scope of authentication for users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To select the scope of authentication for users**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, do one of the following:
   - To select the scope of authentication for users authenticating through an external trust, click the external trust that you want to administer, and then click **Properties**. On the **Authentication** tab, click either **Domain-wide authentication** or **Selective authentication**.
   - To select the scope of authentication for users authenticating through a forest trust, click the forest trust that you want to administer, and then click **Properties**. On the **Authentication** tab, click either **Forest-wide authentication** or **Selective authentication**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To perform this procedure for a forest trust, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- For an external trust, if you select **Selective authentication**, you need to manually enable permissions on the local domain and on the resource to which you want users in the external domain to have access.
- For a forest trust, if you select **Selective authentication**, you need to manually enable permissions on each domain and resource in the local forest to which you want users in the second forest to have access.
- You can use selective authentication only on external and forest trusts. For more information about selective authentication, see Security Considerations for Trusts.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Forest Trusts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage forest trusts**

- Create a forest trust
- Change the routing status of a name suffix
- Enable or disable an existing name suffix from routing
- Exclude name suffixes from routing to a local forest

# Create a forest trust

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a forest trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the forest root domain, and then click **Properties**.
3. On the **Trust** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the DNS name (or NetBIOS name) of another forest, and then click **Next**.
5. On the **Trust Type** page, click **Forest trust**, and then click **Next**.
6. On the **Direction of Trust** page, do one of the following:

   - To create a two-way, forest trust, click **Two-way**.

     Users in this forest and users in the specified forest can access resources in either forest.

   - To create a one-way, incoming forest trust, click **One-way:incoming**.

     Users in the specified forest will not be able to access any resources in this forest.

   - To create a one-way, outgoing forest trust, click **One-way:outgoing**.

     Users in this forest will not be able to access any resources in the specified forest.

7. Continue to follow the wizard.

**Important**

- To successfully create a forest trust, your environment will need to be set up properly. For more information, see the checklist for creating a forest trust in Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If you are a member of the Incoming Forest Trust Builders group, you can create one-way, incoming forest trusts to this forest.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- On a domain controller running Windows Server 2003, the forest root domain is the first domain listed in the console tree in Active Directory Domains and Trusts. This configuration is not provided on domain controllers running Windows 2000.

- If you have the appropriate administrative credentials for each forest, you can create both sides of a forest trust at the same time by clicking **Both this domain and the specified domain** on the **Sides of Trust** page. For more information, see Related Topics.

- If you want users from the specified forest to have access to all computers in the local forest, on the **Outgoing Trust Properties** page, click **Forest-wide authentication**. This option is preferred when both forests belong to the same organization.

- If you want to selectively limit authentication to particular users and groups from the specified forest, on the **Outgoing Trust Properties** page, click **Selective authentication**. This option is preferred if the specified forest belongs to a separate organization.

- In addition to creating new trusts, you can modify existing trusts by clicking the **Trust** tab.

- The command-line tool Dsmod.exe does not support the addition of security principals in one forest to groups that are located in another forest when both forests are joined by a forest trust. You can use the Active Directory Users & Computers snap-in to add security principals across a forest trust.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Command-line reference A-Z

# Change the routing status of a name suffix

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the routing status of a name suffix**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. On the **Name Suffix Routing** tab, under **Name suffixes in the *x.x* forest**, click the suffix for which you want to modify the routing status, and then click **Edit**.
5. In **Existing name suffixes in *x.x***, click the suffix that you want to modify, and then click **Enable** or **Disable**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- You cannot enable a name suffix that is in conflict. If the conflict is with a local UPN name suffix, you must remove the local user principal name (UPN) name suffix before you can enable the routing name. If the conflict is with a name that is claimed by another trust partner, you must disable the name in the other trust before it can be enabled for this trust.
- To view a log of name suffixes, Domain Name System (DNS) names, NetBIOS names and the status that is associated with this trust, click **Save As**. This log can assist you in troubleshooting authentication problems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable an existing name suffix from routing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable an existing name suffix from routing**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. Click the **Name Suffix Routing** tab, under **Name suffixes in the *x.x* forest**, do one of the following:
   - To enable a name suffix, click the suffix that you want to enable, and then click **Enable**. If the **Enable** button appears dimmed, then the name suffix is already enabled.
   - To disable a name suffix, click the suffix that you want to disable, and then click **Disable**. If the **Disable** button appears dimmed, then the name suffix is already disabled.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- When you disable a name suffix, all children of that Domain Name System (DNS) name will also be disabled.
- You cannot enable a name suffix that is in conflict. If the conflict is with a local user principal name (UPN) name suffix, you must remove the local UPN name suffix before you can enable the routing name. If the conflict is with a name that is claimed by another trust partner, you must disable the name in the other trust before it can be enabled for this trust.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Exclude name suffixes from routing to a local forest

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To exclude name suffixes from routing to a local forest**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. On the **Name Suffix Routing** tab, under **Name suffixes in the *x.x* forest**, click the unique name suffix for which you want to exclude the routing status, and then click **Edit**.
5. In **Name suffixes to exclude from routing to *x.x***, click **Add**, type a Domain Name System (DNS) name suffix that is subordinate to the unique name suffix, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- When you exclude a name suffix, all children of that DNS name will also be excluded.
- To view a log of name suffixes, DNS names, NetBIOS names and the status that is associated with this trust, click **Save As**. This log can assist you in troubleshooting authentication problems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Forests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage forests**

- Raise the forest functional level
- Manage Application Directory Partitions
- Manage the Schema

# Raise the forest functional level

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To raise the forest functional level**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the **Active Directory Domains and Trusts** node, and then click **Raise Forest Functional Level**.
3. In **Select an available forest functional level**, click Windows Server 2003, and then click **Raise**.

### Caution

- If you have or will have any domain controllers running Windows NT 4.0 and earlier or Windows 2000, then do not raise the forest functional level to Windows Server 2003. Once the forest functional level has been set to Windows Server 2003, it cannot be changed back to Windows 2000.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.
- Windows 2000 native is the minimum domain functionality requirement for raising the forest functional level to Windows Server 2003.
- To raise the forest functional level, you must first upgrade (or demote) all existing Windows 2000 domain controllers within your forest.
- If you are unable to raise the forest functional level, you can click **Save As** in the **Raise Forest Functional Level** dialog box to save a log file that specifies which domain controllers in the forest still need to be upgraded from Windows NT or Windows 2000.
- The current forest functional level is displayed under **Current forest functional level** in the **Raise Forest Functional Level** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Application Directory Partitions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage application directory partitions**

- Create or delete an application directory partition
- Add or remove an application directory partition replica
- Display application directory partition information
- Set an application directory partition reference domain
- Prepare a cross-reference object
- Set a notification delay

# Create or delete an application directory partition

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create or delete an application directory partition**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **domain management**
4. At the domain management command prompt, type:

   **connection**
5. At the server connections command prompt, type:

   **connect to server** *ServerName*
6. At the server connections command prompt, type:

   **quit**
7. At the domain management command prompt, do one of the following:

   - To create an application directory partition, type:

     **create nc** *ApplicationDirectoryPartition DomainController*
   - To delete an application directory partition, type:

     **delete nc** *ApplicationDirectoryPartition*

| Value | Description |
|---|---|
| *ServerName* | The DNS name of the domain controller to which you want to connect. |
| *ApplicationDirectoryPartition* | The distinguished name of the application directory partition that you want to create or delete. For example, the distinguished name of the application directory partition test.microsoft.com is dc=test,dc=Microsoft,dc=com. |
| *DomainController* | The DNS name of the domain controller on which to create or delete the application directory partition. Type NULL to create the application directory partition on the domain controller to which you are currently connected. |

**Caution**

- Removing the last replica of an application directory partition will result in the permanent loss of any data contained in the partition. For more information, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add or remove an application directory partition replica

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add or remove an application directory partition replica**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **domain management**
4. At the domain management command prompt, type:

   **connection**
5. At the server connections command prompt, type:

   **connect to server** *DomainController*
6. At the server connections command prompt, type:

   **quit**
7. At the domain management command prompt, do one of the following:

   - To add an application directory partition replica, type:

     **add nc replica** *ApplicationDirectoryPartition DomainController*
   - To remove an application directory partition replica, type:

     **remove nc replica** *ApplicationDirectoryPartition DomainController*

| Value | Description |
|---|---|
| *DomainController* | The DNS name of the domain controller on which to add or remove the replica of the application directory partition. |
| *ApplicationDirectoryPartition* | The distinguished name for the application directory partition of which you want to add or remove a replica. For example, the distinguished name of the application directory partition test.microsoft.com is dc=test,dc=microsoft,dc=com. |

**Caution**

- Removing the last replica of an application directory partition will result in the permanent loss of any data contained in the partition.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in

Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- The value NULL can be used for the *DomainController* parameter of the **add nc replica** and **remove nc replica** commands if you are adding or removing the application directory partition replica on the domain controller to which you are currently connected.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display application directory partition information**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command prompt, type:

   **domain management**
4. At the domain management command prompt, type:

   **connection**
5. At the connection command prompt, type:

   **connect to server** *DomainController*
6. At the connection command prompt, type:

   **quit**
7. At the domain management command prompt, do one or more of the following:

   - To show the distinguished names of known directory partitions, type:

     **list**
   - To show the reference domain and replication delays for an application directory partition, type:

     **list nc information** *DistinguishedName*
   - To show the list of domain controllers in the replica set for an application directory partition, type:

     **list nc replicas** *DistinguishedName*

| Value | Description |
|---|---|
| *DomainController* | The DNS name of the domain controller for which you want to display application directory partition information. |
| *DistinguishedName* | The distinguished name of the application directory partition you want information about. |

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command**

**prompt**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set an application directory partition reference domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set an application directory partition reference domain**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command, type:

   **domain management**
4. At the domain management command, type:

   **connection**
5. At the connection command, type:

   **connect to server** *DomainController*
6. At the connection command, type:

   **quit**
7. At the domain management command, type:

   **set nc reference domain** *ApplicationDirectoryPartition ReferenceDomain*

| Value | Description |
|---|---|
| *DomainController* | The DNS name of the domain controller on which the application directory partition resides. |
| *ApplicationDirectoryPartition* | The distinguished name of the application directory partition for which you want to set the reference domain. For example, the distinguished name of the application directory partition test.microsoft.com is dc=test, dc=microsoft, dc=com. |
| *ReferenceDomain* | The distinguished name of the domain that you want to be the reference domain for this application directory partition. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Prepare a cross-reference object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prepare a cross-reference object**

1. Open Command Prompt.
2. Type:

   **ntdsutil**
3. At the ntdsutil command, type:

   **domain management**
4. At the domain management command, type:

   **connection**
5. At the connection command, type:

   **connect to server** *DomainController*
6. At the connection command, type:

   **quit**
7. At the domain management command, type:

   **Precreate** *ObjectNameDomainController*

| Value | Description |
|---|---|
| *DomainController* | The DNS name of the domain controller on which the object will reside. |
| *ObjectName* | The distinguished name of the object that you want to create. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- This procedure can be used for either preparing a domain for use with the Active Directory Installation Wizard or preparing an application directory partition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Managing application directory partitions

# Set a notification delay

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set a notification delay**

1. Open Command Prompt.
2. Type:

   **ntdsutil**

3. At the ntdsutil command, type:

   **domain management**

4. At the domain management command, type:

   **connection**

5. At the connection command, type:

   **connect to server** *DomainController*

6. At the connection command, type:

   **quit**

7. At the domain management command, type:

   **set nc replicate notification delay** *DirectoryPartition DelayInSeconds AdditionalDelayInSeconds*

| Value | Description |
|---|---|
| *DirectoryPartition* | The distinguished name of the directory partition for which you want to set notification delays. |
| *DelayInSeconds* | The number of seconds to delay before sending the change notification to the first replication partner. |
| *AdditionalDelayInSeconds* | The number of seconds to delay before sending subsequent change notifications to the remaining replication partners. |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- This procedure can be applied to any directory partition including application directory partitions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Managing application directory partitions

# Manage the Schema

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage the schema**

- Install the Active Directory Schema snap-in
- Add a member to the Schema Admins group
- Remove a member from the Schema Admins group
- Modify schema permissions
- Add an attribute to the global catalog
- Index an attribute in Active Directory
- Index an attribute for a containerized search
- View a schema class or attribute definition
- Modify an existing schema class or attribute definition
- Add a new schema class or attribute definition
- Deactivate a class or attribute
- Reactivate a class or attribute
- Reload the schema
- Enable schema changes on a schema master running Windows 2000

# Install the Active Directory Schema snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the Active Directory Schema snap-in**

1. Open Command Prompt.
2. Type:

   **regsvr32 schmmgmt.dll**

   This command will register Schmmgmt.dll on your computer. For more information about using **regsvr32**, see Related Topics.
3. Click **Start**, click **Run**, type **mmc /a**, and then click **OK**.
4. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
5. Under **Available Standalone Snap-ins**, double-click **Active Directory Schema**, click **Close**, and then click **OK**.
6. To save this console, on the **File** menu, click **Save**.
7. In **Save in**, point to the systemroot\system32 directory.
8. In **File name**, type **schmmgmt.msc**, and then click **Save**.
9. To create a shortcut on your **Start** menu:

   - Right-click **Start**, click **Open All Users**, double-click the **programs** folder, and then double-click the **Administrative Tools** folder.
   - On the **File** menu, point to **New**, and then click **Shortcut**.
   - In the Create Shortcut Wizard, in **Type the location of the item**, type **schmmgmt.msc**, and then click **Next**.
   - On the **Select a Title for the program** page, in **Type a name for this shortcut**, type **Active Directory Schema**, and then click **Finish**.

**Caution**

- Modifying the schema is an advanced operation best performed by experienced programmers and system administrators. For detailed information about modifying the schema, see the Active Directory programmer's Guide at the Microsoft Web site.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- You can also run the Active Directory Schema snap-in from a computer running Windows XP Professional. Simply install the Windows Server 2003 Administration Tools Pack on the computer, and then complete step 9 above.

- The Windows Server 2003 Administration Tools Pack cannot be installed on computers running Windows 2000 Professional or Windows 2000 Server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a member to the Schema Admins group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a member to the Schema Admins group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users** in the forest root domain.

   **Where?**

   - Active Directory Users and Computers/*forest root domain*/Users

     Or, click the folder that contains the user account.
3. In the details pane, right-click the user account that you want to add, and then click **Properties**.
4. Click the **Member Of** tab, and then click **Add**.
5. In **Enter the object names to select**, type **Schema Admins**, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To add users and computers to a group, you can also select the users and computers to be added, click

  on the toolbar, and then click the group into which they will be added.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod group** *GroupDN* **-addmbr** *MemberDN*

| Value | Description |
|---|---|

| | |
|---|---|
| *GroupDN* | Specifies the distinguished name of the Schema Admins group in your root domain.<br><br>For example, if the name of your root domain is example.microsoft.com, you would type: **"cn=schema admins,cn=users,dc=example,dc=microsoft,dc=com"** |
| *MemberDN* | Specifies the distinguished name of the user you want to add to the Schema Admins group.<br><br>For example, if you want to add a user named "Mary Baker" to the Schema Admins group, you would type: **"cn=mary baker,cn=users,dc=example,dc=microsoft,dc=com"** |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt type:

  **dsmod group /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a member from the Schema Admins group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a member from the Schema Admins group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users** in the forest root domain.

   **Where?**

   - Active Directory Users and Computers/*forest root domain*/Users

3. In the details pane, right-click the **Schema Admins** group, and then click **Properties**.
4. On the **Members** tab, click the member you want to delete, and then click **Remove**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **dsmod group***GroupDN***-rmmbr***MemberDN*

| Value | Description |
|---|---|
| *GroupDN* | Specifies the distinguished name of the Schema Admins group in your root domain.<br><br>For example, if the name of your root domain is example.microsoft.com, you would type: **"cn=schema admins,cn=users,dc=example,dc=microsoft,dc=com"** |
| *MemberDN* | Specifies the distinguished name of the user you want to remove from the Schema Admins group.<br><br>For example, if you want to remove a user named "Mary Baker" from the Schema Admins group, you would type: **"cn=mary baker,cn=users,dc=example,dc=microsoft,dc=com"** |

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt type:

  **dsmod group /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify schema permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify schema permissions**

1. Open the Active Directory Schema snap-in.
2. In the console tree, right-click **Active Directory Schema**, and then click **Permissions**.
3. On the **Security** tab, under **Group or user names**, click the group whose permissions you want to change.
4. Under **Permissions for Administrators**, select **Allow** or **Deny** for the permissions you want to change.

## Notes

- To perform this procedure, you must be a member of the Schema Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- The Active Directory Schema snap-in must be connected to the schema master to perform this procedure. The Active Directory Schema snap-in connects to the schema master by default when it is started.
- If the Active Directory Schema snap-in is not installed, see Other Resources.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Install the Active Directory Schema snap-in

# Add an attribute to the global catalog

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add an attribute to the global catalog**

1. Open the Active Directory Schema snap-in.
2. In the console tree, click **Attributes**.

   **Where?**

   - Active Directory Schema/Attributes

3. In the details pane, right-click the attribute that you want to add to the global catalog, and then click **Properties**.
4. Select the **Replicate this attribute to the Global Catalog** check box.

### Caution

- If the forest functional level is not set to Windows Server 2003, adding a new attribute to the global catalog will cause a full synchronization of the global catalog. In other words, when you add a new attribute to the global catalog attribute set, all attributes that were previously part of the global catalog in addition to the new attribute are immediately synchronized throughout the forest. For more information, see Related Topics.

### Important

- As a best practice, it is strongly recommended that you use global groups or universal groups instead of domain local groups when specifying permissions on domain objects replicated to the global catalog. For more information, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Schema Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- The Active Directory Schema snap-in must be connected to the schema master to perform this procedure. The Active Directory Schema snap-in connects to the schema master by default when it is started.
- If the Active Directory Schema snap-in is not installed, see Other Resources.

**Information about functional differences**
