# Changes to Functionality in Windows Server 2003 Service Pack 1

Applies To: Windows Server 2003 with SP1

This document specifically focuses on the changes between earlier versions of Windows Server 2003 and Windows Server 2003 with Service Pack 1 (SP1) and reflects the current thinking of Microsoft about Service Pack 1 and its implications for IT professionals and developers. Examples and details are provided for several of the technologies that are experiencing the biggest changes.

The goal for Service Pack 1 is to build on the Trustworthy Computing efforts of Microsoft that were applied in Windows Server 2003. For an overview of the Microsoft Trustworthy Computing initiative, see "Trustworthy Computing Defined," on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=20970.

Windows Server 2003 SP1 incorporates many of the changes in functionality introduced with Windows XP Service Pack 2 (XP SP2), so there are many changes that were documented for Windows XP SP2 that are reiterated in this document.

Information that is not directly related to a technology area is contained in the Appendices section.

A downloadable copy of this document is available on the Microsoft Download Center at http://go.microsoft.com/fwlink/?LinkId=49637.

**Document History**
This is the third release of this document for Windows Server 2003 Service Pack 1 (SP1).

- Added new sections: Distributed File System (DFS) in Windows Server 2003 Service Pack 1, Distributed Transaction Coordinator, Internet Information Services (IIS) in Windows Server 2003 Service Pack 1, .NET Framework for x64-based operating systems, Terminal Services in Windows Server 2003 Service Pack 1

- Revised sections: Access-based Enumeration, Data Execution Prevention, DCOM Security Enhancements, Post-Setup Security Updates, Remote Installation Services (RIS) for 64-bit operating systems, Windows Firewall

**Other Resources and Feedback**
If you have any other questions that are not answered by this paper, "Windows Server 2003 Resources for IT Professionals" on TechNet has links to many other resources regarding Windows Server 2003. This page is updated periodically with the most recent information that is available.

In addition, we appreciate feedback on our documentation and our product. The following resources are available to you for providing feedback:

**Windows Server 2003 Newsgroups**
Newsgroups are a great place to ask questions of other users and find general information about other users' experiences with Windows Server 2003. You can examine some of the newsgroups using a Web browser on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=32745.

**Product Support Services**
If you are having a problem with your computer after installing Windows Server 2003 Service Pack 1, check the product support Web site on Microsoft.com first to see if your issue has been identified in Frequently Asked Questions or by a Knowledge Base article. If not, you can contact Product Support Services to get help with your issue. To start, see "Windows Server 2003 Support Center" on the Microsoft Web site at http://go.micorosoft.com/fwlink/?LinkId=42095.

**Microsoft Wish Program**
If you have a suggestion about how to improve a feature in Windows that you would like considered for the next service pack or major Windows version, you can contact the Microsoft Wish Program and tell them your idea. To find out how to send a comment or suggestion, see "How to Contact the Microsoft Wish Program" on the Microsoft Knowledge Base Web site at http://go.microsoft.com/fwlink/?LinkId=32748.

**Documentation feedback**
If you have any comments or suggestions about Windows Server 2003 Service Pack 1 documents, on the Web version of this document on the Microsoft Web site at the bottom of the page, click **Comments** and tell us what you think. Note that this is only for comments on the documentation, not the product itself.

# About this document

Applies To: Windows Server 2003 with SP1

In Windows Server 2003 Service Pack 1, Microsoft is delivering improvements in several technologies to help enhance security and help customers protect themselves against malicious software and other risks to their computer. These technologies are not intended to replace periodic security updates as they are released, but rather to help strengthen the overall defenses against malicious attacks.

The changes to functionality in Windows Server 2003 Service Pack 1 are in the following technology areas:

- Access-based Enumeration
- Active Directory in Windows Server 2003 Service Pack 1
    - Active Directory Preparation Tool (adprep.exe)
    - Domain Controller Diagnostics Tool (dcdiag.exe))
    - Active Directory Directory Services Maintenance Utility (ntdsutil.exe)
    - Security Account Manager (SAM)
- Add or Remove Programs Filter
- DCOM Security Enhancements
- Data Execution Prevention
- Device\PhysicalMemory Object
- Distributed File System (DFS) in Windows Server 2003 Service Pack 1
- Distributed Transaction Coordinator
- Download, Attachment, and Authenticode Enhancements
- Internet Explorer Feature Control Settings in Group Policy
- Internet Explorer URL Action and Advanced Security Settings in Group Policy
- Internet Explorer Using Feature Control Registry Settings with Security Zone Settings
- Internet Explorer Add-on Management and Crash Detection
- Internet Explorer Binary Behaviors Security Setting
- Internet Explorer BindToObject Mitigation
- Internet Explorer Information Bar
- Internet Explorer Local Machine Zone Lockdown
- Internet Explorer MIME Handling Enforcement
- Internet Explorer Network Protocol Lockdown

- Internet Explorer Object Caching
- Internet Explorer Pop-up Blocker
- Internet Explorer Untrusted Publishers Mitigations
- Internet Explorer Window Restrictions
- Internet Explorer Zone Elevation Blocks
- Internet Information Services (IIS) in Windows Server 2003 Service Pack 1
- Kernel patch protection for x64-based operating systems
- Outlook Express
- Post-Setup Security Updates
- Remote Access Quarantine
- Remote Installation Services (RIS) for 64-bit Operating Systems
- Resultant Set of Policy (RSoP)
- RPC Interface Restriction
- Security Configuration Wizard in Windows Server 2003 Service Pack 1
- Setup
- Terminal Services in Windows Server 2003 Service Pack 1
- Transmission Control Protocol/Internet Protocol (TCP/IP)
- WebDAV Redirector
- Windows Firewall in Windows Server 2003 Service Pack 1
- Windows Media Player
- Wireless Provisioning Services (WPS)
- .NET Framework version 1.1 for 64-bit operating systems

# Access-based Enumeration

Applies To: Windows Server 2003 with SP1

Access-based Enumeration is a new feature included with Windows Server 2003 Service Pack 1. This feature allows users of Windows Server 2003–based file servers to list only the files and folders to which they have access when browsing content on the file server. This eliminates user confusion that can be caused when users connect to a file server and encounter a large number of files and folders that they cannot access.

**What does Access-based Enumeration do?**
Access-based Enumeration filters the list of available files and folders on a server to include only those that the requesting user has access to.

**Who does this feature apply to?**
This feature applies to:

- Domain-joined computers.
- IT professionals who want to control the user's experience.

**Detailed description**
Access-based Enumeration allows users to see only files and folders that they have access to on a file server. This feature is not enabled by default.

To enable this feature, a property must be set on a file share to allow access-based enumeration. To enable this feature on your server, you can download a shell extension that provides both a graphical user interface for enabling access-based enumeration and a command-line interface for managing this feature. When this download is installed, a wizard will run that can automatically enable Access-based Enumeration on the shared folders on your computer. This download includes a whitepaper that provides further details about the shell extension, command line interface, and the `NetShareSetInfo` application programming interface (API). This download is available on the Microsoft Download Center at http://go.microsoft.com/fwlink/?LinkId=46228.

If you want to develop a tool yourself, you can use the `NetShareSetInfo` API. This property is an attribute of the `NetShareSetInfo` (API). For more information about the `NetShareSetInfo` API, see the Platform SDK and the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=46511. To enable Access-based Enumeration, you need to set a flag that points to the `SHARE_INFO_1005` structure. For more information about the `SHARE_INFO_1005` structure, see the Platform SDK and the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=45504.

The new flag to enable Access-based Enumeration is

```
#define SHI1005_FLAGS_ENFORCE_NAMESPACE_ACCESS  0x0800
```

This flag is only applicable to Windows Server 2003 Service Pack 1 and will have no effect on other versions of the Windows operating system.

After the feature is enabled, a listing of the content in that share will present the content that the user has access to.

**Why is this change important?**
This change is important because this allows users to see only those files and directories that they have access to and nothing else. This mitigates the scenario where unauthorized users might otherwise be able to see the contents of a directory even though they don't have access to it.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
The `SHI1005_FLAGS_ENFORCE_NAMESPACE_ACCESS` flag has been added to the NetShareSetInfo API. The flag enables you to turn on the Access-based Enumeration feature.

# Active Directory in Windows Server 2003 Service Pack 1

Applies To: Windows Server 2003 with SP1

**What does Active Directory do?**
Active Directory® is a directory service that stores information about objects on a network and makes this information available to users and network administrators. Active Directory objects typically include shared resources such as servers, volumes, printers, and the network user and computer accounts.

Active Directory is composed of the following:

- Schema. This is a set of rules that defines the classes of objects and attributes contained in the directory, the constraints and limits on instances of these objects, and the format of their names.
- Global catalog. This data store contains information about every object in the directory. This allows users and administrators to find directory information regardless of which domain in the directory actually contains the data.
- Query and index. Using this mechanism objects and their properties can be published and found by network users or applications.
- Replication service. This service distributes directory data across a network. All domain controllers in a domain participate in replication and contain a complete copy of all directory information for their domain. Any change to directory data is replicated to all domain controllers in the domain.
- Active Directory client software. The Active Directory client enables many of the Active Directory features available on Windows 2000 Professional or Windows XP Professional clients for computers running Windows 95, Windows 98, and Windows NT 4.0.

**Who does this feature apply to?**
The changes in Active Directory for Windows Server 2003 Service Pack 1 (SP1) will be of interest to:

- IT professionals who support Active Directory, such as Active Directory administrators, Active Directory schema administrators, Domain Name System (DNS) administrators, and domain controller administrators.
- Help desk professionals.
- Application developers.
- System integrators.

**What functionality is changing in Windows Server 2003 Service Pack 1?**
**Directory service backup reminders**
A new event message, event ID 2089, provides the backup status of each directory partition that a domain controller stores, including application directory partitions and Active Directory Application Mode (ADAM) partitions. If halfway through the backup latency interval (tombstone lifetime) a partition has not been backed up, this event is logged in the Directory Service event log and continues daily until the partition is backed up.

**Added replication security and fewer replication errors**
Replication metadata for domain controllers from which Active Directory has been removed is no longer retained by default, although a waiting period can be configured. This change improves replication security and eliminates replication error messages that are caused by failed attempts to replicate with decommissioned domain controllers. For more information about preserving replication metadata, see "How the Active Directory Replication Model Works" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=46510.

**Install from Media improvement for installing DNS servers**
**Install from Media** improvements make it easier to create a new domain controller that is a DNS server by providing the new option to include application directory partitions in the backup media that is used to install the new domain controller. This option eliminates the requirement for replication of the DomainDNSZones and ForestDNSZones application directory

partitions before the DNS server is operational.

**Enhancements for replication and DNS testing**
The Dcdiag.exe command-line tool, which is available in Windows Support Tools, provides new reporting on the overall health of replication with respect to Active Directory security. This test provides a summary of results along with detailed information for each domain controller that is tested and a diagnosis of any security errors. Dcdiag.exe also has new DNS tests for connectivity, service availability, forwarders and root hints, delegation, dynamic update, locator record registrations, external name resolution, and enterprise infrastructure. These tests can be performed on one domain controller or on all domain controllers in a forest. For more information about the changes to Dcdiag.exe, see the Dcdiag.exe section of this article.

**Support for running domain controllers in virtual machines**
On a single physical server that is running Windows Server 2003 and Microsoft Virtual Server 2005, you can install multiple Windows Server 2003 or Windows 2000 Server domain controllers in separate virtual machines. This platform is well suited for test environments. By using virtual machines, you can effectively host multiple domains, multiple domain controllers for the same domain, or even multiple forests on one physical server that is running a single operating system. Windows Server 2003 SP1 also provides protection against directory corruption that can result from improper backup and restoration of domain controller images. For more information about running domain controllers in virtual machines, see "Running Domain Controllers in Virtual Server 2005" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38330.

**Operations master health and status reporting**
If an operation that requires a domain controller that holds an operations master role (also known as flexible single-master operations (FSMO)) cannot be performed, events are now logged in the Directory Service event log. Events identify role holders that do not exist, exist but are not available, or are available but have not replicated recently with the contacting domain controller. For more information about operations masters, see "How Operations Masters Work" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38333.

**Extended storage of deleted objects**
The default period that a copy of a deleted object is retained in Active Directory, called the tombstone lifetime, is extended from 60 days to 180 days. Longer tombstone lifetime decreases the chance that a deleted object remains in the local directory of a disconnected domain controller beyond the time when the object is permanently deleted from online domain controllers. The tombstone lifetime is not changed automatically when you upgrade to Windows Server 2003 with SP1, but you can change the tombstone lifetime manually after the upgrade. New forests that are installed with Windows Server 2003 with SP1 have a default tombstone lifetime of 180 days. For more information about tombstone lifetime, see "How the Data Store Works" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38339.

**Improved domain controller name resolution**
In response to Domain Name System (DNS) name resolution failures that may be encountered during location of replication partners and global catalog servers, domain controllers running Windows Server 2003 with SP1 request other variations of the server name that might be registered, which results in fewer failures due to DNS delays and misconfiguration. For more information about DNS name resolution, see "How DNS Support for Active Directory Works" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38335.

**Simplified process for server metadata removal**
The Ntdsutil.exe command-line tool for managing the Active Directory database has new commands that make it easier to remove domain controller metadata. Preliminary steps, such as connecting to a server, domain, and site, are no longer required. You simply specify the server to remove. You can also specify the server on which to make the deletion. For more information about the changes to Ntdsutil.exe, see the Ntdsutil.exe section of this article.

**Improved security to protect confidential attributes**
To prevent Read access to confidential attributes, such as a Social Security number, while allowing Read access to other object attributes, you can designate specific attributes as confidential by setting a search flag on the respective attributeSchema object. By default, only domain administrators have Read access to confidential attributes, but this access can be delegated. For more information about access to attributes, see "How Security Descriptors and Access Control Lists Work" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=45972.

**Retention of SID history on tombstones**
The sIDHistory attribute has been added to the set of attributes that are retained on an object tombstone when the object is deleted. If a tombstoned object is reactivated (undeleted), the sIDHistory attribute is now restored with the object. For more information about tombstones, see "How the Data Store Works" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=45973.

**Adprep.exe improvements for Windows 2000 Server upgrades**
The Adprep.exe tool has been improved to reduce the impact of File Replication service (FRS) synchronization that results from updating SYSVOL files during upgrade. Adprep.exe is used to upgrade the Windows 2000 Server schema to the Windows Server 2003 schema and to update some forest- and domain-specific configuration, including SYSVOL, that is required for a

Windows Server 2003 domain controller to be operational. The tool now allows performing SYSVOL operations in a separate step when preparing the domain for upgrade. A new switch, `/gpprep`, has been added to accommodate the SYSVOL updates, which can be performed at a convenient time following the upgrade. The `adprep /domainprep` command, which formerly performed both directory and SYSVOL updates, now updates only the directory. Adprep.exe also now detects third-party schema extensions that block an upgrade, identifies the blocking extensions, and recommends fixes. Microsoft Exchange Server schema objects are also detected so that the Exchange Server schema can be prepared appropriately to accommodate InetOrgPerson naming. For more information about the changes to Adprep.exe, see the Adprep.exe section of this article.

**Changes in dragging and dropping objects in Active Directory Users and computers**
In Windows Server 2003, Service Pack 1 two changes to the drag and drop behavior in the Active Directory Users and Computers Microsoft Management Console (MMC) snap-in were made in response to customer feedback.

First, by default there is now a confirmation dialog when dragging and dropping objects in Active Directory Users and Computers Microsoft Management Console (MMC) snap-in. In Windows Server 2003 drag and drop support in Active Directory Users and Computers was enabled. However, it did not provide any confirmation dialog when moving objects. This made it easier to move objects, but also made it easier to inadvertently move an object to the wrong location and cause client workstations to lose access to critical resources. By adding a confirmation dialog to the drag and drop behavior, the administrator has a chance to correct an unintentional error before it impacts the organization. When the confirmation dialog is displayed there is a check box for **Don’t show this warning while this snap-in is open**.

If the user selects the **Don’t show this warning while this snap-in is open** checkbox, then the confirmation dialog will no longer be shown throughout the current snap-in session. Subsequent drag and drop attempts in that snap-in session will occur without any confirmation.

If the user doesn't select the **Don’t show this warning while this snap-in is open** checkbox, then the warning message will be shown every time the user tries to drag or drop an object.

Second, an administrator can choose to disable dragging and dropping completely by setting the **flags** attribute on the **Display Specifiers** container. The display specifiers container is in the directory at: **CN=DisplaySpecifiers,CN=Configuration,DC=**<*insert domain name*>. This attribute can be set using ADSIedit.msc, which is available in Windows Support Tools.

The overall behavior is:

- If the **flags** attribute is set to any value, then drag and drop is disabled. This is not the default.
- If the **flags** attribute is not set (default case), then the user will be able to use drag and drop to move objects in the Active Directory Computers and Users MMC snap-in.

# Active Directory Preparation Tool (adprep.exe)

Applies To: Windows Server 2003 with SP1

**What does ADPrep.exe do?**
Adprep.exe is a command-line tool used to prepare a Microsoft Windows 2000 forest or a Windows 2000 domain for the installation of Windows Server 2003 domain controllers.

**Who does this feature apply to?**
The changes in ADPrep.exe for Windows Server 2003 Service Pack 1 will be of interest to:

- IT professionals who support Active Directory, such as Active Directory administrators, Active Directory Schema administrators, Domain Name System (DNS) administrators, and domain controller administrators.
- Help desk professionals.
- Application developers.
- System integrators.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Adprep.exe enhancement to detect conflicting Exchange Server schema objects**
**Detailed description**
When Microsoft Exchange Server is deployed in an organization, Exchange Server uses Active Directory as a data store and it extends the Windows 2000 Active Directory schema to enable it to store objects specific to Exchange Server. The `ldapDisplayName` of the attribute schema `ms-Exch-Assistant-Name`, `ms-Exch-LabeledURI`, and `ms-Exch-House-Identifier` defined by Exchange Server conflicts with the `iNetOrgPerson` schema that Active Directory uses in Windows Server 2003. When Windows Server 2003 Service Pack 1 is installed, Adprep.exe will be able to detect the presence of the schema conflict and block the upgrade of the schema until the issue has been resolved.

**Why is this change important?**
Upgrading the Active Directory schema from Windows 2000 to Windows 2003 when these schema objects are present causes the `ldapDisplayName` to become corrupted and results in issues with Active Directory replication. Fixing the Exchange Server schema objects before the upgrade occurs results in a much smoother upgrade experience.

**What works differently?**
The Windows 2000 Active Directory schema cannot be upgraded to the Windows Server 2003 schema until the required Exchange Server schema objects are fixed.

**How do I resolve these issues?**
If Adprep.exe detects the presence of the conflicting Exchange Server schema objects, you can use the following procedure to fix these objects and enable Adprep.exe to successfully upgrade your Active Directory schema.

### To fix conflicting Exchange Server schema objects

1. Log on to the computer that holds the Schema Operation Master role. By default, the first domain controller that you install in your forest is the Schema Operation Master. You must log on using an account that is a member of the Schema Admins security group.
2. Click **Start**, click **Run**, type **notepad.exe** in the **Open** box, and then click **OK**.
3. Create the InetOrgPersonPrevent.ldf script by copying the following text including the trailing hyphen after "schemaUpdateNow: 1" to Notepad:

```
dn: CN=ms-Exch-Assistant-Name,CN=Schema,CN=Configuration,DC=X

changetype: Modify

replace:LDAPDisplayName

LDAPDisplayName: msExchAssistantName

-
```

```
dn: CN=ms-Exch-LabeledURI,CN=Schema,CN=Configuration,DC=X

changetype: Modify

replace: LDAPDisplayName

LDAPDisplayName: msExchLabeledURI

-

dn: CN=ms-Exch-House-Identifier,CN=Schema,CN=Configuration,DC=X

changetype: Modify

replace: LDAPDisplayName

LDAPDisplayName: msExchHouseIdentifier

-

dn:

changetype: Modify

add: schemaUpdateNow

schemaUpdateNow: 1

-
```

4. On the **File** menu, click **Save**. In the **Save As** dialog box, follow these steps to save the InetOrgPersonPrevent.ldf script:
   - In **File name**, type the following:

     **\%userprofile%\InetOrgPersonPrevent.ldf**

   - In **Save as type**, click **All Files**.
   - In **Encoding**, click **Unicode**.
   - Click **Save**.
   - Close Notepad.

5. Run the InetOrgPersonPrevent.ldf script using the following steps:
   - Click **Start**, click **Run**, type **cmd** in the **Open** box, and then click **OK**.
   - At a command prompt, type the following, and then press ENTER:

     **cd %userprofile%**

   - Type the following command

     **c:\documents and settings\%username%ldifde -i -f inetorgpersonprevent.ldf -v -c DC=X** "*domain_name_path_for_forest_root_domain*"

6. Verify that the `ldapDisplayNames` for the `CN=ms-Exch-Assistant-Name`, `CN=ms-Exch-LabeledURI`, and `CN=ms-Exch-House-Identifier` attributes in the schema naming context now appear as `msExchAssistantName`, `msExchLabeledURI`, and `msExchHouseIdentifier`.

**Note**

In step 5 of the previous procedure note the following details:

**DC=X** is a case-sensitive constant.

The domain name path for the root domain must be enclosed in quotation marks. For example, the command syntax for an Active Directory forest whose forest root domain is Contoso.com would be:

**c:\documents and settings\administrator>ldifde -i -f inetorgpersonprevent.ldf -v -c DC=X "dc=contoso,dc=com"**

**Adprep.exe enhancement to detect other conflicting schema objects**
**Detailed description**
Many applications use Active Directory as a data store and extend the Windows 2000 Active Directory schema to enable it to store objects specific to the application. If an application defined a non-RFC compliant schema object, such that the ldapDisplayName, object identifier (OID) or other schema attributes conflict with the Windows 2003 Active Directory schema, when Adprep.exe is run it will detect the conflict and display a generic error.

**Why is this change important?**
Upgrading the Active Directory schema from the Windows 2000 Server schema to the Windows Server 2003 schema when these schema objects are present causes the object to become corrupted and results in issues with Active Directory replication. Fixing the schema objects before the upgrade occurs results in a much smoother upgrade experience.

**What works differently?**
The Windows 2000 Active Directory schema cannot be upgraded to the Windows Server 2003 schema until the conflicting schema objects are fixed. In Windows Server 2003 Service Pac 1, Adprep.exe will identify that a conflicting schema object exists, prevent the corruption of the schema object by blocking the upgrade, and if possible identify which objects are in conflict so that you can resolve the conflict.

**Adprep.exe enhancement to perform SYSVOL operations in a separate step**
**Detailed description**
In previous versions of Windows Server 2003 running **adprep /domainprep** resulted in the addition of an inheritable access control entry (ACE) to all Group Policy objects (GPOs) in the SYSVOL folder. This ACE gives Enterprise domain controllers read access to the GPOs to support Resultant Set of Policy (RSoP) functionality for site base policy. The addition of this ACE is detected by the file replication service (FRS) and initiates an FRS synchronization of all GPOs in the SYSVOL folder.

In Windows Server 2003 Service Pack 1, the addition of the ACE to the GPOs in the SYSVOL folder is not performed while running **adprep /domainprep**. Instead, a new switch (**/gpprep**) has been added to **adprep** to add the inheritable ACE to the GPO folders in the SYSVOL directory. This allows administrators to update the ACE of the GPO objects at their convenience.

**Why is this change important?**
If an organization has a large number of files contained in the GPOs or slow links to replication servers, the FRS synchronization triggered by the **/domainprep** operation could adversely affect the deployment schedule for Windows Server 2003. By putting this operation at the discretion of the administrator, the impact of this operation can be planned and scheduled as part of the deployment.

**What works differently?**
The deployment of a Windows Server 2003 domain controller can occur after running **adprep /forestprep** and **adprep /domainprep**. Resultant Set of Policy (RSoP) functionality will only be operational after running **adprep /domainprep /gpprep**.

# Domain Controller Diagnostics Tool (dcdiag.exe)

Updated: February 17, 2010

Applies To: Windows Server 2003 with SP1

**What does DCDiag.exe do?**
This command-line tool analyzes the state of one or all domain controllers in a forest and reports any problems to assist in troubleshooting. DCDiag.exe consists of a variety of tests that can be run individually or as part of a suite to verify domain controller health.

**Tool location**
The `DCDiag` command-line tool is included when you install Windows Server 2003 Support Tools from the product CD or from the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=100114). For more information about how to install Windows Support Tools, see Install Windows Support Tools (http://go.microsoft.com/fwlink/?LinkId=62270).

**Tool requirements**

- Except as noted below, all commands in `DCDiag` can be run on Windows XP Professional and Windows Server 2003 family (member servers and domain controllers).
- The new `DCDIAG /TEST:DNS` command can validate DNS health of Windows 2000 Server (SP3 or later) or Windows Server 2003 family domain controllers when run from the console of Windows XP or Windows Server 2003 member computers or Windows Server 2003 domain controllers.

**Who does this feature apply to?**
This feature is of interest to the following audiences:

- DNS administrators
- Domain controller administrators
- DCDiag.exe users

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
There are two significant improvements to DCDiag in Windows Server 2003 Service Pack 1:

- `DCDIAG /TEST:DNS` to validate DNS health.
- `DCDIAG /CheckSecurityError` to detect security configurations that can cause Active Directory replication to fail.

The details of these new enhancements are described below.

**New DNS diagnostic tests**
**Detailed description**
DCDiag.exe has been enhanced for Windows Server 2003 Service Pack 1 to include new DNS functionality for reporting on the overall DNS health of domain controllers. There are seven new DNS-related tests that can be run individually or simultaneously. These tests may be performed on one or all domain controllers in an Active Directory forest. When the tests have completed, DCDiag.exe presents a summary of the results, along with detailed information for each domain controller tested.

| **Note** |
| --- |
| The new DNS tests require Enterprise Admin credentials.<br><br>The new DNS tests can be run only against Windows 2000 Server (SP3 or later) or Windows Server 2003 family domain controllers. |

**Command line syntax**

Windows Server 2003 SP1 `dcdiag` uses the same basic syntax as previous versions of `dcdiag`. The syntax for running the new DNS tests is as follows:

`Dcdiag /test:DNS [/DnsBasic | /DnsForwarders | /DnsDelegation | /DnsDynamicUpdate | /DnsRecordRegistration | /DnsResolveExtName [/DnsInternetName:` *InternetName* `] | /DnsAll] [/f:` *Logfile* `] [/ferr:` *Logerr* `] /S:` *DCName* `[/e] [/v]`

| Parameter | Description |
|---|---|
| `/test:DNS` | Performs all seven subtests except the `/DnsInternetName` test against the scoped set of domain controllers. The most common DCDIAG command line arguments are `DCDIAG /TEST:DNS /V /S:`*DCNAME* to run the six default DNS subtests against a single domain controller (DC) or `DCDIAG /TEST:DNS /V /E` to run the six default DNS subtests against all DCs in the console computer's test forest. `DCDIAG /TEST:DNS` is identical to the `/DnsAll` command when individual subtests are not defined. |
| `/test:DNS [DNS test]` | Performs the specified DNS test. If no test is specified, defaults to `/DnsAll`. |
| `/DnsBasic` | Performs basic DNS tests, including network connectivity, DNS client configuration, service availability, and zone existence. |
| `/DnsForwarders` | Performs the `/DnsBasic` tests, and also checks the configuration of forwarders. |
| `/DnsDelegation` | Performs the `/DnsBasic` tests, and also checks for proper delegations. |
| `/DnsDynamicUpdate` | Performs the `/DnsBasic` tests, and also determines whether dynamic update is enabled in the Active Directory zone. |
| `/DnsRecordRegistration` | Performs the `/DnsBasic` tests, and also checks whether the A, CNAME, and well-known SRV records are registered. In addition, creates an inventory report based on results. |
| `/DnsResolveExtName [/DnsInternetName:` *InternetName* `]` | Performs the `/DnsBasic` tests, and also attempts to resolve a sample intranet or Internet Name. If `/DnsInternetName` is not specified, then the command attempts to resolve the name www.microsoft.com. If `/DnsInternetName` is specified, then the command attempts to resolve the Internet name supplied by the user. |
| `/DnsAll` | Performs all tests, except for the `DnsResolveExtName` test, and generates a report. |
| `/f:` *Logfile* | Redirects output to the log file supplied by the user. |
| `/ferr:` *Logerr* | Redirects fatal error output to a separate log file. |
| `/s:` *DCName* | Specifies the domain controller against which to run the tests. |
| `/e` | All tests specified by `/test:DNS` are run against all domain controllers in the Active Directory forest. |
| `/v` | Verbose. Presents information about successful test results, in addition to information about errors and warnings. (When the `/v` parameter is not used, only error and warning information is presented.) Microsoft recommends using the `/v` switch when errors or warnings are reported in the summary table |

**Enterprise DNS Infrastructure Test (/e)**

- When `/test:DNS` is run in conjunction with the `/e` parameter, all tests specified by `test:/DNS` are run against all domain controllers in the Active Directory forest.

| **Note** |
|---|
| Run times for DNS tests can be significant in large enterprises when the `/e` parameter is used. Domain controllers and DNS servers that are offline will increase run time due to long time out periods for RPC and other protocols. |

**Connectivity test**

- The connectivity test is a mandatory test and runs automatically before any other `dcdiag` test is run.

- The connectivity test determines whether domain controllers are registered in DNS, can be pinged, and have LDAP/RPC connectivity.
- If the connectivity test fails on a given controller, no other tests are run against that domain controller.

| Note |
| --- |
| The connectivity test has not been changed in SP1, but is included in this document for reference. |

**Basic DNS Test (/DnsBasic)**

- The basic DNS test confirms that the following essential services are running and available on domain controllers tested by `dcdiag`:
    - DNS client service
    - Netlogon service
    - KDC service
    - DNS Server service (if DNS is installed on the domain controller)
- The basic DNS test confirms network connectivity for each domain controller by confirming that DNS servers on all adapters are reachable.
- The basic DNS test confirms that the A record of each domain controller is registered on at least one of the DNS servers configured on the client.
- If a domain controller is running the DNS Server service, the basic DNS test confirms that the Active Directory domain zone and SOA record for the Active Directory domain zone are present.
- The basic DNS test checks whether the root (.) zone is present.

**Forwarder test (/DnsForwarders)**

| Note |
| --- |
| This test runs only if the domain controller being tested is running the Microsoft DNS Server service. |

- The forwarder test determines whether recursion is enabled.
- If forwarders or root hints are configured, the forwarder test confirms that all forwarders or root hints on the DNS server are functioning, and also confirms that the _ldap._tcp.<Forest root domain> DC Locator record is resolved. (Resolution of the _ldap_tcp.<Forest root domain> DC Locator record is not attempted for forwarders or root hints configured on the forest root domain controller.)

**Delegation test (/DnsDelegation)**

| Note |
| --- |
| This test runs only if the domain controller being tested is running the Microsoft DNS Server service. |

- The delegation test confirms that the delegated name server is a functioning DNS Server.
- The delegation test checks for broken delegations by ensuring that all NS records in the Active Directory domain zone in

which the target domain controller resides have corresponding glue A records.

**Dynamic Update Test (/DnsDynamicUpdate)**

- The dynamic update test confirms that the Active Directory domain zone is configured for secure dynamic update and performs registration of a test record (_dcdiag_test_record). The test record is subsequently deleted.

**Record Registration Test (/DnsRecordRegistration)**

- The record registration test verifies the registration of all essential DC Locator records on all DNS Servers configured on each adapter of the domain controllers. This test returns the following records.

| Record | Description |
|---|---|
| CNAME GUID | The GUID registered as the canonical name (CNAME) of the DNS server. |
| A | The host address (A) resource record. Maps a DNS domain name to an Internet Protocol (IP) version 4 32-bit address. |
| LDAP SRV | The service locator (SRV) resource record for the LDAP service. |
| GC SRV | The service locator (SRV) resource record for the global catalog (GC) server. |
| PDC SRV | The service locator (SRV) resource record for the primary domain controller (PDC). |

**External Name Resolution Test (/DnsResolveExtName)**

| **Note** |
|---|
| The external name resolution test is run only if specified explicitly (using `/DnsResolveExtName`); it is not run as part of `/DnsAll`. |

- The external name resolution test verifies basic resolution of external DNS from a given client, using a sample Internet name (www.microsoft.com), or user-provided Internet name.

- The external name resolution test cannot resolve external Internet names in an environment where a proxy server is being used.

- You can test name resolution using either intranet or Internet names.

- To resolve a user-provided Internet or intranet name (rather than the default name of www.microsoft.com), the `/DnsInternetName` parameter must be used.

**How to read the output of DNS enhanced dcdiag**

The following steps summarize how to interpret the results provided by DNS-enhanced `dcdiag`:

1. Run `dcdiag test:DNS /e /f:dns.txt`. Microsoft recommends always using the `/v` switch to obtain verbose information.

2. Open the report in Notepad or a compatible editor.

3. Scroll to end of the report and read the summary table.

4. Identify servers that returned "warn" or "fail" status for any subtest in the summary table.

5. Review the section of output for that server to see what problem was detected (hint: use the **Find** command on the **Edit** menu to search on the string "`DC:` *DC_computername*" (without quotes) to locate the detailed section for a given DC.

6. Resolve problems on DNS clients or DNS server(s) as required.

7. Run `dcdiag /test:DNS /v /e` (or `/s:`*DCName*) again to verify the fix. Repeat steps 1 through 6 as required until all failures are understood and reconciled.

**Warnings and Errors**

`Dcdiag` takes a conservative approach by identifying DNS client or DNS server configurations that may be problematic, do not conform to best practice configurations, or that `dcdiag` cannot fully validate. Therefore, the summary and detailed sections of `dcdiag` may report warnings for DNS configurations that are currently functional. Administrators should investigate and validate such configurations when identified by `dcdiag`.

The tables below contain the configurations that can trigger `dcdiag` to report warnings or errors for each of the DNS subtests.

**Basic**

| Warning | Additional information |
|---|---|
| Warning: Adapter <adapter name> has dynamic IP address | Static IP addresses are recommended for all DNS servers. |
| Warning: Adapter <adapter name> has invalid DNS server: <name> <IP address> | DNS server may not be reachable. |
| Warning: No DNS RPC connectivity (error or non Microsoft DNS server is running) | Disregard this warning if the DNS server is a BIND or other non-Microsoft DNS server. |
| Warning: The Active Directory zone on this DC/DNS server was not found | N/A |
| Warning: Root zone on this DC/DNS server was found | N/A |

| Error | Additional information |
|---|---|
| Error: Authentication failed with specified credentials | DCDIAG requires Enterprise Admin credential to run all the tests. |
| Error: No LDAP connectivity | N/A |
| Error: No DS RPC connectivity | N/A |
| Error: No WMI connectivity | DNS test requires WMI connectivity to run on the remote computer. |
| Error: Can't read operating system version through WMI | This might be caused by the lack of a WMI connection on the remote computer. |
| Error: <Operating system name> not supported (this tool is supported on Windows 2000, Windows XP, and Windows Server 2003 only) | N/A |
| Error: Open Service Control Manager failed | Unable to find whether the service is running or not. |
| Error: Kdc/netlogon/DNS/dnscache is not running | Some of the key services are not running. |
| Error: Can't read network adapter information through WMI | N/A |
| Error: All DNS servers are invalid | DNS servers that the client is pointing to are either not reachable, not a DNS server, or have invalid IP addresses. |
| Error: The A record for this DC was not found | Every DC should register an A record. Make sure A records are registered on all the DNS servers the client is pointing to. |
| Error: Enumeration of zones failed to find root and AD zone | N/A |

| | |
|---|---|
| Error: Could not query DNS zones on this DC | Make sure that the zone in which the DC is supposed to register is present. |

**Forwarder**

| Error | Additional information |
|---|---|
| Error: Forwarders list has invalid forwarder: <IP address of the forwarder> | Forwarders configured on the DNS server have an invalid IP address or are not a DNS server, or name resolution is not working (that is, cannot resolve forest root domain SRV record if it is a non-root domain DC). |
| Error: Both root hints and forwarders are not configured. Please configure either forwarders or root hints | Make sure either forwarders or root hints are configured on the DNS server unless it hosts root zone. |
| Error: Root hints list has invalid root hint server: <IP address of Root hint server> | Root hint servers configured on the DNS server have invalid IP address or are not a DNS server, or name resolution not working (that is, cannot resolve forest root domain SRV record if it is a non root domain DC). |
| Error:<Root hint server Name> IP: <Unavailable> Status:<status of the server> | Configured root hint servers don't have corresponding IP address. Status field will tell you the status of the server |
| Error:<Root hint server Name> IP: <Unavailable> Status: A record not found | Configured root hint servers don't have A record. |
| Error: Enumeration of Root hint servers failed on <DNS server name> | Couldn't list the root hint servers on the target DNS server. |

**Delegation**

| Warning | Additional information |
|---|---|
| Warning: DNS server: <DnsServer name> IP: <Ipaddress> Failure: Missing glue A record | The configured delegation is missing glue A record. |

| Error | Additional information |
|---|---|
| DNS server: <Server name> IP:<IP address> Error: Broken delegation -verbose | Delegation is configured but the name server is not responding. |
| DNS server: <Server name> IP:<IP address> Error: Broken delegated domain <Delegated domain name> -non-verbose | N/A |
| Error: Failed to enumerate the records at the zone root on the server | N/A |

**DynamicUpdate**

| Warning | Additional information |
|---|---|
| Warning: Dynamic update is enabled on the zone but not secure <zone name> | Secure dynamic updates are recommended. |
| Warning: Failed to add test record _dcdiag_test_record with error <error code> in zone <zone name> | Test adds a dummy record dynamically |
| Warning: Failed to delete test record _dcdiag_test_record with error <error code> in zone zone <zone name> | Deletes the added record as well. |

| Error | Additional information |
|---|---|
| Error: Dynamic update is not enabled on the zone <zone name> | Dynamic update is not enabled on the Active Directory zone so client cannot register its records. |

**Record registration**

| Warning | Additional Information |
| --- | --- |
| Warning: Missing DC SRV record at DNS server <record name> | Ignore the error if `DNSAvoidRegisterRecord` registry key or its Group Policy has been configured to prevent registration of this record. |
| Warning: Missing GC SRV record at DNS server <record name> | Ignore the error if `DNSAvoidRegisterRecord` registry key or its Group Policy has been configured to prevent registration of this record. |
| Warning: Missing PDC SRV record at DNS server <record name> | Ignore the error if `DNSAvoidRegisterRecord` registry key or its Group Policy has been configured to prevent registration of this record. |
| Warning: Record Registrations not found in some network adapters | N/A |

| Error | Additional information |
| --- | --- |
| Error: Missing A record at DNS server <DNS Server IP address> : <A record name> | DC hasn't registered its A record on the specified DNS server. |
| Error: Missing CNAME record at DNS server <DNS Server IP address> : <CNAME record name> | DC hasn't registered its CNAME record on the specified DNS server. |
| Error: Missing DC SRV record at DNS server <DNS Server IP address> : <SRV record name> | DC hasn't registered its DC SRV record on the specified DNS server. |
| Error: Missing GC SRV record at DNS server <DNS Server IP address> : <SRV record name> | DC hasn't registered its GC SRV record on the specified DNS server. |
| Error: Missing PDC SRV record at DNS server <DNS Server IP address> : <SRV record name> | DC hasn't registered specified PDC SRV record on the specified DNS server. All these records can be registered by stopping and starting the netlogon service. |
| Error: Record registrations cannot be found for all the network adapters | If there are multiple network adaptors the test checks whether all the records are present on all the DNS servers configured on each adaptor. This error occurs if the record registration is missing on the DNS server. |

**External name resolution**

| Error | Additional information |
| --- | --- |
| Error: Internet name <name> cannot be resolved | Specified Internet name cannot be resolved. Make sure the proxy client, servers, root hints, and forwarders are configured properly. |

**Enterprise DNS infrastructure tests**

| Warning | Additional information |
| --- | --- |
| Warning: Neither forwarders nor root hints are configured from subordinate domain to parent domain | Forwarder or root hints need to be configured in the DNS servers of either the parent or subordinate domains that are hosting the authoritative zones for their respective domain to enable name resolution to work. |

| Error | Additional information |
| --- | --- |
| Error: Delegation is not configured on the parent domain | Delegation should be configured from parent to subordinate domain. |
| Error: Delegation is present but the glue record is missing | Delegation is configured but the name servers are missing their glue record. |
| Error: Forwarders are misconfigured from parent domain to subordinate domain | Forwarders must be configured from subordinate domain to parent domain. |

| | |
|---|---|
| Error: Root hints are misconfigured from parent domain to subordinate domain | Root hints must be configured from subordinate domain to parent domain. |
| Error: Forwarders are configured from subordinate to parent domain but some of them failed DNS server tests (See DNS servers section for error details) | Forwarders configured have an invalid IP address or are not a valid DNS server, or name resolution is not working (cannot resolve forest root domain SRV record if it is in the non-root domain). |
| Error: Root hints are configured from subordinate to parent domain but some of them failed DNS server tests (See DNS servers section for error details) | Root hints configured have an invalid IP address or are not a valid DNS server, or name resolution is not working. |

**Examples:**
The following examples illustrate the use of Windows Server 2003 SP1 `dcdiag`. You should replace the parameters in italics with those appropriate for your environment:

- To run all DNS tests on a single domain controller in non-verbose mode:

  `Dcdiag /test:DNS /s:`*TargetDCName* `/f:`*LogFileName*

- To run all DNS tests on a single domain controller in verbose mode:

  `Dcdiag /test:DNS /s:`*TargetDCName* `/v /f:`*LogFileName*

- To run all DNS tests on an entire forest in non-verbose mode:

  `Dcdiag /test:DNS /e /f:`*LogFileName*

- To run all DNS tests on an entire forest in verbose mode:

  `Dcdiag /test:DNS /v /e /f:`*LogFileName*

- To run the DNS basic test on a single domain controller:

  `Dcdiag /test:DNS /DnsBasic /s:`*TargetDCName* `/f:`*LogFileName*

- To run the DNS forwarders test on a single domain controller:

  `Dcdiag /test:DNS /DnsForwarders /s:`*TargetDCName* `/f:`*LogFileName*

- To run the DNS delegation test on a single domain controller:

  `Dcdiag /test:DNS /DnsDelegation /s:`*TargetDCName* `/f:`*LogFileName*

- To run the DNS dynamic update test on a single domain controller:

  `Dcdiag /test:DNS /DnsDynamicUpdate /s:`*TargetDCName* `/f:`*LogFileName*

- To run the DNS record registration test on a single domain controller:

  `Dcdiag /test:DNS /DnsRecordRegistration /s:`*TargetDCName* `/f:`*LogFileName*

- To resolve a sample Internet or intranet name:

  `Dcdiag /test:DNS /DnsResolveExtName /DnsInternetName:`*InternetName* `/f:` *LogFileName*

**Note**

When an individual test is run, the `/DnsBasic` tests are run by default before running the individual test specified.

If no individual test is specified, all DNS tests (except `/DnsResolveName`) are run by default.

**New Active Directory replication security tests**
**Detailed description**
DCDiag.exe has been enhanced for Windows Server 2003 Service Pack 1 to include new functionality to identify security configurations that can cause Active Directory replication to fail.

The new `CheckSecurityError` test may be performed on one or all domain controllers in an Active Directory forest. The test performs the following operations:

- Checks for the availability of a Key Distribution Center (KDC) in both the destination and source domain controller's domains.
- Verifies that the destination DC can transmit and receive sufficiently large UDP-formatted packets (used by Kerberos).
- Verifies that system clock of the destination DC is no more than 5 minutes different from the system time of the KDC in the destination and source domain, and the source DC.
- Confirms that the root of each naming context on the source domain controller is configured with the necessary permission.
- Confirms that the source and destination DC computer accounts are not disabled, are trusted for delegation, and contain all required service principal names.

When the test has completed, DCDiag.exe presents a summary of the results for each domain controller tested and the diagnosis of the security errors encountered

This test can be run from the command-line using the following syntax:

```
Dcdiag /test:CheckSecurityError
```

Optionally, you can add the switch `/ReplSource:`*SourceDC* to the command to identify a specific domain controller as a source in a replication attempt. The domain controller specified in the `/replsource:` parameter does not need to be a current source domain controller that the domain controller being tested currently replicates from (one that the destination domain controller currently has an inbound connection object from).This test will collect information from the domain controller, key distribution center (KDC) source and destination servers, and Active Directory.

**Note**

`Dcdiag /test:CheckSecurityError` can be executed on the console of a member computer (using the `/e` or `/s:`*servername* commands) as well as a domain controller. For best results, run `Dcdiag /test:CheckSecurityError` on the console of each domain controller that is failing inbound Active Directory replication due to a suspected security error.

**Why is this change important?**
If replication is not working and the error is a security error (such as "Access Denied", "The target account name is incorrect", or "The RPC server is unavailable") there are many different factors that could be causing the issue. This test automates the diagnosis by looking at the most common sources of these errors and reporting them so that you can resolve the issue.

# Active Directory Directory Services Maintenance Utility (ntdsutil.exe)

Applies To: Windows Server 2003 with SP1

**What does Ntdsutil.exe do?**
Ntdsutil.exe is a command-line tool that provides management facilities for Active Directory. You can use Ntdsutil.exe to perform database maintenance of Active Directory, manage and control single master operations, create application directory partitions, and remove metadata left behind by domain controllers that were not successfully demoted using the Active Directory Installation wizard (DCPromo.exe).

**Who does this feature apply to?**
This feature applies to the Ntdsutil.exe utility, and is of interest to Active Directory administrators only.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**General Improvements**
**Detailed description**
Ntdsutil.exe no longer requires the administrator to perform the following tasks in the `ntdsutil metadata cleanup` command:

- Connect to specific domain controller using `ntdsutil metadata cleanup connections`command.
- List and select the Active Directory domain, site, and server using the `ntdsutil metadata cleanup Select Operation Target` command.

Two new variations of this command are introduced in Windows Server 2003 Service Pack 1:

- `Ntdsutil "metadata cleanup" "remove selected server"`*ServerObject*

  When using this command, specify the distinguished name (DN) path of the server object (*ServerObject*) of the domain controller whose metadata you want to remove. The server object is the parent of the NTDS settings object in the configuration container. For example, for the domain controller named DC1 located in the default-first-site-name of the contoso.com forest, the DN path of the server object would be cn=DC1,cn=servers,cn=default-first-site-name ,cn=configuration,dc=contoso,dc=com. If the DN path contains any spaces, enclose the entire DN path in quotes.

- `Ntdsutil "metadata cleanup" "remove selected server"`*ServerObject* `on` *TargetDC*

  This command is identical to the one above, except it allows the administrator to specify the domain controller (*TargetDC*) on which the removal is performed. *TargetDC* must be entered as the DNS or NetBIOS name of the domain controller.

**Why is this change important? What threats does it mitigate?**
This change significantly improves the usability of this command for removing metadata.

**What works differently?**
From the "`metadata cleanup`" menu, the user no longer has to go into the "`connections`" menu or the "`select operations target`" menu to set up the appropriate state.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Improved Metadata Cleanup**
**Detailed description**
The metadata cleanup command has been improved in Windows Server 2003 Service Pack 1 to clean up metadata in Active Directory.

**What works differently? Are there any dependencies?**
The existing "`remove selected server`" command in the "`metadata cleanup`" menu of Ntdsutil.exe has been enhanced with new functionality.

Prior to Service Pack 1, this command only performed the following operations:

- Delete the NTDS settings object for the domain controller (DC).
- Delete all manual and automatic inbound connections to the DC being removed.
- Delete the corresponding DC's FRS member object from the sysvol replica set.

With the release of Service Pack 1, the following additional operations are performed as part of this command:

- Delete the computer account for the DC being deleted, including FRS subscriber objects.
- Delete all manual and automatic outbound Active Directory connections from the DC being removed.
- Delete inbound and outbound FRS connections from any non-sysvol FRS replica sets that the DC being deleted is a member of.
- Check whether the DC being removed holds any operations masters roles. If yes, this command will attempt to reassign (seize) the roles to an active DC that meets criteria for the operations master role(s).

# Security Account Manager (SAM)

Applies To: Windows Server 2003 with SP1

**What does the Security Account Manager (SAM) do?**
The Security Account Manager (SAM) is a database present on servers running Windows Server 2003 that stores user accounts and security descriptors for users on the local computer.

**Who does this feature apply to?**
This feature applies to IT professionals who want to troubleshoot or understand the SAM component's behavior in deployment. Troubleshooting may require that additional tools be downloaded. This topic also applies to developers that have licensed the SAMR and LSAR protocols and developers that use the LSA trust application programming interfaces (APIs) from MSDN.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**SAM WPP Logging**
**Detailed description**
Security Accounts Manager (SAM) debug logs can be collected by Windows software trace preprocessor (WPP) during deployment. WPP can be used to gather information about what the SAM component is doing during a period of time when the Windows system is not behaving as expected. This information can be used by Microsoft Product Support Services to help you troubleshoot issues in your deployment.

**Why is this change important? What threats does it mitigate?**
This may reduce the number of live debug sessions if the log information is sufficient to determine what is occurring.

**What works differently?**
Nothing works differently. A new feature is enabled to generate logging. Following are the logman commands that can be used to enable logging:

```
logman create trace samlog -p "{f2969c49-b484-4485-b3b0-b908da73cebb}" 3
logman start samlog
rem repeat action that is interesting and that should be captured in log
logman stop samlog
```

This will generate an extended transaction log (ETL), which your Product Support Engineer will be able to parse using the debug symbol set.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
A new Event Tracing for Windows (ETW) entry exists, **f2969c49-b484-4485-b3b0-b908da73cebb**. This entry reflects whether or not logging has been enabled for the SAM component. The following sample output from `tracelog -enumguid` includes the new entry.

```
    Guid                        Enabled  LoggerId Level Flags
-------------------------------------------------------------
1046d4b1-fce5-48bc-8def-fd33196af19a     FALSE  0     0     0
5007c7b1-1444-4303-bdbe-359c79fc032a     FALSE  0     0     0
7e4b70ee-8296-4f0f-a3ba-f58ef7bb4e96     FALSE  0     0     0

**Preventing SAM and LSA handles from hijacking**
**Detailed description**
The server side implementation of the SAMR and LSAR protocols now implements security checks to ensure that the current caller is the same caller that opened the first handle returned from `SamConnect` and `LsaOpenPolicy` respectively.

The Security Account Manager Remote Procedure Call (RPC) protocol (SAMR) is an integral subsystem that is used to perform remote Service Account Manager operations, such as user account management and manipulation. The SAMR interface defines the remote Security Account Manager (SAM) methods that are called by the client. `SamConnect` is the function that is used to connect to the SAM database.

**Why is this change important?**
This change is related to the RPC changes that help prevent elevation of privilege attacks on your system. Implementing this change in the Active Directory interfaces helps make your system more secure by default.

**What works differently?**
If your application uses the SAMR or LSAR protocols, access checks are performed on each call received and verify that the client identity that opens the context handle is the same as the client identity that is making the call. If your application does not use that convention, it will no longer function after installation of Windows Server 2003 Service Pack 1 (SP1).

**How do I fix these issues?**
All calls to the SAMR and LSAR methods must be in the same security context as the call that generated the context handle being used in the call. If they are not you must modify your application to comply with this requirement.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Most applications will not need to be changed. However, if the application's code switches security contexts while using context handles obtained from the SAMR and LSAR interface it will need to be modified. If the application is using any of the following APIs, verify with the application developer that the calling security context doesn't change between the call `LsaOpenPolicy` and any subsequent Lsa API call that uses the handle returned from `LsaOpenPolicy`.

- `LsaOpenPolicy`
- `LsaQueryInformationPolicy`
- `LsaSetInformationPolicy`
- `LsaQueryDomainInformationPolicy`
- `LsaSetDomainInformationPolicy`
- `LsaEnumerateTrustedDomains`
- `LsaLookupNames`
- `LsaLookupNames2`
- `LsaLookupSids`
- `LsaEnumerateAccountsWithUserRight`
- `LsaEnumerateAccountRights`
- `LsaAddAccountRights`
- `LsaRemoveAccountRights`

- LsaOpenTrustedDomainByName
- LsaQueryTrustedDomainInfo
- LsaSetTrustedDomainInformation
- LsaDeleteTrustedDomain
- LsaQueryTrustedDomainInfoByName
- LsaSetTrustedDomainInfoByName
- LsaEnumerateTrustedDomainsEx
- LsaCreateTrustedDomainEx
- LsaQueryForestTrustInformation
- LsaSetForestTrustInformation
- LsaForestTrustFindMatch
- LsaStorePrivateData
- LsaRetrievePrivateData

# Add or Remove Programs Filter

Applies To: Windows Server 2003 with SP1

**What does the filter for Add or Remove Programs do?**
The filter for **Add or Remove Programs** provides a means for the user to select whether or not updates, such as security updates downloaded from the Microsoft Web site, are displayed under the **Currently installed programs** list.

**Who does this feature apply to?**
**Add or Remove Programs** can be used by any user with Administrator credentials on the local computer. Although some applications can be installed or removed by non-administrators, most do require administrative credentials.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Filtering out updates from the Change or Remove Programs list**
**Detailed description**
The **Change or Remove Programs** list in **Add or Remove Programs** displays installed programs that the user can change or remove. This list also shows updates to Windows or other programs that have been installed.

In Windows Server 2003 Service Pack 1, the user is able to choose whether to show or hide updates for Windows and other programs in this view. A new **Show updates** check box appears above the list, which enables the user to toggle between showing or hiding installed updates.

**Why is this change important?**
Software vendors are creating more software updates and releasing them more frequently than ever before. These frequent updates help to increase the reliability and security of user's systems. However, by showing every update in the Change or Remove Programs list in Add or Remove Programs, the list of installed programs is overwhelmed by the list of installed updates. A new option to filter out the updates from the list and only show installed programs makes this list easier for users to read.

**What works differently?**
By default, **Change or Remove Programs** will not show installed updates to Windows. To see the updates that have been installed, you can select the **Show Updates** check box at the top of the list.

Any program can take advantage of this feature by marking their updates so that they are hidden when appropriate. Windows programs that were written before the release of Windows XP Service Pack 2 will be shown regardless of the filter option selection. Windows XP Service Pack 2 and Windows Server 2003 Service Pack 1 will also always be shown in the list

**How do I resolve these issues?**
To turn off the filter feature on a single computer, use the following procedure.

### To turn off filter for Add or Remove Programs

1. Open the Registry Editor by clicking **Start**, then clicking **Run**, typing `regedit`, and pressing **Enter**.
2. Navigate to the following registry key: `\\HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Policies\Uninstall`
3. Select the **DontGroupPatches** key.
4. By default, the **DWORD** value is equal to **0**. Change the **DWORD** value to **1** to disable the filter feature.

| ⚠Caution |
|---|
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

In an enterprise environment, you can create a Group Policy object to modify the registry setting that controls the filter feature to make **Add or Remove Programs** work as it did previously.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**Filter for Add or Removed Programs Settings**

| Setting Name | Location | Previous Default Value | Default Value | Possible Values |
|---|---|---|---|---|

| | | | | |
|---|---|---|---|---|
| DontGroupPatches | HKEY_LOCAL_MACHINE\Software\ Microsoft\Windows\ CurrentVersion\ Policies\Uninstall | N/A | REG_DWORD:0 | REG_DWORD:1 |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Programs do not need to change in order to continue to work with the filter for **Add or Remove Programs**. If a program is not changed to use the new feature, it will continue working as it did previously.

A program can take advantage of the new filtering option by marking its updates so that they are not shown by default. Details on how to mark programs as updates are available on MSDN in "Working with Add or Remove Programs in the Control Panel Application" which is located on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=35318.

# DCOM Security Enhancements

Applies To: Windows Server 2003 with SP1

**What does DCOM do?**
The Microsoft Component Object Model (COM) is a platform-independent, distributed, object-oriented system for creating binary software components that can interact. The Distributed Component Object Model (DCOM) allows applications to be distributed across locations that make the most sense to you and to the application. The DCOM wire protocol transparently provides support for reliable, secure, and efficient communication between COM components. For more information, see "Component Object Model" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=20922.

**Who does this feature apply to?**
If you only use COM for in-process COM components, this section does not apply to you.

This feature applies to you if you have a COM server application that meets one of the following criteria:

- The access permission for the application is less stringent than the launch permission that is necessary to run the application.
- The application is usually activated by a remote COM client without using an administrative account.
- The application is only meant to be used locally. This means you can restrict your COM server application so it is not remotely accessible.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Computerwide restrictions**
**Detailed description**
A change has been made in COM to provide computerwide access controls that govern access to all call, activation, or launch requests on the computer. The simplest way to think about these access controls is as an additional AccessCheck call that is done against a computerwide access control list (ACL) on each call, activation, or launch of any COM server on the computer. If the AccessCheck fails, the call, activation, or launch request will be denied. (This is in addition to any AccessCheck that is run against the server-specific ACLs.) In effect, it provides a minimum authorization standard that must be passed to access any COM server on the computer. There will be a computerwide ACL for launch permissions to cover activate and launch rights, and a computerwide ACL for access permissions to cover call rights. These can be configured through the Component Services Microsoft Management Console (MMC).

These computerwide ACLs provide a way to override weak security settings specified by a specific application through CoInitializeSecurity or application-specific security settings. This provides a minimum security standard that must be passed, regardless of the settings of the specific server.

These ACLs are checked when the interfaces exposed by RPCSS are accessed. This provides a method to control who has access to this system service.

These ACLs provide a centralized location where an administrator can set general authorization policy that applies to all COM servers on the computer.

By default, Windows Server 2003 SP1 computer restriction settings are as follows.

**DCOM Computer Restriction Settings**

| Permission | Administrator | Distributed COM Users (Built-in Group) | Everyone | Anonymous |
|---|---|---|---|---|
| Launch | Local Launch<br>Local Activation<br>Remote Launch<br>Remote Activation | Local Launch<br>Local Activation<br>Remote Launch<br>Remote Activation | Local Launch<br>Local Activation | N/A |
| Access | N/A | Local Access<br>Remote Access | Local Access<br>Remote Access | Local Access<br>Remote Access |

**Note**

**Distributed COM Users** is a new built-in group included with Windows Server 2003 Service Pack 1 to expedite the process of adding users to the DCOM computer restriction settings.

**Why is this change important?**
Many COM applications include some security-specific code (for example, calling CoInitializeSecurity), but use weak settings, often allowing unauthenticated access to the process. There is currently no way for an administrator to override these settings to force stronger security in earlier versions of Windows.

COM infrastructure includes the RPCSS, a system service that runs during system startup and always runs after that. It manages activation of COM objects and the running object table and provides helper services to DCOM remoting. It exposes RPC interfaces that can be called remotely. Because some COM servers allow unauthenticated remote access (as explained in the previous section), these interfaces can be called by anyone, including unauthenticated users. As a result, RPCSS can be attacked by malicious users using remote, unauthenticated computers.

In earlier versions of Windows, there was no way for an administrator to understand the exposure level of the COM servers on a computer. An administrator could get an idea of the exposure level by systematically checking the configured security settings for all the registered COM applications on the computer, but, given that there are about 150 COM servers in a default installation of Windows, that task was daunting. There was no way to view the settings for a server that incorporates security in the software, short of reviewing the source code for that software.

DCOM computerwide restrictions mitigate these three problems. They also give an administrator the capability to disable incoming DCOM activation, launch, and access calls.

**What works differently?**
By default, the **Everyone** group is granted local launch, local activation, and local access permissions. This should enable all local scenarios to work without modification to the software or the operating system.

By default, the **Everyone** and **Anonymous** groups are granted remote access permissions. This enables most COM client scenarios, including the common case where a COM client passes a local reference to a remote server, in effect turning the client into a server.

Also by default, only members of the **Administrators** group are granted remote activation and launch permissions. This disables remote activations by non-administrators to installed COM servers.

**How do I resolve these issues?**
If you implement a COM server and expect to support remote activation by a non-administrative COM client or remote unauthenticated calls, then you should consider whether the risk associated with enabling this process is acceptable or if you should modify your implementation to not require remote activation by a non-administrative COM client.

If the risk is acceptable and you want to enable remote activation by a non-administrative COM client, you will need to change the default configuration for this feature.

You can change the configuration settings using either the Component Services Microsoft Management Console (MMC) or the Windows registry.

If you use the Component Services MMC snap-in, these settings can be configured on the **COM Security** tab of the **Properties** dialog box for the computer you are managing. The **COM Security** tab has been modified to enable you to set computerwide limits in addition to the standard default settings for COM servers. Additionally, you can provide separate ACL settings for local and remote access under both limits and defaults.

Alternatively, you can configure these ACL settings using the registry.

These ACLs are stored in the registry at the following locations:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Ole\MachineAccessRestriction= ACL
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Ole\MachineLaunchRestriction= ACL
```

These are named values of the REG_BINARY type that contain data describing the ACL of the principals that can access any COM class or COM object on the computer. The access rights in the ACL are:

```
COM_RIGHTS_EXECUTE 1
COM_RIGHTS_EXECUTE_LOCAL 2
COM_RIGHTS_EXECUTE_REMOTE 4
COM_RIGHTS_ACTIVATE_LOCAL 8
COM_RIGHTS_ACTIVATE_REMOTE 16
```

These ACLs can be created using normal security functions.

| **Note** |
| --- |
| COM_RIGHTS_EXECUTE rights must always be present; absence of this right will generate an invalid security descriptor. Only users with Administrator rights can modify these settings. |

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**RPCSS runs as a network service**
**Detailed description**
RPCSS is a key service for the RPC Endpoint Mapper and DCOM infrastructure that is network facing. This service ran as Local System in previous versions of Windows. To reduce the attack surface of Windows and provide defense in depth, the RPCSS service functionality was split into two services. The RPCSS service with all the original functionality that did not require Local System privileges now runs under the Network Service account. A new DCOMLaunch service that includes functionality that requires Local System privileges runs under the Local System account; however, this service is not network facing.

**Why is this change important?**
This change reduces the attack surface and provides defense in depth for the RPCSS service because an elevation of privilege in the RPCSS service will now be limited to the Network Service privilege.

**What works differently?**
This change should be transparent to users because the combination of the RPCSS and DCOMLaunch services is equivalent to the previous RPCSS service provided in prior versions of Windows.

**More specific COM permissions**
**Detailed description**
COM server applications have two types of permissions: launch permissions and access permissions. Launch permissions control authorization to start a COM server during COM activation if the server is not already running. These permissions are defined as security descriptors that are specified in registry settings. Access permissions control authorization to call a running COM server. These permissions are defined as security descriptors provided to the COM infrastructure through the `CoInitializeSecurity` API, or using registry settings. Both launch and access permissions allow or deny access based on principals, and make no distinction as to whether the caller is local to the server or remote.

The first change distinguishes the COM access rights, based on distance. The two distances that are defined are Local and Remote. A Local COM message arrives by way of the Lightweight Remote Procedure Call (LRPC) protocol, while a Remote COM message arrives by way of a remote procedure call (RPC) host protocol like transmission control protocol (TCP).

COM activation is the act of getting a COM interface proxy on a client by calling `CoCreateInstance` or one of its variants. As a side effect of this activation process, sometimes a COM server must be started to satisfy the client's request. A launch permissions ACL asserts who is allowed to start a COM server. An access permissions ACL asserts who is allowed to activate a COM object or call that object after the COM server is already running.

The second change is that the call and activation rights are separated to reflect two distinct operations and to move the activation right from the access permission ACL to the launch permission ACL. Since activation and launching are both related to acquiring an interface pointer, activation and launch access rights logically belong together in one ACL. Because you always specify launch permissions through configuration (as compared to access permissions, which are often specified programmatically), putting the activation rights in the launch permission ACL provides the administrator with control over activation.

The Launch Permission access control entries (ACEs) are broken into four access rights:

- Local Launch (LL)
- Remote Launch (RL)
- Local Activation (LA)
- Remote Activation (RA)

The Access Permission security descriptor is split into two access rights:

- Local Access calls (LC)

- Remote Access calls (RC)

This allows the administrator to apply very specific security configurations. For example, you can configure a COM server so that it accepts local calls from everyone, while only accepting remote calls from Administrators. These distinctions can be specified through changes to the COM Permissions security descriptors.

**Why is this change important? What threats does it help mitigate?**
Earlier versions of the COM server application have no way to restrict an application so that it can only be used locally without exposing the application on the network by way of DCOM. When a user has access to a COM server application, he or she has access for both local and remote use.

A COM server application might want to expose itself to unauthenticated users to implement a COM callback scenario. In this scenario, the application must also expose its activation to unauthenticated users, which might not be desirable because malicious users could use that scenario to gain unauthorized access to that server.

Precise COM permissions give flexibility to the administrator to control a computer's COM permission policy. These permissions enable security for the described scenarios.

**What works differently? Are there any dependencies?**
To provide backwards compatibility, existing COM security descriptors are interpreted to allow or deny both local and remote access simultaneously. That is, an access control entry will either allow both local and remote, or deny both local and remote.

There are no backwards-compatibility issues for call or launch rights. There is, however, an activation rights compatibility issue. If, in the existing security descriptors for a COM server, the configured launch permissions are more restrictive than the access permissions and are more restrictive than what is minimally needed for client activation scenarios, then the Launch Permissions ACL must be modified to give the authorized clients the appropriate activation permissions.

For COM applications that use the default security settings, there are no compatibility issues. For applications that are dynamically started using COM activation, most will have no compatibility issues, since the launch permissions must already include anyone who is able to activate an object. Otherwise, such applications would have generated activation failures even before applying Service Pack 1, when callers without launch permission try to activate an object and the COM server is not already running.

The applications of most concern for compatibility issues are COM applications that are already started by way of some other mechanism, such as Windows Explorer or Service Control Manager. You can also start these applications by way of a previous COM activation, which overrides the default access and launch permissions and specifies launch permissions that are more restrictive than the call permissions. For more details on addressing this compatibility issue, see "How do I resolve these issues?" in the next section.

If a system that was updated to Windows Server 2003 Service Pack 1 is rolled back to an earlier service pack, any access control entry that was edited to allow local access, remote access, or both, will be interpreted to allow both local and remote access. Any ACE that was edited to deny local access, remote access, or both, will be interpreted to deny both local and remote access. Whenever you uninstall a service pack, you should ensure that no newly set ACEs will cause applications to stop working.

**How do I resolve these issues?**
If you implement a COM server and you override the default security settings, confirm that the application-specific launch permissions ACL grants activation permission to appropriate users. If it does not, you will need to change your application-specific launch permission ACL to give appropriate users activation rights so applications and Windows components that use DCOM do not fail. These application-specific launch permissions are stored in the registry.

The COM ACLs can be created or modified using normal security functions.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| ⚠**Caution** |
| --- |
| Improper use of these settings can cause applications and Windows components that use DCOM to fail. |

In the following table, these abbreviations are used:

LL - Local Launch

LA - Local Activation

RL - Remote Launch

RA - Remote Activation

LC - Local Access calls

RC - Remote Access calls

**DCOM Settings**

| Setting name | Location | Previous default value | Default value | Possible values |

# Data Execution Prevention

Applies To: Windows Server 2003 with SP1

**What does data execution prevention do?**
Data execution prevention (DEP) is a set of hardware and software technologies that perform additional checks on memory to help protect against malicious code exploits. In Windows Server 2003 with Service Pack 1, DEP is enforced by both hardware and software.

**Hardware-enforced DEP**
Hardware-enforced DEP marks all memory locations in a process as non-executable unless the location explicitly contains executable code. There is a class of attacks that attempt to insert and execute code from non-executable memory locations. DEP helps prevent these attacks by intercepting them and raising an exception.

Hardware-enforced DEP relies on processor hardware to mark memory with an attribute that indicates that code should not be executed from that memory. DEP functions on a per-virtual-memory-page basis, usually changing a bit in the page table entry (PTE) to mark the memory page.

The actual hardware implementation of DEP and marking of the virtual memory page varies by processor architecture. However, processors that support hardware-enforced DEP are capable of raising an exception when code is executed from a page marked with the appropriate attribute set.

Both Advanced Micro Devices (AMD) and Intel Corporation have defined and shipped Windows-compatible architectures that are compatible with DEP.

32-bit versions of Windows Server 2003 with Service Pack 1 utilize the no-execute page-protection (NX) processor feature as defined by AMD or the Execute Disable bit (XD) feature as defined by Intel. In order to use these processor features, the processor must be running in Physical Address Extension (PAE) mode. The 64-bit versions of Windows use the NX or XD processor feature on 64-bit extensions processors and certain values of the access rights page table entry (PTE) field on IPF processors.

It is hoped that all future 32-bit and 64-bit processors will provide support for hardware-enforced DEP. Microsoft continues to work with processor vendors to encourage the adoption and development of DEP technologies.

**Software-enforced DEP**
An additional set of DEP security checks has been added to Windows Server 2003 with Service Pack 1. These checks, known as software-enforced DEP, are designed to mitigate exploits of exception handling mechanisms in Windows. Software-enforced DEP runs on any processor that is capable of running Windows Server 2003 with Service Pack 1. By default, software-enforced DEP protects only limited system binaries, regardless of the hardware-enforced DEP capabilities of the processor.

**Who does this feature apply to?**
Application and driver developers should be aware of DEP and the requirements of software running on a supporting platform. Applications that perform just-in-time (JIT) code generation or execute memory from the default process stack or heap should pay careful attention to DEP requirements.

Driver developers are encouraged to be aware of PAE mode on platforms supporting hardware-enforced DEP. PAE mode behavior on systems running Windows Server 2003, Standard Edition with Service Pack 1, is changed to improve driver compatibility.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Data execution prevention on 32-bit and 64-bit versions of Windows and applications**
**Detailed description**
**Hardware-enforced DEP**
To provide consistency for application and driver developers, the memory protection model (including DEP) is designed to be the same for both 32-bit and 64-bit versions of Windows.

Application developers should be aware of DEP behavior in user mode. A user-mode DEP exception results in a `STATUS_ACCESS_VIOLATION (0xc0000005)` on Windows systems. The first parameter of `ExceptionInformation` that is located inside the `EXCEPTION_RECORD` structure contains the type of access violation that occurred. A value of 8 for `ExceptionInformation[0]` indicates the access violation was an execution violation.

In most processes, the `STATUS_ACCESS_VIOLATION` exception will be an unhandled exception and result in termination of the process.

DEP is also applied to drivers in kernel mode. DEP for memory regions in kernel mode cannot be selectively enabled or

disabled. On 32-bit versions of Windows, DEP is applied to the stack by default. This differs from kernel-mode DEP on 64-bit versions of Windows, where the stack, paged pool, and session pool have DEP applied.

Device drivers are not permitted to execute code from the stack when DEP is enabled. A DEP access violation in kernel mode will result in an error `0xFC: ATTEMPTED_EXECUTE_OF_NOEXECUTE_MEMORY`.

**Software-enforced DEP**

Software-enforced DEP performs additional checks on exception handling mechanisms in Windows. If the program's image files are built with Safe Structured Exception Handling (SafeSEH), software-enforced DEP ensures that before an exception is dispatched, the exception handler is registered in the function table located within the image file.

If the program's image files are not built with SafeSEH, software-enforced DEP ensures that before an exception is dispatched, the exception handler is located within a memory region marked as executable.

**DEP application close behavior**

The majority of applications will not encounter a problem with DEP. However, when an application does encounter a problem with DEP, a Data Execution Prevention message is presented to the user, alerting them to the problem.

The Data Execution Prevention message indicates that a DEP problem occurred with the application and provides the ability for the user to learn more about DEP and optionally disable DEP for the application that was closed.

**Important**

If a DEP problem occurs with an application, Microsoft recommends contacting the application vendor for an update. The security implications of disabling DEP for an application should be thoroughly considered before disabling DEP for an application.

The ability to change DEP settings for a closed application using the **Change Settings** button on the Data Execution Prevention message window depends on the system-wide DEP configuration. Changes to DEP protection for an application can be made only if the system-wide DEP configuration is set to the **OptOut** mode.

The Data Execution Prevention message is presented immediately before a Windows Error Reporting window, which provides the opportunity to submit a report about the DEP problem to Microsoft.

On Windows Server 2003 with Service Pack 1, the Data Execution Prevention message will be presented the next time an Administrator logs onto the system interactively. The behavior is changed on Windows Server 2003 with Service Pack 1 from Windows XP with Service Pack 2 because Windows Error Reporting is configured in queued mode by default. Queued mode causes error reporting messages to be queued until the next time an administrator interactively logs onto the system.

To learn more about Windows Error Reporting, or to configure Windows Error Reporting such that DEP and Windows Error Reporting messages are displayed immediately following an application problem, see the "Using Windows Server 2003 in a Managed Environment: Windows Error Reporting" article on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38443.

Windows Error Reporting generates an error signature when an application is closed due to DEP. The error signature can be viewed by following the "click here" link on the Windows Error Reporting dialog. The error signature for a DEP problem has the following attributes:

| Parameter | Example Value | Description |
|---|---|---|
| EventType | BEX | Indicates a buffer overflow (/GS) or DEP exception (BEX64 indicates a buffer overflow (/GS) or DEP exception on 64-bit versions of Windows) |
| P1 | DEPDemo.exe | Name of the application executable that encountered the problem |
| P2 | 5.1.2600.2180 | Version of the application executable that encountered the problem |
| P3 | 416725f2 | Faulting application stamp |
| P4 | DEPDemo.exe | Faulting module name |
| P5 | 5.1.2600.2180 | Faulting module version |
| P6 | 416725f2 | Faulting module stamp |

| | | |
|---|---|---|
| P7 | 00002060 | Fault offset (Instruction address if a module is not loaded at the faulting address) |
| P8 | C0000005 | Indicates a STATUS_ACCESS_VIOLATION exception (If this parameter is c0000409, the problem is a /GS-related fault) |
| P9 | 00000008 | Indicates an execution STATUS_ACCESS_VIOLATION (00000002 indicates an execution STATUS_ACCESS_VIOLATION on 64-bit versions of Windows for the Intel Itanium architecture) |

Finally, the Data Execution Prevention message might not be shown for some applications when they encounter a problem with DEP, regardless of the Windows Error Reporting configuration. These applications handle the STATUS_ACCESS_VIOLATION exception raised by DEP, or they install an unhandled exception filter (UEF), which overrides the default Win32 UEF. The default Win32 UEF is responsible for triggering both the Data Execution Prevention and Windows Error Reporting messages. The Data Execution Prevention message may also not be shown if an application has called the `SetErrorMode()` function with the `SEM_NOGPFAULTERRORBOX` flag.

**Why is this change important? What threats does it help mitigate?**
The primary benefit of DEP is that it helps to prevent code execution from data pages such as the default heap, various stacks, and memory pools. In normal operations of the system, code is not typically executed from the default heap and stack. Hardware-enforced DEP detects code that is running from these locations and raises an exception when execution occurs. If the exception is unhandled, the process will be terminated. Execution of code from protected memory in kernel mode results in an error.

Although terminating a process or causing the system to fail with an error do not appear to be ideal experiences, this helps prevent malicious code from executing. Preventing malicious code from executing on the system may prevent damage to the system or propagation of malicious code whose harmful effects could easily exceed those of a terminated process or system error.

DEP can help prevent some exploits in which a virus or other attack has injected a process with executable code and then attempts to execute the injected code. On a system with DEP, execution of the injected code should result in an exception. Software-enforced DEP can help mitigate exploits of exception handling mechanisms within Windows.

A secondary benefit of DEP relates to good engineering and best practices for application and driver developers. DEP forces developers to avoid executing code out of data pages without explicitly marking the pages as executable.

**What works differently?**
**Application Compatibility**
Some application behaviors are expected to be incompatible with DEP. Applications that perform dynamic code generation (such as just-in-time code generation) and that do not explicitly mark generated code with Execute permission might have compatibility problems with DEP. Applications that are not built with SafeSEH must have their exception handlers located in executable memory regions.

Applications that attempt to violate DEP will receive an exception with status code `STATUS_ACCESS_VIOLATION (0xC0000005)`. If an application requires executable memory, it must explicitly set this attribute on the appropriate memory by specifying `PAGE_EXECUTE`, `PAGE_EXECUTE_READ`, `PAGE_EXECUTE_READWRITE` or `PAGE_EXECUTE_WRITECOPY` in the memory protection argument of the `Virtual*` memory allocation functions. Heap allocations using the `malloc()` and `HeapAlloc()` functions are non-executable.

**Driver compatibility**
Driver compatibility issues with DEP mostly center on PAE mode-induced compatibility issues.

| **Note** |
|---|
| PAE is required only on systems running 32-bit versions of Windows with processors that support hardware-enforced DEP. |

On its own, DEP might create compatibility problems with drivers that perform code generation or use other techniques to generate executable code in real time. Although many drivers with such behavior would have been fixed — as DEP is "always on" for drivers loaded on 64-bit versions of Windows — there is no guarantee that all drivers have been updated. However, there are few drivers that employ these techniques, and it is not expected that DEP alone will cause a large quantity of driver compatibility problems.

The primary driver compatibility concern is running Physical Address Extension (PAE) mode on 32-bit systems. PAE mode enables processors to address greater than 4 gigabytes (GB) of memory. The primary difference between PAE memory paging and non-PAE memory paging schemes is the extra level of paging that is required in PAE mode (three levels instead of two).

Some drivers might fail to load if PAE is enabled, because the device might be unable to perform 64-bit addressing or the

drivers might assume that PAE mode requires more than 4 GB of random access memory (RAM). Such drivers expect that they will always receive 64-bit addresses when in PAE mode and that they or their device are incapable of interpreting the address.

Other drivers might load in PAE mode but cause system instability by directly modifying system page table entries (PTEs). These drivers expect 32-bit PTEs, but receive 64-bit PTEs in PAE mode instead.

The largest driver PAE compatibility issue involves direct memory access (DMA) transfers and map register allocation. Many devices that support DMA, usually 32-bit adapters, are not capable of performing 64-bit physical addressing. When run in 32-bit mode, the device can address all physical address space. In PAE mode, it is possible that data would be present at a physical address greater than 4 GB. To allow devices with these constraints to function in this scenario, Windows 2000 Server and later operating systems provide double-buffering for the DMA transaction by providing a 32-bit address that is indicated by a map register. The device can perform the DMA transaction to the 32-bit address and the kernel copies the memory to the 64-bit address that is provided to the driver.

When the system runs with PAE disabled, drivers for 32-bit devices never require their map registers to be backed by real memory. This means that double-buffering is not necessary, since all devices and drivers are contained within the 32-bit address space. Based on testing of drivers for 32-bit devices on 64-bit processor–based computers, it is expected that most client-tested, DMA-capable drivers expect unlimited map registers.

To constrain compatibility issues, Windows Server 2003, Standard Edition with Service Pack 1, includes hardware abstraction layer (HAL) changes that mimic the 32-bit HAL DMA behavior. The altered HAL grants unlimited map registers when the system is running in PAE mode. In addition, the kernel memory manager ignores any physical address above 4 GB. Any system RAM beyond the 4 GB barrier would be made unaddressable by Windows and be unusable in the system. By limiting the address space to 4 GB, devices with 32-bit DMA bus master capability will not see a transaction with an address above the 4 GB barrier. Because these changes remove the need to double-buffer the transactions, they avoid a class of bugs in some drivers related to proper implementation of double buffering support.

Note that the PAE behavior of Windows Server 2003, Enterprise Edition with Service Pack 1, and Windows Server 2003, Datacenter Edition with Service Pack 1, is unchanged from the versions without the service pack.

As a result of these changes to the HAL and memory manager, the impact to device driver compatibility is expected to be minimal on systems running Windows Server 2003 with Service Pack 1 with DEP enabled.

**System compatibility**

A final DEP compatibility concern derives from systems with PAE mode enabled, even though they may not be designed for more than 4 GB of physical RAM. During internal testing Microsoft has noticed that some systems with processors that support hardware-enforced DEP fail to start up or have other stability issues when the processor is running in PAE mode.

PAE mode is a requirement for leveraging the NX processor feature. Therefore, system designers and firmware engineers should be aware that even though the system's chipset and firmware may not have been designed to support more than 4 GB of physical RAM, the system may be running in PAE mode.

Of particular concern is system firmware that interprets page table entries to determine instructions executed by the operating system. Page table entries are extended to 64 bits in length when the processor is running in PAE mode. System designers and firmware developers are encouraged to contact their processor and chipset vendors for more information about how to safely determine instructions executed by the operating system.

System designers working with AMD processors can obtain more information in the "BIOS and Kernel Developer's Guide for AMD Athlon 64 and AMD Opteron Processors." To obtain this paper, go to the AMD Athlon 64 Web site at http://go.microsoft.com/fwlink/?LinkId=28165 and click "BIOS and Kernel Developer's Guide for AMD Athlon 64 and AMD Opteron Processors."

Intel does not make detailed information about System Management Mode (SMM) available publicly. System designers working with Intel processors are encouraged to contact Intel directly for more information.

For more information regarding Windows support for PAE mode, see "Physical Address Extension - PAE Memory and Windows" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=45912.

**How do I resolve these issues?**

Applications that require executable regions of memory must use the `PAGE_EXECUTE`, `PAGE_EXECUTE_READ`, `PAGE_EXECUTE_READWRITE`, or `PAGE_EXECUTE_WRITECOPY` attributes when allocating memory. Additionally, applications cannot execute from the default process heap or the stack. Most applications that perform actions incompatible with DEP will need to be updated to be compatible. Applications must also be built with SafeSEH or ensure their exception handlers are located in memory explicitly marked as executable.

An application can use the `VirtualAlloc()` application programming interface (API) function to allocate executable memory

with the appropriate memory protection options. At a minimum, the `PAGE_EXECUTE` memory protection option should be used. After the executable code has been generated, it is recommended that the application set memory protections to disallow write access to the allocated memory. Applications can disallow write access to allocated memory using the `VirtualProtect()` API function. Disallowing write access ensures maximum protection for executable regions of process address space.

If a malicious process attempts to insert code into an executable region, the access would result in a `STATUS_ACCESS_VIOLATION` write exception. The application should attempt to make the executable regions of its address space as small as possible. This would result in a smaller attack surface through which executable memory could be injected into the process address space and be executed.

Additionally, sophisticated applications can control the layout of their virtual memory and create executable regions. These applications should attempt to locate executable regions in a lower memory space than non-executable regions. The purpose of locating executable regions below non-executable regions is to protect a buffer overflow from overflowing into executable memory.

A small number of executables and libraries may contain executable code in a data section of the image file. In some cases, applications may place small segments of code (commonly referred to as thunks) in the data sections. However, DEP will mark sections of the image file loaded in memory as non-executable unless the section has the executable attribute applied.

Therefore, executable code in data sections should be moved to a code section, or the data section containing the executable code should be explicitly marked as executable. The executable attribute, `IMAGE_SCN_MEM_EXECUTE (0x20000000)`, should be added to the Characteristics field of the corresponding section header for sections that contain executable code.

The Microsoft linker that is distributed with Microsoft Visual Studio products can add the executable attribute to a section using the `/SECTION` linker option. The `/SECTION` linker option has the following format:

**/SECTION:** *Name* **,[E][R][W][S][D][K][L][P][X][,ALIGN=#]**

The `E` value indicates the executable attribute (0x20000000). More information about `/SECTION` and other Microsoft linker options is available on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=28167.

Additionally, the Microsoft COFF Binary File Editor (Editbin.exe) utility can be used to change the section attributes of an existing image. The Editbin utility has a `/SECTION` option with the following format:

**/SECTION:** *Name* **[=** *newname* **][,[[!]{CDEIKOMPRSUW}][A{1248PTSX}]]**

The `C` and `E` values indicate code and executable attributes respectively. For more information about the Editbin utility and the `/SECTION` option, see the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=28168.

Microsoft has provided service packs for Microsoft .NET Framework version 1.0 and version 1.1 to take advantage of DEP in Windows Server 2003 with Service Pack 1. Applications that use the Microsoft .NET Framework will continue to function normally, but will not benefit from DEP if it is enabled unless the appropriate Microsoft .NET Framework Service Pack has been installed.

Microsoft encourages application developers who redistribute the Microsoft .NET Framework to update to Microsoft .NET Framework version 1.0 Service Pack 3 or version 1.1 Service Pack 1, which take advantage of DEP.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**System-wide configuration of DEP**
The primary difference in DEP behavior on Windows Server 2003 Service Pack 1 as compared to Windows XP Service Pack 2 (SP2) is that on the server operating system the default configuration is to protect all applications and services. In Windows XP SP2, DEP was turned on by default only for essential Windows operating system programs and services.

DEP configuration for the system is controlled through Boot.ini switches. Additionally, changes to System in Control Panel have been made to enable end users to easily configure DEP settings if they are logged onto the system as an administrator.

System DEP configuration settings apply only for 32-bit applications and processes when running on 32-bit or 64-bit versions of Windows. On 64-bit versions of Windows, if hardware-enforced DEP is available it is always applied to 64-bit processes and kernel memory spaces and there are no system configuration settings to disable it.

Windows supports four system-wide configurations for both hardware-enforced and software-enforced DEP.

**DEP Configuration**

| Configuration | Description |
|---|---|

| | |
|---|---|
| OptIn<br><br>(default for Windows XP SP2 and Windows XP 64-bit edition) | On systems with processors capable of hardware-enforced DEP, DEP is enabled by default for limited system binaries and applications that opt in. With this option, only Windows system binaries are covered by DEP by default. |
| OptOut<br><br>(default for Windows Server 2003 Service Pack 1) | DEP is enabled by default for all processes. Users can manually create a list of specific applications that do not have DEP applied using System in Control Panel. IT pros can use the Application Compatibility Toolkit to opt-out one or more applications from DEP protection. System Compatibility Fixes ("shims") for DEP do take effect. |
| AlwaysOn | This provides full DEP coverage for the entire system. All processes always run with DEP applied. The exceptions list for exempting specific applications from DEP protection is not available. System Compatibility Fixes ("shims") for DEP do not take effect. Applications that have been opted-out using the Application Compatibility Toolkit run with DEP applied. |
| AlwaysOff | This does not provide any DEP coverage for any part of the system, regardless of hardware DEP support. However, the processor will run in PAE mode with 32-bit versions of Windows unless the `/noexecute=alwaysoff` option is replaced with the `/execute` option in the boot entry. |

Hardware-enforced and software-enforced DEP are configured in the same manner. If the system-wide DEP policy is set to OptIn, the same Windows core binaries and applications will be protected by both hardware and software-enforced DEP. If the system is not capable of hardware-enforced DEP, the Windows core binaries and applications will be protected only by software-enforced DEP.

Similarly, if the system-wide DEP policy is set to OptOut, applications that have been exempted from DEP protection will be exempted from both hardware and software-enforced DEP.

The four system-wide DEP configurations are controlled through Boot.ini switches. The Boot.ini settings are as follows:

`/noexecute=policy_level`

where *policy_level* is defined as `AlwaysOn`, `AlwaysOff`, `OptIn`, or `OptOut`.

Any existing `/noexecute` setting in the Boot.ini file is not changed when Windows Server 2003 Service Pack 1 is installed or if a Windows operating system image is moved across computers with and without hardware-enforced DEP support.

During installation of Windows Server 2003 Service Pack 1, the `OptOut` policy level is enabled by default unless a different policy level is specified in an unattended installation. If the `/noexecute=`*policy_level* setting is not present in the boot entry for a version of Windows that supports DEP, the behavior is the same as if the `/noexecute=OptIn` option was included.

End users who are logged on as administrators can manually configure DEP between the `OptIn` and `OptOut` policies using the **Data Execution Prevention** tab inside the **Performance Options** dialog box. The following procedure describes how to manually configure DEP on the computer:

**To configure DEP settings**

1. Click **Start**, click **Control Panel**, and then double-click **System**.
2. Click the **Advanced** tab. Then, under **Performance**, click **Settings**.
3. Click the **Data Execution Prevention** tab.
4. Click **Turn on DEP for essential Windows programs and services only** to select the **OptIn** policy.
5. Click **Turn on DEP for all programs and services except those I select** to select the **OptOut** policy.
6. If you selected the **OptOut** policy, click **Add** and add the applications that you do not want to use DEP with.

IT professionals can control system-wide DEP configuration with a variety of methods. The Boot.ini file can be modified directly with scripting mechanisms or with the Bootcfg.exe tool, which is included as part of Windows Server 2003 Service Pack 1.

For unattended installations of Windows Server 2003 with Service Pack 1, you can use the Unattend.txt file to prepopulate a specific DEP configuration. You can use the `OSLoadOptionsVar` entry in the `[Data]` section of the Unattend.txt file to specify a

system-wide DEP configuration.

**Per-application DEP configuration**
For the purposes of application compatibility when DEP is set to the `OptOut` policy level, it is possible to selectively disable DEP for individual 32-bit applications. However, DEP is always enabled for 64-bit applications.

For end users, the **Data Execution Prevention** tab in **System Properties** can be used to selectively disable DEP for an application.

For IT professionals, a new application compatibility fix named DisableNX is included with Windows Server 2003 Service Pack 1. The DisableNX compatibility fix disables DEP for the program it is applied to.

The DisableNX compatibility fix can be applied to an application by using the Application Compatibility Toolkit. For more information about Windows application compatibility, see "Windows Application Compatibility" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=23302.

# Device\PhysicalMemory Object

Applies To: Windows Server 2003 with SP1

**What does \Device\PhysicalMemory Object do?**
The \Device\PhysicalMemory section object is used by some applications to access physical memory. Common examples of this use are management applications that attempt to read System Management BIOS (SMBIOS) or other BIOS data that is stored in the lowest 1 MB of physical memory.

**Who does this feature apply to?**
This feature will be of interest to hardware and hardware management application developers.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Device\PhysicalMemory section object**
**Detailed description**
In Windows Server 2003 SP1, user-mode access to the \Device\PhysicalMemory object is not permitted. All forms of access (read, write) are refused when the \Device\PhysicalMemory object is accessed from a user-mode application. Access to the \Device\PhysicalMemory object is refused regardless of the user context (Administrators, Users, Local System, etc.) the application is running in.

Kernel-mode (driver) access to the \Device\PhysicalMemory object is unchanged for Windows Server 2003 SP1.

There are no means to revert this changed behavior in Windows Server 2003 SP1.

**Why is this change important? What threats does it help mitigate?**
This change was made to help prevent security exploits that might leverage the functionality of the \Device\PhysicalMemory object from user-mode.

In previous versions of Windows, access to the \Device\PhsyicalMemory object was protected by an access control list (ACL). However, the ACL may be inadvertently changed. Refusing all access to the \Device\PhysicalMemory object from user-mode ensures this scenario cannot occur.

**What works differently? Are there any dependencies?**
While the majority of applications do not attempt to access physical memory, some management applications that require information from the BIOS may be affected by this change. Many of these management applications may be attempting to read SMBIOS data.

**How do I fix these issues?**
Management application vendors are encouraged to review their applications for access to the \Device\PhysicalMemory object and implement one of the workarounds proposed in this section.

| **Note** |
| --- |
| The following methods can be used to read low physical memory and firmware table data from an application in Windows Server 2003 SP1. Applications that require write access to low physical memory must do so from a kernel-mode driver. |

**Reading SMBIOS information**
Windows Management Instrumentation (WMI) is the preferred method for reading SMBIOS information in Windows. WMI supports reading individual SMBIOS properties (such as the BIOS version or the system manufacturer) from the Win32 classes contained in the root\cimv2 namespace.

WMI also supports reading the entire contents of SMBIOS data in a single buffer using the MSSMBios_RawSMBiosTables class inside of the root\wmi namespace. The SMBiosData property returns a buffer containing the entire SMBIOS data table, except the SMBIOS Structure Table Entry Point as defined in section 2.1.1 of the SMBIOS specification.

WMI supports both a COM and script API to access WMI information. Additionally, WMI is supported in the Windows XP SP2 and Windows Server 2003 SP1 versions of the Windows Preinstallation Environment (WinPE).

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
If your application uses the \Device\PhysicalMemory object you will need to change your code for your application to work with Windows Server 2003 SP1. There are two new user-mode APIs that can be used by applications to read various system firmware tables. These APIs can be used to read SMBIOS and ACPI data, as well as raw BIOS data from low physical memory. The details of the API implementation are available in the Platform SDK at the MSDN Web site. The following are the two new APIs:

- `EnumSystemFirmwareTables`, described on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=45562.

- `GetSystemFirmwareTable`, described on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=45563.

**For more information**

The following Web resources may also be of interest to you if you are affected by this change in functionality:

- The Windows Management Instrumentation (WMI) section of the Windows Platform SDK available on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=159.

- The System Management BIOS (SMBIOS) standard specification provide by the Distributed Management Task Force, Inc. (DMTF) which is available on the DMTF Web site at http://go.microsoft.com/fwlink/?LinkId=38721.

- The Microsoft® Windows® Preinstallation Environment (Windows PE) tool, which is available for download on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38722.

# Distributed File System (DFS) in Windows Server 2003 Service Pack 1

Applies To: Windows Server 2003 with SP1

**What does DFS do?**
Distributed File System (DFS) allows administrators to group shared folders located on different servers by transparently connecting them to one or more DFS namespaces. A DFS namespace is a virtual view of shared folders in an organization. Using the DFS tools, an administrator selects which shared folders to present in the namespace, designs the hierarchy in which those folders appear, and determines the names that the shared folders show in the namespace. When a user views the namespace, the folders appear to reside on a single, high-capacity hard disk. Users can navigate the folders in the namespace without needing to know the server names or shared folders hosting the data. DFS also provides many other benefits, including fault tolerance and load-sharing capabilities, making it ideal for all types of organizations

**Who does this feature apply to?**
Storage administrators managing a DFS namespace, or administrators considering deploying DFS, should be aware of the changes incorporated in SP1.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**DFS Consolidation Roots**
**Detailed description**
New functionality in Distributed File System (DFS) maintains the original Universal Naming Convention (UNC) path of files after they are moved to a new server. This reduces the impact of file server consolidation and migration, saves end users time spent searching for files, and ensures that line-of-business applications keep running.

**Why is this change important?**
There are many scenarios where you will want Universal Naming Convention (UNC) paths to remain unchanged when the underlying files are moved to other servers or to other paths. For example, you may want to preserve the UNC paths that users are accustomed to if you migrate or consolidate your existing file servers to new computers running Microsoft Windows Server 2003. The paths may be embedded in links, in line-of-business applications, and in other places where the names are difficult to change

**What works differently?**
The consolidation root functionality is most easily configured using the File Server Migration Toolkit, available on the Microsoft Web site at http://go.microsoft.com/fwlink/LinkId=37029.

This functionality can also be configured manually by modifying keys in the Windows Registry, as described in the article about using the Distributed File System update to support consolidation roots at the Microsoft Web site at http://go.microsoft.com/fwlink/LindId=43006.

**Move and Rename Support for DFS Namespaces**
**Detailed description**
Administrators can modify the DFS namespace to correct mistakes or to adjust the hierarchy as business needs change or as new folders are added to the namespace.

**Why is this change important?**
Prior to Windows Server 2003 Service Pack 1, there was no way for administrators to rename elements of their namespace. Renaming or moving an element near the top of the namespace was particularly difficult as it required manually deleting and recreating every element below it.

**What works differently?**
DFS administrators may now use the command-line utility **dfscmd** to move or rename links. The syntax for this new command is as follows:

**dfscmd /move ** *DFSName* **** *DFSShareName* **** *Path* **** *ServerName* **** *ShareName* **** *Path*

The following examples illustrate the different ways that this command can be used:

- To create a new folder, move the contents of an existing folder into it, and adjust any links under the folder as appropriate:

```
dfscmd /move \\domain\root\old_folder \\domain\root\new_folder
```

- To make an existing folder a subfolder of a new top-level folder and adjust any links under the folder as appropriate:

```
dfscmd /move \\domain\root\old_folder \\domain\root\new_top_folder\old_folder
```

- To move the contents of one folder to another existing folder

```
dfscmd /move \\domain\root\folder \\domain\root\other-folder\
```

**Client Failback**
**Detailed description**
Client failover in DFS namespaces is the process in which clients attempt to access another server in a referral after one of the servers fails or is removed from the namespace. DFS administrators can specify that clients "failback" to a preferred, local server when it is restored. The target failback policy may be set for the entire root, or for individual links.

**Why is this change important? What threats does it mitigate?**
Prior to Windows Server 2003 Service Pack 1, there was no way for administrators to configure clients to fail back to their local servers; this behavior can be problematic in branch office environments when clients continue to access the hub server even after the branch server is restored.

**What works differently?**
The failback settings for roots and links can be set using the **/TargetFailback** option of **dfsutil**. In addition, the DFS Client Failback hotfix for Windows XP and Windows Server 2003 must be installed to enable the client to perform the failback.

Setting the `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Dfs\Parameters\SysvolNetlogonTargetFailback` registry key and restarting the DFS service on the domain controller enables target failback for SYSVOL/NETLOGON referral requests handled by that controller.

**Target Priority**
**Detailed description**
Target priority enables DFS administrators to explicitly assign the priority of a DFS link or root target.

**Why is this change important? What threats does it mitigate?**
Prior to Windows Server 2003 Service Pack 1, administrators had no way of designating preference between servers that host the same data in a namespace. To work around this, administrators created special subnets for such servers and artificial sites in Active Directory with high link cost. This workaround is time consuming, complex, and leads to increased support costs.

DFS management APIs have been added to configure whether a server appears first or last in a referral, which is the list of servers returned to the client for a given folder (link) in the namespace. Assigning target priority is useful in many scenarios, such as “hot-standby” scenarios where one server is considered the server of last resort. In this scenario, the administrator specifies that the standby server always appears last in referrals, and clients will fail over to this server only if all the other servers fail or become unavailable due to network outages.

**What works differently?**
Targets in a DFS referral response are grouped into sets based on the cost of accessing targets from a client. Within each set, targets are shuffled randomly and these sets are ordered by increasing cost from the DFS client. Prior to Windows Server 2003 SP1, the number of sets in the referral response depended on whether or not Windows Server 2003 site costing was enabled. With site costing disabled there are exactly two sets, one set containing targets in the same site as the DFS client and the other set containing the remaining targets. With site costing enabled sets are grouped on the basis of actual site cost of the target from the DFS client, and hence there could be many more of these sets. Note that there is no information in the current DFS V1, V2, or V3 referral responses that allows a DFS client to identify these sets.

With server target priority, these sets will still be based on the cost of accessing targets. Server target priority simply extends the cost sorting criteria for targets, so the sets are now those targets having the same site cost and server target priority. In addition, the new V4 protocol will indicate where the set boundaries are in the target list.

Server target priority is broken out into two values: a priority class and a priority rank. Priority classes are defined at two levels: locally, within sets of targets of equal site cost, and globally. Within each of these, there is a coarse ordering of high, normal and low priority targets. This gives us five priority classes in the following order:

- Global high

- Site-cost high

- Site-cost normal
- Site-cost low
- Global low

Note that there is no separate “global normal”. If global high or global low is not specified then the referral is placed in the "global normal" set. Priority rank is evaluated by a simple integer ranking – 0, 1, 2, and so forth.

In ordering a referral, the complete process now works as follows:

- The sets of global high and global low targets are identified, along with the remaining “global normal” targets.
- These three sets are placed in order – global high, normal and low.
- If set, INSITE is applied to the “normal” set and targets outside the client’s site are removed. It is not applied to global high and global low.
- Within each of these three sets, the targets are ordered by the site cost mechanism (either local site or by full site costing), producing sets of targets of equal site cost
- Within the sets of “global normal” targets of equal site cost, targets are ordered by priority class – site cost high, normal and low.
- Within the sets of targets of equal site cost and priority class, targets are now ordered by priority rank (0 being the highest).
- Within the sets of targets of equal site cost, priority class, and priority rank, targets are randomly shuffled for load balancing.

The **/targetpriority** option of **dfsutil** can be used to set the priority options listed above.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Better Delegation**
**Detailed description**
As of Windows Server 2003 Service Pack 1, administrators may delegate the ability to manage domain DFS roots by setting rights to the DFS object in Active Directory. Administrators may also delegate the ability to manage stand alone DFS roots by setting rights to the DFS object in the registry. This is in addition to the existing delegation model of adding DFS administrators to the local Administrators group on every server that hosts the namespace.

**Why is this change important?**
In the previous versions of Windows Server 2003, administrators who want to delegate the ability to manage a namespace must make the user a member of the local Administrators group on every server that hosts the namespace. This requirement can lead to an inconsistent management experience if the group memberships are not assigned correctly, and it also allows the user full access to the local file system of each namespace server.

**What works differently?**
The following procedures have been updated as a result of this change in functionality:

**To grant a user permission to administer only a domain DFS namespace:**

1. In the **Active Directory Users and Computers** MMC snap-in, on the **View** menu, click **Advanced Features**.
2. In the console tree, double-click the **System** folder to expand it.
3. Click the **DFS-Configuration** folder.

   Any existing root objects appear in the details pane.
4. Right-click the root object that you want to allow the user to administer, and then click **Properties**.

5. On the **Security** tab, click **Add**.
6. Type the name of the user, and then click **OK**.
7. Verify that the user is granted the **Full Control** permission, and then click **OK**.

| **Note** |
| --- |
| The user's rights as defined by the access control list applied to the DFS object in Active Directory are evaluated at the individual root targets. Because of this, rights granted to well known users and groups are ignored due to potential differences between the membership of the well known groups in Active Directory and at each root target. For example, granting Power Users full control over the DFS root object in Active Directory will not enable Power Users on the individual root targets to manage the corresponding DFS root. Additionally, if a well known user or group is granted rights to a root target but is denied access to the DFS root object in Active Directory, that denial will be ignored by the DFS root targets. |

**To grant a user permission to administer a standalone DFS namespace**

1. Using regedit, locate the following key:

   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\DFS\Roots\Standalone**

2. Right-click the root object you want to allow the user to administer, and then click **Permissions...**
3. On the **Security** tab, click **Add**.
4. Type the name of the user, and then click **OK**.
5. Verify that the user is granted the **Full Control** permission, and then click **OK**.

**Referral Time to Live Values Are Not Renewed for DFS Clients**
**Detailed description:**
For DFS clients that are not running Windows XP with SP2 or Windows Server 2003 with SP1, the Time to Live for a referral determines the earliest time that a client will request a new referral, but only if the existing referral expires before it is accessed again. Clients that use a cached referral will renew the Time to Live of the referral and thus use the referral indefinitely until the client's referral cache is cleared or the client is restarted.

This behavior has changed for clients running Windows XP with SP2 and Windows Server 2003 with SP1. Specifically, the Time to Live value is not renewed each time a client accesses a target using a cached referral. Instead, the referral expires after the Time to Live value lapses.

**Why is this change important?**
This change allows DFS clients running Windows XP with SP2 or Windows Server 2003 with SP1 to honor the actual Time to Live value of a referral. One benefit of this change is that DFS clients running these service packs will more quickly react to changes to links and roots. For example, if the link targets of a link named Current are changed daily, DFS clients without these service packs would refresh the Time to Live value each time they access the Current link, causing them to continue to reference stale link targets well beyond the Time to Live value associated with the initial referral request.

**What works differently?**
This change has several effects:

- Clients running Windows XP with SP2 or Windows Server 2003 with SP1 will request referrals more frequently than other DFS clients, which can cause moderately increased load on the domain-based DFS root servers, stand-alone root servers, and domain controllers.
- Because they request new referrals more frequently, clients running Windows XP with SP2 or Windows Server 2003 with SP1 will discover namespace updates more quickly than other DFS clients.
- In terms of DFS failover, this new behavior can cause the DFS client to fail over to a new target if the previously active target is not in the new referral, such as when the namespace is changed to remove the target that the client had accessed.

**Service Disabled By Default**
**Detailed description**
The DFS service is disabled by default in Windows Server 2003 Service Pack 1.

**Why is this change important?**
Unnecessary services are disabled by default in Windows Server 2003 SP1 to reduce the attack surface of the server.

**What works differently?**
Computers that are new installations of Windows Server 2003 with Service Pack 1 will have the DFS service disabled by default.

Upgrading a computer that is running Windows Server 2003 by installing Service Pack 1 will result in the DFS service being disabled unless the server is either a domain controller or is already hosting an existing DFS root.

When a server running Windows Server 2003 Service Pack 1 is promoted to domain controller status, the DFS service is enabled.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| Server Consolidation Retry | HKEY_LOCAL_MACHINE \SYSTEM \CurrentControlSet \Services\Dfs \Parameters\Replicated | N/A | 0 | 0,1 |
| LogServer Consolidation | HKEY_LOCAL_MACHINE \SYSTEM \CurrentControlSet \Services\Dfs \Parameters\Replicated | N/A | 0 | 0,1 |
| Sysvol Netlogon Target Failback | HKEY_LOCAL_MACHINE \SYSTEM \CurrentControlSet \Services\Dfs \Parameters | N/A | 0 | 0,1 |

# Distributed Transaction Coordinator

Updated: January 12, 2011

Applies To: Windows Server 2003 with SP1

**What does Distributed Transaction Coordinator do?**
The Distributed Transaction Coordinator (DTC) service coordinates transactions that update two or more transaction-protected resources, such as databases, message queues, files systems, and so on. These transaction-protected resources may be on a single computer or distributed across many networked computers.

**Who does this feature apply to?**

- Users of any computers that participate in DTC transactions, either directly or through other computers.
- System administrators of networks that use DTC components to perform transactions across networks.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Securing all network communication by default**
**Detailed description**
In Windows Server 2003 Service Pack 1, DTC provides the administrator with greater control over the network communication between computers. By default, all network communication is disabled.

In order to manipulate the communication settings, the DTC security settings properties page has been enhanced. To see the page, use the following procedure:

**To open the DTC security settings properties page**

1. Open the **Component Services** snap-in Microsoft Management Console (MMC).
2. In the console tree, click the **Computers** folder.
3. In the results pane, right click **My Computer** and then click **Properties**.
4. Click the **MSDTC** tab, and then click **Security Configuration**.

The table below defines the new fields in the property page, along with the registry keys affected for the different settings. All the registry keys related to MSDTC are located in the following registry key:

`MyComputer\HKEY_LOCAL_MACHINE\Software\Microsoft\MSDTC`

| **Caution** |
|---|
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. These registry keys might not be supported in future releases. |

The following table tells you where to find the MSDTC key specific values.

| Setting | Description | Corresponding registry value |
|---|---|---|
| Network DTC Access | Determines whether DTC on the local computer is allowed to access the network. This setting must be enabled in combination with one of the other settings to enable network DTC transactions.<br><br>Default setting: Off | Security\NetworkDtcAccess<br><br>0 = Off<br><br>1 = On |

| | | |
|---|---|---|
| Allow inbound | Allows a distributed transaction that originates from a remote computer to run on this computer.<br><br>Default setting: Off | To enable this setting you must set the following registry key values to 1:<br><br>`Security\NetworkDtcAccess`<br><br>`Security\NetworkDtcAccessTransactions`<br><br>`Security\NetworkDtcAccessInbound`<br><br>To disable this setting, you only need to set the following registry key value to 0:<br><br>`Security\NetworkDtcAccessInbound` |
| Allow Outbound | Allows the local computer to initiate a transaction and run it on a remote computer. | To enable this setting, you need to set the following registry key values to 1:<br><br>`Security\NetworkDtcAccess`<br><br>`Security\NetworkDtcAccessTransactions`<br><br>`Security\NetworkDtcAccessOutbound`<br><br>To disable this setting, you only need to set the following registry key value to 0:<br><br>`Security\NetworkDtcAccessOutbound` |
| Mutual Authentication Required | Adds support for mutual authentication in future versions and is the highest secured communication mode. In the current versions of Windows and Windows Server, it is functionally equivalent to the Incoming Caller Authentication Required setting. This is the recommended transaction mode for clients running Windows XP SP2 and servers running a member of the Windows Server 2003 family.<br><br>**Warning**<br>You cannot use the **Mutual Authentication Required** transaction mode with computers that are in a clustered environment, or any computers that are negotiating transactions with such computers. In that context, you can use the **Incoming Caller Authentication Required** transaction mode instead. In a clustered environment, the computer account for the Distributed Transaction Coordinator service specifies the cluster node's host name instead of the transaction node's host name, which prevents the authentication request from succeeding when the **Mutual Authentication Required** transaction mode is enabled. | AllowOnlySecureRpcCalls = 1<br><br>FallbackToUnsecureRPCIfNecessary = 0<br><br>TurnOffRpcSecurity = 0 |
| Incoming Caller Authentication Required | Requires the local DTC to communicate with a remote DTC using only encrypted messages and mutual authentication. This setting is recommended for servers running Windows Server 2003 that are operating in a cluster.<br><br>Only Windows Server 2003 and Windows XP SP2 support this feature, so you should only use this if you know that the DTC on the remote computer runs either the Windows Server 2003 or Windows XP SP2 operating system. | AllowOnlySecureRpcCalls = 0<br><br>FallbackToUnsecureRPCIfNecessary = 1<br><br>TurnOffRpcSecurity = 0 |

| | | |
|---|---|---|
| No Authentication Required | Provides system compatibility between previous versions of the Windows operating system. When enabled, communication on the network between DTCs can fall back to a non-authentication or non-encrypted communication if a secure communication channel cannot be established. This setting should be used if the DTC on the remote computer runs a Windows 2000 operating system or a Windows XP operating system earlier than SP2. This setting is also useful when the DTCs that are involved are located on computers that are in domains that do not have an established trust relationship or if the computers are part of a Windows workgroup. | AllowOnlySecureRpcCalls = 0<br><br>FallbackToUnsecureRPCIfNecessary = 0<br><br>TurnOffRpcSecurity = 1 |

**Why is this change important? What threats does it help mitigate?**
These changes are important in order to secure any communication coming into or going out from the computer. By default, after installing Windows Server 2003 Service Pack 1, the computer will not accept or issue any network traffic and therefore will be less vulnerable to network attacks.

Additionally, the online network protocol has been upgraded to support a more securely encrypted and mutually authenticated communication mode. This helps to ensure that attackers can not intercept or take over communications between DTCs.

**What works differently?**
After installing Windows Server 2003 Service Pack 1, all network communication coming out of or getting into DTC is disabled. For example, if a COM+ object attempts to update a SQL database on a remote computer using a DTC transaction, the transaction fails. Conversely, if your computer is hosting a SQL database that components from remote computers try to access using a DTC transaction, their transactions fail.

**How do I fix these issues?**
If your transactions fail because of network connectivity, you can use MSDTC security properties, as described previously in this document, select the **Network DTC Access** check box, and then select the **Allow Inbound** and **Allow Outbound** check boxes, as appropriate.

If you want to change these setting programmatically as part of your Windows Server 2003 Service Pack 1 deployment, you can directly change the registry values that correspond to your desired setting as described in the table in "Securing all network communication by default," earlier in this document. After you have changed the registry settings, you must restart the MSDTC service.

If you are using Windows Firewall to protect the computers in your organization, you must add MSDTC into the exception list in the Windows Firewall settings. To do so, use the following steps:

1. In **Control Panel**, open **Windows Firewall**.
2. Click the **Exceptions** tab, and then click **Add Program**.
3. Click **Browse**, and then add **c:\windows\system32\msdtc.exe**.
4. In **Programs and Services**, select the **Msdtc.exe** check box, and then click **OK**.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| NetworkDtcAccess | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \MSDTC \Security | 1 | 0 | 0,1 |
| NetwordDtcAccessTransactions | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \MSDTC \Security | 1 | 0 | 0,1 |
| NetworkDtcAccessInbound | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \MSDTC \Security | n/a | 0 | 0,1 |
| NetworkDtcAccessOutbound | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \MSDTC \Security | n/a | 0 | 0,1 |

| | | | | |
|---|---|---|---|---|
| AllowOnlySecureRpcCalls | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \MSDTC | n/a | 1 | 0,1 |
| FallbackToUnsecureRPCIfNecessary | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \MSDTC | n/a | 0 | 0,1 |
| TurnOffRpcSecurity | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \MSDTC | n/a | 0 | 0,1 |

# Download, Attachment, and Authenticode Enhancements

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What do the download, attachment and Authenticode enhancements do?**
In Windows Server 2003 with Service Pack 1, the prompts that are used for file downloads, mail attachments, shell process execution, and program installation have been modified to be more consistent and clearer than they were in previous versions of Windows Server. In addition, the publisher information will be shown before a file type that is signable and can potentially harm the user's machine is opened. (Common examples of signable file types that can potentially harm the user's machine are .exe, .dll, .ocx, .msi, and .cab.)

There is a new application programming interface (API), which allows application developers to make use of this new user interface. For more information regarding the API, see "AES API Integration," in the section of this document on changes to e-mail features in Windows Server 2003 Service Pack 1.

**Who does this feature apply to?**
Application developers will be able to call the new Attachment Manager dialog box from their Windows applications by using the API that is described in the "Attachment Manager API Integration" topic in the "Outlook Express" section of this document.

Application developers should also be aware that, in certain scenarios, such as attempting to open an attachment or downloading a file that is potentially dangerous, file types that can potentially harm a user's computer will have their digital signatures checked before they are opened. The signature information is presented to the user to help inform the user of the file's publisher.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Internet Explorer file download prompt**
**Detailed description**
When a user uses Internet Explorer to download a file, the dialog box that appears has the following changes:

- A file handler icon has been added.
- A new information area has been added to the bottom of the dialog box that provides slightly different information, depending on whether the downloaded file type is of higher or lower risk.

All file types that are signable and that can potentially harm a user's computer are checked for publisher information. This information will be shown to the user before opening the file.

The publisher information is shown before opening a file type that is signable and that can potentially harm the user's computer. The **Authenticode** dialog box presents this information to the user, who can then make a more informed decision about running the file.

**Why is this change important?**
This change helps bring consistency and clarity to the experience of downloading files and code to a user's computer. The publisher check provides crucial information when a signature is found in a file and provides a systematic way to prevent files that are from suspicious publishers from compromising the security of a computer.

**What works differently?**
Files with blocked publishers are not allowed to run.

**How do I resolve these issues?**
You can unblock a publisher of an add-on by using **Manage Add-ons** in Internet Explorer. To unblock a publisher to enable

the download of a specific file, you can remove the publisher from the **Untrusted Publishers** list. To do this, in Internet Explorer, on the **Tools** menu, click **Internet Options**, click the **Content** tab, click the **Publishers** button and then remove the publisher's name from the **Untrusted Publishers** list.

**Outlook Express e-mail attachment prompt**
**Detailed description**
The Outlook Express e-mail attachment prompt uses the same procedures as file downloads and leverages the AES API Integration. As a result e-mail attachments in Outlook Express show the publisher information for files types that can potentially harm a user's computer and any file whose publisher has been blocked will not be allowed to run.

**Why is this change important?**
This change helps bring consistency and clarity to the experience of downloading files and code to a user's computer.

**Add-on install prompt**
**Detailed description**
The Internet Explorer add-on install prompt has been simplified and only displays the file name and publisher information from the digital signature. It provides a warning about the risk associated with installing the add-on in order to help the user make a good decision about installing the add-on. Also, additional functionality was added to the prompt so that users always block a publisher, indicating that Windows should never trust anything from the publisher. This blocks the publisher from running code on the computer.

**Why is this change important?**
This change helps bring consistency and clarity to the experience of downloading files and code to a user's computer. In addition, the user can choose not to trust a publisher when the user is prompted to install the add-on. This gives users more control over their experience.

**What works differently? Are there any dependencies?**
When you install an add-on, the user interface is more clear and concise.

**How do I resolve these issues?**
By default, Internet Explorer will not allow users to run invalid or unsigned ActiveX controls. The Information Bar will provide an alternative way for the user to choose to install a blocked control. For more information see Internet Explorer Information Bar.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
Users now have the ability to block a publisher from running code on their computer.

# Internet Explorer Feature Control Settings in Group Policy

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Internet Explorer Feature Control Settings in Group Policy do?**
Windows XP Service Pack 2 introduced new registry keys and values for Internet Explorer security features called Feature Controls. These security features have been incorporated in Windows Server 2003 Service Pack 1. The specific behavior of the feature control registry settings is discussed with each security feature throughout this section.

A modified Inetres.adm file contains the feature control settings as policies. Administrators can manage the feature control policies by using Group Policy objects (GPOs). When Internet Explorer is installed, the default preferences settings for these feature controls are registered on the computer in `HKEY_LOCAL_MACHINE`. In Group Policy, the Administrator can set them in either `HKEY_LOCAL_MACHINE (Computer Configuration)` or `HKEY_CURRENT_USER (User Configuration)`.

**Who does this feature apply to?**
Group Policy administrators can uniformly configure the Internet Explorer Feature Control settings for the computers and users that they manage.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Group Policy Internet Explorer settings**
**Detailed description**
The new feature control policies are:

- Binary Behavior Security Restriction
- MK Protocol Security Restriction
- Local Machine Zone Lockdown Security
- Consistent MIME Handling
- MIME Sniffing Safety Feature
- Object Caching Protection
- Scripted Window Security Restrictions
- Protection from Zone Elevation
- Information Bar
- Restrict ActiveX Install
- Restrict File Download
- Add-on Management
- Network Protocol Lockdown

In the Group Policy Management Console, the local computer policies for Feature Controls are in **\Computer Configuration\Administrative Templates\Windows Components\Internet Explorer\Security Features**.

The current user policies for Feature Controls are in **\User Configuration\Administrative Templates\Windows Components\Internet Explorer\Security Features**.

The policy for the feature needs to be enabled for the process — for example, IExplore.exe — before the zones' individual security setting policies or preferences will be applied. For more about the behavior of Feature Controls keys and setting them for a process, see the section on each feature and the section Internet Explorer Using Feature Control Registry Settings with Security Zone Settings. For more information about specific security settings by zone, see Internet Explorer URL Action and Advanced Security Settings in Group Policy.

Administrators of Group Policy can manage these new policies in the Administrative Templates extension to the Group Policy Management Console. When configuring these policies, the administrator can enable or disable the security feature for explorer processes (Internet Explorer and Windows Explorer), for executable processes that they defined, or for all processes that host the WebOC.

Users cannot see the feature control policies or preference settings through the Internet Explorer user interface, except for Local Machine Zone Lockdown Security. Feature control policies can only be set using the Group Policy Management Console, and feature control preference settings can only be changed programmatically or by editing the registry.

**Configuring policies and preferences**

Group Policy is the recommended tool for managing Internet Explorer for client computers on a corporate network. Internet Explorer supports Group Policy management for the IE feature controls included in Windows XP Service Pack 2 and Windows Server 2003 Service Pack 1 as well as for Security page settings or URL actions. Administrators of Group Policy can manage these policy settings in the Administrative Templates extension of the Group Policy Management Console.

When implementing policy settings, it is recommended to configure template policy settings in one Group Policy object (GPO) and configure any related individual policy settings in a separate GPO. You can then use Group Policy management features (for example, precedence, inheritance, or enforce) to apply individual settings to specific client computers.

Policies can be read by users but can only be changed by Group Policy management or by an administrator. Preference settings can be changed programmatically, by editing the registry, or in the case of URL actions and Local Machine Zone Lockdown Security, by using Internet Explorer. Note that settings that are associated with policies will take precedence over settings specified using Internet Explorer preferences.

**IEAK/IEM**

For operating systems prior to Windows XP SP2 and Windows Server 2003 SP1 and previous Internet Explorer versions, Internet Explorer Administration Kit (IEAK) 6 Service Pack 1 remains the recommended tool for solution providers and application developers to customize Internet Explorer for their end users. IEAK support and the IEAK/IEM process does not change for Internet Explorer versions prior to Windows XP Service Pack 2. The process also has not changed for using IEAK/IEM to set user setting preferences in Internet Explorer versions prior to and including Windows Server 2003 SP1. This includes the new Internet Explorer 6 in Windows XP Service Pack 2 and Windows Server 2003 SP1 preference settings. However, the true policy settings incorporated by this feature can only be managed within Group Policy. For more information about IEAK, see "Microsoft Internet Explorer 6 Administration Kit Service Pack 1" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=26002.

In summary, the IEAK can still be used as before for all Internet Explorer versions prior to Windows XP Service Pack 2, and is still the tool to use for branding in Windows XP Service Pack 2 and Windows Server 2003 SP1. IEM/IEAK can be still be used to set user preference settings, but true policies should be set using the Group Policy Management Console.

**Frequently asked questions for existing users of the IEAK**

| Question | Answer |
|---|---|
| I currently use the IEAK with a corporate license to configure Internet Explorer on desktop computers and I don't have Active Directory in my organization. How can I configure Internet Explorer if the IEAK doesn't work with Windows XP SP2 or Windows Server 2003 SP1? | You can still use Group Policy to configure settings even if you don't use Active Directory. You can use Group Policy to create a local Group Policy object (GPO) with your settings and then deploy that GPO. After you have configured your GPO for Internet Explorer, you can deploy it using your standard deployment methods. For example, you might use startup or logon scripts, Systems Management Server scripts, or you might send links to users in e-mail. |

| | |
|---|---|
| I currently use the IEAK with a corporate license to configure Internet Explorer on desktops and I don't have Active Directory in my organization. What happens if I keep running my IEAK 6 SP1 packages against Windows XP SP2 or Windows Server 2003 SP1? | If you install an IEAK 6 SP1 package on a computer running either Windows XP SP2 or Windows Server 2003 SP1, the settings from Internet Explorer 6 SP1 will be updated, but the security settings will not be configurable, since IEAK 6 SP1 wasn't designed to deploy those settings. |
| I currently use the IEAK with an Internet service provider (ISP) license to brand Internet Explorer bits and setup connections for my ISP customers. Will my IEAK 6 SP1 packages still be able to apply settings on Windows XP SP2 and Windows Server 2003 SP1? | The branding settings in your ISP license IEAK 6 SP1 package should be applied correctly. |

**Why is this change important?**

By adding the Internet Explorer Feature Controls policies to Group Policy, administrators can manage these true policies to establish standard security settings for all the computers that they configure.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**

Internet Explorer in Windows Server 2003 SP1 adds policies to Group Policy but does not change how policies are managed. Developers need to be aware of how each feature control setting affects security-related behavior for their applications. The effects of the different security-related behaviors on application development are discussed within this document in the specific sections for each feature.

# Internet Explorer Using Feature Control Registry Settings with Security Zone Settings

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What do Feature Control Registry Settings and Security Zone Settings do?**
Feature Control registry settings are provided for Internet Explorer so that a specific process can be configured to opt-in to a particular security feature. Each security feature has a corresponding registry key that you can use to opt-in or opt-out of the security feature.

When a process has been configured to use a security feature, the security feature is running. Once the feature is running, there might be corresponding security zone settings that can be applied for more precision. Some security features do not have additional security zone settings.

In the **Security Settings** tab of **Internet Options**, the user can adjust these settings for many of the new feature controls. If you select **Enable**, it lowers the security settings and allows the behavior to run less securely, or in the same manner as it did in previous version of Internet Explorer. The feature control can be applied again by setting the security zone setting to **Disable**, which blocks the less-secure behavior while the feature control is enabled for that process.

Each of the Feature Controls is discussed in more detail in this document. For more information about URL action settings and how they relate to security zones, see "About URL Security Zones Templates" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=26001.

Using security zone settings for a feature provides additional precision in control for security features in Internet Explorer and can help manage application compatibility for organizational intranet applications. A user or administrator can select different behaviors based on risk.

**Who does this feature apply to?**
Web application developers need to be aware that the Internet Explorer security settings are dependent on the zone in which an application is run. Therefore, you should assign security zones carefully; this should be a part of your information security considerations. The security zones that you use should also be considered when assessing application compatibility.

Administrators of Group Policy may want to adjust the default values for each zone to suit the particular environments in their organization.

Unless prevented by policies in Group Policy, users can manage the values for these security zone settings (or URL actions) for each zone through **Internet Options** in Control Panel. Note that the Local Machine zone is not available through Control Panel. To access the security settings for a zone, click **Start**, click **Control Panel**, click **Internet Options**, click the **Security** tab, click a Web security zone, and then click **Custom Level**.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Feature control registry settings**
**Detailed description**
Windows Server 2003 Service Pack 1 introduces new feature control registry settings.

For many of these features, when the registry setting is on, users can configure the security settings (also known as URL action flags) to fine tune the feature control in each individual security zone

If you choose **Enable** as the action to take for an Internet Explorer feature control, the zone is secured as it was for the previous version of Internet Explorer. Relevant security control features will not apply in this zone; the security zone will run without the added layer of security provided by this feature.

If you choose to disable the security zone setting, the actions that may be harmful cannot run; this Internet Explorer security feature will be turned on in this zone, as dictated by the feature control setting for the process.

Security settings are often applied to a zone by a URL security zone template. The default values for the security settings and the settings by zone template are listed in the section Internet Explorer URL Action and Advanced Security Settings in Group Policy.

**Why is this change important? What threats does it help mitigate?**
As originally envisioned, each feature control setting would either be on or off for all security zones. Customer feedback indicated that more precise tuning with the settings was necessary for some features. For example, the internal workflow of some organizations depends on intranet applications. A feature control that protects users in the Internet zone may cause an intranet application to stop working. Because of this, Microsoft has incorporated the ability to control many security settings by zone.

**What works differently?**
Adding security settings by zone provides more flexibility in applying the new security features. This flexibility will provide a more manageable implementation of this new security feature, particularly in intranet scenarios.

**How do I resolve these issues?**
If the feature control setting is suspected of causing problems for an application, changing the feature control setting in the zone where the application is running to **Enable** allows the administrator or user to return to the previous behavior in that zone for that specific feature while maintaining the more secure behavior in other security zones. For some security settings, additional configuration options such as **Prompt** and **Admin-approved** are available, as well as **Enable** and **Disable**.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
If the code uses the default URLmon security manager, the developer must call `CoInternetIsFeatureEnabledForURL` to check the security settings for a particular zone.

# Internet Explorer URL Action and Advanced Security Settings in Group Policy

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the Enhanced Security Configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Internet Explorer Settings in Group Policy do?**
Windows XP Service Pack 2 introduced true policies for the configurable actions in the Internet Explorer **Security** tab settings. In addition to incorporating these policies into Internet Explorer in Windows Server 2003 Service Pack 1, additional policies were created for selected configurable actions in the Internet Explorer **Advanced** tab, as well as for URL action policies in Locked-Down zones used only by the Network Protocol Lockdown security feature. In this release, these security settings are managed using the Group Policy Management Console and, if set, can only be changed by a Group Policy object (GPO) or by an administrator.

An updated Inetres.adm file contains a list of settings as policies, including Advanced settings, which are also found in the Internet Explorer user interface as preferences. Administrators can manage the new feature control policies by using Group Policy objects (GPOs). When Internet Explorer is installed, the default HKEY_CURRENT_USER preferences settings for these settings are registered on the computer as they were in previous versions. The Administrator has to use the Group Policy Management Console (GPMC) to add these settings as policies.

**Who does this feature apply to?**
Group Policy administrators can uniformly configure the new Internet Explorer Advanced setting policies, as well as policies for Locked-Down security zones, for the computers and users that they manage. It is important to inform the end-user which actions are controlled by policy, as these actions will override user preference settings.

| Note |
| --- |
| The Internet Options control panel will display policy settings when opened and users can interact with user interface and appear to change their preferences. However, these preferences will not actually override Group Policy settings, which may cause a confusing user experience. The administrator can also set a policy to disable the **Advanced** page user interface so that it is clearer to the user that these settings are not available to be changed. This is not an issue for the Locked-Down zones' settings as they are not accessible through the user interface. |

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Group Policy Internet Explorer advanced settings**
**Detailed description**
The following definitions apply to Internet Explorer settings for Windows Server 2003 with Service Pack 1:

- Security zones: Locked-Down Intranet Zone, Locked-Down Trusted Sites Zone, Locked-Down Internet Zone, and Locked-Down Restricted Sites zone.

- Templates: Standard settings for all URL actions in these security zones. Templates can be applied in any zone, and settings will provide a range of choices from low security, medium-low, medium, and up to high security for the zone.

- URL actions: Security settings in the registry that identify the action to take for that feature in the security zone where the URL resides. URL action settings include enable, disable, prompt, and others as appropriate.

- URL action policies: URL action policies can be added individually by enabling the desired URL action policy, then selecting the setting for the policy registry key value. They can also be set by zone template.

Internet Explorer will look for a policy in the following order:

- HKEY_LOCAL_MACHINE policy hive
- HKEY_CURRENT_USER policy hive
- HKEY_CURRENT_USER preference hive
- HKEY_LOCAL_MACHINE preference hive

If Internet Explorer finds a policy in the HKEY_LOCAL_MACHINE policy hive, it stops and does not continue; that is the setting it respects. If Internet Explorer does not find a policy in HKEY_LOCAL_MACHINE policy hive, it looks in the HKEY_CURRENT_USER policy hive, and so on. The administrator can set a policy for one or more URL actions in one or more zones, and allow the end user to manage preferences for URL actions that do not require policy-level security management.

**Policy values for URL action**
The new URL action policies have the same numeric values as their related preference keys. The following table provides a reference to these URL actions.

| URL action flag name | Security setting UI | Numeric name |
|---|---|---|
| URLACTION_DOWNLOAD_SIGNED_ACTIVEX | Download signed ActiveX controls | 1001 |
| URLACTION_DOWNLOAD_UNSIGNED_ACTIVEX | Download unsigned ActiveX controls | 1004 |
| URLACTION_ACTIVEX_RUN | Run ActiveX controls and plugins | 1200 |
| URLACTION_ACTIVEX_OVERRIDE_OBJECT_SAFETY | Initialize and script ActiveX controls not marked as safe | 1201 |
| URLACTION_SCRIPT_RUN | Active scripting | 1400 |
| URLACTION_SCRIPT_JAVA_USE | Scripting of Java applets | 1402 |
| URLACTION_SCRIPT_SAFE_ACTIVEX | Script ActiveX controls marked safe for scripting | 1405 |
| URLACTION_CROSS_DOMAIN_DATA | Access data sources across domains | 1406 |
| URLACTION_SCRIPT_PASTE | Allow paste operations via script | 1407 |
| URLACTION_HTML_SUBMIT_FORMS | Submit non-encrypted form data | 1601 |
| URLACTION_HTML_FONT_DOWNLOAD | Font download | 1604 |
| URLACTION_HTML_USERDATA_SAVE | Userdata persistence | 1606 |
| URLACTION_HTML_SUBFRAME_NAVIGATE | Navigate sub-frames across different domains | 1607 |
| URLACTION_HTML_META_REFRESH | Allow META REFRESH | 1608 |
| URLACTION_HTML_MIXED_CONTENT | Display mixed content | 1609 |
| URLACTION_SHELL_INSTALL_DTITEMS | Installation of desktop items | 1800 |
| URLACTION_SHELL_MOVE_OR_COPY | Drag and drop or copy and paste files | 1802 |
| URLACTION_SHELL_FILE_DOWNLOAD | File download | 1803 |
| URLACTION_SHELL_VERB | Launching applications and files in an IFRAME | 1804 |
| URLACTION_SHELL_POPUPMGR | Use Pop-up blocker | 1809 |

| | | |
|---|---|---|
| URLACTION_NETWORK_MIN | Logon | 1A00 |
| URLACTION_CLIENT_CERT_PROMPT | Don't prompt for client certificate selection when no certificates or only one certificate exists | 1A04 |
| URLACTION_JAVA_PERMISSIONS | Java permissions | 1C00 |
| URLACTION_CHANNEL_SOFTDIST_PERMISSIONS | Software channel permissions | 1E05 |
| URLACTION_BEHAVIOR_RUN | Script and Binary Behaviors | 2000 |
| URLACTION_MANAGED_SIGNED | Run .NET Framework-reliant components signed with Authenticode | 2001 |
| URLACTION_MANAGED_UNSIGNED | Run .NET Framework-reliant components not signed with Authenticode | 2004 |
| URLACTION_FEATURE_MIME_SNIFFING | Open files based on content, not file extension | 2100 |
| URLACTION_FEATURE_ZONE_ELEVATION | Web sites in less privileged Web content zones can navigate into this zone | 2101 |
| URLACTION_FEATURE_WINDOW_RESTRICTIONS | Allow script-initiated windows without size or position constraints | 2102 |
| URLACTION_AUTOMATIC_DOWNLOAD_UI | Automatic prompting for file downloads | 2200 |
| URLACTION_AUTOMATIC_ACTIVEX_UI | Automatic prompting for ActiveX controls | 2201 |
| URLACTION_ALLOW_RESTRICTEDPROTOCOLS | Allow active content over restricted protocols to access my computer | 2300 |

For more information about using URL action flags, see "URL Action Flags" on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=32776.

The following table provides a reference to the setting options available for each URL action.

| **Numeric Name** | **URL Action Policy Setting Options** |
|---|---|
| 1001 | "Enable"=0x00000000<br>"Disable"=0x00000003<br>"Prompt"=0x00000001 |
| 1004 | "Enable"=0x00000000<br>"Disable"=0x00000003<br>"Prompt"=0x00000001 |
| 1200 | "Administrator approved"=0x00010000<br>"Enable"=0x00000000<br>"Disable"=0x00000003<br>"Prompt"=0x00000001 |
| 1201 | "Enable"=0x00000000<br>"Disable"=0x00000003<br>"Prompt"=0x00000001 |

| 2102 | "Enable"=0x00000000<br>"Disable"=0x00000003 |
| 2200 | "Enable"=0x00000000<br>"Disable"=0x00000003 |
| 2201 | "Enable"=0x00000000<br>"Disable"=0x00000003 |
| 2300 | "Enable"=0x00000000<br>"Disable"=0x00000003<br>"Prompt"=0x00000001 |

**Key for numeric translation of URL policy settings**

| Value | DWORD | Setting |
|---|---|---|
| 0 | 0x00000000 | Enable |
| 1 | 0x00000001 | Prompt |
| 3 | 0x00000003 | Disable |
| 65536 | 0x00010000 | High Safety |
| 131072 | 0x00020000 | Medium Safety |
| 196608 | 0x00030000 | Low Safety |

For descriptions for each of the URL policy settings, see "URL Action Flags" on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=32777.

**Default settings for each URL action in zones and templates**

Each URL action has a default that is set in each zone and set when a specified template is applied. The default settings for each zone are described in the following table.

**URL action default settings**

| URL action numeric name | Locked-Down Restricted zone | Locked-Down Internet zone | Locked-Down Intranet zone | Locked-Down Trusted zone |
|---|---|---|---|---|
| 1001 | 3 | 1 | 1 | 0 |
| 1004 | 3 | 3 | 3 | 3 |
| 1200 | 3 | 3 | 3 | 3 |
| 1201 | 3 | 3 | 3 | 3 |
| 1400 | 3 | 3 | 3 | 3 |
| 1402 | 3 | 0 | 0 | 0 |
| 1405 | 3 | 0 | 0 | 0 |

| | | | | |
|---|---|---|---|---|
| 1406 | 3 | 3 | 1 | 0 |
| 1407 | 3 | 0 | 0 | 0 |
| 1601 | 1 | 1 | 0 | 0 |
| 1604 | 1 | 0 | 0 | 0 |
| 1606 | 3 | 0 | 0 | 0 |
| 1607 | 3 | 0 | 0 | 0 |
| 1608 | 3 | 0 | 0 | 0 |
| 1609 | 1 | 1 | 1 | 1 |
| 1800 | 3 | 1 | 1 | 0 |
| 1802 | 1 | 0 | 0 | 0 |
| 1803 | 3 | 0 | 0 | 0 |
| 1804 | 3 | 1 | 1 | 0 |
| 1809 | 0 | 0 | 3 | 3 |
| 1A00 | 65536 | 131072 | 131072 | 0 |
| 1A04 | 3 | 3 | 3 | 3 |
| 1C00 | 0 | 0 | 0 | 0 |
| 1E05 | 65536 | 131072 | 131072 | 196608 |
| 2000 | 3 | 65536 | 65536 | 65536 |
| 2001 | 3 | 3 | 3 | 3 |
| 2004 | 3 | 3 | 3 | 3 |
| 2100 | 3 | 3 | 3 | 3 |
| 2101 | 3 | 3 | 3 | 3 |
| 2102 | 3 | 3 | 3 | 3 |
| 2200 | 3 | 3 | 3 | 3 |
| 2201 | 3 | 3 | 3 | 3 |
| 2300 | 3 | 1 | 1 | 1 |

**Group Policy Settings Paths**

These paths locate the available Advanced settings in the Group Policy Management Console:

- HKEY_LOCAL_MACHINE policies for Advanced settings:

```
\Computer Configuration\Administrative Templates\Windows Components\Internet Explorer\Internet Control
Panel\Advanced Page
```

- HKEY_CURRENT_USER policies for Advanced settings:

```
\User Configuration\Administrative Templates\Windows Components\Internet Explorer\Internet Control
Panel\Advanced Page
```

These paths locate the security zone settings in the Group Policy Management Console:

- HKEY_LOCAL_MACHINE policies by security zone for URL actions:

```
\Computer Configuration\Administrative Templates\Windows Components\Internet Explorer\Internet Control
Panel\Security Page
```

- HKEY_CURRENT_USER policies by security zone for URL actions:

```
\User Configuration\Administrative Templates\Windows Components\Internet Explorer\Internet Control
Panel\Security Page
```

These paths locate the Advanced settings in policy and in preference in the Windows registry (in either HKEY_LOCAL_MACHINE or HKEY_CURRENT_USER):

| **Advanced setting UI** | **Preference key name** | **Policy key name** |
|---|---|---|
| Install on Demand (Internet Explorer) | HKCU \Software \Microsoft\Internet Explorer\Main \NoJITSetup | Software\Policies\Microsoft\Internet Explorer\Main\NoJITSetup |
| Install on Demand (Other) | HKCU\Software\Microsoft\Internet Explorer\Main \NoWebJITSetup | Software\Policies\Microsoft\Internet Explorer\Main\NoWebJITSetup |
| Third-party Browser Extensions | HKCU\Software \Microsoft\Internet Explorer\Main\Enable Browser Extensions | Software\Policies \Microsoft\Internet Explorer\Main\Enable Browser Extensions |
| Automatically check for IE Updates | HKCU\Software \Microsoft\Internet Explorer\Main \NoUpdateCheck | Software\Policies \Microsoft\Internet Explorer\Main \NoUpdateCheck |
| Play Animations in Web Pages | HKCU\Software \Microsoft\Internet Explorer\Main \Play_Animations | Software\Policies \Microsoft\Internet Explorer\Main \Play_Animations |
| Play Sounds in Web Pages | HKCU\Software \Microsoft\Internet Explorer\Main \Play_Background_Sounds | Software\Policies \Microsoft\Internet Explorer\Main \Play_Background_Sounds |
| Play Videos in Web Pages | HKCU\Software \Microsoft\Internet Explorer\Main\Display Inline Videos | Software\Policies \Microsoft\Internet Explorer\Main\Display Inline Videos |
| Allow software to run or install even if the signature is invalid | HKCU\Software \Microsoft\Internet Explorer\Download \RunInvalidSignatures | Software\Policies \Microsoft\Internet Explorer\Download \RunInvalidSignatures |
| Allow active content from CDs to run on user machines | HKCU\Software \Microsoft\Internet Explorer\Main \FeatureControl \FEATURE_LOCALMACHINE_LOCKDOWN \Settings \LocalMachine_CD_Unlock | \Software\Policies \Microsoft\Internet Explorer\Main \FeatureControl \FEATURE_LOCALMACHINE_LOCKDOWN \Settings \LocalMachine_CD_Unlock |
| Check for Server Certificate Revocation | HKCU\Software \Microsoft\Internet Explorer\Download \CertificateRevocation | Software\Policies \Microsoft\Windows \CurrentVersion \InternetSettings \CertificateRevocation |
| Check for Signatures on Downloaded Programs | HKCU\Software \Microsoft\Internet Explorer\Main\ CheckExeSignatures | Software\Policies \Microsoft\Internet Explorer\Main\ CheckExeSignatures |
| Do Not Save Encrypted Pages to Disk | HKCU\Software \Microsoft\Windows \CurrentVersion \InternetSettings \DisableCachingOfSSLPages | Software\Policies \Microsoft\Windows \CurrentVersion \InternetSettings \DisableCachingOfSSLPages |
| Empty Temporary Internet Files Folder When Browser is Closed | HKCU\Software \Microsoft\Internet Explorer\Cache \Persistent | Software\Policies \Microsoft\Windows \CurrentVersion \InternetSettings\Cache \Persistent |

These paths locate the security zone settings in policy and in preference in the Windows registry (in either

HKEY_LOCAL_MACHINE or HKEY_CURRENT_USER):

- Location of Locked-Down Intranet zone policy values:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings\Lockdown_Zones\1
```

- Location of Locked-Down Trusted Sites policy:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings\Lockdown_Zones\2
```

- Location of Locked-Down Internet zone policy values:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings\Lockdown_Zones\3
```

- Location of Locked-Down Restricted Sites policy values:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings\Lockdown_Zones\4
```

- Location of Locked-Down Intranet zone template:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Intranet Lockdown Settings
```

- Location of Locked-Down Trusted Sites template:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Trusted Sites Lockdown Settings
```

- Location of Locked-Down Internet zone template:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Internet Lockdown Settings
```

- Location of Locked-Down Restricted Sites template:

```
Software\Policies\Microsoft\Windows\CurrentVersion\Restricted Sites Lockdown Settings
```

**Configuring policies and preferences**
Group Policy is the recommended tool for managing Internet Explorer for client computers on a corporate network. Internet Explorer supports Group Policy management for all new Internet Explorer Feature Controls in Windows Server 2003 Service Pack 1, and for Security page settings or URL actions. Administrators of Group Policy can manage these new policy settings in the Administrative Templates extension of the Group Policy Management Console.

When implementing policy settings, it is recommended that you configure template policy settings in one Group Policy object (GPO) and configure any related individual policy settings in a separate GPO. You can then use Group Policy management features (for example, precedence, inheritance, or enforce) to apply individual settings to specific client computers.

Policies can be read by users but can only be changed by via Group Policy management or by an administrator. Preference settings can be changed programmatically, by editing the registry, or in the case of URL actions, by using Internet Explorer. Settings specified by Group Policy take precedence over settings specified using preferences.

**Why is this change important?**
By adding the new Advanced setting policies and Locked-Down security policies to Group Policy, administrators can manage these true policies to establish standard settings for all the computers that they configure. The administrator can control these settings in such a way that they cannot be changed except through Group Policy or by a user with administrator privileges, thus ensuring that security and certain Advanced settings are not set by end users.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Windows Server 2003 Service Pack 1 adds new policies to Group Policy but does not change how policies are managed. Developers need to be aware of how each Feature Control and URL action setting or setting combination affects security-related behavior for their applications in each security zone.

For greater security, the administrator should enable policies for all zones, so that there is a known configuration set by policy rather than an unknown setting read from HKEY_LOCAL_MACHINE or HKEY_CURRENT_USER preference settings not set by

policy. If the administrator sets policies for all zones, we recommend that the policy to disable the **Security** page be enabled, which will make the user interface in Internet Explorer unavailable.

**Feature Control Policies**
The administrator should also understand the Feature Control policy settings. Some of the URL action settings will not be valid unless the corresponding Feature Control policy is enabled. Internet Explorer checks to see whether the feature is enabled, and if it is, then looks for the setting for the action based on the security zone of the URL.

**Zone Map Policies**
The method for adding Zone Map keys to policy is as follows:

1. To set computer policy, go to \Computer Configuration\Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel\Security Page within Group Policy. To set user policy, go to \User Configuration\Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel\Security Page within Group Policy.

2. Select the **Site to Zone Assignment List** policy.

3. Select **Enabled** and click **Show...**

4. For each site you would like to map:

   a. Click **Add...**

   b. Enter the name, IP address, or IP range of the site you want to map (for example, http://www.contoso.com, www.contoso.com, 127.0.0.1, 127.0.0.1-10)

   c. Enter the value identifying the zone to which this site should be mapped. The choices are (1) Intranet zone, (2) Trusted Sites zone, (3) Internet zone, (4) Restricted Sites zone.

   d. Click **OK.**

   e. The site name and value should appear in the list.

5. Click **OK** in the **Show Contents** window.

6. Click **OK** again to close the **Site to Zone Assignment List Properties** window.

| **Note** |
| --- |
| Policies created by following these instructions are ignored by computers with the Windows Server 2003 Internet Explorer Enhanced Security Configuration component installed. To set zone map policy on a computer with Windows Server 2003 Internet Explorer Enhanced Security Configuration component installed, use the Internet Explorer Maintenance (IEM) snap-in to Group Policy. When using the IEM to create a Group Policy object to apply to a computer with the Windows Server 2003 Internet Explorer Enhanced Security Configuration component installed, you must be using a computer with the Windows Server 2003 Internet Explorer Enhanced Security Configuration component installed. |

| **Note** |
| --- |
| For more information about using Group Policy, see "Implementing Registry-based Group Policy" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=28188. For more information about using Internet Explorer security zone and privacy settings, see "Description of Internet Explorer Security Zones Registry Entries" on the Microsoft Knowledge Base Web site at http://go.microsoft.com/fwlink/?LinkId=28195. |

# Internet Explorer Add-on Management and Crash Detection

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Information Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Internet Explorer Add-on Management and Crash Detection do?**
These are two new, closely-related features that are included in Internet Explorer.

Internet Explorer Add-on Management allows users to view and control the list of add-ons that can be loaded by Internet Explorer with more detailed control than before. It also shows the presence of some add-ons that were previously not shown and could be very difficult to detect.

Internet Explorer Add-on Crash Detection attempts to detect crashes in Internet Explorer that are related to an add-on. When the add-on is successfully identified, this information is presented to the user. The user has the option of disabling add-ons to diagnose crashes and improve the overall stability of Internet Explorer.

**Who does this feature apply to?**
Users will be able to view, enable, and disable the add-ons used by Internet Explorer, and identify add-ons that might be related to Internet Explorer crashes. Administrators can enforce a list of add-ons that are allowed or disallowed and restrict the ability of users to manage add-ons.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Internet Explorer Add-on Management**
**Detailed description**
Internet Explorer Add-on Management allows users to view and control the list of add-ons that can be loaded by Internet Explorer with more detailed control than before. It also shows the presence of some add-ons that were previously not shown and could be very difficult to detect. These add-ons might provide undesired functionality or services and, in some cases, might present a security risk.

For example, a user might unintentionally install an add-on that secretly records all Web page activity and reports it to a central server. Previously, specialized software and deep technical knowledge might have been required to identify and remove that add-on. Internet Explorer Add-on Management provides an easier way to detect and disable that add-on.

Add-ons include:

- Browser help objects
- ActiveX controls
- Toolbar extensions
- Browser extensions

Add-ons can be installed from a variety of locations and in several ways, including:

- Download and installation while viewing Web pages.
- Installation by the user by way of an executable program.
- As pre-installed components of the operating system.

- As pre-installed add-ons that come with the operating system.

#### Manage Add-ons

Users can enable and disable each add-on individually and view information about how often the add-ons have been used by Internet Explorer. To do this, use one of the following procedures to open Manage Add-ons.

**Open Manage Add-ons Using Internet Explorer**

1. Click **Start**, and then click **Internet Explorer**.
2. On the **Tools** menu, click **Manage Add-ons**.

**Open Manage Add-ons using the Control Panel**

1. Click **Start**, and then click **Control Panel**.
2. Double-click **Internet Options**.
3. Click the **Programs** tab, and then click **Manage Add-ons**.

**Manage Add-ons** has several options that allow you to change your add-on configuration.

You can use the **Show** drop-down list in **Manage Add-ons** to control the way in which the add-ons list is displayed. It has two options:

- **Add-ons currently loaded in Internet Explorer.** This option lists the add-ons that have been instantiated (or loaded into memory) within the current Internet Explorer process and those that have been blocked from instantiating. This includes ActiveX controls that were used by Web pages that were previously viewed within the current process.

- **Add-ons that have been used by Internet Explorer.** This option lists all add-ons that have been referenced by Internet Explorer and are still installed.

The list of add-ons shows all installed add-ons of the types listed previously in the detailed description section. To enable or disable an installed add-on, click the add-on in the list, then click **Enable** or **Disable**.

If you click an ActiveX control in the list, then click **Update ActiveX**, Windows searches for an update at the location where the original control was found. If a newer version is found at that location, Internet Explorer attempts to install the update.

The list of add-ons also contains signed add-ons that were blocked from installation because their publisher was untrusted. After selecting one of these controls, the user can unblock the control by clicking **Allow**. Caution should be exercised when doing this, because clicking **Allow** removes the publisher from the **Untrusted** list.

#### Blocked Add-on status bar icon

A **Blocked Add-on** icon appears in the status bar when a Web page attempts to instantiate an ActiveX control that is disabled or blocked because its publisher is untrusted. You can double click the icon to open **Manage Add-ons**. The status bar icon is accompanied by a balloon tip the first five times it appears.

#### Add-on notification balloon tip

When a Web page attempts to instantiate a disabled add-on and there is no current Blocked Add-on status bar icon, a message appears to tell the user that the current Web page is requesting an add-on that is disabled. The user can click the message for more details on blocking add-ons.

You can use the Internet Options Control Panel to suppress the message.

#### Why is this change important?

Windows Error Reporting data has shown that add-ons are a major cause of stability issues in Internet Explorer. These add-ons significantly affect the reliability of Internet Explorer. These add-ons can also pose a security risk, because they might contain malicious and unknown code.

Many users are unaware of the add-ons they have installed on their computer. Some add-ons are loaded whenever Internet Explorer is started, but cannot be detected unless the user searches the registry. When users experienced crashes, there was no easy way to diagnose whether the issue was related to an add-on. Even if they suspected that the problem stemmed from recently-installed software, it was difficult to isolate the cause and often impossible to resolve if the software did not provide an uninstall option.

Internet Explorer Add-on Management, together with Add-on Crash Detection, gives users the ability to improve the security and stability of their systems by identifying and disabling problematic add-ons. Administrators are also provided with a powerful administrative tool to control add-on use in their organization.

**What works differently?**
**Behavior when add-ons are disabled**
Disabling an add-on does not remove it from the computer. It only prevents Internet Explorer from instantiating the object and executing its code. There is no guarantee that the disabled add-on will never be loaded, since an add-on that is considered by Internet Explorer to be disabled can still be used by another component in the system. The behavior that is displayed by disabling different object types varies.

- If an ActiveX control is disabled, Web pages that rely on the control might not work as expected. They behave as if the user has uninstalled the control from the computer and declined to install it. Users are not prompted to upgrade controls that have been disabled.

- If a browser helper object is disabled, functionality that depends on the object is not available, and there is no visual indication that a component is disabled.

- If a browser extension is disabled, toolbar buttons and menu entry points are not shown for that extension. Internet Explorer behaves as if the extension was not installed.

- If a toolbar extension is disabled, the toolbar does not appear in Internet Explorer and, on the View menu, the Toolbars item is disabled. Internet Explorer behaves as if the toolbar was not installed.

The concept of a disabled add-on only applies to instances of Internet Explorer (Iexplore.exe) and Windows Explorer (Explorer.exe) by default. Currently, other programs based on Internet Explorer components, such as the `WebBrowser` control, do not respect the disabled state. However, you can use the `featurecontrol` key to extend this functionality to other applications.

Some software programs depend on a combination of multiple add-ons to work correctly, and disabling any one of them might cause problems. Caution should be exercised when deciding to disable one or more add-ons.

**Uninstallation**
If the user disables a non-ActiveX add-on and subsequently uninstalls and then re-installs it, the add-on might remain in a disabled state. This is because Internet Explorer is not notified of application installations and does not detect any application state changes. However, if Internet Explorer is started while the add-on is not installed, it detects a change and automatically clears the disabled state.

If the user disables an ActiveX control and then uninstalls it, the next time a Web page attempts to use the control, Internet Explorer detects that the control is no longer present and clears the disabled state. However, if the ActiveX control is reinstalled using an executable file (as opposed to a Web page download) before there are any attempts to instantiate the control, then it remains disabled. This is because Internet Explorer does not detect a state change.

**How do I resolve these issues?**
In the event that disabling an add-on causes a lack of functionality, it can be restored by enabling the add-on in **Manage Add-ons**. Internet Explorer must be restarted for new settings to take effect, with the exception of ActiveX controls, where reloading the affected page might be sufficient.

**Internet Explorer Add-on Management for Administrators**
**Detailed description**
**Disabling the Crash Detection feature**
To disable the Crash Detection feature of Add-on Management, see "What settings are added or changed in Windows Server 2003 Service Pack 1?" below. When Crash Detection is disabled, a crash in Internet Explorer exhibits previous behavior, which is usually to invoke Windows Error Reporting. All policies for Windows Error Reporting continue to apply.

**Disabling Add-on Management user interface**
To disable the Add-on Management user interface, see "What settings are added or changed in Windows Server 2003 Service Pack 1?" below. When the Add-on Management user interface is disabled, the **Enable** and **Disable** options are unavailable in **Manage Add-ons**.

**Deny all add-ons unless specifically allowed in the Add-on list**
This policy setting allows administrators to ensure that any Internet Explorer add-ons not listed in the Add-on List policy setting will be denied.

To set this policy, an administrator can modify the `RestrictToList` registry key in either of the following locations:

- `HKCU\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\Ext\`
- `HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\Ext\`

**Key reference**
Name: `RestrictToList`

Type: **DWORD**

Value:

- 1 (Anything not on the Add-on list is considered disabled.)
- 0 (Anything not on the Add-on list works as it would without policy.)

**Add-on List**
Administrators can control the use of specific add-ons through the add-on list policy. Administrators can choose to enable or disable an add-on as well as allow a specific add-on to be managed by the user.

To set this policy, an administrator can create a registry value based on the GUID of the add-on in either of the following keys and then set the desired value:

- `HKCU\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\Ext\CLSID`
- `HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\Ext\CLSID`

Each add-on is a value in this registry key with the following properties.

**Key reference**
Name: *GUID* of add on

Type: **REG_SZ**

Value:

- 0 - Add-on is disabled and cannot be managed by the end user.
- 1 - Add-on is allowed and cannot be managed by the end user.
- 2 - Add-on is allowed and can be managed by the end user.

The Add-on (CLSID) lists are empty by default.

**Behavior of Management user interface when policies are applied**
When an Add-on Management policy is in effect, and the user selects an add-on from the management list that is disabled by policy, **Enable** and **Disable** are unavailable.

**Why is this change important?**
This feature allows administrators to control the usage of the new features.

**What works differently?**
The new features for allowing and disallowing add-ons work in conjunction with existing policies for managing ActiveX controls. Add-on disabling is applied on top of existing checks and does not replace other security restrictions that might be in place. For example, if an ActiveX control is blocked by its ActiveX compatibility flags, it will always be blocked, regardless of the add-on management settings.

Using the "Deny all add-ons unless specifically allowed in the Add-on List" policy will disable script and other controls necessary for some Web pages to function properly. For a list of CLSIDs that might need to be enabled for certain Web sites to function correctly, see the article on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=45658

**How do I resolve these issues?**
If you are using the "Deny all add-ons unless specifically allowed in the Add-on list" policy some Web applications might break

due to disabled scripting and other disabled controls. For information about enabling scripting and other commonly used Web controls, see the article on the Microsoft Web site at http://go.microsoft.com/fwlink/?linkid=45658

In the event that these controls do not address the issue and adding these policies continues to remove functionality that is required for a Web application that you want to use, remove the policies that were applied and restart Internet Explorer.

**Internet Explorer Add-on Crash Detection**
**Detailed description**
Whenever Internet Explorer stops unexpectedly, Windows starts the Add-on Crash Detection program. Add-on Crash Detection is an error analysis program that examines the state of the Iexplore.exe (Internet Explorer) process. It collects the list of dynamic link libraries (DLLs) that are loaded, and the value of the instruction pointer register (EIP) at the time of the crash. Add-on Crash Detection then attempts to find the DLL whose memory range the EIP lies within. This DLL is often the cause of the crash. If a DLL is found, it is not a system DLL, and the DLL is the COM server for an Internet Explorer add-on, the Internet Explorer Add-on Crash Detection dialog box appears. This dialog box contains information that indicates which add-on caused the crash, the name of the company associated with the add-on, and the description of the DLL file that contains the add-on code. To display Manage Add-ons, which you can then use to disable the identified add-on, click **Advanced**. After you review the information and click **Continue**, the standard Windows Error Reporting window opens.

**Why is this change important? What threats does it help mitigate?**
For this information, see "Internet Explorer Add-on Management for Users," earlier in this subject.

**What works differently?**
Since this feature only runs when Internet Explorer stops operating, there should be no changes to normal operation.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**Internet Explorer Add-on Management and Crash Detection Settings**

| Setting name | Location | Default value | Possible values |
|---|---|---|---|
| Disable Crash Detection | HKCU {or HKLM} \Software\Policies \Microsoft\Internet Explorer \Restrictions<br><br>Name: NoCrashDetection<br><br>Type: DWORD | 0 | 0 — Off,<br><br>1 — On |
| Deny all add-ons unless specifically allowed in the Add-on List | HKCU {or HKLM} \Microsoft\Windows\CurrentVersion \Policies\Ext\<br><br>Name: RestrictToList<br><br>Type: DWORD | 0 | 0 — Off,<br><br>1 — On |
| Add-on List | HKCU {or HKLM} \SOFTWARE\Microsoft\Windows \CurrentVersion\Policies\Ext\CLSID<br><br>Name: GUID of the control<br><br>Type: REG_SZ | Not available | 0 – Add-on is disabled and cannot be managed by the end user.<br><br>1 – Add-on is allowed and cannot be managed by the end user.<br><br>2 – Add-on is allowed and CAN be managed by the end user. |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Your code does not need to change to work with Internet Explorer Add-on Crash Detection or Add-on Management.

# Internet Explorer Binary Behaviors Security Setting

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does binary behaviors security setting do?**
Internet Explorer contains dynamic binary behaviors: components that encapsulate specific functionality for HTML elements to which they were attached. These binary behaviors are not controlled by any Internet Explorer security setting, allowing them to work on Web pages in the Restricted Sites zone. In Windows Server 2003 Service Pack 1, there is a new Internet Explorer security setting for binary behaviors. This new setting disables binary behaviors in the Restricted Sites zone by default. In combination with the Local Machine Lockdown security feature, it also requires administrative approval for binary behaviors to run in the Local Machine zone by default. This new binary behaviors security setting provides a general mitigation to vulnerabilities in Internet Explorer binary behaviors.

For more information about binary behaviors, such as how they work and how to implement them, see "Cutting Edge: Binary Behaviors in Internet Explorer 5.5" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=21862. Note that binary behaviors, which are defined in C++ and compiled, are different from attached behaviors and element behaviors, which are defined in script.

**Who does this feature apply to?**
Application developers whose applications use Internet Explorer functionality in the restricted sites or local machine zones should review this feature to plan to adopt changes in their applications. For example, e-mail applications that render HTML e-mail in the Restricted Sites zone might need to be modified.

Users can only be affected by applications that do not completely render HTML content with this new setting. These applications will typically alert the user that some active behavior has been blocked from display. For example, when Outlook Express encounters this situation, it informs the user that it has restricted active content in the e-mail.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**New Internet Explorer security setting**
**Detailed description**
A new URL action setting, Binary and Script Behaviors, is in each Internet Explorer security zone. The default value for this setting is **Enable** for all zones except the Restricted Sites zone and the Locked-Down Local Machine zone. In the Restricted Sites zone, the default value is **Disable**. In the Locked-Down Local Machine zone, the default value is **Administrator approved**.

**Why is this change important? What threats does it help mitigate?**
This new setting helps mitigate attacks in which binary behaviors were being used maliciously and allows the user to control the use of binary behaviors on a per-zone basis.

**What works differently?**
Any use of any binary behaviors for HTML rendering from the Restricted Sites zone is blocked.

**How do I resolve these issues?**
To use binary behaviors from the Restricted Sites zone, an application will have to implement a custom security manager. (For more information, see "Creating a Customized URL Security Manager" in "Introduction to URL Security Zones" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=21863.)

When the binary behaviors URL action is exercised from a custom security manager, the URL action will pass in a string representation of the particular binary behaviors that can be enabled by that custom security manager as needed for application compatibility. The following process takes place when this URL action is exercised:

- Internet Explorer calls into a custom security manager (if available), using the `ProcessUrlAction` method with a `dwAction`

of `URLACTION_BEHAVIOR_RUN`.

- The *pContext* parameter points to a `LPCWSTR` that contains the behavior that a policy is being queried for. For example, `#default#time`.

- You set `*pPolicy =URLPOLICY_ALLOW` for your **SmartTag** behavior, from within your custom security manager, as appropriate.

In the absence of the custom security manager, the default action is to disallow running behaviors in the Restricted Sites zone, and to disallow running most behaviors in the Local Machine zone.

If you are a desktop administrator you can decide which binary behaviors to allow in the Locked-down Local Machine zone. To enable a behavior in the Locked-down Local Machine zone, you can add it to the list of administrator-approved behaviors as follows, replacing the namespace and behavior variables as appropriate to your environment:

`HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Internet Settings\AllowedBehaviors`

`#%` *Namespace* `%#%` *Behavior* `%=dword:00000001`

Behaviors that are defined in this list will also be used for any other zone where the binary behavior restriction setting is configured to "Admin-Allowed" (65536).

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
None. This is only a setting to turn on or off the existing binary behaviors functionality.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**Internet Explorer Binary Behaviors Settings**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| * | HKEY LOCAL MACHINE [or Current User] \Software\Microsoft \Internet Explorer\Main \Feature Control \FEATURE_BEHAVIORS | None | 1 | 0 - Off<br>1 - On |
| 2000 | HKEY_CURRENT_USER \Software \Microsoft \Windows \CurrentVersion \Internet Settings\Zones [or Lockdown_Zones] *\ | None | 3 - Disabled (for Restricted Sites zone)<br>65536 - Admin-approved (for the Locked-down Local Machine zone)<br>0 - Enabled (for all other zones) | 3 - Disabled<br>65536 - Admin-approved<br>0 - Enabled |

**Note**

* is used in the preceding table to represent that all processes are opted-in for this feature control setting by default.

The binary behaviors setting can also be modified through Group Policy as part of the Internet Explorer Security Zones and Content Ratings setting.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
If your code uses binary behaviors in the Restricted Sites zone, then you will need to change your code by implementing a custom security manager for your application. If your code uses binary behaviors in the Local Machine zone, then you will need to either implement a custom security manager, add your behaviors to the list of approved behaviors, or use Mark of the Web to load your pages in less restrictive zones. For more information, see the "Creating a Customized URL Security Manager" section in "Introduction to URL Security Zones" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=21863.

# Internet Explorer BindToObject Mitigation

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does BindToObject Mitigation do?**
In Windows Server 2003 with Service Pack 1, the ActiveX security model is applied in all cases where URL binding is used to instantiate and initialize an object. The ActiveX security model allows controls to be marked as "safe for scripting" and "safe for initialization" and provides users with the ability to block or allow ActiveX controls by security zone, based on those settings. This allows greater flexibility and control of active content in Internet Explorer.

**Who does this feature apply to?**

- Web developers and network administrators need to be aware of these new restrictions to plan changes or workarounds for any possible impact to their Web site.
- Application developers should review this feature to plan to adopt changes in their applications.
- Users could be affected by sites that are not compatible with these stricter rules.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
None. Existing security functionality is being extended.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**ActiveX security model applied to URL object initializations**
**Detailed description**
The most effective way to remove ActiveX safety vulnerabilities is to apply security policies consistently at the source of the URL binding: URLMON. Declaring an ActiveX control in an HTML page using the `<object>` tag and `CODEBASE` attribute is one commonly known example of using `BindToObject`. The same functionality is used by any component that wants to resolve a URL and get back a stream or object. The ActiveX security model is now applied to all object initializations with a URL as a source.

**Why is this change important?**
In the case of ActiveX controls, the ActiveX security model allows controls to be marked as "safe for scripting" or "safe for initialization" and provides users with the ability to block or allow ActiveX controls by zone, based on those settings. In earlier versions of Windows, this security framework was not applied in all cases where URL binding took place. Instead, the calling code was responsible for assuring the integrity and security of the control, which could often result in security vulnerabilities. There are now a number of public exploit variations that expose this exact issue by going through Internet Explorer to compromise vulnerabilities in the calling code.

**What works differently?**
The ActiveX security model is applied to all object initializations with a URL as a source, and the "Safe for initialization" tag is applied to all objects. This mitigation only applies to cases where Internet Explorer resolves a URL, instantiates an object, and initializes the object with data retrieved from that URL.

**How do I resolve these issues?**
Application compatibility problems should be minimal. Applications can opt out if they have their own security manager. For more information about opting out of this security model, see "Security Considerations: URL Security Zones API," on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=21814.

Applications can also opt in or out of this mitigation using the feature control key FEATURE_SAFE_BINDTOOBJECT, as

described in the topic Internet Explorer Using Feature Control Registry Settings with Security Zone Settings.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**Internet Explorer Object Caching**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| IExplore.exe<br><br>Explorer.exe<br><br>WMPlayer.exe | HKEY_LOCAL_MACHINE (or Current User)\Software \Microsoft \Internet Explorer\Main \FeatureControl \FEATURE_SAFE_BINDTOOBJECT | None | 1 | 0 - Off<br><br>1 - On |

# Internet Explorer Information Bar

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Information Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does the Internet Explorer Information Bar do?**
The Internet Explorer Information Bar in Windows Server 2003 Service Pack 1 replaces many of the common dialog boxes that prompted users for information in previous versions and provides a prominent area for displaying information that users may want to view or act upon. Examples of dialog boxes that have been replaced by Information Bar notifications include blocked ActiveX installs, downloads, and active content. The Information Bar will provide information similar to the notification area in Microsoft Outlook 2003, which informs users of blocked content.

**Who does this feature apply to?**
This feature applies to the following audiences:

- Users who need to understand how the new behavior will affect their Web browsing experience.
- System administrators, who need to know how to turn this functionality on or off for the client computers in their organization.
- Designers of Web sites that rely on add-ons, which will provide a different user experience.
- Developers of Web-based applications who need to understand how their experience changes. For example, this affects the development of ActiveX controls. ActiveX controls that are updates to controls that are currently installed on other computers will only be treated as updates if the GUID of the new control matches the current GUID.
- Developers of applications hosting the Web browser control will need to know how to use the new application programming interface (API) to take advantage of this new functionality.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Information Bar user interface**
**Detailed description**
The Information Bar looks and acts in a similar way to the Outlook 2003 blocked content notification area. It appears below Internet Explorer toolbars and above the Web page in view when a notification is present and disappears on the next navigation. The text in the Information Bar varies, depending on the notification that is provided, and wraps to two lines if the text exceeds the bounds of the notification area. If a user controls the focus (that is, which object in the browser can receive input) by pressing the TAB key, the Information Bar gets focus after the toolbar and before the Web page.

Either clicking or right-clicking the Information Bar brings up a menu that relates to the notification that is presented. This menu always contains a link to Information Bar Help, which provides more detailed information about the notification. Additional menu items related to the notification appear above the **Help** menu item.

Users can configure the Information Bar to play a sound when it appears; the default setting for the sound is **On**. When the Information Bar appears, the Windows trust icon appears in place of the **Error on page** notification on the status bar.

In certain cases, more than one action can be blocked. For example, a pop-up window may be blocked at the same time that an add-on install is blocked. In those cases, the text becomes more generic and the menus merge to show each action blocked at the top level, with each action's menus in a submenu.

There is a custom security zone setting for the Information Bar that enables users to change the settings of the Information Bar

by security zone. Users can choose to be notified with the Information Bar or to go back to the previous behavior and get a less prominent notification for file and code downloads.

**Why is this change important?**
In Windows Server 2003 Service Pack 1, Internet Explorer may block content that is necessary to complete certain online tasks. The Information Bar provides a prominent notification that informs users how to get Web pages they trust working again without the more intrusive prompt that was provided in Windows Server 2003.

**What works differently?**
For this information, see the next section, "What existing functionality is changing in Windows Server 2003 Service Pack 1?"

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Add-on install prompts**
**Detailed description**
In previous versions of Internet Explorer included with Windows Server 2003, when a Web page refers to an ActiveX control that is not currently on the computer, users are asked whether they want ActiveX controls to be downloaded. In the current version of Internet Explorer, this prompt is displayed in the Information Bar. The following table describes the elements in the Information Bar. Text in italics will be replaced by the specific items appropriate to the situation.

**Information Bar details for Add-on Install Prompts**

| Information Bar element | Message text |
|---|---|
| Information Bar text | This site might require the following ActiveX control: *Control_Name* from *Publisher_Name*. Click here to install... |
| Short text | Installation Blocked |
| Menu options | Install ActiveX Control...<br><br>What's the risk? |

Trusted publishers will work as they did in previous versions. The controls that are provided by these publishers install without requiring additional configuration.

Blocked publishers display the status bar icon. The control provided by these publishers will not install on the computer and does not go into the Information Bar.

Add-on upgrades work as they did in Windows XP SP1. Internet Explorer uses the following criteria when determining whether the control is an upgrade:

- The file that is registered as the ActiveX control must be signed with Authenticode technology. (This file is referenced from `HKEY_CLASSES_ROOT\CLSID\`*Control_clsid*`\InProcServer32`, where *Control_clsid* is the *CLSID* specified by the `OBJECT` tag.)

- The publisher name in the digital signature of the new control matches the publisher name in the digital signature of the existing control.

- If the ActiveX control is packaged in a CAB file, the CAB file must be signed. The DLL or OCX to be installed should also be signed in order for subsequent upgrades to bypass the Information Bar.

**Why is this change important?**
Providing add-on install prompts in the Information Bar rather than a dialog box reduces the occurrences of users inadvertently installing code on their computer.

**What works differently?**
Certain Web pages currently rely on users installing code to function correctly. Some sites redirect the user to a separate page that explains how to install the ActiveX control. If a site automatically redirects the page without providing the control on the new page, the Information Bar will appear on the redirect page to offer the opportunity to install the control. If, however, the site closes the window that attempted to install the ActiveX control, the customer might not get a chance to install the control.

**How do I resolve these issues?**
Web authors should ensure that the ActiveX control is also available on the page to which the user is redirected. This will ensure that users have ample opportunity to install the control.

Web page authors should not suggest that users lower their security settings, because it will not help in this situation. For additional guidance for Web authors on the changes introduced with Windows XP SP2 and subsequently included in Windows Server 2003 Service Pack 1, see "Fine-Tune Your Web Site for Windows XP Service Pack 2" on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=32775.

**Pop-up blocked notification**
**Detailed description**
Internet Explorer displays a notification in the Information Bar when a pop-up is blocked. This becomes a more obvious entry point to the Pop-up Blocker functionality, such as replaying the pop-up, adding the site to an "allow" list for pop-ups, or navigating to Pop-up Blocker settings. The Information Bar also provides a top level entry point to turn off the Information Bar for pop-ups if the user decides the notification is too big for this event.

**Information Bar details for pop-up blocked notification**

| Information Bar element | Message text |
|---|---|
| Information Bar text | Pop-up blocked. To see this pop-up or additional options, click here... |
| Short text | Pop-up Blocked |
| Menu options | Temporarily Allow Pop-ups<br><br>Allow Pop-ups for this Site<br><br>Settings |

**Why is this change important?**
Showing the pop-up blocked notification in the Information Bar gives higher priority to that notification. Users have a better understanding of where to go to see a blocked pop-up window or to see their Pop-up Blocker settings.

**What works differently?**
Turning off the Information Bar for the Pop-up Blocker causes the Pop-up Blocker to return to notifying users with the status bar icon. All the same menu items are accessible from this status bar icon if the bar is disabled for pop-ups. For more information, see "Internet Explorer Pop-up Blocker," later in this document.

**Automatic download prompts**
**Detailed description**
File download prompts that are launched automatically now appear in the Information Bar.

The Information Bar includes descriptive text that explains why the action was taken and provides a context sensitive menu that you can use to respond to the notification. The following table identifies the text that will appear in the Information Bar and the actions that you can select from the menu.

**Information Bar details for automatic download prompts**

| Information Bar element | Message text |
|---|---|
| Information Bar text | To help protect your security, Internet Explorer blocked this site from downloading files to your computer. Click here for more options... |
| Short text | File Download Blocked |
| Menu options | Download Software...<br><br>What's the Risk? |

**Why is this change important?**
By moving download prompts to the Information Bar, users can be prevented from installing unwanted code on their computers. Previously, sites could overwhelm users with file download prompts and, as a result, users could accidentally run unwanted software on their computer. With this change, file download prompts that are launched automatically are more likely the result of a user's deliberate click and not an accidental action.

**What works differently?**
Any time a site refers to a file download prompt without a user action, such as clicking on an element of the page, the prompt appears in the Information Bar.

**How do I resolve these issues?**
Web authors should ensure there is a link on the Web page that a user can click to get to the file download. If you use a script to navigate to the resource, the script should run synchronously within the context of the `OnClick` event handler for the link.

For additional guidance for Web authors on the changes introduced with Windows XP SP2 and subsequently included in Windows Server 2003 Service Pack 1, see "Fine-Tune Your Web Site for Windows XP Service Pack 2" on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=32775.

# Internet Explorer Local Machine Zone Lockdown

Updated: January 5, 2009

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What Does Local Machine Zone Lockdown do?**

When Internet Explorer opens a Web page, it places restrictions on what the page can do, based on the page's Internet Explorer security zone. There are several possible security zones, each with different sets of restrictions. The security zone for a page is determined by its location. For example, pages that are located on the Internet will normally be in the more restrictive Internet security zone. They might not be allowed to perform some operations, such as accessing the local hard drive. Pages that are located on your corporate network would normally be in the Intranet security zone, and have fewer restrictions. The precise restrictions that are associated with most of these zones can be configured by the user through **Internet Options** on the **Tools** menu.

Prior to Windows XP Service Pack 2, the content on the local file system, aside from that cached by Internet Explorer, was considered to be secure and was assigned to the Local Machine security zone. This security zone normally allows content to run in Internet Explorer with relatively few restrictions. However, attackers often try to take advantage of the Local Machine zone to elevate privilege and compromise a computer.

Many of the exploits that involve the Local Machine zone were mitigated by other changes to Internet Explorer in Windows XP SP2. These changes were incorporated into Internet Explorer in Windows Server 2003 Service Pack 1. However, attackers may still be able to figure out ways to exploit the Local Machine zone. Currently, Internet Explorer further protects the user by locking down the Local Machine zone by default. Local HTML hosted in other applications will run under the less restrictive settings of the Local Machine zone used in previous version of Internet Explorer unless that application makes use of Local Machine Zone Lockdown.

Administrators will be able to use Group Policy to manage Local Machine Zone Lockdown and more easily apply it to groups of computers.

**Who does this feature apply to?**

All application developers should review this feature. Applications that host local HTML files in Internet Explorer are likely to be affected. Developers of standalone applications that host Internet Explorer will want to modify their applications to make use of Local Machine Zone Lockdown.

By default, Local Machine Zone Lockdown is only enabled for Internet Explorer. Developers will need to register their applications to take advantage of the changes. Applications that do not use this mitigation should independently review their applications for Local Machine zone attack vectors.

Software developers with applications that host Internet Explorer should use this feature by adding their process name to the registry as described later in this document. In the future, Microsoft might implement this feature using an "opt out" policy rather than an "opt in" policy. Applications that host Internet Explorer should be tested to ensure that they function properly with Local Machine Zone Lockdown enabled for their process.

Network Administrators might have local scripts that will be affected by these restrictions. Administrators should review the available solutions to enable their local scripts without compromising the security of their users' client computers.

Developers of Web sites that are hosted on the Internet or Local Intranet zones should not be affected by changes to the Local Machine zone, except when loading those files from the local machine during development.

Users could be affected by applications that are not compatible with these more stringent restrictions.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**

**Changes to Local Machine zone security settings**

**Detailed description**
The Local Machine zone is now more restrictive than the Internet zone. Any time that content attempts one of the following actions in this zone, the Information Bar will appear in Internet Explorer with the following text:

**To help protect your security, Internet Explorer has restricted this file from showing active content that could access your computer. Click here for options...**

The user can click the Information Bar to remove the lockdown from the restricted content.

The security settings that control the privileges that are granted to content running in the Local Machine zone are known as URL actions. When Local Machine Zone Lockdown is applied to a given process, it changes the behavior of URL actions from the previous Local Machine zone setting of **Enabled** to **Disabled**. As a result, scripts and ActiveX controls will not run. The default URL actions changed are:

- URLACTION _SCRIPT_RUN
- URLACTION_DOWNLOAD_UNSIGNED_ACTIVEX
- URLACTION_ACTIVEX_RUN
- URLACTION_ACTIVEX_OVERRIDE_OBJECT_SAFETY (to **Prompt**, not **Disabled**)
- URLACTION_CLIENT_CERT_PROMPT
- URLACTION_BEHAVIOR_RUN
- URLACTION_JAVA_PERMISSIONS
- URLACTION_BEHAVIOR_RUN (to **Administrator approved**, not **Disabled**)
- URLACTION_FEATURE_MIME_SNIFFING
- URLACTION_FEATURE_WINDOWS_RESTRICTIONS
- URLACTION_AUTOMATIC_DOWNLOAD_UI
- URLACTION_AUTOMATIC_ACTIVEX_UI

| **Note** |
| --- |
| URLACTION_FEATURE_ZONE_ELEVATION is set to **Disabled** in the Local Machine zone with or without this feature. |

For Local Machine Zone Lockdown, these settings are stored under a separate registry key:

```
HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Internet
Settings\Lockdown_Zones\0
```

The default Local Machine zone URL action settings are found under:

```
HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Internet Settings\Zones\0
```

**Why is this change important?**
This change helps prevent content on a user's computer from elevating privilege. Code with such elevated privilege can then run any code through an ActiveX control or read information with a script.

**What works differently?**
If a Web page uses any of the restricted types of content that were previously listed, Internet Explorer displays the Information Bar, as previously described.

HTML files that are hosted on the res: protocol on the local computer will automatically run under the security settings for the Internet zone. For more information about what these templates allow, see "Introduction to URL Security Zones" on the MSDN

Web site at http://go.microsoft.com/fwlink/?LinkId=26003.

**How do I resolve these issues?**
You can allow ActiveX and scripts to always run in Web pages that are launched from a CD by clicking **Yes** when presented with the following message:

**Active content can harm your computer or disclose personal information. Are you sure that you want to allow CDs to run active content on your computer?**

If your Web page needs to run ActiveX or scripting, you can add a Mark of the Web comment in the HTML code. This Internet Explorer feature allows the HTML files to be forced into a zone other than the Local Machine zone so that they can then run the script or ActiveX code based on the security template that would be applied to the URL identified in the comment. For example, if the URL specified is www.contoso.com and that URL is present in your Local Intranet sites list, the page uses the security template for the Local Intranet Sites zone. However, if www.contoso.com is listed in the Trusted Sites zone, the page is treated as if it were part of the Internet zone. This is by design for security purposes in Windows XP Service Pack 2 and later. This setting works in Internet Explorer 4 and later. To insert a Mark of the Web comment into your HTML file, add one of the following comments:

`<!-- saved from url=` *(0022)http://www.example.com* `-->`

Use this comment when you are inserting a Mark of the Web into a page whose domain is identified, replacing *http://www.example.com* with the URL of the Internet or intranet domain that the page is hosted by. Include the length of the URL in parenthesis used for the Mark of the Web before the URL, for example *(0022)*.

If you want your Web page to always be treated as though it were part of the Internet zone, you can use the following Mark of the Web:

```
<!-- saved from url=(0014)about:internet -->
```

Use this comment when you need to generically insert a Mark of the Web. The `about:internet` portion will place the page in the Internet zone.

Beginning with Windows Server 2003 Service Pack 1 and Windows XP Service Pack 2, this HTML comment can also be used with .mht files, known as multipart HTML or .xml files. Mark of the Web will be ignored for .mht or .xml files in earlier versions of Internet Explorer.

As another option, you can create a separate application that hosts the HTML content in the Internet Explorer Web Object Control (WebOC). The HTML is then no longer bound by the same rules that apply to content run in Internet Explorer. When the HTML content runs in the other process, it can have full rights as defined by the developer or the zone policy for that process.

An easy way to do this is to save your content as an .hta (HTML application) file and try to run the file again in the Local Machine zone. An .hta file is hosted in a different process and therefore is not affected by the mitigation. However, .hta files run with full privileges, so you should not allow code that is not trusted to run in this manner.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Developers should test their applications and enable the lockdown in order to offer enhanced levels of security. Developers of standalone applications should plan to adopt these changes in their applications that host Internet Explorer.

Developers of ActiveX controls that previously allowed elevated privileges in the Local Machine zone should not change their controls to allow elevated privileges in another zone. Instead, these controls should be converted to run only from an HTML application (.hta file) or a standalone application that runs outside of Local Machine Zone Lockdown.

By default, Local Machine Zone Lockdown is not enabled for non-Internet Explorer processes. Developers must explicitly register their applications to take advantage of the changes. Application developers that do not use this mitigation should independently review their applications for Local Machine zone attack vectors. To enable Local Machine Zone Lockdown for your application, go to the following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Internet Explorer\Main\FeatureControl\FEATURE_LOCALMACHINE_LOCKDOWN
```

Add a `REG_DWORD` value to this key named for your application (for example, MyApplication.exe) and set it to 1. Any other setting for this value will disable Local Machine Zone Lockdown for the application.

To control whether Local Machine Zone Lockdown is applied to Web pages launched from a CD, go to the following registry key and value:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Internet
Explorer\Main\FeatureControl\FEATURE_LOCALMACHINE_LOCKDOWN\Settings\LOCALMACHINE_CD_UNLOCK
```

Setting this value to 1 disables this feature for Web pages launched from a CD on the user's computer.

# Internet Explorer MIME Handling Enforcement

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Information Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does MIME Handling Enforcement do?**
Internet Explorer uses Multipurpose Internet Mail Extensions (MIME) type information to decide how to handle files that have been sent by a Web server. For example, when there is a Hypertext Transfer Protocol (HTTP) request for .jpg files, when they are received, they will generally be displayed to the user in an Internet Explorer window. If Internet Explorer receives an executable file, Internet Explorer generally prompts the user for a decision on how to handle the file.

Internet Explorer in Windows Server 2003 with Service Pack 1 will follow stricter rules than Internet Explorer in Windows Server 2003. These rules are designed to protect users from accidentally downloading or executing a dangerous file due to misleading MIME or file name extension information.

**Who does this feature apply to?**
Web developers need to be aware of these new restrictions to plan changes or workarounds for any possible impact to their Web site.

Application developers should review this feature to plan to adopt changes in their applications. The feature is not enabled for non-Internet Explorer processes by default and developers will need to register their applications to take advantage of the changes.

End users will be affected by sites or applications that are not compatible with these stricter rules.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**MIME-handling file type agreement enforcement**
**Detailed description**
When files are served to the client, Internet Explorer uses the following pieces of information to decide how to handle the file:

- File name extension, the corresponding ProgID and CLSID for the registered handler of that file name extension.
- Content-Type from the HTTP header (MIME type), the corresponding ProgID, and CLSID for the registered handler of that Content or MIME type.
- Content-Disposition from the HTTP header.
- Results of the MIME sniff.

Internet Explorer is more restrictive about executing a downloaded file that could be dangerous than it was in Windows Server 2003.

Internet Explorer will enforce consistency between how a file is handled in the browser and how it is handled in the Windows shell. As the file is downloaded into the cache, Internet Explorer will compare the MIME-type of the cache file to the extension of the cache file. If there is a mismatch between the MIME-type and the file name extension, Internet Explorer will attempt to reconcile that mismatch by renaming the file in the cache.

Before a file is loaded in its MIME handler or executed by its extension handler, Internet Explorer will compare the CLSIDs of the MIME handler and the extension handler. If there is still a mismatch between the two handlers, Internet Explorer will impose a mandatory prompt for the user to confirm that the user wants to load the file in the MIME handler. If the MIME handler rejects the mismatched file, Internet Explorer will show a download error dialog and not automatically execute the file in the Windows

shell extension handler but the dialog will allow saving the file.

There is a related but separate change to prevent execution of potentially corrupt files in their shell extension handlers. Internet Explorer will show the download error dialog for any file that is rejected by its MIME handler with the error code `E_Cannot_Load_Data` and will not execute that file in its shell extension handler regardless of MIME-type or file name extension.

These changes do not affect cases where a `"Content-disposition=attachment"` HTTP header is used for the file. In those cases, the file name or extension suggested by the server is considered final and the file can be executed regardless of MIME/extension mismatch if the user chooses to accept the file download prompt.

**Why is this change important?**
If file type information is misreported by the server and that information is saved to the computer, a dangerous file could be incorrectly executed later. For example, Internet Explorer might download a file that appears to be a text file. If the file can't be loaded by its MIME handler and has a .doc file name extension, the .doc file might run in an application such as Microsoft Word without prompting the user. In Microsoft Word, the file may be able to use active content, such as a macro, to run a program (such as a virus) on the user's machine.

**What works differently?**
Internet Explorer will now attempt to rename downloaded files in the Internet Explorer cache to have matching content types and extensions to protect against files that mislead the user about their type.

Internet Explorer will prompt the user to download the file and will no longer execute MIME and extension mismatched files that are rejected by the registered MIME handler.

Internet Explorer will also not execute a file in its shell handler if the `E_Cannot_Load_Data` error code was reported by its MIME handler.

Instead of executing such a file in the shell-handler, Internet Explorer will show an error dialog and give the user an option to save the file.

Web developers can isolate nonworking applications due to this behavior by switching off the functionality, as covered in the Settings section later in this document.

**How do I resolve these issues?**
Web developers must change their Web servers to host files, using consistent content-type headers and file name extensions. If this is not possible, Web developers can use the `"Content-disposition=attachment"` HTTP header to directly send the file to its extension handler rather than to the MIME handler. Note that file downloads with the `"Content-disposition=attachment"` header will prompt the user to open or save the file.

If you have developed a MIME handler and intentionally rely on Internet Explorer to execute files that your MIME handler rejects, you will need to make changes in your MIME handler to accommodate this change. The most secure change would be to natively handle the file directly in the MIME handler rather than rejecting the file.

For some scenarios, it may not be possible to change the behavior of the MIME handler to natively handle downloaded files. In those scenarios, there are a few options.

You may choose to develop a MIME handler and file name extension handler that are both part of the same CLSID; Internet Explorer will accept the CLSID match and therefore not prompt the user to download the file or block the file from execution in the extension handler.

If the MIME handler does not need to be loaded and will cause errors due to MIME and extension mismatch, the developer can mark the MIME handler to be ignored by Internet Explorer in the case of a MIME and extension mismatch. For example, if the MIME handler for a certain media MIME type has a mismatched extension and needs to be executed directly to be played properly, the developer can mark the ProgID of their MIME handler to be ignored on the mismatch when the media file name extension belongs to a different ProgID. To do this, the developer sets the following value in the registry with the MIME handler to ignore:

```
HKEY_CLASSES_ROOT\PROG_ID_OF_MIMEHANDLER_TO_IGNORE\"PreferExecuteOnMismatch"=DWORD:00000001
```

If neither of these solutions is viable, developers should notify their users of the incompatibility and explain to the user how to save the mismatched file to the file system and then launch it manually.

If your scenario is affected by unwanted file-download prompts because of an irreconcilable MIME/extension mismatch, you can register you MIME handler ProgID to bypass all download prompts including the new prompt on mismatch.

Before doing this, you should confirm that your MIME handler can securely deal with any file that is delegated to it. For example, you should confirm that your handler would never allow an attacker to gain more privilege than allowed by the zone

of the originating file. This should be done through threat modeling, code review for secure failure modes, and buffer overruns. If you determine that your MIME handler is capable of safely handling any file that might be delegated to it, you can register your handler to circumvent download prompts by adding a new key to one of the following registry settings:

```
HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\InternetSettings\Secure_Mime_Handlers
HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\InternetSettings\Secure_Mime_Handlers
```

The key should be named with the ProgID of your MIME handler and have a DWORD=00000001.

**MIME sniffing file type elevation**
**Detailed description**
One of the backup criteria for determining a file type is the result of the MIME sniff. By examining (or sniffing) a file, Internet Explorer can recognize the bit signatures of certain types of files. In Windows Server 2003 Service Pack 1, Internet Explorer MIME sniffing will not promote files of type text\plain to more dangerous file types in the Restricted Sites zone. For example, files that are received as plain text but that include HTML code will not be promoted to the HTML type, which could contain active content.

**Why is this change important?**
This change provides users additional defense in depth against malicious content posted on a friendly Web server where the server serves files with content-type=text\plain for a file but an attacker has managed to load HTML with active content into the file.

**What works differently?**
Web servers that do not include the correct Content-Type header with their files and that use nonstandard file name extensions for HTML pages now may have their pages rendered as plain text rather than HTML.

**How do I resolve these issues?**
You should configure Web servers to use the correct Content-Type headers or you can name the files with the appropriate file name extension for the application that should handle the file.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| IExplore.exe<br>Explorer.exe | HKEY_LOCAL_MACHINE(or Current User)\Software \Microsoft \Internet Explorer\Main \FeatureControl \FEATURE_MIME_HANDLING\ | None | 1 | 0 - Off<br>1 - On |
| IExplore.exe<br>Explorer.exe | HKEY_LOCAL_MACHINE(or Current User)\Software \Microsoft \Internet Explorer\Main \FeatureControl\FEATURE_MIME_SNIFFING\ | None | 1 | 0 - Off<br>1 - On |

**MIME Sniffing behavior per-zone settings**
The new MIME sniffing restriction is controlled by the **Open files based on content, not file extension** security setting which can be enabled or disabled for individual security zones. The following table provides a reference of the default settings per security zone:

| Security zone | "Open files based on content, not file extension" Default security setting |
|---|---|
| Restricted Sites zone | Disable |
| Internet zone | Enable |
| Intranet zone | Enable |
| Trusted Sites zone | Enable |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
You should configure Web servers to use the correct Content-Type headers. You can also name the files with the appropriate file name extension for the application that should handle the file.

# Internet Explorer Network Protocol Lockdown

Applies To: Windows 7, Windows Server 2003 with SP1, Windows Vista, Windows XP

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What Does Network Protocol Lockdown Do?**
Internet Explorer can be configured to lock down HTML content from particular network protocols in additional zones besides the Local Machine zone. This feature allows an administrator to extend the same restrictions of the Local Machine Zone Lockdown (which is described previously in this document) to be applied to any content on any arbitrary protocol in any security zone. For example, an administrator can configure Internet Explorer to lock down HTML content hosted on the Shell: protocol if it is in the Internet zone. Since the Shell: protocol's most common use is for local content and not Internet content, this mitigation can reduce the attack surface of the browser against possible vulnerabilities in protocols less commonly used than HTTP.

**Who does this feature apply to?**
By default, Network Protocol Lockdown is not enabled for any application.

All application developers should review this feature. Applications that host HTML files over non-HTTP protocols in Internet Explorer may be affected in organizations where administrators elect to apply additional restrictions. Developers of standalone applications that host Internet Explorer might want to modify their applications to make use of Network Protocol Lockdown.

Developers who chose to opt in to Network Protocol Lockdown should register their applications to take advantage of the changes. Applications that do not use this mitigation should independently review their applications for support for arbitrary protocols.

Software developers with applications that host Internet Explorer can use this feature by adding their process name to the registry as described later in this document. In the future, Microsoft might implement this feature with certain uncommonly used protocols restricted by default and with an "opt-out" policy for applications rather than the current "opt-in" policy for applications. Applications that host Internet Explorer should be tested to ensure that they function properly with Network Protocol Lockdown enabled for their process.

Network Administrators should consider adding unused protocols to the restricted protocol list on managed desktop machines. If the network administrator enables this restriction, there may be HTML files that will be affected.

Developers of Web sites that are hosted on the HTTP protocol should not be affected by restrictions to other protocols.

Users are most likely to be affected by these more stringent restrictions if their Network Administrator chose to restrict certain protocols for their desktop.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Changes to security settings for restricted protocols**
**Detailed description**
With Windows Server 2003 Service Pack 1, HTML content in an application that has "opted in" to use the Network Protocol Lockdown feature that is served on one of the restricted protocols will be restricted to run at a higher security level. Any time the restricted protocol content attempts to use a restricted feature, such as ActiveX controls, the Information Bar will appear in Internet Explorer with the following text (text may be different for other blocked URL actions):

**Internet Explorer has blocked this site from using an ActiveX control in an unsafe manner. As a result this page may not display correctly.**

The user can click the Information Bar to remove the lockdown from the restricted content. The change in setting using the Information Bar is per session only, unless the policies are changed in the registry.

The security settings that are locked down for the content on the restricted protocols are the same as the settings enforced for

the Local Machine zone lockdown, which is described earlier in this document. Please consult that section to review exactly which security settings are enforced for the content on the restricted protocols.

**Restricted protocols feature is off by default for Internet Explorer and all applications**
**Detailed description**
The behavior of the Network Protocol Lockdown is controlled per-process by a new Internet Explorer Feature Control setting. Since this feature is designed to provide an additional layer of defense-in-depth for network administrators, the default Internet Explorer processes, IExplore.exe and Explorer.exe are not opted in by default. To opt in to the Network Protocol Lockdown, network administrators or developers should add a DWORD at either of the following locations where the name is their process name and the value is set to 1 to have the mitigation apply to them. To forcibly opt out, set the value of the key to 0. If the administrator decides to put the setting under the Policies hive, set a REG_SZ instead of a DWORD.

- `HKEY_LOCAL_MACHINE\Software\(Policies)\Microsoft\Internet Explorer\Main\FeatureControl\FEATURE_PROTOCOL_LOCKDOWN`

- `HKEY_CURRENT_USER\Software\(Policies)\Microsoft\Internet Explorer\Main\FeatureControl\FEATURE_PROTOCOL_LOCKDOWN`

Applications may want to proactively opt out to prevent the mitigation from being applied to them when a wildcard is used to force the mitigation into Opt-out mode.

**Behavior per-zone when an application has opted in**
For an opted in process, the behavior of the Network Protocol Lockdown is also controlled per zone by a new Internet Explorer security setting or URL action called URLACTION_ALLOW_RESTRICTEDPROTOCOLS. This URL action will be set to the following values.

| Security Zone | Default behavior for restricted protocols | Example user situation |
|---|---|---|
| Restricted Sites Zone | Disallow | Since ActiveX is never allowed in the Restricted Sites zone by default, the Information Bar is not shown when a restricted protocol is encountered. The Information Bar might be shown in the case where a URL action that was previously allowed in the Restricted Sites zone is now disallowed under network protocol lockdown. In this case, the user will NOT be able to click the Information Bar to allow the action. |
| Internet Zone | Prompt | If the administrator locks down the file:// protocol, HTML that uses script over the file:// protocol is restricted, but users can click the Information Bar to allow it. |
| Intranet Zone | Prompt | If the administrator locks down the local:// protocol, HTML that uses Java over the local:// protocol is restricted, but users can click the Information Bar to allow it. |
| Trusted Sites Zone | Prompt | If the administrator locks down the Shell:// protocol, HTML that uses Binary Behaviors over the Shell:// protocol is restricted, but users can click the Information Bar to allow it. |
| Local Machine Zone | Prompt | If local machine lockdown is enabled, its settings will supersede those established by network protocol lockdown settings. |

**Per-Zone Protocol Lock Down**
The list of protocols that are restricted is defined separately for each zone to allow some protocols to be locked down in some zones but run without restrictions in other zones. Protocols can be restricted for a given zone by writing the protocol name to the restricted list for a particular security zone.

| Security Zone | Registry location of the list of restricted protocols for each zone | Security settings applied to restricted protocol content |
|---|---|---|

| | | |
|---|---|---|
| Restricted Sites Zone | HKEY_LOCAL_MACHINE<br>-or-<br>HKEY_CURRENT_USER<br>\Software\(Policies) \Microsoft\Windows \CurrentVersion\Internet Settings \RestrictedProtocols\4 | HKEY_CURRENT_USER \Software\Microsoft \Windows\CurrentVersion \Internet Settings \Lockdown_Zones\4 |
| Internet Zone | HKEY_LOCAL_MACHINE<br>-or-<br>HKEY_CURRENT_USER<br>\Software\(Policies) \Microsoft\Windows \CurrentVersion\Internet Settings \RestrictedProtocols\3 | HKEY_CURRENT_USER \Software\Microsoft \Windows\CurrentVersion \Internet Settings \Lockdown_Zones\3 |
| Intranet Zone | HKEY_LOCAL_MACHINE<br>-or-<br>HKEY_CURRENT_USER<br>\Software\(Policies) \Microsoft\Windows \CurrentVersion\Internet Settings \RestrictedProtocols\2 | HKEY_CURRENT_USER \Software\Microsoft \Windows\CurrentVersion \Internet Settings \Lockdown_Zones\2 |
| Trusted Sites Zone | HKEY_LOCAL_MACHINE<br>- or -<br>HKEY_CURRENT_USER<br>\Software\(Policies)<br>\Microsoft\Windows \CurrentVersion\Internet Settings<br>\RestrictedProtocols\1 | HKEY_CURRENT_USER \Software\Microsoft \Windows\CurrentVersion \Internet Settings \Lockdown_Zones\1 |
| Local Machine Zone | HKEY_LOCAL_MACHINE<br>- or -<br>HKEY_CURRENT_USER<br>\Software\(Policies)<br>\Microsoft\Windows \CurrentVersion\Internet Settings<br>\RestrictedProtocols\0 | HKEY_CURRENT_USER \Software\Microsoft \Windows\CurrentVersion \Internet Settings \Lockdown_Zones\0 |

**Protocols to consider for lock down**

The default list of restricted protocols is blank. Network administrators should add additional protocols to the lockdown that they know are not needed in their organization for a particular zone. Network administrators should consider restricting some of the following default Windows protocols on managed desktop machines and other protocols that are not needed for rendering HTML with active content in the organization.

- local://
- file://
- shell://

- hcp://
- ftp://

**Why is this change important?**
This change provides general defense-in-depth against vulnerabilities in less frequently used protocols. For example, an ActiveX control running under the local:// protocol might assume that it is loaded in the Local Machine zone and it may grant elevated privilege to the hosting page.

**What works differently?**
If a Web page served on a protocol that is restricted for a given zone uses any restricted content, such as ActiveX, Internet Explorer will display the Information Bar, as previously described.

**How do I resolve these issues?**
If your Web page needs to run ActiveX or scripting on a protocol that should be restricted for your intranet, you might allow the HTML to render correctly by moving the domain for that HTML to the trusted sites zone on the managed desktop machines. As a long term solution, you can look for ways to move the content off of the restricted protocol or if that's not possible, you might remove the active content from the restricted protocol pages entirely by performing needed computations on the server using a server-side script such as an Active Server Page.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Since this feature is off by default, you will probably not need to change your HTML content unless it runs over a protocol that is restricted by a network administrator for your organization.

# Internet Explorer Object Caching

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Information Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Object Caching do?**
In previous versions of Windows Server 2003 with Internet Explorer, some Web pages could access objects cached from another Web site. In Windows Server 2003 Service Pack 1, a reference to an object is no longer accessible when the user navigates to a new domain.

**Who does this feature apply to?**
Web developers should review this feature and plan to adopt changes to their Web site.

Application developers should review this feature and plan to adopt changes in their applications.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
None. Existing functionality has been extended.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Security context is invalidated upon navigation to a different domain**
**Detailed description**
For Windows Server 2003 Service Pack 1, there is now a new security context on all scriptable objects so that access to cached objects (except for ActiveX controls) is blocked. In addition to blocking access when navigating across domains, access is also blocked when navigating within the same domain. (In this context, a domain is defined as a fully qualified domain name, or FQDN.) A reference to an object is no longer accessible after the context has changed due to navigation.

**Why is this change important? What threats does it help mitigate?**
Prior to Internet Explorer 5.5, navigations across HTML pages (or to subframes) purged instances of MSHTML, which is the Microsoft HTML parsing and rendering engine. With the Internet Explorer 5.5 Native Frames architecture, an instance of MSHTML lives across navigations. This introduced a new class of vulnerabilities, because objects could be cached across navigations. If an object can be cached and provide access to the contents of a Web page from another domain, there is a cross-domain hole.

Once you can get to properties on the inner document, script outside of a page's domain can access the contents of an inner page. This is a violation of the Internet Explorer cross-domain security model.

For example, you can use this method to create scripts that listen to events or content in another frame, such as credit card numbers or other sensitive data that is typed in the other frame.

**What works differently? Are there any dependencies?**
In those few classes that don't already have them, four more bytes are added for the cached markup. There should be no noticeable impact on speed.

**How do I resolve these issues?**
For most of these classes of vulnerabilities, Internet Explorer 5 would have crashed, so the application compatibility risk of resolving the exploit should be small. Other applications might need to be addressed on a case by case basis.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**Internet Explorer Object Caching**

| Setting name | Location | Previous default value | Default value | Possible values |
| --- | --- | --- | --- | --- |

| | | | | |
|---|---|---|---|---|
| IExplore.exe<br><br>Explorer.exe | HKEY_LOCAL_MACHINE (or Current User)\Software \Microsoft \Internet Explorer\Main \FeatureControl \FEATURE_OBJECT_CACHING | None | 1 | 0 - Off<br><br>1 - On |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
If your application is attempting to use a cached object, you might encounter Access Denied errors. In this instance you must recache the object before you access it using a script.

In the following example, the security context is invalidated when the `designMode` property is set on a document object.

Broken script example

```
var d = myFrame.document;
d.designMode = "On";
d.open();  <-------------------------causes permission denied error
```

Fixed script example

```
var d = myFrame.document;
d.designMode = "On";
d = myFrame.document;   // re-establish pointer to document object.
d.open();
```

Also, when you compare the values of the two `frame.frames` properties of an object, the results may be incorrect, or the values may not be retained. This is because the frames object is now wrapped with a security wrapper. When the object caching feature is enabled, this security wrapper is applied. Therefore, access to all cached objects is blocked. This can cause the frames object comparison to return false even though the frames are equal. To resolve this problem, you can use the following method to compare the value of the frames:

```
a.name == parent.frames[1].frames.name
```

# Internet Explorer Pop-up Blocker

Applies To: Windows Server 2003 with SP1

| **Note** |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Information Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Pop-up Blocker do?**
Pop-up Blocker blocks most unwanted pop-up windows from appearing. Pop-up windows that are opened when the end user clicks a link will not be blocked.

End users and IT administrators can let specific domains open programmatic pop-up windows. Developers will be able to use or extend the pop-up functionality in Internet Explorer for applications hosting Internet Explorer.

**Who does this feature apply to?**
For most end users, browsing the Web will be less annoying, because unwanted pop-up windows will not automatically appear.

For Web developers, Pop-up Blocker affects the behavior of windows opened by Web sites, for example, by using the `window.open()` and `showHelp()` methods

For application developers, there is a new user interface called `INewWindowManager`.

Applications that use the rendering engine in Internet Explorer to display HTML can choose to use or extend the Pop-up Blocker functionality.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
The Pop-up Blocker is a new feature for Internet Explorer which can be broken down into three sections:

- User experience changes, defaults, and advanced options.
- Changes in behavior of current application programming interfaces (APIs), such as `window.open` and `showHelp`.
- The new `INewWindowManager` interface, which allows applications to use the pop-up technology in Internet Explorer.

**Pop-up Blocker features**
**Detailed description**
**Defaults**
Pop-up Blocker is turned on by default. There are restrictions on the size and position of pop-up windows, regardless of the Pop-up Blocker setting. Pop-up windows cannot be opened larger than or outside the viewable desktop area. For more information, see "Windows Restrictions" in this document.

When this functionality is enabled, automatic and background pop-up windows are blocked, but windows that are opened by a user click will still open in the usual manner. Note that sites in the Trusted Sites and Local Intranet zones do not have their pop-up windows blocked by default, as they are considered safe. This setting can be configured in the **Security** tab in **Internet Options**.

**Enabling Pop-up Blocker**
Pop-up Blocker is enabled by default. You can change this in the **Tools** menu, with the **Pop-up Blocker** item, or in the Information Bar when a pop-up is blocked.

**When a pop-up window is blocked**
If a site opens a pop-up window that is blocked by Internet Explorer, a notification appears in the Information Bar and status bar and a sound is played. If you click the notification in the Information Bar or status bar, you see a menu with the following

options:

- **Temporarily Allow Pop-ups**. Reloads the page, allowing pop-up windows.
- **Always Allow Pop-ups from This Site**. Adds the current site to the Allow list.
- **Settings**. Shows more Pop-up Blocker settings menu items and gives access to the **Pop-up Blocker Settings** window.

| **Note** |
| --- |
| You can allow pop-up windows to open by pressing CTRL while the pop-up is opening |

**Advanced options**

Internet Explorer provides advanced configuration options through **Pop-up Blocker Settings**. To access these settings, open **Internet Options**, click **Privacy** and then in the **Pop-up Blocker** area click **Settings** to open **Pop-up Blocker Settings**. You can configure the following options:

- **Address of Web site to allow**. Enter a URL and click **Add** to add sites to the **Allowed sites** list. Any site on the list can open pop-up windows.
- **Filter Level**. There are three different filter levels that you can use with Pop-up Blocker:
    - **High: Block All Pop-ups**. The default behavior of Pop-up Blocker allows sites to open a pop-up window when the user clicks a link. This setting changes that behavior by blocking windows that are opened from a link. If this setting is enabled, you can allow pop-up windows to open by pressing the CTRL key at the same time that you click the link to launch the pop-up.
    - **Medium: Block most automatic pop-ups**. This is the default Pop-up Blocker setting. This setting blocks most pop-ups that launch automatically when a Web site is loaded into your browser, but doesn't block pop-ups that are opened when you click a link.
    - **Low: Allow pop-ups from secure sites**. This setting allows secure Web sites (those that use the https:// protocol) to automatically launch pop-up windows without requiring that you add them to the **Allowed sites** list.
- **Configure Sound**. You can toggle whether or not Pop-up Blocker plays a sound when a pop-up is blocked through **Pop-up Blocker Settings**. To do this, open **Internet Options**, click **Privacy** and then in the **Pop-up Blocker** area click **Settings** to open **Pop-up Blocker Settings**. In the **Notification and Filter Level** area, select or clear the check box next to **Play a sound when a pop-up is blocked** as appropriate.

  You can also change the sound that plays. To do this, click **Start**, click **Control Panel**, and then double-click the **Sounds and Audio Devices** icon to open its properties sheet. Then click the **Sounds** tab, click the **Blocked Pop-up Window** program event and choose the sound to play in the **Sounds** drop-down list.

| **Note** |
| --- |
| The Pop-up Blocker is used by default in the Internet and the Restricted Sites security zones. You can expand the scope of the Pop-up Blocker to include the Local Intranet or Trusted Sites security zone by clicking the zone and then either moving the slider in the **Security level for this zone** area to **Medium** or **High** or clicking **Custom level** and then changing the setting for **Use Pop-up Blocker** to **Enabled**. |

**When will you see pop-up windows while Pop-up Blocker is enabled?**

You will still see pop-ups windows opened in the following cases:

- The pop-up is opened by a link that the user clicked.
- The pop-up is opened by software that is running on the computer.

- The pop-up is opened by ActiveX controls that are instantiated from a Web site.
- The pop-up is opened from the Trusted Sites or Local Intranet zones and you have not expanded the scope of the Pop-up Blocker to include those zones.

**Why is this change important?**
Pop-ups have been misused in many ways. By blocking pop-ups, you have more control over your browsing experience.

**INewWindowManager**
**Detailed description**
By default, the Pop-up Blocker functionality does not apply to applications that host the `WebBrowser` control or MSHTML. These applications have the ability to use or extend Pop-up Blocker, use their own Pop-up Blocker, or disable pop-up management for their application through the `INewWindowManager` interface.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Methods: window.open(), window.external.navigateAndFind(), showHelp()**
**Detailed description**
If one of these functions normally returns a window object, then the function will return null when a window is blocked. Web developers can check for null to determine whether the window they attempted to open was blocked.

Windows that are outside the viewable screen when they are opened are positioned onto the viewable area.

Windows that are larger than the viewable screen when they are opened are resized to the viewable area.

For more information, see "Internet Explorer Window Restrictions" later in this document.

**What works differently?**
In the Internet zone, the Pop-up Blocker blocks windows that are automatically opened by these methods without the user clicking a link. Windows that are opened by these methods by clicking a link might also be blocked if the customer has enabled the more restrictive blocking setting.

**How do I resolve these issues?**
Ensure that all windows that are opened with `window.open()` are opened through user interaction and not automatically through your code.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**Pop-up Blocker Settings**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| URLname | HKEY_CURRENT_USER \Software\Microsoft \Internet Explorer\New Windows\Allow | None | Empty | URL names of trusted sites |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Web page authors should check for a NULL return value for any windows that you open. This will indicate whether the pop-up window opened successfully and allow you to handle either case.

If your software opens windows automatically, they will be blocked. Look for alternative ways of doing the same thing as described earlier in this document. The best way to open a window is to have the customer click a link or graphical element.

# Internet Explorer Untrusted Publishers Mitigations

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Information Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Untrusted Publishers Mitigations do?**
This feature allows the user to block all signed content from a given publisher without showing the Authenticode dialog box to the user while doing so. This stops code from the blocked publisher from being installed. This feature also blocks installation of code with invalid signatures.

**Who does this feature apply to?**
This feature applies to all users, since it deals with installation and running of applications that are signed.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Blocked publisher**
**Detailed description**
Through Authenticode, the user can block content for a given publisher from installing or running. To do this, the user selects the **Never install software from** *PublisherName* check box in the Authenticode dialog box. If selected, the user is never prompted when code that is identified with the publisher's digital signature is trying to install itself on the system. It will be automatically blocked without showing the Authenticode dialog box.

**Why is this change important?**
This feature was designed to help users block ActiveX controls and other signed file formats from repeatedly prompting them on the Web. Users had no way of saying, "I don't want content from this publisher. Do not ask me again." Because they didn't have this feature, many users installed applications or content just to keep from encountering repeated prompts.

**What works differently?**
Previously, the Authenticode dialog box only supported selecting the **Always trust content from** *PublisherName* check box, which allowed the automatic installation of code from a specified publisher without prompting the user. Now the user can perform the opposite action and designate a publisher as untrusted. No application compatibility issues should be encountered for trusted code.

**How do I resolve these issues?**
You can unblock a publisher of an add-on by using **Manage Add-ons** in Internet Explorer. To unblock a publisher to enable the download of a specific file, you can remove the publisher from the **Untrusted Publishers** list. To do this, in Internet Explorer, on the **Tools** menu, click **Internet Options**, click the **Content** tab, click the **Publishers** button and then remove the publisher's name from the **Untrusted Publishers** list.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Blocking invalid signatures**
**Detailed description**
By default, Windows blocks the installation of signed code if it has an invalid digital signature.

**Why is this change important? What threats does it help mitigate?**
If code has an invalid signature, it usually means that the code has been changed since it was signed. When this happens, Internet Explorer considers the code to be unsigned, because someone might have tampered with it. By default, Internet Explorer blocks ActiveX applications that are unsigned that come from the Internet zone. This extends that functionality so that it applies to all code with invalid signatures.

**What works differently?**
By default, code with invalid signatures cannot be installed.

**How do I resolve these issues?**
To revert to previous functionality and allow unsigned code to run, see the `RunInvalidSignatures` setting in the "What settings

are added or changed in Windows Server 2003 Service Pack 1?" section below.

**One prompt per control per page**
**Detailed description**
Internet Explorer only prompts once per ActiveX control per page.

**Why is this change important? What threats does it help mitigate?**
This change helps defend against the social engineering trick of prompting the user a number of times for the same control. Even though users repeatedly refuse, they cannot get out of the loop, and they might eventually accept the installation out of frustration.

**What works differently?**
The user only sees one prompt per page per control.

**Ellipsis placed on text for application description and publisher name**
**Detailed description**
When the text that is given for the application description, file name, or publisher name is wider than the dialog box in width, Internet Explorer places an ellipsis on the text. This helps indicate to the user that there is more text that they are not seeing.

**Why is this change important? What threats does it help mitigate?**
This reduces the ability of control authors from placing marketing text and EULAs in the dialog box or using other social engineering tricks to overwhelm the users and get them to install the control.

**What works differently?**
Application description, file names, and publisher names will contain an ellipsis if the text is longer than the width of the dialog box. No applications or Web pages should need to be modified.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| RunInvalidSignatures | HKEY_CURRENT_USER \Software\Microsoft \Internet Explorer \Download<br><br>HKEY_LOCAL_MACHINE \Software\Microsoft \Internet Explorer \Download | None | 0<br><br>(Controls with invalid signatures will be blocked, regardless of zone.) | 1<br><br>(Controls with invalid signatures will be allowed to run, regardless of zone.) |

# Internet Explorer Window Restrictions

Applies To: Windows Server 2003 with SP1

| **Note** |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Information Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Window Restrictions do?**

Internet Explorer provides the capability for scripts to programmatically open additional windows of various types, and to resize and reposition existing windows. The Window Restrictions security feature, formerly called UI Spoofing Mitigation, restricts two types of script-initiated windows that have been used by malicious persons to deceive users:

- HTML popup windows created by the `window.createPopup()` method; the appearance of these HTML pop-ups is determined completely by the caller.
- New Internet Explorer frame windows (also referred to as "pop-up windows") created by the `window.open()` method. These new frame windows can either show or not show interface elements (such as a title bar, status bar, address bar, and so on) depending on the `sFeatures` parameter of the `window.open()` call.

The Window Restrictions feature also constrains script-initiated movement of the frame window to prevent repositioning or resizing the frame window in such a manner that key elements are outside the visible display area. This affects the following methods:

- `moveTo`
- `moveBy`
- `resizeTo`
- `resizeBy`

and the following properties:

- `Left`
- `Top`
- `Width`
- `Height`

The Window Restrictions feature also forces the status bar to be displayed on all windows created by the `window.open()` method.

**Who does this feature apply to?**

Web developers should be aware of these new restrictions to plan changes or workarounds for any possible impact to their Web site.

Application developers should review this feature to plan to adopt changes in their applications. This feature is only enabled by default for Internet Explorer processes. Developers must register non-Internet Explorer applications to take advantage of the changes

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Script positioning of Internet Explorer windows**
**Detailed description**
Script-initiated placement of new Internet Explorer frame windows and script-initiated positioning of existing frame windows are constrained to ensure that key security-related interface components (the title and status bars, and address bar if displayed) remain visible after the operation completes.

Scripts cannot position windows so that the title bar or address bar are above the visible top of the display.

Scripts cannot position windows such that the status bar is below the visible bottom of the display.

**Why is this change important?**
Without this change, existing-window movement using the `moveTo` and `moveBy` methods and the `Left` and `Top` properties, and new windows that are created by the `window.open()` method can be called by scripts and used to spoof a user interface or desktop or to hide malicious information or activity by one of the three following methods:

- Positioning the window such that the title bar, status bar, or address bar are off-screen.
- Positioning the window to hide important elements of the user interface from the user.
- Positioning the window so that it is entirely off-screen.

The visible security features of Internet Explorer windows provide information to the user to help the user ascertain the source of the Web page and the security of the communication that uses that page. When these elements are hidden from view, users might think they are on a more trusted page or interacting with a system process when they are actually interfacing with a malicious host. Malicious use of window relocation can present false information to the user, obscure important information, or otherwise "spoof" important elements of the user interface in an attempt to motivate the user to take unsafe actions or to divulge sensitive information.

**What works differently?**
This change places constraints on script-initiated positioning of existing Internet Explorer frame windows and of new frame windows created using the `window.open()` method, to ensure that the title bar and status bar in these windows are always visible to the user. Scripts cannot move a window off-screen, although the user can still move a window off-screen. If you maintain a script that creates off-screen windows in Internet Explorer, you need to change your code.

**How do I resolve these issues?**
If your script creates or moves a window off-screen, you should examine this requirement and alternate ways to accomplish your goal.

**Script sizing of Internet Explorer windows**
**Detailed description**
Script-initiated resize operations on Internet Explorer frame windows are constrained to ensure that the title bar and status bar remain visible after the operation completes.

Scripts cannot resize existing frame windows or create new frame windows in such a manner that the title bar, address bar, or status bar cannot be seen.

When creating a window, the definition of the `fullscreen=yes` specification is changed to mean "show the window as maximized," which will keep the title bar, address bar, and status bar visible.

**Why is this change important?**
Without this change, existing Internet Explorer frame windows can be resized or new frame windows can be created using the `window.open()` method and used to spoof a user interface or desktop or to hide malicious information or activity by sizing the window so that the status bar is not visible.

Internet Explorer windows provide visible security information to the user to help them ascertain the source of the Web page and the security of the communication with that page. When these elements are not in view, the user might think they are on a more trusted page or interacting with a system process when they are actually interacting with a malicious host. Malicious uses of window sizing can obscure important security-related information, and otherwise spoof important elements of the user interface in an attempt to motivate the user to take unsafe actions or to divulge sensitive information

**What works differently?**
With this change, there are constraints on script-initiated resizing operations on existing Internet Explorer frame windows and on the size of the new frame windows created using the `window.open()` method, to ensure that the title bar and status bar of these windows is always visible to the user. The result is that a script cannot open a window in kiosk mode, a mode that does not display the title bar, address bar, and status bar, which present important security information to the user.

The user can choose to display a window in kiosk mode. This election is still persistent.

**How do I resolve these issues?**
Script-initiated windows will be displayed fully, with the Internet Explorer title bar and status bar. The user or the site administrator can manually change this state.

**Script management of Internet Explorer status bar**
**Detailed description**
Internet Explorer has been modified to always display the status bar in Internet Explorer frame windows created using the `window.open()method`.

**Why is this change important?**
Without this change, windows that are created using the `window.open()` method can be called by scripts and spoof a user interface or desktop or hide malicious information or activity by hiding important elements of the user interface from the user.

The status bar is a security feature of Internet Explorer windows that provides Internet Explorer security zone information to the user. This zone cannot be spoofed, and lets the user know exactly what security zone the displayed content is in. When the status bar is hidden from view, the user might think they are on a more trusted page when they are actually interacting with a malicious host.

**What works differently?**
On all windows created by the `window.open()` method, the status bar will be displayed so that the security zone is visible to the user. The '`status=no`' or '`status=0`' specifications in the `sFeatures` parameter of the `window.open()` method are ignored. Application impact depends on the operation carried out on the window as follows:

- `window.open()` method calls will not need to be modified, because the optional width and height values passed in the `sFeatures` parameter specify the size of the content area of the windows and do not include the title bar, status bar, and other window attributes.

- `resizeTo()` method calls might need to be modified because the size parameters of the `resizeTo()` method are for the entire Internet Explorer frame window. Application that have been creating new frame windows with no status bar using the `windows.open()` method and subsequently resizing them using the `resizeTo()` method will need to be modified to account for the fact that the windows now have a status bar.

**Internet Explorer HTML pop-up window placement**
**Detailed description**
HTML pop-up windows are now constrained so that they:

- Do not extend above the top or below the bottom of the content window from which they are created. The "content window" is the top-level DOM window object for the page; visually it is the area where the HTML content is displayed, and extends from the bottom of the lowest displayed interface component at the topic of the Internet Explorer frame window (the title bar, menu, tool bar, or address bar) to the top of the status bar).

- Are not taller in height than the content window.

- Overlap the content window horizontally.

- Appear immediately above the content window, so that other windows (such as a dialog box) cannot be hidden.

- Are automatically repositioned to satisfy the constraints above if the content window moves.

**Why is this change important?**
Pop-up windows are created by the `window.createPopup()` method and are also called chromeless windows because they do not have the border "chrome" components, such as the address bar, title bar, status bar, and toolbars. Without the constraints previously described, these windows:

- Can be opened on top of a dialog box and obscure or replace important elements.
- Can be used to overlay the address bar with a different address.
- Can simulate a full-screen Windows desktop with a password dialog box.

Unrestricted chromeless windows can deceive the user in several ways:

- A chromeless pop-up window that is opened on top of a dialog box can obscure or replace important elements of the dialog box, such as warning text and selection or action controls. (These include check boxes, option buttons, and so on.) This might lead the user to a response that might be inappropriate or harmful.
- A chromeless pop-up window can overlay the address bar with an address that is different from the actual address of the page, which gives the user a false sense of security. In the same way, it can overlay the status notification area, so it might indicate that Internet Explorer is displaying a secure Web page (which displays a URL beginning with https://) Because of this, the user might think that security is in effect for the page when no such security exists.
- A chromeless pop-up can use the entire display. With this method, a malicious user can simulate a full-screen Windows desktop with a password dialog box, with a malicious script that captures the user's private authentication information.

**What works differently?**
HTML pop-up windows are constrained horizontally, vertically, and in order of placement on top of other windows.

An HTML pop-up window must appear between the top and bottom of its parent window's chrome, so it does not overlap the Internet Explorer address bar, title bar, status bar, or toolbars.

Horizontally, an HTML pop-up window must always overlap some area of its parent window.

An HTML pop-up window must stay immediately on top of its parent, so it cannot be placed over other windows.

These constraints might affect the appearance of an HTML pop-up window if it has been designed to display in an area that is larger or separate from its parent window. The HTML pop-up windows might be repositioned and might also be truncated, which might obscure some of the information displayed in that window.

**How do I resolve these issues?**
Redesign the HTML pop-up window to fit into the constraints of this mitigation.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
There is only one setting for this feature. This setting either enables the Windows Restrictions or does not enable them. For application compatibility, this feature is not enabled by default for non-Internet Explorer processes.

**Internet Explorer Windows Restrictions Settings**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| IExplore.exe<br>Explorer.exe<br>Msimn.exe<br>WMPlayer.exe | HKEY_LOCAL_MACHINE (or Current User)\Software \Microsoft \Internet Explorer\Main \FeatureControl \FEATURE_WINDOW_RESTRICTIONS\ | Not applicable | 1 | 0 - Off<br>1 - On |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
The script will call the same methods for the creation of an Internet Explorer window with chrome (using the `window.open()` method) or an Internet Explorer chromeless pop-up window (using the `window.createPopup()` method). However, the design might need to be reviewed to ensure that pop-up windows are appropriately visible to the user and that the status bar contains accurate information.

# Internet Explorer Zone Elevation Blocks

Applies To: Windows Server 2003 with SP1

| Note |
| --- |
| The Microsoft Windows Server 2003 Internet Explorer Enhanced Security Configuration component (also known as Microsoft Internet Explorer hardening) reduces a server's vulnerability to attacks from Web content by applying more restrictive Internet Explorer security settings that disable scripts, ActiveX components, and file downloads for resources in the Internet security zone. As a result, many of the security enhancements included in the latest release of Internet Explorer will not be as noticeable in Windows Server 2003 Service Pack 1. For example, the new Internet Explorer Notification Bar and Pop-up Blocker features will not be used unless the site is in a zone whose security setting allows scripting. If you are not using the enhanced security configuration on your server, these features will function as they do in Windows XP Service Pack 2. |

**What does Zone Elevation Blocks do?**
When a Web page is opened in Internet Explorer, Internet Explorer puts restrictions on what the page can do, based on where that Web page came from: the Internet, a local intranet server, a trusted site, and so on. For example, pages on the Internet have stricter security restrictions than pages on a user's local intranet. Web pages on a user's computer are in the Local Machine security zone, where they have the fewest security restrictions. This makes the Local Machine security zone a prime target for malicious users. Zone Elevation Blocks makes it harder to get code to run in this zone. In addition, Local Machine Zone Lockdown makes the zone less vulnerable to malicious users by changing its security settings.

**Who does this feature apply to?**
Web developers must plan changes or workarounds for any possible impact to their Web site.

Application developers should review this feature to plan to adopt changes in their applications that run in the Local Machine security zone. Because the feature is not enabled for processes other than Internet Explorer by default, developers must register their applications to take advantage of the changes.

End users might be affected by sites that are not compatible with these stricter rules and settings.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Zone Elevation Blocks**
**Detailed description**
Internet Explorer prevents the overall security context for any link on a page from being higher than the security context of the root URL. This means, for example, that a page in the Internet zone cannot navigate to a page in the Local Intranet zone. A script, for example, could not cause this navigation. For the purpose of this mitigation, the security context ranking of the zones, from highest security context to lowest, is: Restricted Sites zone, Internet zone, Local Intranet zone, Trusted Sites zone, and Local Machine zone.

Zone Elevation Blocks also disables JavaScript navigation if there is no security context.

If a user clicks a link that causes the Web site to attempt to navigate to a higher zone, navigation is blocked for navigation to the Local Machine zone, but a dialog box will appear in Internet Explorer when a Web page attempts to open a page in a security zone that has a higher security context and you will be prompted as in the following message. The italicized portion changes, according to the security zone that the Web page is attempting to navigate to.

- The current Web page is trying to open a site in your *Trusted* sites list. Do you want to allow this?

In any case, the default action does not allow the zone elevation. The user must explicitly allow the requested zone elevation.

**Why is this change important?**
Elevation of privilege is one of the most exploited vulnerabilities in Internet Explorer, with the ultimate goal of running malicious code in the Local Machine zone. Zone Elevation Blocks helps mitigate many privilege escalation attacks.

**What works differently?**
Navigation from one zone to a "higher" zone is blocked. This means that Web pages that automatically call more privileged Web pages fail.

**How do I resolve these issues?**
If you have a trusted Web application that is impacted by this change because it navigates between different security zones without user interaction, you should map the domains that the Web application uses into the security zone with the least

privilege necessary to perform the task for which the application was designed.

# Internet Information Services (IIS) in Windows Server 2003 Service Pack 1

Applies To: Windows Server 2003 with SP1

**What does Internet Information Services do?**
Windows Server 2003 Service Pack 1 includes Internet Information Services (IIS), Version 6.0, which makes it possible for you to host your own Web site on the Internet or your intranet.

IIS is an optional component of Windows Server 2003, is not enabled by default, and must be installed separately.

**Who does this feature apply to?**
This feature applies to the following audiences:

- IT professionals that use IIS to host and administer a Web site.
- Web developers that use IIS to develop Web content.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Metabase auditing**
Beginning with Windows Server 2003 Service Pack 1 (SP1), IIS 6.0 includes a metabase auditing feature that allows tracking of each change that is made to the metabase. Metabase auditing is enabled by enabling an audit access control entry (ACE) on a node in the metabase. After the ACE is enabled, whenever a metabase change takes place on that node, an audit event is published in the Security event log. Using metabase auditing, you can keep track of:

- What was changed (metabase node, property, and old and new values).
- When the change was made (date and time).
- Who made the change (domain and user name).
- Success or failure of the change attempt (HRESULT).
- When a change is made remotely (client IP number).

| **Note** |
| --- |
| To avoid disclosing sensitive information, such as passwords, values of secure properties do not appear in audit event log entries. |

**Request tracing**
The Windows operating system includes the Event Tracing for Windows (ETW) infrastructure to help individuals troubleshoot problems in the operating system, including problems in HTTP components. If an HTTP request in IIS fails or becomes unresponsive while ETW is enabled, you can view ETW trace data, called events, to determine which component caused the failure. IIS includes the following tracing features:

- IIS Currently-executing Requests Tracing: This tracing feature provides general statistics and details about all requests executing on the server at the moment tracing was started.
- IIS Request-Based Tracing: This tracing feature tracks HTTP requests as they move through IIS components.

Windows Server 2003 Service Pack 1 or later also includes a provider for tracing the IIS Admin service during startup and shutdown.

**Kernel-mode SSL.**
You can run Secure Sockets Layer (SSL) in kernel mode, instead of the default user mode. Running in kernel mode means that components or processes run in the core address space of the operating system. Moving encryption and decryption operations

to the kernel improves SSL performance by reducing the number of transitions between kernel mode and user mode. Enabling kernel-mode SSL requires setting a new registry key, `EnableKernelSSL`.

**SSL host headers**
IIS 6.0 now supports using SSL to secure Web sites that use host headers — a security feature that many users want to have. SSL host header support requires obtaining a wildcard server certificate and specifying the SSL port number on the SecureBindings metabase property.

**Running 32-bit applications on 64-bit Windows**
Windows Server 2003 Service Pack 1 enables IIS 6.0 to run 32-bit Web applications on 64-bit Windows using the Windows-32-on-Windows-64 (WOW64) compatibility layer. IIS 6.0 using WOW64 is intended to run 32-bit personal productivity applications needed by software developers and administrators, including 32-bit IIS Web applications.

**W3C centralized logging**
World Wide Web Consortium (W3C) centralized logging is a global configuration on the server where all Web sites write data to a single log file. Data is stored in the log file using the W3C Extended log file format. The log file can be viewed in a text editor, unlike IIS Centralized Binary Logging, which writes data in binary format and requires a parsing tool to view the data.

**Secure configuration for Web servers**
Windows Server 2003 Service Pack 1 includes a Security Configuration Wizard (SCW), which is a role-based tool you can use to create a policy that enables the services, inbound ports, and settings required for a selected server to perform a specific role. If you select the Web Server role in the wizard, SCW configures IIS 6.0 to help further reduce the attack surface of your Web server.

# Kernel patch protection for x64-based operating systems

Applies To: Windows Server 2003 with SP1

**What does kernel patch protection do?**
Kernel patch protection prohibits kernel-mode drivers that extend or replace kernel services through undocumented means. This feature describes changes in policy related to patching the kernel for Microsoft Windows Server 2003 Service Pack 1 x64-based operating systems.

**Who does this feature apply to?**
This feature primarily applies to driver developers, but IT professionals may also find this information useful.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Patching policy for x64-based systems**
**Detailed description**
Microsoft Windows Server 2003 SP1 and later versions of Windows for x64-based systems do not allow the kernel to be patched except through authorized Microsoft-originated hotfixes.

**Why is this change important?**
Kernel-mode drivers that extend or replace kernel services through undocumented means (such as hooking the system service tables) can interfere with other software and affect the stability of the operating system. For x86-based systems, Microsoft discourages such practices but does not prevent them programmatically, because doing so would break compatibility for a significant amount of released software. A similar base of released software does not exist for x64-based systems, so it is possible to add this level of protection to the kernel without breaking compatibility.

**What works differently?**
Many system structures are protected on x64-based systems, including the system service dispatch tables, the interrupt descriptor table (IDT), and the global descriptor table (GDT). The operating system also does not allow third-party software to allocate memory "on the side" and use it as a kernel stack. If the operating system detects one of these modifications or any other unauthorized patch, it will generate a bug check with the stop code 0x109 and shut down the system.

**How do I fix these issues?**
For compatibility with Windows for x64-based systems, drivers cannot modify the kernel. The following actions are blocked in Windows Server 2003 SP1 for x64-based systems:

- Modify system services tables, for example, by hooking the KeServiceDescriptor table
- Modify the IDT
- Modify the GDT
- Use kernel stacks that are not allocated by the kernel
- Patch any part of the kernel (detected on AMD64-based systems only)

Kernel patch protection might be extended in future system updates to protect against additional malicious patching techniques as new vulnerabilities are detected. To avoid compatibility issues with these updates, drivers should not attempt to update the kernel using other mechanisms.

Drivers for other platforms should also avoid patching the kernel to help ensure stability and reliability of the operating system and a better experience for users.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Windows Server 2003 SP1 for x64-based systems is a new platform that requires new drivers. These new drivers must conform to x64 patch policy documented on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38447.

For additional information see The Microsoft Windows Driver Development Kit (DDK) on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=38448.

# Outlook Express

Applies To: Windows Server 2003 with SP1

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Plain text mode**
**Detailed description**
The plain text mode feature of Outlook Express provides users with the option to render incoming mail messages in plain text instead of Hypertext Markup Language (HTML). When Outlook Express is running in plain text mode, the rich edit control is used instead of the MSHTML control. You avoid some security issues that result from the use of MSHTML by using the rich edit control.

**Why is this change important?**
The use of the rich edit control provides an additional barrier to malicious code that is transmitted using e-mail. Computers running earlier versions of Windows XP had a vulnerability to malicious code because Outlook Express processes HTML header scripts in the HTML content. The MSHTML control automatically executes these scripts. The rich edit control does not execute HTML scripts, so this is mitigated. Because plain text e-mail does not require HTML header processing to be displayed properly, there is usually little visible difference from this processing change in standard message formats. Portions of e-mail messages that do not appear to render correctly are relying on HTML rendering and could present a danger to your system.

**What works differently?**
The following Outlook Express features are not available when running in plain text mode:

- Changing text size to a larger or smaller font.
- Full text searching through the body of a mail message.

You can configure plain text mode in several ways, including:

- Reading a message.

  In Outlook Express, on the **Tools** menu, click **Options**, and then click the **Read** tab. Select the **Read all messages in plain text** check box.

- Composing a message.

  In Outlook Express, on the **Tools** menu, click **Options**, and then click the **Send** tab. Under **Mail Sending Format**, select the **Plain Text** option.

- With a new menu option.

  On the **View** menu, click **Message in HTML**.

  This new menu item switches the current message view to HTML if it is currently in plain text view, both in the preview display as well as in the full message display.

**How do I resolve these issues?**
If you are sure that the source of an e-mail message can be trusted and you want to use the full feature set that is provided with the MSHTML control to support rich HTML e-mail for reading or composing, you can switch to the HTML mode by using the **View** menu option procedure as described above in "With a new menu option."

**Limit external HTML content downloads**
**Detailed description**
This Outlook Express feature helps users to avoid getting repeated spam mailings by preventing the user from unknowingly validating his or her e-mail address to spam originators. Businesses that use spam as a marketing technique typically include references to images that reside on their Web servers inside the e-mail message. Some of these spam e-mail messages contain single pixel images that are not visible to the recipient of the e-mail so that the recipient will not be aware that there is any content that is malicious. When the user opened an e-mail that contains the image, previous versions of Outlook Express automatically contacted the Web server to download and display the images. When the request for the image was made to the Web server, it could ascertain that a spam e-mail message was received by an active e-mail account, which validated the e-mail

address in the spam originator's mailing list. Now, when the **Block images and other external content in HTML e-mail** setting is enabled, the default behavior of Outlook Express changes so that it does not contact the Web server to download external content, which helps prevent the verification of the e-mail address with the spam originator. This download behavior is configurable and is enabled by default when you install Windows Server 2003 Service Pack 1.

This feature also helps to minimize a common problem that is experienced by people whose computers use dial-up network connections. Prior to implementing this feature, if users downloaded mail messages and then disconnected their network connection, when they attempted to view an HTML messages that included pictures or other external Internet content, their modem would automatically start to dial out to download the external content.

**Why is this change important?**
This feature increases the privacy that is provided to users of Outlook Express. Their e-mail address is not automatically validated by the Web server of spam originators without their knowledge when a spam e-mail message is opened. Using this feature may result in the following advantages:

- The user receives less spam.
- The user is less distracted by the receipt of spam.
- Automatic attempts by a user's modem to reconnect to the Internet after receiving HTML e-mail decrease.

**What works differently?**
Implementing this feature in Outlook Express helps prevent the rendering of pictures in HTML e-mail if the pictures must be retrieved from servers that are in either the Internet or Restricted Web content zones. This new default behavior results in the user's name not being validated by the Web site hosting the pictures, which makes the user's e-mail name less useful to spam senders. This may result in the user getting less spam over time.

To communicate that these pictures are missing, there is now an External Message Information Bar that is displayed in both the Outlook Express message window as well as in the preview area. This External Message Information Bar appears whenever the message contains references to external Internet content, such as images or script and the options are set to render the message in HTML.

When Outlook Express blocks content, the actual image is replaced with the standard placeholder for the blocked image in the text of the mail message. Images are the only blocked items that provide a visual cue that something is not being displayed. For sounds, IFrames, and other content, there is no visual indication in the body of the mail message. When users print an HTML e-mail that has blocked content, Outlook Express prints the e-mail exactly as it appears on the screen, with a placeholder for the blocked images. The external content is not downloaded.

An added benefit of this feature is that it minimizes a common dial-up user problem: undesired automatic dial-up network connection attempts. When viewing an HTML e-mail message off-line, previous versions of Outlook Express would automatically dial out to connect to the Internet and retrieve any reference images. However, because almost all external HTML references in e-mail messages point to resources on the Internet that are part of the Internet zone, the content is not displayed by default and a dial-up network connection is not requested.

**How do I resolve these issues?**
To turn off all external content blocking, on the **Tools** menu, point to **Options**, and then click **Security**. Clear the **Block images and other external content in HTML e-mail** check box. From that point, no content is blocked, which returns Outlook Express to the prior behavior of automatically downloading external content.

To explicitly download external content for an e-mail message, click the External Message Information Bar to download the external content that was included with the message.

**Attachment Manager API integration**
**Description**
Outlook Express now integrates a new set of application programming interfaces (APIs), called the Attachment Manager, to check e-mail attachments. This allows applications to eliminate custom code that performs similar safety checks and instead rely on this centrally-managed API set. The use of Attachment Manager provides a consistent user experience across all applications that check the security of an attachment.

**Why is this change important?**
It is important to have a more unified approach for attachment security across all Windows applications. This helps to ensure that users get a consistent experience with regard to the security check performed on attachments.

**What works differently?**

Apart from the consistent user experience, this feature does not provide any visible change to the user.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
There are several differences in functionality that a developer should be aware of.

When API names are provided, they are the Attachment Manager API. If the **Do not allow attachments to be saved or opened that could potentially be a virus** setting is disabled, Outlook Express calls `SetReferer()` and passes http://URL as a parameter. This is done so that the subsequent call to `CheckPolicy()` considers Outlook Express to be in the Internet Web content zone. Attachment Manager discriminates differently, depending on whether the caller is in the context of the Internet or Restricted security zones. The following sections provide overviews of different behaviors that the Attachment Manager API supports.

**Behavior when previewing a message that includes an attachment**
Before the preview area is rendered, `CheckPolicy()` is called to determine the state of the menu options associated with the attachment icon in the preview area header, and the corresponding actions as follows:

- If `CheckPolicy()` returns `E_Fail` (dangerous attachment), `S_OK`, or `S_False` (safe attachment), there is no change to the previous functionality of Outlook Express.
- Opening the attachment saves the file as a temporary file and then calls `Execute()` to execute the file instead of the currently used `ShellExecute()` call.
- If `Execute()` fails, subsequent user actions are handled by Attachment Manager.
- When the **Save Attachments** dialog box is opened, the list of attachments contains items that are enabled in the menu. Blocked attachments do not appear in the **Save Attachments** dialog box. When the user selects the destination folder and clicks **Save**, Outlook Express saves the files to the specified folder and then calls `Save()` on each of the saved files.

In the case of previewing mail with multiple attachments, `CheckPolicy()` is called on each of the attachments. Depending on whether the return value is `E_Fail`, or `S_OK`, or `S_False`, Outlook Express either disables or enables the attachment name in the menu.

In future implementations, `Save()` could fail if `CheckPolicy()` does not return `S_OK`. In this case, Outlook Express will display the error message "The following attachments were not saved because they could not be verified as being safe", followed by a list of failed files.

**Behavior when reading a message that includes an attachment**
Before the Outlook Express message window is rendered, `CheckPolicy()` is called for every attachment to determine which attachments are shown and which are blocked from access to the user.

- If `CheckPolicy()` returns `E_Fail` (dangerous attachment), `S_OK` or `S_False` (safe attachment), Outlook Express behaves just as it did in the past. Double-clicking the attachments that are displayed in the Attach area of the message window follows the exact same steps as described when executing attachments from the preview area.
- When the user clicks **Save As**, selects the destination folder and file name, and then clicks **Save**, Outlook Express saves the attachment in the specified folder and then calls `Save()` to sync.
- Selecting **Print** is similar to running the attachment, except that, instead of calling `Execute()` without any parameters, Outlook Express issues a call to `Execute("print")`. All other tasks, such as saving the file to a temporary file remain the same as when executing the attachment.
- If the **Do not allow attachments to be saved or opened that could potentially be a virus** setting is disabled, Outlook Express calls `SetReferer()` and passes http://URL as a parameter. The subsequent call to `CheckPolicy()` then considers Outlook Express to be in the Internet Web content zone.

**Behavior when moving a message that includes an attachment**
If the user moves an item to a location outside Outlook Express — for example, dragging a message containing an attachment to the desktop — Outlook Express performs these actions:

- Generates a temporary file with `HDROP`.

- Saves a temporary file
- Calls `Save()` on the temporary file

If it is successful, `HDROP` is made available

If it fails, `HDROP` is not made available and the drop target is disabled.

# Post-Setup Security Updates

Applies To: Windows Server 2003 with SP1

**What does Post-Setup Security Updates do?**
Post-Setup Security Updates is designed to help protect a new server installation from risk of infection between the time the server is first connected to the network and the application of the most recent security updates from Windows Update.

Post-Setup Security Updates is a user interface that appears the first time an administrator logs onto the new server and provides links for you to apply updates to your server and to configure automatic updates. Post-Setup Security Updates also informs the administrator that all inbound connections other than those specifically opened during setup or by policy settings, were blocked. If the administrator set exceptions to the firewall through Group Policy or by an unattended setup script, inbound connections assigned to these exceptions remain open.

Post-Setup Security Updates is not available from the **Start** menu and is only available under specific conditions as described later in this document.

| **Note** |
| --- |
| Post-Setup Security Updates does not appear when the server is being upgraded from the following operating systems:<br><br>- Windows NT Server 4.0 to Windows Server 2003 with Service Pack 1<br><br>- Windows 2000 Server to Windows Server 2003 with Service Pack 1<br><br>- Windows Server 2003 to Windows Server 2003 with Service Pack 1 |

**Who does this feature apply to?**
Post-Setup Security Updates applies to Windows server administrators who are performing a full installation of Windows Server 2003 that includes Service Pack 1 or later (such as a slip-stream version of Windows Server 2003 with Service Pack 1). This feature does not apply if either of the following statements is true:

- Windows Firewall is enabled or disabled using an unattended-setup script for operating system installation.
- Windows Firewall is enabled or disabled by application of Group Policy before Post-Setup Security Updates is displayed.

This feature does not apply if the administrator is updating an existing Windows Server 2003 operating system by adding a service pack or if the administrator is upgrading an existing Windows 2000 Server operating system to Windows Server 2003 with Service Pack 1.

**Why is this change important?**
Security updates that mitigate virus threats may have been released by Microsoft since the release of the operating system files being installed. If the new server is connected to the network and a firewall is not enabled, the server may be infected with a virus before the security updates can be downloaded and installed. Post-Setup Security Updates uses the Windows Firewall to mitigate this risk.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
Post-Setup Security Updates is a new feature in Windows Server 2003 Service Pack 1.

**Post-Setup Security Updates**
**Detailed description**
If Windows Server 2003 with Service Pack 1 or later is installed as a new installation and Windows Firewall is not explicitly enabled or disabled using an unattended-setup script during the installation or by application of Group Policy, Windows Firewall will be enabled by default on first startup and logon in order to allow the administrator to securely download and install updates from Windows Update, and the Windows Server Post-Setup Security Updates screen will be shown. The Post-Setup Security Updates screen informs you that all inbound connections other than those specifically opened during setup or by policy settings, were blocked.

Windows Firewall blocks all inbound connections with the following exceptions:

- If Remote Desktop was enabled using an unattended-setup script during installation, port 3389 is not blocked.

- If Group Policy is used to apply policy settings that do not enable or disable Windows Firewall, but define exceptions to the firewall, exceptions defined by the policy settings are not blocked.

Post-Setup Security Updates offers links to Windows Update to allow you to download any security updates released since this operating system version was released and, if you have not already done so, provides the opportunity for you to configure Automatic Updates to help protect this server in the future.

**What happens when Post-Setup Security Updates is closed?**
If Windows Update or any other configuration change causes a restart before you click the **Finish** button on Post-Setup Security Updates, it reopens the next time an administrator logs on to the server.

If you close Post-Setup Security Updates using ALT+F4 or Task Manager, no change is made to the configuration of Windows Firewall. The tests the server uses to determine whether Post-Setup Security Updates should be displayed run again the next time a user logs on.

When you click the **Finish** button on the **Post-Setup Security Updates** dialog box, a dialog box explaining the consequences of closing Post-Setup Security Updates is displayed. In order to provide correct information, the following steps are taken to determine the current status of Windows Firewall:

- If you made no changes to the Windows Firewall configuration since Post-Setup Security Updates appeared, a confirmation dialog box appears explaining that inbound connections will now be opened and giving you the opportunity to confirm that you are done with any post-setup security updates. When the action is confirmed, Post-Setup Security Updates attempts to disable Windows Firewall and stop and disable the Windows Firewall/Internet Connection Sharing service.

- If Windows Firewall is disabled successfully, a registry value is set to suppress Post-Setup Security Updates in the future. It is possible that Windows Firewall is disabled successfully, but the attempt to stop the Windows Firewall/Internet Connection Sharing service fails.

- If Windows Firewall settings cannot be changed, a dialog box appears explaining that no changes will be made to inbound connection settings. Post-Setup Security Updates is not suppressed and the tests to determine whether Post-Setup Security Updates should be displayed will be run again the next time a user logs on.

- If Windows Firewall was explicitly enabled or disabled since Post-Setup Security Updates appeared, a dialog box appears explaining that no changes will be made to inbound connection settings. These changes could have been made by the application of Group Policy settings or by opening the Windows Firewall control panel and clicking **OK** to confirm the firewall settings. A registry value is set to suppress Post-Setup Security Updates in the future.

- If the Windows Firewall/Internet Connection Sharing service was stopped or disabled since Post-Setup Security Updates appeared, a dialog box appears explaining that no changes will be made to inbound connection settings. A registry value is set to suppress Post-Setup Security Updates in the future.

- If Internet Connection Sharing was enabled since Post-Setup Security Updated appeared, a confirmation dialog box appears explaining that inbound connections will now be opened and giving you the opportunity to confirm that you are done with any post-setup security updates. When the action is confirmed, Post-Setup Security Updates attempts to disable Windows Firewall. The service shared between Windows Firewall and Internet Connection Sharing is not turned off.

- If the state of the firewall cannot be determined, a dialog box appears explaining that no changes will be made to inbound connection settings. Post-Setup Security Updates is not suppressed and the tests to determine whether Post-Setup Security Updates should be displayed will be run again the next time a user logs on.

| **Note** |
| --- |
| The text on Post-Setup Security Updates is not refreshed if the firewall status changes after the initial display. If the status of the firewall changes after it appears and before the **Finish** button is clicked, the text may state that all inbound connections are blocked when, in fact, they are not. When you click **Finish**, Post-Setup Security Updates checks the status of the firewall again before displaying a dialog box explaining any changes to be made on closure. |

**When will the Post-Setup Security Updates screen be displayed?**
Because this feature runs automatically and cannot be started on request, you can use the following information to determine whether your server will display the Post-Setup Security Updates feature.

The following tests are run to determine whether or not to display Post-Setup Security Updates.

| Test | Positive Result | Negative result |
|---|---|---|
| Is the logged-on user an administrator? | Continue on to the next test | Skip the remaining tests and do not display Post-Setup Security Updates. These tests run again the next time a user logs on. |
| Is this is a new installation of a version of Windows Server 2003 that includes Service Pack 1 or later (not an upgrade) | Continue on to the next test | Skip the remaining tests and do not display Post-Setup Security Updates. The registry value is set to suppress Post-Setup Security Updates in the future. |
| Has Post-Setup Security Updates been suppressed in the registry? | Skip the remaining tests and do not display Post-Setup Security Updates | Continue on to the next test |
| Is the Windows Firewall/Internet Connection Sharing service running? | Continue on to the next test. | Repeat this test for two minutes. If the service has still not started, do not display Post-Setup Security Updates. These tests are run again the next time a user logs on. |
| Has Windows Firewall been explicitly enabled or disabled for the current Windows Firewall profile?<br><br>(The firewall may have been enabled or disabled using an unattended-setup script at the time of installation or through the application of Group Policy settings or by opening the Windows Firewall control panel and clicking OK to confirm the firewall settings.) | Skip the remaining tests and do not display Post-Setup Security Updates. A registry value is set to suppress Post-Setup Security Updates in the future. | If Windows Firewall is enabled and the user did not enable it, display Post-Setup Security Updates.<br><br>If the status of Windows Firewall cannot be determined do not display Post-Setup Security Updates. These tests are run again the next time a user logs on. |

**What works differently?**
Manage Your Server is not automatically displayed until Post-Setup Security Updates closes.

Post-Setup Security Updates does not cause any applications to work differently.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
Windows Firewall (previously known as Internet Connection Firewall) was not enabled by default at the end of a new installation unless the administrator enabled it using an unattended-setup script. Under the circumstances described earlier in this document, Windows Firewall is now enabled automatically until Post-Setup Security Updates is finished.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
No new policy settings were created relating to Post-Setup Security Updates. The following value in the registry was added. This key does not affect firewall settings.

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| DontLaunchSecurityOOBE<br><br>(DWORD) | HKEY_LOCAL_MACHINE \SOFTWARE \Microsoft \Windows \Current Version \ServerOOBE \SecurityOOBE | N/A | This key does not exist by default. | The key can exist or not exist. If the key exists, Post-Setup Security Updates does not display. The numerical value of this setting is irrelevant. |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**

If you do new installations of a version of Windows Server 2003 that includes a service pack by using an unattended-setup script and you want to suppress Post-Setup Security Updates, it is recommended that you explicitly enable or disable Windows Firewall in either your setup script or by Group Policy. This change automatically suppresses Post-Setup Security Updates.

# Remote Access Quarantine

Applies To: Windows Server 2003 with SP1

**What does Remote Access Quarantine do?**
Remote Access Quarantine control provides network administrators the ability to validate the configuration of remote client computers before they are permitted to access the corporate network. Typical remote access connections only validate the credentials of the remote access user. Therefore, the computer used to connect to a private network can often access network resources even when its configuration does not comply with organization network policy. For example, a remote access user with valid credentials could connect to a network with a computer that does not have the following:

- The correct service pack or the latest security patches installed.
- The correct antivirus software and signature files installed.
- Routing disabled. A remote access client computer with routing enabled might pose a security risk, providing an opportunity for a malicious user to access corporate network resources through the client computer, which has an authenticated connection to the private network.
- Firewall software installed and active on the Internet interface.
- A password-protected screensaver with an adequate wait time.

Despite the efforts made within organizations to ensure that computers used internally comply with network policy, those used from employees' homes for remote access can still present significant risk to the network.

Remote Access Quarantine, a new feature in Windows Server 2003 Service Pack 1, delays normal remote access to a private network until the configuration of the remote access computer has been examined and validated by an administrator-configured script (included in the connection settings). When a remote access computer initiates a connection to a remote access server, the user is authenticated and the remote access computer is assigned an IP address. However, the connection is placed in quarantine mode, in which network access is limited. The administrator-configured script is run on the remote access computer. When the script notifies the remote access server that it has successfully run and the remote access computer complies with current network policies, quarantine mode access restrictions are removed and the remote access computer is granted normal remote access.

The quarantine restrictions placed on individual remote access connections can consist of the following:

- A set of quarantine packet filters that restrict the traffic that can be sent to and from a quarantined remote access client.
- A quarantine session timer that restricts the amount of time the client can remain connected in quarantine mode before being disconnected.

You can use either restriction, or both, as needed. The administrator also has the option to help the client to remedy the configuration, by say updating the signature file for the antivirus software, through the validation script.

The components required for this Remote Access Quarantine solution include the following:

- The Remote Access Quarantine Service (RQS or Listener) to be run on the routing and remote access (RRAS) server that listens for requests from the remote clients for removal of quarantine restrictions.
- A RADIUS server (or the RRAS server itself) where a quarantine policy can be defined for applying IP filters or session timeouts to remote connections.
- A configuration validation script that performs the validation checks to verify that the remote access client computer conforms to the minimum security guidelines required to access the corporate network.
- A Connection Manager profile configured to run the Remote Access Quarantine Client (RQC) as a Post-Connect action on the remote client computer. The Quarantine CM profile will update the validation scripts from an administrator-specified

share path and run the validation scripts. If the minimum requirements are verified by the scripts to have been met, RQC will notify RQS and request removal of the quarantine restrictions.

- Remote access clients configured to run the Remote Access Quarantine Client and the validation script (distributed through the Connection Manager Profile).

| ⚠Caution |
| --- |
| Remote Access Quarantine is not a security solution. It is designed to help prevent computers with unsafe configurations from connecting to a private network; not to protect a private network from malicious users who have obtained a valid set of credentials. |

**Who does this feature apply to?**
This feature applies to:

- Remote access servers, running Windows Server 2003 with Service Pack 1.
- Remote access client computers connecting to the corporate network from remote locations, running Windows 2000 or Windows XP.
- Network Administrators who want to validate configuration of client computers before they are allowed access to the corporate network.

**Why is this change important?**
Remote Access Quarantine provides network administrators with a mechanism to quarantine remote access clients by providing VPN access to limited parts of the private network, and allowing administrators to validate that the computer meets the minimum security requirements. After the computers have been verified to meet the guidelines for accessing the network, quarantine restrictions can be lifted allowing the client computers to have normal access to the network resources.

This mitigates the threat to a private or corporate network from vulnerable client computers that are at remote locations or are not domain-joined and thus outside the administrator's purview.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| Setting name | Location | Previous default value | Default value | Possible values |
| --- | --- | --- | --- | --- |
| AllowedSet, REG_MULTI_SZ | HKEY_LOCAL_MACHINE \System \CurrentControlSet \Services\Rqs | N/A | RASQuarantineConfigPassed | N/A |
| Port, REG_DWORD | HKEY_LOCAL_MACHINE \System \CurrentControlSet \Services\Rqs | N/A | Not set<br><br>When this key is not set the server listens for client notification on port 7250 | port number to listen to |
| Authenticator, REG_SZ | HKEY_LOCAL_MACHINE \System \CurrentControlSet \Services\Rqs | N/A | Not set | NULL |
| Verifier, REG_SZ | HKEY_LOCAL_MACHINE \System \CurrentControlSet \Services\Rqs | N/A | Not set | NULL |

# Remote Installation Services (RIS) for 64-bit Operating Systems

Applies To: Windows Server 2003 with SP1

**What does Remote Installation Services (RIS) do?**
The Remote Installation Services feature simplifies the task of installing an operating system on computers throughout an organization. It provides a mechanism for computers to connect to a network server during the initial boot process, while the server controls a local installation of Windows. This can be used either to install the correct configuration of the operating system on a new computer, or to restore a failed computer to a known operating system configuration.

**Who does this feature apply to?**
This feature applies to IT professionals who want to use RIS to deploy x64-based operating system images in an enterprise.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1**
**Support for x64 operating system images**
**Detailed description**
Remote Installation Services in Windows Server 2003 supported the installation of Windows Server 2003 Itanium-based editions using RISETUP. With Windows Server 2003 SP1, Remote Installation Services now supports the deployment of both RISETUP and RIPREP images for the x64 architecture.

There are two methods for adding operating system images to a Remote Installation Services (RIS) computer – RISETUP and RIPREP. RISETUP images are images built from the Windows CD media. When adding the images, a path to the Windows setup files, either on CD or on a network share, must be specified. RISETUP images are generally added by one of three methods:

- Using the **Remote Installation Services Setup** option from the **Start** menu of the RIS server. To start **Remote Installation Services Setup**, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Add a new OS image to this remote installation server**.

- Using the **Add a new installation image** option available from the **Properties** tab of the RIS server in the Active Directory Users and Computers Microsoft Management Console (MMC) snap-in.

- Running the `RISETUP /add` command from a command prompt on the RIS server.

RIPREP-generated images are also file system based images located on a RIS server. However, unlike RISETUP images, RIPREP images more closely resemble the hard disk images created using a third-party disk-imaging tool and the Windows System Preparation tool (Sysprep). RIPREP images are created by running the RIPREP wizard (Riprep.exe) on a master computer that has the operating system configuration, applications and settings, and desktop customizations that are to be captured and deployed to client computers in the organization.

With the changes in Windows Server 2003 SP1, RISETUP and RIPREP images created for x64-based operating systems can be deployed from a RIS server of any architecture – be that a 32-bit operating system, an x64-based operating system, or an Itanium-based operating system.

**Why is this change important?**
This change enables the rapid deployment of x64-based versions of Windows Server 2003 and Windows XP throughout an enterprise by leveraging Remote Installation Services (RIS) as the image deployment mechanism.

**What works differently?**
In order to support x64-based RIPREP and RISETUP images, several pieces of functionality were added to Remote Installation Services (RIS).

**RISETUP**
Beginning with Windows Server 2003 SP1, RISETUP now allows for the addition of x64-based images to the RIS server. Prior to Windows Server 2003 SP1, trying to add a RISETUP x64-based image would result in the following error message:

**A file that is needed to set up the installation image on the server was not found.**

**This may indicate that the image source is corrupt or that the source is not a valid Windows installation source.**

**Verify that the path you entered points to a valid Windows installation source.**

This message occurred because prior to Windows Server 2003 SP1 RISETUP did not include the x64-based image structure when examining the source media. RISETUP would find an i386 directory in the CD image source; however, RISETUP would not

find all of the files defined for the source. Therefore, the program determined that the image source was missing files and displayed the appropriate error condition.

Changes to RISETUP were also necessary to populate the *****RIS_Server***\RemInst\Admin\amd64** folder with the x64-based version of RIPREP. The x64-based version of RIPREP only ships on x64-based editions of Windows (both client and server). However, it is possible to deploy x64-based images from x86-based and Itanium-based Windows Server 2003 SP1 RIS servers. In these cases, the x64-based RIPREP files would not natively be on the x86-based and Itanium-based servers.

Each RIPREP image requires a supporting RISETUP image. So, before a RIPREP image of an x64-based version of Windows Server 2003 SP1 can be made, a RISETUP image of an x64-based version of Windows Server 2003 SP1 must first be loaded to the RIS server. On the initial RISETUP load of the x64-based image, the necessary 64-bit files for RIPREP – Riprep.exe, Riprep.inf, and Setupcl.exe – are copied from the x64-based RISETUP image location (either flat image or CD) and placed in the **\RemoteInstall\Admin\amd64** folder. In addition, a file version checking mechanism has been put in place to ensure that the most up-to-date versions of Riprep.exe, Riprep.inf, and Setupcl.exe are in place on the RIS server. If the file versions in the copied x64-based RISETUP image are newer than the existing x64-based versions on the RIS server, the RIS server versions will be updated to contain the latest available versions of the files. This is the desired behavior since Riprep.exe, Riprep.inf, and Setupcl.exe are backwards compatible. If the existing x64-based versions in the copied x64-based RISETUP image are the same as or older than the existing x64-based version on the RIS server, the files on the RIS server will remain untouched.

**Client Installation Wizard**

Remote Installation Services (RIS) provides a set of Client Installation Wizard (CIW) screens that prompt a user through the installation of an operating system. These screens are maintained as simple text files in an OS Chooser Markup Language (OSCML) format and stored with an .osc extension.

You can customize and tailor these screens to include Help Desk phone numbers, additional contact information, or any other additional information using Hypertext Markup Language (HTML) 2.0. The Client Installation Wizard screens are kept in the **RemoteInstall\OSChooser\Language** directory.

Windows Server 2003 SP1 includes changes to the Client Installation Wizard (CIW) screens to allow for the selection of 32-bit or 64-bit operating systems when both are available as installation options.

A new .osc screen, x8664.osc, was added. This new screen, in conjunction with its associated registry settings, allows the system administrator to restrict or filter operating system selection based on architecture for x64-based RIS clients.

With the x64 architecture, computers can run either 32-bit or 64-bit operating systems. To assist in the selection process, the new .osc screen, x8664.osc, is placed in the **RemoteInstall\OSChooser\Language** directory upon copy of the first Windows Server 2003 SP1 RISETUP image. If the Windows Server 2003 SP1 RISETUP image is the first image to be uploaded to the RIS server, the new x8664.osc screen will be copied by default. If there are existing images on the RIS server at the time the first Windows Server 2003 SP1 image is added, the installer must choose the option to overwrite (or backup and overwrite) the .osc screens during the installation to get the new screen.

| **Note** |
| --- |
| If custom actions or automations exist in the .osc screen flow, choosing to overwrite the .osc screens upon RISETUP of an image may cause those customizations to be lost. |

The x8664.osc screen is used to determine whether the operating system choices displayed to the end-user will be 32-bit x86-based or 64-bit x64-based when the booting client computer is x64-based. The behavior is controlled using manual selection of the appropriate installation choice on x8664.osc. Alternatively, a new registry setting, `DefaultPlatformforX8664`, found at `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\BINLSVC\Parameters`, may be used to force all x64-based clients to see only one architecture of images, x86-based or x64-based. For example, if the registry value is set to `i386`, only i386 operating system images will be displayed in OSChoice.osc. If the registry value is set to `amd64`, only x64-based operating system images will be displayed in OSChoice.osc. If the registry value is not set, then the default behavior will cause the x8664.osc screen to prompt for user input. At that point the user can choose one of two available choices:

- **Install Microsoft Windows 32-bit Edition**
- **Install Microsoft Windows 64-bit Edition**

Choosing the first option limits installation image choices to only 32-bit operating systems. If only one 32-bit operating system image exists, the CIW will proceed directly on to warning.osc. Choosing the second option limits installation image choices to only 64-bit operating systems. If only one 64-bit operating system image exists, the CIW will proceed directly on to warning.osc.

Some other points of clarification regarding the new x8664.osc screen behavior:

- The x8664.osc screen will only be seen by x64-based client computers. Computers running x86-based and Itanium-based operating systems will not see the new screen.

- If no Windows Server 2003 SP1 RISETUP images (or Windows XP Professional x64 Edition images) exist on the RIS server, the new behavior will not be in place. This is because the new x8664.osc screen is not copied to the server until the first upload of a Windows Server 2003 SP1 (or Windows XP Professional x64 Edition) RISETUP image.

- If the new x8664.osc screen was not copied on upload of the first x64 RISETUP image (for example, if the Administrator chose to keep the current .osc screens and not copy the new .osc screens on x64-based RISETUP image creation), the new functionality will not be in place. To obtain the new functionality to restrict x64-based RIS client computers to only view x86-based 32-bit or x64-based 64-bit operating system images, the new .osc screens must be in place and the registry value must be configured appropriately.

- A third option, **Install Default Windows**, can be seen in the x8664.osc screen source. This option allows the x8664.osc screen to be automatically processed with no user interaction. This option will be used in the following situations:

    - If the booting client computer is not x64-based. If the client computer is x86-based or Itanium-based, installation using the Client Installation Wizard will continue automatically and the user will not be prompted for input in x8664.osc.

    - If a Windows Server 2003 SP1 x86-based or Itanium-based RISETUP image is placed on a RIS server that is running Windows Server 2003 without Service Pack 1. In this case, it is possible that the new x8664.osc will be placed on a Windows Server 2003 RIS server if the option to replace .osc screens was chosen upon image upload. Since the RIS server has not been updated it does not have the ability to process the new **Install 32-bit Windows** and **Install 64-bit Windows** options in x8664.osc. Since the default option is the only menu choice populated, it is processed and the screen is bypassed.

**Maintenance and Troubleshooting menu**

64-bit maintenance and troubleshooting tools can be provided to users through the Client Installation Wizard (CIW). To do this, the existing tools.osc screen was repurposed and a new CIW screen, Tlchoice.osc, was implemented.

There are two paths that can be taken when choosing an operating system image to deploy from within the Client Installation Wizard. The first path involves selection of either **Automatic Setup** or **Custom Setup** from the Choice.osc screen. When choosing either of these options, a computer account, if one does not already exist, will be created in Active Directory. In the former case, Remote Installation Services creates the account on behalf of the user based on policy as stored in Active Directory. In the latter case, the user may choose both the computer name and location (for example, Organizational Unit) when creating the computer account. The second path involves selection of the **Maintenance and Troubleshooting** menu option from the Choice.osc screen. This installation method differs from the first in that no computer account will be created. The most common use of starting an operating system from the **Maintenance and Troubleshooting** menu option is starting the Windows Preinstallation Environment (Windows PE) to aid in operating system deployment. Because Windows PE is usually an "interim" operating system – used to start a computer temporarily before applying an operating system image – creating a computer account in Active Directory at this point is not useful.

There are two ways that Windows PE images can be made available from the **Maintenance and Troubleshooting** menu option on the Choice.osc screen:

- Setting `'Imagetype=WinPE'` in the `[OSChooser]` section of Ristndrd.sif answer file.

- Creating a \Tools folder at the same level as \Images (for example, \RemoteInstall\Setup*Language*\Tools) and placing the folder structure containing the Windows PE image into the \Tools folder.

X64-based computers can run either 32-bit or 64-bit maintenance and troubleshooting tools. To assist the user in the selection process, the Tools.osc screen has been updated to present the user a choice of two options:

- **Display 32-bit Tools**

- **Display 64-bit Tools**

Choosing the first option displays only 32-bit tools in the new Tlchoice.osc screen. Selecting the second option displays only 64-bit tools in the Tlchoice.osc screen. Functionality that was previously in the Tools.osc screen has been moved to the Tlchoice.osc screen.

Some points of clarification regarding the new Tools.osc and Tlchoice.osc behavior:

- The Tools.osc screen will only be seen by x64-based clients. X86-based and Itanium-based clients will not see the screen.

- If no Windows Server 2003 SP1 RISETUP images (or Windows XP Professional x64 Edition images) exist on the RIS server, the new behavior will not be in place. This is because the new Tlchoice.osc screen and the updated Tools.osc screen will not be copied to the server until the first upload of Windows Server 2003 SP1 (or Windows XP Professional x64 Edition images) RISETUP image.

- If the new Tlchoice.osc screen and updated Tools.osc screen were not copied on upload of the first x64 RISETUP image (for example, the administrator chose to keep the current .osc screens and not copy the new .osc screens on x64 RISETUP image creation), the new functionality will not be in place. To obtain the new functionality to restrict x64 RIS client machines to only view x86 32-bit or x64 64-bit maintenance and troubleshooting tools, the new .osc screens must be in place and the registry value must be configured appropriately.

- The same registry value that controls the x8664.osc behavior in the **Automatic Setup** and **Custom Setup** choices, `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\ BINLSVC\Parameters\DefaultPlatformForX8664 (REG_SZ)`, also controls the **Maintenance and Troubleshooting** behavior.

In some situations the Tools.osc screen will be automatically processed with no user interaction required. This is accomplished through the third option **Display Default Tools** that can be seen in the Tools.osc screen source. This option is used in the following situations:

- The booting client computer is not x64-based. If the client computer is x86-based or Itanium-based, installation via the Client Installation Wizard will continue automatically and the user will not be prompted for input in Tools.osc.

- A Windows Server 2003 SP1 x86 or Itanium RISETUP image is placed on a Windows Server 2003 RTM RIS server. In this case, it is possible that the new Tools.osc is placed on a RIS server running Windows Server 2003 RTM if the option to replace .osc screens was chosen upon image upload of a Windows Server 2003 SP1 image. Because the RIS server program has not been updated to Windows Server 2003 Service Pack1, the RIS server does not have the logic to process the new **Display 32-bit Tools** and **Display 64-bit Tools** options in the Tools.osc screen. Because the default option is the only menu choice pre-populated, it is processed and the screen is bypassed.

| **Note** |
| --- |
| As a consequence of the changes in Windows Server 2003 SP1, the screen menu order for the **Maintenance and Troubleshooting** menu option has changed as follows: |

1. Choice.osc

2. Tools.osc

3. TLchoice.osc

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| Setting name | Location | Previous default value | Default value | Possible values |
| --- | --- | --- | --- | --- |

| | | | | |
|---|---|---|---|---|
| DefaultPlatformForX8664 | HKLM\System \CurrentControlSet \Services\BINLSVC \Parameters | N/A | Not set | Not set<br><br>(Platform type to be selected by users in x8664.osc)<br><br>i386<br><br>(Only display x86-based images in OSChoice.osc)<br><br>amd64<br><br>(Only display x64-based images in OSChoice.osc) |

# Resultant Set of Policy (RSoP)

Applies To: Windows Server 2003 with SP1

**What does Resultant Set of Policy do?**
Group Policy Resultant Set of Policy (RSoP) reports Group Policy settings that are applied to a user or computer. Group Policy Results in Group Policy Management Console (GPMC) requests RSoP data from a target computer and presents this in a report in HTML format. Group Policy Modeling requests the same type of information, but the data reported is from a service that simulates RSoP for a combination of computer and user. This simulation is performed on a domain controller running Windows Server 2003 and is then returned to the computer running GPMC for presentation. Finally, the RSoP Microsoft Management Console (MMC) provides an alternative way to display this information, although Group Policy Results is generally the preferred method.

**Who does this feature apply to?**
Group Policy administrators in an Active Directory domain environment. In addition, an IT professional who needs to plan or validate the application of Group Policy might be interested in RSoP.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**RSoP Use with Windows Firewall Enabled**
**Detailed description**
In Windows XP Service Pack 2 (SP2), Windows Firewall is enabled by default. Incoming requests against unopened ports—as opposed to responses to requests originated from the computer—are blocked by Windows Firewall. In Windows Server 2003 Service Pack 1 (SP1), Windows Firewall is not enabled by default.

If you elect to use Windows Firewall, you should be aware of the impact on its use on RSoP across the network.

For more information about Windows Firewall, see "Windows Firewall," in this document.

**Why is this change important?**
Enabling a firewall, such as Windows Firewall, provides more protection from many network-based attacks. For example, if Windows Firewall had been enabled the recent MSBlaster attack would have been greatly reduced in impact, regardless of whether users were up-to-date with patches.

**What works differently?**
There are two important changes to RSoP in Windows Server 2003 SP1.

- After Windows Firewall is installed on a computer, remote access to RSoP data no longer works from that target computer.
- If Windows Firewall is enabled, when GPMC is run for the purpose of using Group Policy Results or Group Policy Modeling to retrieve RSoP data it will be unable to retrieve this data.

**How do I resolve these issues?**
The following table summarizes the changes necessary to fully support remote RSoP tasks when running Windows XP SP2 or Windows Server 2003 SP1 with Windows Firewall enabled. Please see the sections below for further details.

| Task | Target Computer | Administrative Computer |
|---|---|---|
| Generate Group Policy results | Enable **Windows Firewall Allow remote administration exception** Group Policy setting.<br><br>This Group Policy setting is located in Computer Configuration \Administrative Templates\Network \Network Connections\Windows Firewall\[Domain \| Standard] Profile\. | GPMC with SP1.<br><br>No action required.<br><br>RSoP snap-in.<br><br>Enable Windows Firewall: Define program exceptions. Configure the program exception list with the full path to Unsecapp.exe so that the WMI messages can be transmitted. In a default installation Unsecapp.exe is located in the C:\Windows\System32\Wbem folder.<br><br>Enable **Windows Firewall: Define port exception policy** to open Port 135. |

| | | |
|---|---|---|
| Delegate access to Group Policy results | Enable **Windows Firewall: Allow remote administration exception** Group Policy setting.<br><br>Configure the following DCOM security settings:<br><br>DCOM: Machine access restrictions...<br><br>DCOM: Machine launch restrictions...<br><br>These policy settings are located in Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options. | No changes necessary |
| Remotely edit a Local Group Policy object | Enable **Windows Firewall: Allow file and printer sharing administration exception** policy setting.<br><br>This policy setting is located in Computer Configuration \Administrative Templates\Network \Network Connections\Windows Firewall\[Domain \| Standard] Profile\. | No changes necessary. |

**Administering Remote RSoP with GPMC SP1**

The initial release of GPMC used a callback mechanism when waiting for the results of a Group Policy Results or Modeling request. The administrative computer must be "listening" for this response. If Windows Firewall is enabled, Windows will block these responses. Although opening the appropriate ports can address this issue, using the updated Group Policy Management Console (GPMC) with Service Pack 1 completely removes the use of the callback mechanism. We recommend that you install GPMC with Windows Server 2003 Service Pack 1, because this allows Group Policy Results and Modeling to continue to work without opening up ports on the administrative computer. To install GPMC with Windows Server 2003 Service Pack 1, see "Group Policy Management Console with Service Pack 1" on the Microsoft Download Center at http://go.microsoft.com/fwlink/?LinkId=23529.

In order to administer RSoP remotely, you must enable the **Windows Firewall: Allow remote administration exception** Group Policy setting on target computers.

**Administering Remote RSoP with the RSoP MMC snap-in**

In order to administer RSoP remotely using the RSoP MMC snap-in, the target computer must listen on the appropriate network ports to ensure that incoming RSoP requests can be serviced. This can be managed through Group Policy using the following policy settings:

- Enable the **Windows Firewall: Define program exceptions** Group Policy setting to permit Unsecapp.exe. Make sure you enter the full path to Unsecapp.exe.

- Enable the **Windows Firewall: Define port exception** Group Policy setting and open Port 135. Click **Show** and enter **135:TCP:*:Enabled:135**.

| **Caution** |
|---|
| Enabling the **Windows Firewall: Define port exception** Group Policy setting may also allow unwanted data to be accepted on this port. Be sure to fully review this Group Policy setting before enabling it in your environment.<br><br>Enabling this policy setting is not necessary if the **Windows Firewall: Allow remote administration exception** Group Policy setting is enabled on the administrative computer. |

**Delegating access to Group Policy Results**

By default, Group Policy Results and the RSoP snap-in can only be used remotely when the person originating the request is a local administrator on the target computer. Beginning in Windows Server 2003, a delegation model is available that allows this right to be delegated to users who are not Administrators on the target computer. This is a common scenario when help desk personnel require access to computers without being made Administrators on those computers.

In Windows XP Service Pack 2 and Windows Server 2003 Service Pack 1, the security model for DCOM authentication (on which RSoP relies) has been strengthened. Even if RSoP delegation has been configured correctly, this strengthening prevents local non-administrators from retrieving RSoP information from a target computer. Note that this issue does not impact Group Policy Modeling, since the request for simulated RSoP data is made against a domain controller running Windows Server 2003, which, by definition, is not running Windows XP.

You can manage the list of users and groups associated with DCOM authentication through Group Policy. To allow continued use of delegated RSoP, users to whom you want to grant this right must also have access through the DCOM authentication model. For more information about the security changes to DCOM in Windows Server 2003 Service Pack 1, see "DCOM Security Enhancements" earlier in this document.

Use the following procedure to delegate access to Group Policy Results:

**To delegate access to Group Policy Results**

1. Enable the **Windows Firewall: Allow remote administration exception** Group Policy setting on target computers.
2. Set the following DCOM security policy settings on target computers. (They are located in Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options.)

   **DCOM: Machine access restrictions in Security Descriptor Definition Language (SDDL) syntax**

   **DCOM: Machine launch restrictions in Security Descriptor Definition Language (SDDL) syntax**
3. Right-click the Group Policy object, and then click **Properties**.
4. Click **Edit Security**. **Access Permission opens**.
5. Click **Add**, and then **Select Users, Computers, or Groups opens**.
6. Enter the desired delegation targets.

**Remotely editing a local Group Policy object**

In order to remotely edit a local Group Policy object on a target computer that has Windows Firewall enabled, you need to enable the following policy setting: **Windows Firewall: Allow file and printer sharing administration**.

The policy setting is located in Computer Configuration\Administrative Templates\Network\Network Connections\Windows Firewall\[Domain|Standard] Profile\.

# RPC Interface Restriction

Applies To: Windows Server 2003 with SP1

**What does RPC Interface Restriction do?**
A number of changes have been made in the Remote Procedure Call (RPC) service for Windows Server 2003 with Service Pack 1 that help make RPC interfaces secure by default and reduce the attack surface of Windows Server 2003. The most significant change is the addition of the `RestrictRemoteClients` registry key. This key enables you to modify the behavior of all RPC interfaces on the system and can be used to eliminate remote anonymous access to RPC interfaces on the system, with some exceptions. Additional changes include the `EnableAuthEpResolution` registry key and three new interface registration flags.

**Who does this feature apply to?**
This feature applies to RPC application developers. System administrators should also be familiar with this change to RPC.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**RestrictRemoteClients Registry Key**
**Detailed description**
When an interface is registered using **RpcServerRegisterIf**, RPC allows the server application to restrict access to the interface, typically through a security callback. The `RestrictRemoteClients` registry key forces RPC to perform additional security checks for all interfaces, even if the interface has no registered security callback.

RPC clients that use the named pipe protocol sequence (**ncacn_np**) are exempt from all restrictions discussed in this section. The named pipe protocol sequence cannot be restricted due to several significant backwards compatibility issues.

The `RestrictRemoteClients` registry key can have one of three DWORD values that can also be controlled programmatically in rpcdce.h. If the key is not present, it is equivalent to setting the DWORD=0 value (RPC_RESTRICT_REMOTE_CLIENT_NONE) for server SKUs and DWORD=1 value (RPC_RESTRICT_REMOTE_CLIENT_AUTH) for client SKUs.

The following table provides a reference to the `RestrictRemoteClients` registry key:

| Type | Description |
|---|---|
| Key name | `RestrictRemoteClients` |
| Type | DWORD |
| Configurable through User Interface | Yes. This key can be configured using the Group Policy Object Editor. |
| Key values | 0 (Default for server SKUs)<br><br>This value is the default value in Windows Server 2003 Service Pack 1 for Server SKUs. It causes the system to bypass the RPC interface restriction. This corresponds to the value RPC_RESTRICT_REMOTE_CLIENT_NONE in rpcdce.h. It is entirely the responsibility of the server application to impose appropriate RPC restrictions. This setting is equivalent to the behavior in previous versions of Windows.<br><br>1<br><br>This value is the default value in Windows XP Service Pack 2 and client SKUs built from the SRSP1 code base. It restricts access to all RPC interfaces. All remote anonymous calls are rejected by the RPC runtime except calls coming in through named pipes (ncacn_np). This corresponds to the value RPC_RESTRICT_REMOTE_CLIENT_DEFAULT in rpcdce.h. If an interface registers a security callback and provides the RPC_IF_ALLOW_CALLBACKS_WITH_NO_AUTH flag, then this restriction does not apply to that interface.<br><br>2<br><br>All remote anonymous calls are rejected by the RPC runtime with no exemptions. This corresponds to the value RPC_RESTRICT_REMOTE_CLIENT_HIGH in rpcdce.h. When this value is set, a system cannot receive remote anonymous calls using RPC. |

**Why is this change important? What threats does it help mitigate?**

It is much more difficult to attack an interface if you require calls to perform authentication, even a relatively low level of authentication. Enabling `RestrictRemoteClients` can be a particularly useful mitigation against worms that rely on exploitable buffer overruns that can be invoked remotely through anonymous connections.

**What works differently?**
If your RPC application expects to receive calls from remote anonymous RPC clients, using this feature might not allow your application to run correctly. As a result, applications that use DCOM might not work correctly if this value is set.

Because secure RPC calls over connectionless protocols such as User Datagram Protocol (UDP) and Internetwork Packet Exchange (IPX) (`ncadq_ip_udp` and `ncadg_ipx`) use a lower level of security than calls over connection-oriented protocols, these calls are always considered nonsecure for the purposes of this policy. As a result, RPC calls over connectionless protocols will fail if this key is enabled in Windows Server 2003 with Service Pack 1.

To allow RPC client calls using connectionless protocols, keep the `RestrictRemoteClients` value set to 0 (RPC_RESTRICT_REMOTE_CLIENT_NONE), the default setting for Windows Server 2003 with Service Pack 1.

**How do I resolve these issues?**
There are the following options that may allow you to use `RestrictRemoteClients` on your server:

- Require your RPC clients to use RPC security when contacting your server application. This is the best method to mitigate security threats.

- Exempt your interface from requiring authentication by setting the RPC_IF_ALLOW_CALLBACKS_WITH_NO_AUTH flag during interface registration. This configures RPC to allow anonymous connections to only your application's interface.

**EnableAuthEpResolution Registry Key**
**Detailed description**
An RPC interface that is remotely and anonymously accessible and is registered by default on Windows Server 2003 presents a significant attack surface. RPC itself must register such an interface to provide endpoint resolution for calls using dynamic endpoints.

If you enable the `RestrictRemoteClients` flag, the RPC Endpoint Mapper interface will not be accessible anonymously. This is a significant security improvement, but it changes the task of resolving an endpoint. Currently, an RPC client that attempts to make a call using a dynamic endpoint will first query the RPC Endpoint Mapper on the server to determine what endpoint it should connect to. This query is performed anonymously, even if the RPC client call itself is performed using RPC security. Anonymous calls to the RPC Endpoint Mapper interface will fail on Windows Server 2003 with Service Pack 1 if the `RestrictRemoteClients` key is set to 1 or higher . This makes it necessary to modify the RPC client runtime to perform an authenticated query to the Endpoint Mapper. If the `EnableAuthEpResolution` key is set, the RPC client runtime will use NTLM to authenticate to the endpoint mapper. This authenticated query will take place only if the actual RPC client call uses RPC authentication.

**Why is this change important?**
This change enables an RPC client to make a call to an RPC server that has registered a dynamic endpoint on a system running Windows Server 2003 with Service Pack 1 with `RestrictRemoteClients` enabled. The client computer must set this registry key so that it will perform an authenticated query to the RPC Endpoint Mapper.

**What works differently?**
This registry key is used to enable the specific scenario described in the previous section. When this key is turned on, all RPC Endpoint Mapper queries that are performed on behalf of authenticated calls are performed using NTLM authentication.

This setting can also be specified using the Group Policy Object Editor to configure the Group Policy object located in Computer Configuration\Administrative Templates\System\Remote Procedure Call\RPC Endpoint Mapper Client Authentication.

**New RPC Interface Registration Flags**
**Detailed description**
Three new interface registration flags have been created to make it easier for an application developer to secure an RPC interface.

- RPC_IF_ALLOW_CALLBACKS_WITH_NO_AUTH

  When this flag is registered, the RPC runtime invokes the registered security callback for all calls, regardless of the call security settings. Without this flag, RPC rejects all unauthenticated calls before they reach the security callback. This flag works only when a security callback is registered.

- RPC_IF_SEC_NO_CACHE

  A security callback is registered for an interface in order to restrict access to that interface. The typical security callback impersonates the client to determine whether the client has sufficient rights to make a call to the interface. If a particular client identity passes a security callback once, it usually passes the same security callback every time.

  The RPC runtime takes advantage of this pattern by remembering when an individual client identity passes a security callback and skips the security callback for subsequent calls by that client to the same interface. This feature is called security callback caching and has existed since the Microsoft Windows 2000 family of operating systems. For Windows Server 2003 with Service Pack 1, you can use the RPC_IF_SEC_NO_CACHE flag to disable security callback caching for a given interface. This is useful if the security check might change, possibly rejecting a client identity that was previously permitted.

- RPC_IF_LOCAL_ONLY

  When an interface is registered with this flag, RPC rejects calls made by remote RPC clients. In addition, local calls over all `ncadg_*` protocol sequences and all `ncacn_*` protocol sequences (except for named pipes, using `ncacn_np`) are also rejected. If a call is made on`ncacn_np`, RPC allows the call only if it does not come from SRV, which filters out all remote calls. `Ncalrpc` calls are always allowed through.

**Why is this change important?**
This change provides RPC application developers with additional security tools to help secure their RPC interface.

**What works differently?**
These flags will not change any existing Windows Server 2003–based application or cause it not to run correctly. The use of these new flags is at the discretion of the application developer.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**RPC Settings**

| Setting name | Location | Default value | Possible values |
|---|---|---|---|
| RestrictRemoteClients | HKEY_LOCAL_MACHINE\ SOFTWARE\Policies\ Microsoft\Windows NT\RPC<br><br>-or-<br><br>(Group Policy object)<br><br>Computer Configuration\ Administrative Templates\System\Remote Procedure Call\Restrictions for Unauthenticated RPC Clients | 0 | 0 – None<br><br>1 – XP SP2 and SRSP1 client SKUs Default<br><br>2 – High |
| EnableAuthEpResolution | HKEY_LOCAL_MACHINE\ SOFTWARE\Policies \Microsoft\Windows NT\RPC<br><br>-or-<br><br>(Group Policy object)<br><br>Computer Configuration\ Administrative Templates\System\Remote Procedure Call\RPC Endpoint Mapper Client Authentication | 0 | 0 – Disabled<br><br>1 – Enabled |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
You may need to change your code to work with Windows Server 2003 Service Pack 1 if you decide to enable `RestrictRemoteClients`. For more information about application changes that might be required, see the previous sections on `RestrictRemoteClients` and `EnableAuthEpResolution`.

# Security Configuration Wizard in Windows Server 2003 Service Pack 1

Applies To: Windows Server 2003 with SP1

**What does Security Configuration Wizard do?**
Security Configuration Wizard (SCW) is a new feature in Windows Server 2003 with Service Pack 1 that provides guided attack surface reduction for your servers. SCW is highly recommended for creating security policies for servers based on their roles. SCW includes the following features:

- Remote or local role-based lockdown ensures that all necessary services are turned on, minimizing risk of breakage.
- Any services not specifically needed by the role(s) performed by the target system can be disabled.
- Firewall and IPsec configuration ensures that the server presents the minimum possible attack profile based on the needs of the selected role(s).
- Automated selection of key security settings based on a guided wizard to minimize compatibility problems and maximize security.
- Selection of appropriate audit settings.
- Inclusion of standard security templates for detailed customization of security policy.
- Integration with Group Policy for Active Directory-based deployment of security policies.
- Fully functional and scriptable command line interface for automated deployment to multiple servers across the network.
- Rollback of policies for testing and troubleshooting purposes.
- Declarative extensibility of role knowledge base to allow authoring of new roles.

When you run SCW you will be asked a series of questions to determine the functional requirements of your server. Any functionality that is not required based on your selections can be disabled automatically.

**Who does this feature apply to?**
SCW can be used with any system running Windows Server 2003 with Service Pack 1 and in any network configuration. SCW will be of interest to:

- Security professionals responsible for authoring corporate security policies.
- Information technology (IT) professionals responsible for deploying, configuring, and managing servers.
- Developers of server-based applications who want their applications to be managed with SCW.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Security Configuration Wizard**
**Detailed description**
Security Configuration Wizard uses a roles-based metaphor driven by an extensible XML knowledge base that defines the services, ports, and other functional requirements for almost 200 different system roles, including roles for Windows Server System applications such as Microsoft ISA Server and SQL Server.

SCW uses this extensible XML knowledge base to perform role discovery, solicit user input, and author security policies that disable services, block ports, modify registry values, and configure audit settings. Even ports that are left open can be restricted to specific subnets or systems using Internet Protocol security (IPsec). SCW also allows you to roll back previously applied policy settings. It includes a command line tool you use with administrative scripts and other administrative utilities to apply a

security configuration and perform compliance analysis on groups of servers in your organization. SCW also integrates with Active Directory to support deployment of SCW-generated policy settings through Group Policy.

**Summary of SCW security coverage**
Security Configuration Wizard allows users to easily:

- Disable unnecessary services.
- Protect Internet Information Services (IIS).

| **Note** |
| --- |
| IIS policies cannot be deployed with Group Policy since Group Policy does not currently configure IIS. If a policy containing IIS settings is converted to a Group Policy object the IIS settings are lost. |

- Block unused ports, including support for multi-homed scenarios.
- Secure ports that are left open using IPsec.
- Reduce protocol exposure for Lightweight Directory Access Protocol (LDAP), LAN Manager, and server message block (SMB).
- Configure audit settings with a high signal-to-noise ratio.
- Import Windows security templates for coverage of settings that are not configured by the wizard.

**Summary of SCW operational features**
In addition to roles-based guided security policy authoring, SCW also supports:

- **Rollback**. Enables you to return your server to the state it was in before you applied the SCW security policy.
- **Analysis**. Enables you to check that servers are in compliance with expected policies.
- **Remote** configuration and analysis support. All SCW functionality can be performed on both local and remote systems.
- **Command line support**. A command-line tool is provided for scripting use.
- **Active Directory integration**. Supports deploying SCW policies using Group Policy.
- **Editing**. A security policy created using SCW can be modified when necessary, such as when machines are repurposed or when a system configured with a particular policy does not behave as expected.
- Reports. Provides the ability to view the data stored in the knowledge base, policies, and analysis results XML files.

**Why is this change important?**
Attack surface reduction is a fundamental security best practice, yet it is often difficult for server administrators to find the time to properly secure, test, and deploy a Windows server without breaking required functionality, which can lead to vulnerable servers within an organization.

Security configuration guides (such as the Windows Server 2003 Security Guide on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=14845) provide general settings that support a broad range of systems but that do not provide an optimal security versus functionality tradeoff for a specific class of systems. SCW automates the lockdown process of systems providing specific functionality and is fully tested and supported by Microsoft. Reducing the attack surface of Windows servers can minimize the number of servers that need to be immediately patched when a vulnerability is discovered, as a given vulnerability will not necessarily be present or exploitable in all configurations.

**What works differently?**

Today, Windows administrators typically define security policies using the Security Configuration Editor on their own, in conjunction with documented guidance, or with existing security templates designed for specific scenarios. In contrast, Security Configuration Wizard is an authoring tool that allows you to create a custom security policy by answering a series of questions. For settings that are not configured by the wizard, SCW allows the administrator to import existing security templates.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
No, but SCW is extensible so that developers can create their own SCW role definitions for their own applications. A whitepaper about how to extend the SCW knowledge base will be available when Windows Server 2003 Service Pack 1 is released.

**What do I need to change in my environment to deploy Windows Server 2003 Service Pack 1?**
Nothing, however SCW can be used during the deployment process to ensure servers are deployed with the expected security policy.

If unattended setup is used to deploy servers, consider the following:

- Install the SCW optional component automatically during unattended setup by adding the following entry to the `[Components]` section of unattend.txt: `SCW = On`.
- To apply an SCW policy during the unattended installation, also carry out the following steps:
  - Create the policy file on a server that already has SCW installed.
  - Either create a Cmdlines.txt file or modify the existing one so that it has a `[Commands]` section containing the following line: `scwcmd configure /p:SCWPolicy.xml`
  - Copy the Cmdlines.txt file and the previously created policy file (SCWPolicy.xml in this case) to the $OEM$ directory.
- If an imaging solution is used to deploy servers, you can apply an SCW on the reference machine that will be imaged prior to creating the image.

For additional information on Security Configuration Wizard go to the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=45503.

# Setup

Applies To: Windows Server 2003 with SP1

**What does Setup do?**
Setup is the program that installs and configures the operating system on your computer. When you originally install Windows Server 2003, Setup installs and configures the operating system to work properly with the computer.

Often, any program that is used to install and configure software programs is called Setup. However, in Windows Server 2003, there are two different programs that install and configure programs after the operating system is operational. When Windows Server 2003 Service Pack 1 (SP1) or any other software update is installed on Windows Server 2003, the Package Installer for Windows updates and changes the existing installation of Windows Server 2003. If an application, such as Microsoft Office, is installed, configured, or upgraded, then Windows Installer is the program that is responsible for that task.

**Who does this feature apply to?**
All users and administrators who install or deploy Windows Server 2003 Service Pack 1 should become familiar with the changes in this feature.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Package Installer for Windows**
**Detailed description**
The Package Installer for Windows (Update.exe) installs Windows Server 2003 Service Pack 1. This is different installation technology from what is used to install the complete operating system. For a complete discussion of the Package Installer, see "The Package Installer for Windows and Windows Components" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=26004.

Changes in Package Installer in Windows Server 2003 Service Pack 1 include:

- Command line switches

  Microsoft has moved to a standard for Installer switches, which will be available later this year. There are no new switches to replace the **/D** and **/S** switch functions; the old switches are still valid. The following table describes the former, new, and legacy switches for use with the Package Installer.

| Old Switch | New Switch | Description |
|---|---|---|
| None | /Uninstall | Used to automate removal of a service pack. |
| /? | /Help | Displays help text. |
| /D:*FolderName* | No change | For service pack installations, backs up files to the specified folder. |
| None | /ER | Enables extended return codes. (For more information about extended return codes, see Appendix F in the "The Package Installer for Windows and Windows Components" white paper.) |
| /F | /F | Forces other applications to close when the computer restarts after the installation. |
| None | /Forcerestart | Forces restart after installation finishes. |
| /L | /L | Lists installed hotfixes (Windows updates only). |
| /N | /N | Does not back up files for removing the service pack or hotfix. In Add or Remove Programs, there is no Remove button for the hotfix, so it cannot be uninstalled. |
| /O | /O | Overwrites OEM files without prompting. |
| /Q | /Quiet | Uses quiet mode, which is the same as unattended mode, except that the user interface is hidden. No prompts appear during the installation. |

| | | |
|---|---|---|
| /Intergrate:*FolderName* | No change | Combines the operating system image with Windows Server 2003 Service Pack 1 in a shared distribution folder for an integrated installation. When using this switch, type the name of the shared distribution folder after the colon. |
| /U | /Passive | Uses unattended setup mode. Only critical errors and a progress bar appear during setup. |
| /Z | /Norestart | Does not restart the computer after the installation finishes. |

- **/O** command line switch

  The **/O** command line switch prevents Update.exe from performing an exhaustive search for original equipment manufacturer (OEM) supplied files, such as video drivers. Use this switch only if you want to overwrite all files supplied by the OEM on your system. By default, OEM files are not overwritten.

- Do not apply updates during installation

  If you are running in an environment that uses a utility to scan and apply updates or security updates automatically, the utility may conflict with the service pack installation. This conflict can occur when a service pack is in the process of installation or uninstallation and has not fully completed due to the need to restart and then run the post-installation processes. If the update utility attempts to apply updates to the system at shutdown or restart, it may attempt to install updates prior to completing the service pack installation, which may result in the computer being left in an unusable state.

- Improved recovery following installation failure

  In the event that there is a failure to complete the service pack installation, in most cases, automatic recovery will occur. For example, if power failure occurs during the latter parts of installation, when you restart the computer, the service pack uninstall procedure automatically starts and rolls back all the changes that were made during the service pack installation.

- Antivirus software

  Although antivirus software is a critical factor in keeping a computer secure, it can affect the overall time required to install a service pack. Disabling your antivirus software during installation of the service pack could reduce the installation time by up to 20%. If you decide to disable the antivirus software, be aware of the risks involved and be sure to enable it after the service pack is installed.

**What works differently?**

A new prerequisite to service pack installation is a check as to whether the file SpUpdSvc.inf exists on the computer. This file will be present only if Windows Server 2003 Service Pack 1 was previously installed on the computer. If this file is found on your computer by the SP1 installer you will be presented with the message:

**Setup has detected an .INF file from the beta installation that will prevent successful installation of the Service Pack. Please see Deleting SpUpdSvc.inf before install in the Readme document accompanying this release for details on how to unblock the Windows Server 2003 Service Pack 1 installation.**

There is also a prerequisite that blocks installation of the service pack if the Distributed Transaction Coordinator (also know as MSDTC) service status is **Disabled** and **Stopped** at the time of installation. In this case the installation will stop and you will be presented with the message:

**Setup has detected that the Distributed Transaction Coordinator (MSDTC) service is disabled. The MSDTC service is required for the successful installation of Microsoft ® Windows Server™ 2003 Service Pack 1 (SP1). Please enable the MSDTC service, and then restart the installation of Windows Server 2003 SP1. For more information about enabling the MSDTC service, contact your network administrator.**

**How do I resolve these issues?**

**To manually delete the SPUpdSvc.INF file**

1. Locate the SPUpdSvc.INF file in the Windows directory.

2. Rename the file from SPUpdSvc.INF to SPUpdSvc.BAK.
3. Restart your computer.
4. Attempt to install the service pack
5. If the service pack successfully installs, delete the SPUpdSvc.BAK file.

**To enable the MSDTC service**

1. Open a command prompt.
2. At the command prompt, type the following command:

   **sc config MSDTC start=demand**

   This will change the status of the MSDTC service from disabled to enabled, but will not start the service.

# Terminal Services in Windows Server 2003 Service Pack 1

Applies To: Windows Server 2003 with SP1

**What does Terminal Services do?**
On Windows Server 2003 operating systems, the Terminal Server feature gives users at client computers throughout your network access to Windows-based programs installed on terminal servers. With Terminal Server, you can provide a single point of installation that allows multiple users access to Windows Server 2003 operating system desktops, where they can run programs, save files, and use network resources, all from a remote location, as if these resources were installed on their own computers.

Terminal Services is ideal for rapidly deploying Windows-based applications to computing devices across an enterprise—especially applications that are frequently updated, infrequently used, or hard to manage. Terminal Server lets you deliver Windows-based applications, or the Windows desktop itself, to virtually any computing device—including those that cannot run Windows.

Windows Server 2003 Service Pack 1 includes several new features designed to maximize both the speed and efficiency of Terminal Services administration, and the security of communications between Terminal Services clients and servers.

**Who does this feature apply to?**
The features described here will be of interest to Terminal Server client users as well as IT professionals who deploy and configure Terminal Services.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**New fallback printer driver capability**
**Detailed Description**
With the release of Windows Server 2003 with Service Pack 1 (SP1), you can make local printing more accessible for Terminal Server clients by configuring Terminal Services to default to a printer driver compatible with PostScript (PS) or Printer Control Language (PCL). The new fallback printer driver capability is exceptionally useful if a terminal server does not have a printer driver installed that matches the Terminal Server client user's specific printer brand and model.

A new Group Policy setting, **Terminal Server fallback printer driver behavior**, allows you to specify the location and file name of a fallback printer driver, in the event that no printer drivers installed on a terminal server are compatible with the local printer for a Terminal Server client.

By default, the Terminal Server fallback printer driver is disabled. If the terminal server does not have a printer driver that matches the client's printer, no printer will be available for the terminal server session.

If the fallback printer driver is enabled, Terminal Server's default behavior is to locate a suitable printer driver. If one is not found, the client user cannot print Terminal Server session documents to a local printer. The Group Policy setting allows you to select one of four options to modify Terminal Server printing behavior:

- **Do nothing if one is not found**. This is the default setting. In the event of a printer driver mismatch, the server attempts to find a suitable driver. If one is not found, the client's printer is unavailable during the Terminal Server session.

- **Default to PCL if one is not found**. If no suitable printer driver can be found, Terminal Server uses the Hewlett-Packard compatible Printer Control Language (PCL) fallback printer driver.

- **Default to PS if one is not found**. If no suitable printer driver can be found, Terminal Server uses the Adobe PostScript (PS) fallback printer driver.

- **Show both PCL and PS if one is not found**. In the event that no suitable driver can be found, show both PS-based and PCL-based fallback printer drivers.

If this setting is disabled or not configured, Terminal Server does not use a fallback printer driver.

Printing Terminal Server session documents may still be disabled for some client computers, if the fallback printer driver's vendors have deviated from PS or PCL specifications.

**Note**

If the Group Policy setting **Do not allow client printer redirection** is enabled, any configuration for the **Terminal Server fallback printer driver behavior** policy setting is ignored, and the fallback driver is disabled.

**Why is this change important?**
This change simplifies local printing for Terminal Server client users. The new Group Policy setting allows client users to print documents locally, if the printer driver installed on the terminal server to which they're connected is incompatible with their local printers, provided their printers are compatible with either a PCL or a PS printer driver.

**Authentication and encryption for Terminal Services connections**
**Detailed description**
In Windows Server 2003 SP1, you can enhance the security of Terminal Server by configuring Terminal Services connections to use Secure Sockets Layer (SSL)/Transport Layer Security (TLS) 1.0 for server authentication, and to encrypt terminal server communications. The version used by Terminal Services in Windows Server 2003 SP1 is TLS 1.0.

**Server prerequisites**
For SSL (TLS) authentication to work correctly, the terminal server must meet both the following prerequisites:

- The terminal server must be running Windows Server 2003 SP1.
- You must obtain a certificate for the terminal server. To obtain a certificate, use one of the following methods:
  - Visit the Web site for your certification authority. For example, visit http://*servername*/certsrv.
  - Run the Windows Server 2003 Certificate Request Wizard or the Windows 2000 Server Certificate Request Wizard.
  - Obtain a certificate from a third-party certification authority, and then manually install the certificate.

If you plan to obtain a certificate by using the certification authority Web site or the Certificate Request Wizard, a public key infrastructure (PKI) must be configured correctly to issue SSL-compatible X.509 certificates to the terminal server. Each certificate must be configured as follows:

- The certificate is a computer certificate.
- The intended purpose of the certificate is server authentication.
- The certificate has a corresponding private key.
- The certificate is stored in the terminal server's personal store. You can view this store by using the Certificates snap-in.
- The certificate has a cryptographic service provider (CSP) that can be used for the SSL (TLS) protocol (for example Microsoft RSA SChannel Cryptographic Provider).

For more information, see Microsoft Cryptographic Service Providers (http://go.microsoft.com/fwlink/?LinkID=40983).

**Client prerequisites**
In order for SSL (TLS) authentication to function correctly, clients must meet the following prerequisites:

- Clients must run Windows 2000 or Windows XP.
- Clients must be upgraded to use the Remote Desktop Protocol (RDP) 5.2 (Windows Server 2003) client. You can install this client-side Remote Desktop Connection package by using the %systemdrive\system32\clients\tsclient\win32\msrdpcli.msi file. The msrdpcli.msi file is located on Windows Server 2003 terminal servers. Installing this file from the terminal server installs the 5.2 version of Remote Desktop Connection to the %systemdrive\Program files\Remote Desktop folder on the destination computer. For more information, see Remote Desktop Connection for Windows Server 2003 [5.2.3790] (http://go.microsoft.com/fwlink/?LinkID=41068).

- Clients must trust the root of the server's certificate. That is, clients must have the certificate of the certification authority (CA) that issued the server certificate in their Trusted Root Certification Authorities store. You can view the certificate by using the Certificates snap-in.

| **Important** |
| --- |
| Because RDP runs on port 3389, when using SSL (TLS) to secure RDP, SSL (TLS) will run on port 3389. |

**Why is this change important?**
By default, Terminal Server uses native Remote Desktop Protocol (RDP), which provides data encryption, but does not provide authentication to verify the identity of a terminal server.

For more information about Terminal Services and security protocol settings, see the following:

- Configure Authentication and Encryption (http://go.microsoft.com/fwlink/?LinkId=45407)
- How to configure a Windows Server 2003 terminal server to use TLS for server authentication (http://go.microsoft.com/fwlink/?LinkId=64593)

**New Group Policy settings for Terminal Services Licensing**
**Detailed Description**
Windows Server 2003 SP1 includes new Group Policy settings for Terminal Services Licensing described as follows.

**Set the Terminal Server licensing mode**
The new Group Policy setting **Set the Terminal Server licensing mode** determines the type of Terminal Server client access license (CAL) a device or user requires to connect to a terminal server.

When this setting is enabled, you can choose one of the following two licensing modes:

- **Per User**: Each user connecting to the terminal server requires a Per User Terminal Server CAL.
- **Per Device**: Each device connecting to the terminal server requires a Per Device Terminal Server CAL.

If you enable this policy setting, the licensing mode that you specify overrides the licensing mode specified during setup, or in Terminal Services Configuration (TSCC.msc).

If you disable or do not configure this policy setting, Terminal Services uses the licensing mode specified during setup or found in TSCC.msc.

To configure the Terminal Services licensing mode on a specific terminal server using TSCC.msc, see Configure the Terminal Server licensing mode (http://go.microsoft.com/fwlink/?LinkId=45592) in the Terminal Services Help.

**Use the specified Terminal Server license servers policy setting**
The Group Policy setting **Use the specified Terminal Server license servers** determines whether terminal servers must first attempt to locate Terminal Server license servers that are specified in this policy setting before attempting to locate license servers elsewhere on the network.

During the automatic discovery process, terminal servers attempt to contact license servers in the following order:

1. Enterprise license servers or domain license servers that are specified in the LicenseServers registry key.
2. Enterprise license servers that are specified in Active Directory.
3. Domain license servers.

If you enable this policy setting, terminal servers attempt to locate license servers that are specified in this setting, before following the automatic license server discovery process.

If you disable or do not configure this policy setting, terminal servers follow the automatic license server discovery process.

You can configure a specific terminal server to locate a Terminal Server license server using TSCC.msc. For more information,

see Set preferred Terminal Server license servers (http://go.microsoft.com/fwlink/?LinkId=45410) in the Terminal Server Licensing Help.

**Show ToolTips for licensing problems on Terminal Server policy setting**
This Group Policy setting allows you, after successfully logging on to a terminal server as an administrator, to display ToolTips that show any licensing problems with the terminal server, and also display the expiration date of the terminal server's licensing grace period. If this Group Policy setting is not configured, ToolTip display is defined by registry settings.

**Why is this change important?**
Specifying the name of a preferred licensing server in Group Policy saves time and may eliminate roadblocks to successful configuration of your terminal servers. With the name of a specific licensing server added to Group Policy, Terminal Services does not need to search the network for a licensing server.

Using ToolTips to view Terminal Server license statistics at a glance speeds administration tasks. By configuring Group Policy to show ToolTips for Terminal Server licenses, you do not need to open the **Properties** dialog box for specific licenses to view status and expiration information.

Allowing administrators to configure a global Terminal Server licensing mode makes it possible for them to implement unified license policies regardless of the configuration of Terminal Services client computers. With the new Group Policy setting, differences in configuration between terminal servers and clients can be resolved by defining a global policy that overrides other settings.

For more information about Terminal Server Licensing, see the following:

- Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkId=45409)
- Set preferred Terminal Server license servers (http://go.microsoft.com/fwlink/?LinkId=45410)

**Update to Group Policy setting for starting a program on connection to a terminal server**
**Detailed Description**
The Group Policy setting **Start a program on connection** configures Terminal Services to run a specified program automatically when a client connects to a terminal server.

By default, Terminal Services sessions provide access to the full Windows desktop, unless the server administrator has otherwise specified using this policy setting, or unless the user has specified during configuration of the client connection. Enabling this Group Policy setting overrides the **Start program** settings made by the server administrator or user. The **Start** menu and Windows Desktop are not displayed, and when the user exits the program, the Terminal Server session is automatically logged off.

If the **Start a program on connection** policy setting is enabled, Terminal Services sessions automatically run the specified program and use the specified working folder (or the program default folder, if a working folder is not specified) as the working folder for the program.

If this policy setting is disabled or not configured, Terminal Services sessions start with the full desktop, unless the server administrator or client user specifies otherwise.

| **Note** |
| --- |
| This setting appears in both **Computer Configuration** and **User Configuration**. If both settings are configured, the **Computer Configuration** setting overrides local user settings. |

You can configure a specific terminal server to start a program when a client successfully logs on using TSCC.msc. For more information, see Specify a program to start automatically when a user logs on (http://go.microsoft.com/fwlink/?linkid=64608) in the Terminal Services Configuration Help.

**Why is this change important?**
Before the release of Windows Server 2003 with Service Pack 1 (SP1), this policy setting could only be edited in Group Policy if the computer was a domain controller, and it was necessary to access Group Policy by opening **Active Directory Users and Computers**. Now, you can modify the **Start program on connection** policy setting in Group Policy for the local policy object, meaning that you can configure this policy setting for individual terminal servers within a domain.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
The following table lists the Group Policy settings that have changed for Terminal Services in Windows Server 2003 with SP1, and provides their locations in Group Policy.

| Setting name | Location | Default value | Possible values |
|---|---|---|---|
| Terminal Server Fallback Printer Driver Behavior | Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection | Not configured | Enabled, disabled, not configured |
| Set the Terminal Server licensing mode | Administrative Templates\Windows Components\Terminal Services | Not configured | Enabled, disabled, not configured |
| Use the specified Terminal Server license servers | Administrative Templates\Windows Components\Terminal Services | Not configured | Enabled, disabled, not configured |
| Show ToolTips for licensing problems on Terminal Server | Administrative Templates\Windows Components\Terminal Services | Not configured | Enabled, disabled, not configured |
| Start a program on connection | Administrative Templates\Windows Components\Terminal Services | Not configured | Enabled, disabled, not configured |

# Transmission Control Protocol/Internet Protocol (TCP/IP)

Applies To: Windows Server 2003 with SP1

**What does TCP/IP do?**
Transmission Control Protocol/Internet Protocol (TCP/IP) is a suite of standard protocols for connecting computers across networks. TCP/IP enables Windows-based computers to connect and share information with other Microsoft and non-Microsoft systems.

**Who does this feature apply to?**
All users who use TCP/IP to connect and communicate information over a network should be aware of the changes incorporated in Windows Server 2003 Service Pack 1.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**SYN attack protection is enabled by default**
**Detailed Description**
When a SYN attack is detected, TCP/IP in Windows Server 2003 and Windows XP lowers the number of retransmissions of the SYN-ACK segment and does not allocate memory or table entry resources for the connection until the TCP three-way handshake has been completed.

A TCP Synchronize (SYN) attack is a denial-of-service attack that exploits the retransmission and time-out behavior of the Synchronize-Acknowledgement (SYN-ACK) segment during the TCP three-way handshake to create a large number of half-open TCP connections. Depending on the TCP/IP protocol implementation, a large number of half-open TCP connections could do any of the following:

- Use all available memory.
- Use all possible entries in the TCP Transmission Control Block (TCB), an internal table used to track TCP connections. When the half-open connections use all the entries, further connection attempts are responded to with a TCP connection reset.
- Use all available half-open connections. When all the half-open connections are used, further connection attempts are responded to with a TCP connection reset.

**Why is this change important? What threats does it help mitigate?**
To mitigate the impact on a host experiencing a SYN attack, TCP/IP minimizes the amount of resources devoted to incomplete TCP connections and reduces the amount of time before abandoning the connection. When a SYN attack is detected, TCP/IP in Windows Server 2003 and Windows XP lowers the number of retransmissions of the SYN-ACK segment and does not allocate memory or table entry resources for the connection until the TCP three-way handshake has been completed.

You can control SYN attack protection through the `SynAttackProtect` registry setting at `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Tcpip\Parameters`(REG_DWORD type). You set `SynAttackProtect` to 0 to disable SYN attack protection and to 1 to enable it.

For TCP/IP in Windows XP (all versions) and Windows Server 2003 with no service packs installed, `SynAttackProtect` is set to 0 by default. For TCP/IP in Windows Server 2003 SP1, `SynAttackProtect` is set to 1 by default.

**New SYN attack notification IP Helper APIs**
**Detailed Description**
To allow an application to notify network administrators that a SYN attack is taking place, the IP Helper API supports new SYN attack notification APIs named `NotifySecurityHealthChange` and `CancelSecurityHealthChangeNotify`. Information about these new APIs has not yet been published in the Microsoft Developer Network (MSDN). A link to the MSDN topics describing these new APIs will be posted here when available.

**Smart TCP port allocation**
**Detailed Description**
TCP/IP in Windows Server 2003 SP1 has implemented a smart TCP port allocation algorithm. When an application requests any available TCP port, TCP/IP first attempts to find an available port that does not correspond to a connection in the TIME WAIT state. If a port cannot be found, then it picks any available port.

**Why is this change important? What threats does it mitigate?**
When a TCP peer initiates a TCP connection termination and the connection termination completes, the TCP connection enters

the TIME WAIT state. When the TIME WAIT state is reached, TCP must wait twice the maximum segment lifetime (MSL) before a connection with the same set of socket addresses can be created. The set of socket addresses consists of the combination of the source and destination IP addresses and source and destination TCP ports. The MSL is the maximum amount of time a TCP segment can exist in an internetwork, and its recommended value is 120 seconds. This delay prevents a new connection's TCP segments using the same set of socket addresses from being confused with duplicated TCP segments of the old connection.

The TCP port for a connection in the TIME WAIT state is considered an available port and can be assigned for use by an application. This can lead to the following series of events:

1. An application requests any available TCP port.
2. TCP/IP assigns a TCP port to use for the application socket.
3. The application attempts to open a socket with a specific destination IP address.
4. The application establishes a TCP connection and sends data.
5. The application terminates the TCP connection.
6. TCP/IP places the application's TCP connection in the TIME WAIT state until 2*MSL has passed.
7. The same application requests another available TCP port.
8. TCP/IP assigns a TCP port to use for the application socket. Because the port for the connection in the TIME WAIT state is considered open, it can be chosen as the next port to assign to the requesting application. Assume that TCP/IP assigns the same TCP port number.
9. The application attempts to open a socket with the same destination IP address.
10. Because the connection is using the same set of socket addresses as the connection in the TIME WAIT state, TCP/IP indicates an error to the application.

Mitigating this error situation required adjusting the registry settings in one of the following ways:

- Setting the `MaxFreeTWTcbs` registry setting at `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Tcpip\Parameters` (REG_DWORD type) to a lower value. The value of `MaxFreeTWTcbs` controls the number of connections that can be in the TIME WAIT state. When this number is exceeded, the oldest connection is automatically removed from the TIME WAIT state.
- Setting the `TcpTimedWaitDelay` registry setting at `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Tcpip\Parameters` (REG_DWORD type) to a lower value. The value of `TcpTimedWaitDelay` determines the length of time that a connection stays in the TIME WAIT state.

However, lowering the value of these registry settings is contrary to the original design of TCP and the MSL and is not recommended.

Therefore, Windows Server 2003 SP1 includes this port allocation algorithm change to prevent an application from creating a connection with the same set of socket addresses of a connection that is in a TIME WAIT state if another port is available.

This new behavior makes it much more unlikely that an application will be assigned a TCP port that is in the TIME WAIT state when connecting to the same destination, so that it is no longer necessary to modify the values of the `MaxFreeTWTcbs` and `TcpTimedWaitDelay` registry keys to avoid the error situation described above.

**Improved receive Winsock APIs**
**Detailed description**
Winsock APIs now support a mechanism that allows applications to specify that a receive request should not be completed until the receive buffer is full. This helps reduce network latency and better supports high performance applications. For more information about the Winsock implementation, see "About the Winsock SPI" on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=45684.

**Winsock self-healing**
**Detailed description**
Winsock, the consortium-based networking application programming interface (API), is extensible by a mechanism known as the Winsock Service Provider Interface (SPI). The SPI provides a mechanism for layering providers on top of each other. Providers that are layered in this fashion are called Winsock Layered Service Providers (LSPs). Winsock LSPs are available for a wide range of useful purposes, including parental controls and Web content filtering. The specific layering order of all providers is kept in the Winsock Catalog. In previous versions of Windows Server 2003, improperly removed LSPs (possibly due to poorly implemented LSP install/removal code) could result in corruption of the Winsock Catalog, potentially resulting in a loss of all network connectivity. Winsock now has the ability to detect improperly removed LSPs and automatically repair itself.

**Why is this change important? What threats does it help mitigate?**
Customers need to be able to safely remove LSPs from their systems.

**New Winsock Netsh commands**
**Detailed description**
Two new Netsh commands are available in Windows Server 2003 Service Pack 1:

- `netsh winsock reset catalog`

  This command resets the Winsock catalog to the default configuration. This can be useful if a malformed LSP is installed that results in loss of network connectivity. While use of this command can restore network connectivity, it should be used with care because any previously installed LSPs will need to be reinstalled.

- `netsh winsock show catalog`

  This command displays the list of Winsock LSPs that are installed on the computer.

**Why is this change important? What threats does it help mitigate?**
These commands provide additional management capabilities for maintaining and troubleshooting Winsock LSPs and can be used in a script to aid in recovering from a widespread installation of malformed LSPs.

**New Netstat parameter**
The following new parameter can be used with the **netstat** command:

- `netstat -b`

Using this parameter with the **netstat** command displays the executable involved in creating each connection or listening port. In some cases well-known executables host multiple independent components, and in these cases the sequence of components involved in creating the connection or listening port is displayed with components being displayed prior to the executable that called the component. The executable name will be denoted by brackets ([]) on either side of the executable name.

| **Note** |
| --- |
| Using this parameter can take a considerable amount of time and might fail if the account it is running under does not have sufficient permissions to gather the information requested. |

**What new settings are added in Windows Server 2003 Service Pack 1?**
A new registry key has been added as shown in the table below. This registry key sets the maximum number of ICMP host routes that can be added. This key should not be changed unless ICMP is being used to add a large number of host routes.

| Setting name | Location | Default value |
| --- | --- | --- |
| MaxICMPHostRoutes | HKEY_LOCAL_MACHINE \SYSTEM \CurrentControlSet \Services\Tcpip\Parameters | 1000 |

# WebDAV Redirector

Applies To: Windows Server 2003 with SP1

**What does WebDAV Redirector do?**
The WebDAV Redirector (DAVRdr) allows computers running Windows Server 2003 to use WebDAV (Web-based Distributed Authoring and Versioning) servers, such as Windows SharePoint Services and MSN Communities, as if they were standard file servers. It consists of a kernel component that connects to a Windows NT remote file system stack, and a user-level component (Web client service) that translates file system requests into WebDAV requests.

**Who does this feature apply to?**
This feature is used by people who access WebDAV servers through the remote file system. WebDAV Redirector is implemented in the remote file system stack. Client administrators, and users who are concerned with the security of their computer credentials, need to be aware of this change if they access remote files on a WebDAV server using a Universal Naming Convention (UNC) path, for example, a file request such as \\ServerName\ShareName\File.txt will be processed by WebDAV Redirector and will be affected by this change in functionality.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Disabling Basic Authentication over a clear channel**
**Detailed description**
WebDAV is an extension of Hypertext Transfer Protocol (HTTP), and as such includes the use of Basic Authentication (BasicAuth). BasicAuth is one form of user authentication, or means by which a user is identified to the server. With BasicAuth, the client transmits the user's credentials (user name and password) to the server. If the channel is unencrypted, such as with normal HTTP traffic, any computer on the network can see the user's user name and password and therefore steal their identity. The DAVRdr does not support encrypted HTTP (HTTPS or SSL), and will transmit the user's credentials in the clear (without encryption) if the server supports basic authentication. Although a server most likely would not be configured to use basic authentication, it would be possible to set up the server expressly to obtain users' credentials.

Because of this possibility, Windows Server 2003 Service Pack 1 (SP1) includes the ability to enable or disable the use of BasicAuth by the DAVRdr. By default, use of BasicAuth is disabled with SP1. When BasicAuth is disabled, the client will either use a different authentication method (if the server supports one) or fail the request.

**Why is this change important?**
Users can log on to WebDAV servers for remote file access without fear of transmitting their password in the clear.

**What threats does it help mitigate?**
Imagine a corporate user at Contoso Corporation who routinely accesses the file share \\Contoso_Server\Sales outside the corporation on a public network, and uses an application that attempts to access that share as part of normal background activity. Since the user's portable computer is outside the corporate network, the request should fail. However, the DAVRdr will transmit a request to see if there is a DAV server named Contoso_Server, even though the actual server that the portable computer is attempting to access is an SMB server.

An attacker can be operating on that same public network with a computer that spoofs WINS requests, returning a pointer to itself in response to any WINS request. The portable computer will then try to access a DAV share on that rogue server. If the rogue server responds with BasicAuth as the authentication method, a dialog box appears that asks for the user's credentials. The dialog box identifies the server as Contoso_Server, leading the user to believe the request is legitimate. If the user enters their user name and password, the client transmits that information in the clear and the attacker thus gains access to that user's login information. There is no indication to the user that the channel is not secure, that the request is being handled by the DAVRdr, or that the portable computer will transmit the user name and password in the clear. Note that the current default Windows authentication methods never transmit a user's password in the clear.

**What works differently?**
Since the change to default behavior only affects the DAVRdr, the only scenarios that fail to work are those that require basic authentication, and that use the DAVRdr. An example is using Notepad.exe to access a Web site that only allows BasicAuth. This scenario will no longer work. Also, even if the server was configured to only use basic authentication, other applications such as Microsoft Office will continue to work, since they use a different DAV client.

**How do I resolve these issues?**
You can enable BasicAuth by adding the following registry key and setting it to a non-zero value:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services \WebClient\Parameters\UseBasicAuth
(DWORD)
```

If you delete the registry key or set it to 0, the behavior reverts to the default, or disabling the use of BasicAuth.

**WinINet: Disabling Basic Authentication over a clear channel**
**Detailed description**
Because the DAVRdr is part of the remote file system stack, a computer is open to attack whenever an attempt is made to remotely access files. Although the threat to other applications that use the Internet APIs is less severe than it is for the DAVRdr, a similar attack is possible whenever an application (or the user) attempts to access a URL. For this reason, WinINet is exposing the mechanism by which the DAVRdr disables BasicAuth to other users of the Internet APIs.

There are two ways to block the use of Basic Authentication over clear (or unencrypted) channels:

- Create the following registry key and set it to a non-zero value.

  `HKEY_CURRENT_USER\SOFTWARE\Microsoft\Windows \CurrentVersion\ Internet Settings\DisableBasicOverClearChannel` (DWORD)

  This prevents WinINet from attempting to use BasicAuth unless the channel is secured (using HTTPS or SSL).

- The application can disable the use of BasicAuth for its connections by setting the AUTH_FLAG_DISABLE_BASIC_CLEARCHANNEL flag (0x4) in the value supplied in the call to **InternetSetOption** using INTERNET_OPTION_AUTH_FLAGS.

**Why is this change important?**
Users can log on to WebDAV servers for remote file access without fear of transmitting their password in the clear.

**What threats does it help mitigate?**
Imagine a corporate user who routinely accesses the Web site http://www.contoso.com/sales. While outside the corporation on a public network, the user attempts to access that site using Internet Explorer. Since the laptop is outside the corporation, the request should fail with a "Server not found" message. An attacker can run on that same public network with a computer that spoofs WINS requests, returning a pointer to itself in response to any WINS lookup. The laptop will then try to send the HTTP request to load the page from the rogue server. If the rogue server responds with BasicAuth as the authentication method, the laptop responds to the user, asking for his or her credentials. It identifies the site http://www.contoso.com/sales, leading the user to believe the request is legitimate. If the user enters his or her user name and password, the client will transmit that information in the clear, and the attacker thus gains access to that user's login information. In particular, there is no indication to the user that the channel is insecure, or that the laptop will transmit the user name and password in the clear.

**What works differently?**
By default, there is no change in behavior for WinINet applications (except for the DAVRdr as noted above). If this setting is disabled, the user is unable to connect to HTTP servers that only support Basic Authentication.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**
**WebDAV Redirector Settings**

| Setting name | Location | Previous default value (if applicable) | Default values | Possible values |
|---|---|---|---|---|
| UseBasicAuth | HKEY_LOCAL_MACHINE\System \CurrentControlSet \Services \WebClient \Parameters \UseBasicAuth | Not applicable. | Key doesn't exist.<br><br>(BasicAuth disabled for DAVRdr) | 0, non-zero |
| DisableBasicOverClearChannel | HKCU\SOFTWARE \Microsoft \Windows \CurrentVersion \Internet Settings \DisableBasicOverClearChannel | Not applicable. | Key doesn't exist. (BasicAuth enabled for everything else) | 0, non-zero |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
No changes are necessary. Developers who write applications that use the Internet APIs and want to disable BasicAuth, such as the DAVRdr, can add a call to **InternetSetOptions()**.

# Windows Firewall in Windows Server 2003 Service Pack 1

Applies To: Windows Server 2003 with SP1

**What does Windows Firewall do?**
Windows Firewall (previously called Internet Connection Firewall or ICF) is a software-based, stateful filtering firewall for Microsoft Windows XP and Microsoft Windows Server 2003. Windows Firewall provides protection for computers that are connected to a network by preventing unsolicited incoming traffic through TCP/IP version 4 (IPv4) and TCP/IP version 6 (IPv6). Configuration options include:

- Configuring and enabling port-based exceptions
- Configuring and enabling program-based exceptions
- Configuring basic ICMP options
- Logging dropped packets and successful connections

Windows Firewall in Windows Server 2003 Service Pack 1 is not enabled by default when the update is applied to your server. It will only be enabled in the following situations:

- If Internet Connection Sharing was previously enabled.
- If Internet Connection Firewall was previously enabled.
- If the server is a new installation of Windows Server 2003 with Service Pack 1 (also known as a slipstream installation).

The best resources to help you fully understand how Windows Firewall works and how it can be used in your environment are the Windows Firewall Information and Help topics on the Windows Server 2003 Tech Center Web site at http://go.microsoft.com/fwlink/?LinkId=48911 and the Windows Firewall Operations Guide on the Windows Server 2003 TechCenter Web site at http://go.microsoft.com/fwlink/?LinkId=48912.

| **Note** |
| --- |
| If you decide to use Windows Firewall with your server, it is strongly recommended that you restart your servers after turning on and configuring the firewall. Windows Firewall in Windows Server 2003 with Service Pack 1 now supports application exceptions and needs to maintain the state of those applications. As a result, any applications or services that you add to the firewall exceptions list that were running prior to the firewall starting will still fail. After the server is restarted, the firewall will be running before any of the applications on the exceptions list and will be able to successfully maintain the state of the applications and handle them correctly. |

**Who does this feature apply to?**
This feature applies to:

- All computers that are connected to a network, including the Internet.
- All programs (applications and services) that listen on the network.
- All programs that do not work with stateful filtering.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Integration of Internet Connection Firewall and IPv6 Internet Connection Firewall into Windows Firewall**
**Detailed description**
The version of Internet Connection Firewall that was introduced with Windows XP filtered only IPv4 traffic. IPv6 Internet Connection Firewall was introduced with the Advanced Networking Pack for Windows XP. With Windows Server 2003 Service Pack 1, Internet Connection Firewall and IPv6 Internet Connection Firewall are integrated into a single component called

Windows Firewall.

With this change, any configuration change applies to both IPv4 and IPv6 traffic. For example, when a static port is opened, it is opened for both IPv4 and IPv6 traffic.

**Why is this change important?**
This allows for easier configuration management and application compatibility.

**What works differently?**
The Internet Connection Firewall service is removed from the system and replaced with the Windows Firewall service, which filters both IPv4 and IPv6 traffic. All firewall APIs are superseded by new APIs introduced with Windows Server 2003 Service Pack 1.

**How do I resolve these issues?**
For more information, see "Do I need to change my code to work with Windows Server 2003 Service Pack 1?" later in this document.

**On-by-default for new installations of Windows Server 2003 that include a service pack**
**Detailed description**
Windows Firewall is on by default only during new installations of Windows Server 2003 that include a service pack (also known as a slipstream release). Windows Firewall provides network protection while users update their system with the latest patches using the new Post-Setup Security Updates feature. As soon as the updates are finished the firewall is turned off unless it was explicitly enabled.

If a server running Windows Server 2003 is updated or upgraded to Service Pack 1 the firewall is off by default and the Post Setup Security Updates feature is not used.

**Why is this change important? What threats does it help mitigate?**
By enabling Windows Firewall by default on new installations, the computer has more protection from many network-based attacks while it is being set up and configured. For example, if Windows Firewall had been enabled by default, the MSBlaster attack would have been greatly reduced in impact, whether or not users had installed the relevant updates on their computers.

**What works differently?**
After a new installation of a slipstream version of Windows Server 2003 with Service Pack 1, Windows Firewall is enabled by default and incoming traffic is blocked until after Post-Setup Security Updates have been completed. This might create application or service incompatibility if the application or service does not work with stateful filtering by default.

**How do I resolve these issues?**
Complete Post-Setup Security Updates, which will automatically turn off the firewall, before proceeding with any other server configuration tasks.

It is also possible to configure the firewall to work with applications or services you need to use, if you don’t want to complete Post-Setup Security Updates until a later time.

**Configuration by the Security Configuration Wizard**
**Detailed description**
The recommended means of turning on Windows Firewall and performing its initial configuration for Windows Server 2003 with Service Pack 1 is to use the Security Configuration Wizard (SCW). SCW will automatically turn on Windows Firewall and create the appropriate settings based on the needs of your server. For more information about SCW, see "Security Configuration Wizard", in this document.

**Why is this change important?**
Some server components and applications should not be used with Windows Firewall or should be used in very specific configurations. SCW has been designed to help you determine the recommended settings for the Windows Firewall based on your environment.

**Boot-time security**
**Detailed description**
In earlier versions of Windows, there is a period of time between when the network stack comes up and when Internet Connection Firewall provides protection. This results in the ability for a packet to be received and delivered to a service without Internet Connection Firewall providing filtering and potentially exposes the computer to vulnerabilities. This was due to the firewall driver not starting to filter until the firewall user-mode service was loaded and had applied appropriate policy settings. The firewall service has a number of dependencies, which causes the service to wait until those dependencies are cleared before it pushes the policy down to the driver. This time period is based upon the speed of the computer.

In Windows Server 2003 Service Pack 1, the IPv4 and IPv6 firewall drivers have a static rule to perform stateful filtering. This static rule is called a boot-time policy. This allows the computer to perform basic networking functions such as DNS and DHCP

and communicate with a domain controller to obtain policy settings. After the Windows Firewall service is running, it loads and applies the runtime policy settings. The boot-time policy cannot be configured.

There is no boot-time security if the Windows Firewall service (which is listed as Windows Firewall/Internet Connection Sharing (ICS) in the Service Control Manager) is set to either Manual or Disabled.

**Why is this change important? What threats does it help mitigate?**
With this change, the computer is open to fewer attacks during startup and shutdown.

**What works differently?**
If the Windows Firewall service fails to start, boot-time security remains in effect. This means that all incoming connections are blocked. In this case, an administrator will not be able to remotely troubleshoot the issue because all the ports will be closed, including the port used by Remote Desktop.

If a service attempts to start before the firewall service a "race condition" might result. If a necessary service is blocked by this condition you will need to disable Windows Firewall.

**How do I resolve these issues?**
To turn off boot-time security, stop the Windows Firewall/Internet Connection Sharing (ICS) service and set its startup type to either Manual or Disabled.

If the computer is in boot-time security mode because the firewall service has not started, an administrator must log on to the computer, resolve the cause of the failure, and then manually start the firewall service.

**Running in safe mode (Safe mode firewall)**
**Detailed description**
The firewall state is maintained when the server is started in safe mode.

**Why is this change important?**
With this change your computer is less vulnerable to attack when starting in safe mode with network connectivity.

**What works differently?**
In previous versions, Internet Connection Firewall was not available when running in safe mode.

**Global configuration**
**Detailed description**
In earlier versions of Windows, Internet Connection Firewall was configured on a per-interface basis. This meant that each network connection had its own set of firewall settings, for example, one set of settings for wireless, another set of settings for Ethernet. This made it difficult to synchronize firewall settings between connections. Additionally, new connections would not have any of the configuration changes that had been applied to the existing connections. Non-standard network connections, such as those created by proprietary dialers (for instance, ISP-configured dial-up networking connections) could not be protected.

With global configuration in Windows Firewall, whenever a configuration change occurs, it automatically applies to all network connections in the Network Connections folder, as well as any non-Microsoft dialers. When new connections are created, the configuration is applied to them as well. Configuration can still be performed on a per-interface basis. Non-standard network connections will have only global configuration. Configuration changes also apply to both IPv4 and IPv6.

**Why is this change important?**
Having global configuration makes it easier for users to manage their firewall policy across all network connections and enables configuration through Group Policy. It also allows you to enable applications to work on any interface with a single configuration option.

**What works differently?**
In earlier versions of Windows Server, firewall configuration was on a per-interface basis. In Windows Server 2003 Service Pack 1, the configuration is global and applies to both IPv4 and IPv6.

**How do I resolve these issues?**
If your application or service requires static openings to work, you should open the ports globally, as described later in this topic, in "Do I need to change my code to work with Windows Server 2003 Service Pack 1?"

**Audit logging**
**Detailed description**
Audit logging enables you to track changes that are made to Windows Firewall settings and to see which applications and services asked your computer to listen on a port. After audit logging is enabled, audit events will be logged in the security event log. Audit logging can be enabled on client computers running Windows XP Service Pack 2 and servers running Windows Server 2003 Service Pack 1. You can use the following procedure to enable audit logging on your computer.

**To enable audit logging**

1. Log on using an account that is a local administrator.
2. Click **Start**, click **Control Panel**, and then click **Administrative Tools**.
3. In **Administrative Tools**, double-click **Local Security Policy** to open the **Local Security Settings** console.
4. In the console tree of the **Local Security Settings** console, click **Local Policies**, and then click **Audit Policy**.
5. In the details pane of the **Local Security Settings** console, double-click **Audit policy change**. Select **Success** and **Failure**, and then click **OK**.
6. In the details pane of the **Local Security Settings** console, double-click **Audit process tracking**. Select **Success** and **Failure**, and then click **OK**.

You can also enable audit logging for multiple computers in an Active Directory directory service domain using Group Policy by modifying the **Audit policy change** and **Audit process tracking** settings at **Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policy** for the Group Policy objects in the appropriate domain system containers.

After audit logging is enabled, you can use the Event Viewer snap-in to view audit events in the security event log.

Windows Firewall uses the following event IDs:

- 848 - Displays the startup configuration of Windows Firewall.
- 849 - Displays an application exception configuration.
- 850 - Displays a port exception configuration.
- 851 - Displays a change made to the application exceptions list.
- 852 - Displays a change made to the port exceptions list.
- 853 - Displays a change made to the Windows Firewall operation mode.
- 854 - Displays a change made to Windows Firewall logging settings.
- 855 - Displays a change made to ICMP settings.
- 856 - Displays a change made to the Prohibit unicast response to multicast or broadcast requests setting.
- 857 - Displays a change made to the Remote Administration setting.
- 858 - Displays the application of Windows Firewall Group Policy settings.
- 859 - Displays the removal of Windows Firewall Group Policy settings.
- 860 - Displays a change made to a different profile.
- 861 - Displays an application attempting to listen for incoming traffic.

**Why is this change important?**
Auditing the activity of Windows Firewall is part of a defense in depth strategy because it can be used to alert you to malicious software that is attempting to modify firewall settings. Auditing also generally helps administrators determine the network needs of their applications and design an appropriate policy for deployment to large numbers of users.

**Traffic scoping for exceptions**
**Detailed description**
ICF allowed excepted traffic to come from any IPv4 address. With Windows Firewall in Windows Server 2003 with Service

Pack 1, you can also configure an exception to allow incoming traffic only from addresses that are directly reachable by selecting the **My network (subnet) only** scope option (based on entries in the IPv4 and IPv6 routing table), or from specific IPv4 address ranges by selecting the **Custom list** scope option.

For computers in a workgroup, some exceptions are restricted to locally reachable addresses by default. These exceptions are those needed for file and printer sharing and the UPnP framework. Additionally, when these exceptions are opened for locally reachable addresses on an Internet Connection Sharing (ICS) host, the exceptions will not be opened on the ICS public interface. If you enable these exceptions for all possible addresses they will be opened on the ICS public interface, which is not recommended. When the File and Printer Sharing built-in exception is enabled with the NetShare application programming interface (API), with the Network Setup Wizard, or through the Windows Firewall user interface, incoming file and printer sharing connection requests can come only from directly reachable addresses by default.

If you are enabling Windows Firewall on a server that is already configured for file and printer sharing, the File and Printer Sharing exception might be enabled automatically. It is recommended that you apply the locally reachable addresses restriction to any exception that is used for communicating on the local network. It can be done programmatically at the command line using Windows Firewall Netsh Helper, or by clicking **Windows Firewall** in **Control Panel**.

**Note**

As a best practice, identify custom scopes with specific addresses or subnets for the exceptions that you specify for Windows Firewall.

When you configure and enable an exception, you are instructing Windows Firewall to allow specific unsolicited incoming traffic sent from the specified scope (from any address, from an address that can be reached directly, or from a custom list). For any scope, enabling an exception makes the computer accessible to attacks based on incoming unsolicited traffic from computers that are assigned the allowed addresses and from malicious computers that spoof traffic. There is no way to prevent spoofed attacks from the Internet on connections assigned public IPv4 addresses except by disabling the exception. Therefore, you should try to configure scope options so that the number of computers that are allowed to send unsolicited traffic through an exception is kept to a minimum. This will reduce, but not eliminate, the likelihood of a spoof attack.

If your organizational security policy requires you to ensure that no one outside your network can access a resource, then you should consider using an approach such as IPsec that supports network-level peer authentication, data origin authentication, data integrity, data confidentiality (encryption), and replay protection.

**Why is this change important? What threats does it help mitigate?**
Some applications need to communicate only with other computers on the local network and not computers on the Internet. Configuring Windows Firewall to allow only traffic from locally reachable addresses or from specific address ranges corresponding to locally attached subnets restricts the set of addresses from which unsolicited incoming traffic can be accepted. This mitigates, but does not eliminate, attacks that can occur for enabled exceptions.

**What works differently?**
When the File and Printer Sharing or the UPnP framework built-in exception is enabled using the Control Panel on a computer that is a member of a workgroup, the locally reachable addresses scope is applied to the ports opened. If an application or service also uses these ports, it will be able to communicate only with other nodes that are assigned locally reachable addresses. However, if the computer is a member of a domain, the global scope is applied.

If these exceptions are enabled using an API call or using Netsh.exe instead of from Control Panel, the default scope setting is locally reachable addresses, regardless of whether the computer is a member of a workgroup or a domain.

**How do I resolve these issues?**
If your application or service does not work with this type of restriction, you should open the port for any computer, as described in "Do I need to change my code to work with Windows Server 2003 Service Pack 1?" later in this document.

**Command-line support**
**Detailed description**
The Windows Firewall Netsh Helper was added to Windows XP in the Advanced Networking Pack. This helper applied only to IPv6 Windows Firewall. With Windows Server 2003 Service Pack 1, the structure and syntax of the helper changed and expanded to include support for configuring IPv4 as well. With the Netsh Helper, you can fully configure Windows Firewall, including:

- Configure the default state of Windows Firewall (Off, On, On with no exceptions).
- Configure the ports that must be open.

- Configure the ports to enable global access or to restrict access to the local subnet.
- Set ports to be open on all interfaces or only on a specific interface.
- Configure the logging options.
- Configure the Internet Control Message Protocol (ICMP) handling options.
- Configure and enable program-based exceptions.

Windows Firewall configuration and status information can be retrieved at the command line by using the Netsh.execontext: `firewall`.

To use this context, type `netsh firewall` at a command prompt, and then use additional Netsh commands as needed.

The following commands are useful for gathering firewall status and configuration information and can be useful for troubleshooting the operation of your firewall:

- `Netsh firewall show state`
- `Netsh firewall show config`

The following commands can be used to modify the configuration of Windows Firewall.

| **Command** | **Description** |
|---|---|
| add allowedprogram | Used to add excepted traffic by specifying the program's file name. |
| set allowedprogram | Used to modify the settings of an existing allowed program exception. |
| delete allowedprogram | Used to delete an existing allowed program exception. |
| set icmpsetting | Used to specify allowed ICMP traffic. |
| set logging | Used to specify logging options. |
| set notifications | Used to specify whether notifications to the user when programs try to open ports are enabled. |
| set opmode | Used to specify the operating mode of Windows Firewall either globally or for a specific connection (interface). |
| add portopening | Used to add excepted traffic by specifying a TCP or UDP port. |
| set portopening | Used to modify the settings of an existing open TCP or UDP port exception. |
| delete portopening | Used to delete an existing open TCP or UDP port exception. |
| set service | Used to enable or drop RPC and DCOM traffic, Remote Desktop, file and printer sharing, and UPnP traffic. |
| reset | Resets firewall configuration to Default. This provides the same functionality as the **Restore Defaults** button in Control Panel/Windows Firewall. |

The following table details the show commands supported for Windows Firewall.

| **Command** | **Description** |
|---|---|
| show allowedprogram | Displays the allowed programs. |

| | |
|---|---|
| show config | Displays the detailed local configuration information. |
| show currentprofile | Displays the current profile. |
| show icmpsetting | Displays the ICMP settings. |
| show logging | Displays the logging settings. |
| show notification settings | Displays the current settings for notifications. |
| show opmode | Displays the operational mode for profiles and interfaces. |
| show portopening | Displays the excepted ports. |
| show service | Displays the services exception settings. |
| show state | Displays the current state information. |

You can compare the output from these commands with the output from the `netstat -ano` command to identify the programs that may have listening ports open and that do not have corresponding exceptions in the firewall configuration.

**Why is this change important?**
Providing a command-line interface provides administrators with a method to configure Windows Firewall without going through the graphical user interface. The command-line interface can be used in logon scripts and remote management.

**What works differently?**
Any script that was created with the Netsh Helper that was made available with the Advanced Networking Pack for Windows XP no longer works and must be updated.

**How do I resolve these issues?**
Update any scripts you might have so that they include the new firewall context and syntax.

**"On with no exceptions" operational mode**
**Detailed description**
Windows Firewall can be configured for exceptions to allow specific unsolicited incoming traffic during normal use. Typically, this is because key scenarios, like file and printer sharing, must be enabled. If a security issue is discovered in one or more of the listening services or applications that are running on the computer, it may be necessary for the computer to switch into a client-only mode, which is called "On with no exceptions." Switching into this client-only mode configures Windows Firewall to prevent all unsolicited incoming traffic without having to reconfigure the firewall.

When in this mode, all exceptions are temporarily disabled and any existing connections are dropped. Any application interface that calls into Windows Firewall to create an exception is allowed and the requested firewall configuration is stored, but it is not enabled until the operational mode switches back to normal operation. All listen requests by applications are also ignored and notification dialogs are not displayed, effectively blocking the application from listening on a port while the computer is in this operational mode.

**Why is this change important?**
When a network system is under attack by viruses, worms, and other attackers, the attacker looks for services to exploit. The “On with no exceptions” operational mode provides a way for you to quickly lock-down your system in the event of an attack so that valid exceptions cannot be used to circumvent the protection provided to your computer by Windows Firewall.

**What works differently?**
When in this operational mode, the computer cannot listen for requests that originate from the network. Any existing incoming connections are terminated. Outgoing connections are the only connections that succeed.

**How do I resolve these issues?**
When in this operational mode, it is expected that some functionality will fail because of the strict network security in place. You can restore functionality by returning the operational mode to On. This action should be performed by the user only after the threat has been identified and mitigated, because the security of the computer is reduced by performing this action.

**Program-based exceptions**
**Detailed description**
Some programs (applications or services) act as both network clients and servers. When they act as servers, they must allow unsolicited incoming traffic, because they do not know in advance who the peer will be.

In earlier versions of Windows, a program needed to call the firewall APIs to enable the necessary listening ports to be open. This proved difficult in peer-to-peer situations when the port was not known in advance. It was up to the program to close the

port again after communication was completed. If the program terminated unexpectedly this could result in unnecessary open ports in the firewall.

An additional issue with the previous method of opening firewall ports was that ports could be opened only if programs were running in the security context of a local administrator. This violated the basic information security principle of least privilege by requiring programs to run in an administrative context, rather than only with the minimum necessary privileges.

In Windows Server 2003 with Service Pack 1, a program that needs to listen to the network can be added to the Windows Firewall exceptions list. If a program is enabled on the Windows Firewall exceptions list, Windows Firewall opens and closes the necessary listening ports automatically, regardless of the program's security context. For more information about adding programs to the Windows Firewall exceptions list, see "How do I resolve these issues?" later in this document.

Programs that work with stateful filtering do not need to be placed on the Windows Firewall exceptions list. Only administrators can add a program to the Windows Firewall exceptions list.

**Why is this change important? What threats does it help mitigate?**
When a program is on the Windows Firewall exceptions list, only the necessary ports are opened, and they are opened only for the duration that the program is listening on those ports.

**What works differently?**
If a program needs to listen on the network, it must be enabled on the Windows Firewall exceptions list. If it is not, then the necessary port in Windows Firewall is not opened and the program will not be able to receive unsolicited inbound traffic.

**How do I resolve these issues?**
A program can be placed on the Windows Firewall exceptions list in five ways:

1. **Programmatically**. It is recommended that independent software vendors (ISVs) place their programs on the Windows Firewall exceptions list during installation. For more information about how to programmatically add a program to the exceptions list, see "Do I need to change my code to work with Windows Server 2003 Service Pack 1?" later in this section.

2. **Command-line interface**. This method can be used by IT administrators who manage Windows XP and Windows Server 2003 systems using scripts or other command-line tools.

3. **Group Policy settings**. This method can be used by IT administrators to add the program to the exceptions list through Group Policy.

4. **Windows Firewall notification message**. A user with Administrator rights can interact with the Windows Firewall notification message and add the application to the exceptions list.

   When an application performs a TCP listen or UDP bind to a non-wildcard port, the network stack passes the application name and port to Windows Firewall. Windows Firewall looks up the application name on the exceptions list. If the application is on the exceptions list and enabled, then the corresponding port is opened in the firewall. If the application is on the exceptions list and disabled, then the corresponding port is not opened. If the application is not on the exceptions list, then users are asked to make a choice. If the users have administrative rights, they can:

   - Unblock the application to allow it to listen on the network. It is added to the exceptions list as Enabled and the port is opened.

   - Block the application from listening on the network. It is added to the exceptions list as Disabled and the port is not opened.

   - Choose to be asked again later. The application is not added to the exceptions list and the port is not opened.

   If the user does not have administrative rights, the user is notified that the application is not allowed to listen on the network and that an Administrator must enable the program exception. If the user selects the **Do not ask me again** check box, the application is listed in the exceptions list as Disabled.

**Note**

| |
|---|
| Notification messages can only be used with applications. They cannot be used with services. |

5. **Manual configuration**. Administrators can decide to enable a program manually in the Windows Firewall control panel by selecting it from a list that is populated from the list of programs in the **Start** menu or by browsing for the program.

**Multiple profiles**
**Detailed description**
Multiple profile support in Windows Firewall allows you to create two sets of firewall policy settings: one for when the computer is connected to a managed network and one for when the computer is not. You can specify settings that are less strict when the computer is connected to the corporate network to enable line-of-business applications to work. You can also have more aggressive security policy settings that will be enforced when the computer leaves the corporate network, which helps to protect mobile users.

| **Note** |
|---|
| Multiple profiles for Windows Firewall apply only to computers that are joined to an Active Directory domain. Computers that are in a workgroup use only one profile. |

**Why is this change important? What threats does it help mitigate?**
For a mobile computer, it is desirable to have more than one firewall configuration. Often, a configuration that is safe on a corporate network is likely to be susceptible to attack on the Internet. Therefore, being able to have ports opened on the corporate network and not on other networks is critical to ensuring that only the necessary ports are exposed at any given time.

**What works differently?**
If an application needs to be listed in the Windows Firewall exceptions list in order to work correctly, it might not work on both networks as the two profiles might not have the same set of policy settings. For an application to work on all networks, it must be listed in both profiles. For more information about the Windows Firewall exceptions list, see the earlier section.

**How do I resolve these issues?**
If the computer is joined to a domain, you must ensure that the application is listed in both firewall configurations. Consider creating exceptions though the command-line interface or Group Policy as you will only have access to the currently running profile through **Windows Firewall** in **Control Panel**.

**RPC support for System Services**
**Detailed description**
In earlier versions of Windows, Internet Connection Firewall blocked remote procedure call (RPC) communication. While Internet Connection Firewall could be configured to allow network traffic to the RPC Endpoint Mapper, the port that an RPC server used was unknown and the application would still fail.

Many enterprise applications and components fail if RPC is not allowed to communicate over the network. Some examples include, but are not limited to, the following:

- Remote administration, such as the Computer Management feature and the **Select User, Computers, and Groups** dialog box, which is used by many applications
- Remote Windows Management Instrumentation (WMI) configuration
- Scripts that manage remote clients and servers

RPC opens several ports and then exposes many different servers on those ports. It then requests that Windows Firewall create associated exceptions for these ports. If Windows Firewall is configured to allow such requests, the required ports will be opened for as long as RPC needs the exception (similar to a program exception).

**Why is this change important? What threats does it help mitigate?**
In order to enable remote administration scenarios, many enterprise-wide deployments require that the system services that use RPC work with Windows Firewall by default.

**What works differently?**
By default, RPC does not function through Windows Firewall. All system services that use RPC are affected. However, Windows Firewall can be configured to allow RPC to work for these services using the remote administration setting. This setting also

enables exceptions for the RPC Endpoint Mapper (TCP 135), SMB over TCP (TCP 445), and ICMP echo requests.

**How do I resolve these issues?**
See "Do I need to change my code to work with Windows Server 2003 Service Pack 1?" later in this document.

**Restore defaults**
**Detailed description**
Previously, there was no way for a user to reset the configuration of Internet Connection Firewall (ICF). Over time, the firewall might be configured to allow unsolicited incoming traffic to ports no longer used by other applications. This might make it difficult for the user to easily and quickly go back to a default configuration.

This option enables the user to restore Windows Firewall settings to their original defaults. In addition, the Windows Firewall defaults can be modified by original equipment manufacturers (OEMs) and businesses to provide custom default configuration options.

**Why is this change important?**
This option allows end-users to restore their Windows Firewall settings to the out-of-the-box defaults.

**What works differently?**
No functional changes in Windows Firewall result from this addition. However, use of this feature disables Internet Connection Sharing and Network Bridge.

**Unattended setup support**
**Detailed description**
In earlier versions of Windows, it was not possible to configure Internet Connection Firewall during installation. This made it difficult for OEMs and businesses to preconfigure Internet Connection Firewall before distributing a computer to their end users. In Windows Server 2003 with Service Pack 1, you can configure the following options of Windows Firewall through unattended setup:

- Operational mode
- Applications on the Windows Firewall exception list
- Static ports on the exception list
- ICMP options
- Logging options

**Why is this change important?**
A method to preconfigure Windows Firewall allows Windows resellers and large enterprises more flexibility and customization options for Windows Firewall.

**What works differently?**
This feature adds configuration flexibility to Windows Firewall. No functional changes in Windows Firewall result from this addition.

The syntax used to enable or disable ICF in an unattend script has been replaced with the new syntax for Windows Firewall.

The sections of the Unattend.txt file for Windows Firewall configuration consist of the following:

- `[WindowsFirewall]`

  A required section that defines which profiles to use and Windows Firewall log file settings.

- `[WindowsFirewall.profile_name]`

  The domain profile section, `[WindowsFirewall.Domain]`, contains settings for when a computer is connected to a network that contains domain controllers for the domain of which the computer is a member. The standard profile, `[WindowsFirewall.Standard]`, contains settings for when a computer is not connected to a network that contains domain controllers for the domain of which the computer is a member. If you do not want Windows Firewall to be used you can specify `Profiles = WindowsFirewall.TurnOffFirewall`

The `[WindowsFirewall.profile_name]` section is a user-defined section that is referenced by the `[WindowsFirewall]` section to make changes to Windows Firewall's default configuration, including programs, services, ports, and ICMP settings.

- `[WindowsFirewall.program_name]`

  A user-defined section that adds a program to the Windows Firewall exceptions list.

- `[WindowsFirewall.service_name]`

  A user-defined section that adds a predefined service to the Windows Firewall exceptions list (such as file and printer sharing, UPnP framework, Remote Desktop service, and Remote Administration).

- `[WindowsFirewall.portopening_name]`

  A user-defined section that adds a port to the Windows Firewall exceptions list.

- `[WindowsFirewall.icmpsetting_name]`

  A user-defined section that adds ICMP message types to the Windows Firewall exceptions list.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
**Enhanced multicast and broadcast support**
**Detailed description**
Multicast and broadcast network traffic differs from unicast traffic because the response comes from an unknown host. As such, stateful filtering prevents the response from being accepted. This stops a number of scenarios from working, ranging from streaming media to discovery.

To enable these scenarios, Windows Firewall will allow a unicast response for three seconds from any directly reachable source address on the same port from which the multicast or broadcast traffic originated.

**Why is this change important? What threats does it help mitigate?**
This allows applications and services that use multicast and broadcast for communicating to work without either the user or application/service needing to alter the firewall policy. This is important for things like NETBIOS over TCP/IP, so that sensitive ports such as port 135 are not exposed.

**What works differently? Are there any dependencies?**
In Windows Server 2003, Internet Connection Firewall statefully filtered multicast and broadcast traffic, which required the user to manually open the port to receive the response. In Windows Server 2003 Service Pack 1, Windows Firewall accepts the response to the multicast or broadcast traffic without additional configuration.

**Updated user interface**
**Detailed description**
The firewall user interface is updated in Windows Server 2003 Service Pack 1 to accommodate the new configuration options and the integration of IPv6 Internet Connection Firewall. The new Windows Firewall interface provides the user with the ability to change the operational states, the global configuration, logging options, and ICMP options.

The primary entry to the user interface has been moved from the **Properties** dialog box of the connection to a Control Panel icon. A link from the old location is still provided. Additionally, Windows Server 2003 Service Pack 1 creates a link from the Network Connections folder.

**Why is this change important?**
The functionality that is added in Windows Server 2003 Service Pack 1 required updates to the user interface.

**What works differently?**
The user interface is moved from the **Advanced** tab of the network connection's **Properties** dialog box to a specific Windows Firewall icon in Control Panel.

**New Group Policy support**
**Detailed description**
In earlier versions of Windows, Internet Connection Firewall had a single Group Policy object (GPO): Prohibit Use of Internet Connection Firewall on your DNS domain network. With Windows Server 2003 Service Pack 1, every global configuration

option can be set through Group Policy. Examples of the new configuration options available include:

- Define program exceptions
- Allow local program exceptions
- Allow ICMP exceptions
- Prohibit notifications
- Allow file and printer sharing exception
- Allow logging

Each of these objects can be set for both the corporate and standard profile. For more information about Group Policy options, see "Deploying Windows Firewall Settings for Microsoft Windows XP with Service Pack 2" in the Microsoft Download Center at http://go.microsoft.com/fwlink/?linkid=23277. This document also covers developments in Windows Server 2003 Service Pack 1.

**Why is this change important?**
It is important for administrators to centrally manage Windows Firewall policy settings to enable applications and scenarios to work in the corporate environment.

**What works differently?**
The IT administrator can now decide the default Windows Firewall policy set. This can either enable or disable applications and scenarios. This allows more control, but the policies do not change the underlying functionality of Windows Firewall.

**What settings are added or changed in Windows Server 2003 Service Pack 1?**

| Setting name | Location | Previous default value | Default value | Possible values |
|---|---|---|---|---|
| Protect all network connections | (Group Policy object) Computer Configuration \Administrative Templates \Network\Network Connections\ \Windows Firewall | Not applicable | Not configured | Enabled<br>Disabled |
| Do not allow exceptions | (Group Policy object) Computer Configuration \Administrative Templates \Network\Network Connections \Windows Firewall | Not applicable | Not configured | Enabled<br>Disabled |

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**

We recommend that you use the Security Configuration Wizard to configure Windows Firewall for use with Windows

Server 2003 Service Pack 1. SCW is designed to accommodate the requirements of different server roles and workloads and configure the firewall settings correctly. If you are going to manually configure your firewall settings, review the following information for how your applications might be affected.

**Outbound connections**
**Description**
For typical consumer and office computers, the computer is a client on the network. Software on the computer connects out to a server (an outbound connection) and gets responses back from the server. Windows Firewall allows all outbound connections, but applies rules to the types of communication that are allowed back into the computer.

Some examples of tasks involving Microsoft applications that might work this way include:

- Surfing the Web using Microsoft Internet Explorer.
- Checking e-mail in Outlook Express.
- Chatting in MSN Messenger or Windows Messenger.

**Action Required**
None. Windows Firewall will automatically allow all outbound connections, regardless of the program and the user context.

| **Note** |
| --- |
| When a computer initiates a TCP session request to a target computer, it will accept a response only from that target computer.<br><br>When the computer sends UDP packets, Windows Firewall allows UDP responses to the port from which the UDP packets were sent from any IP address for approximately 90 seconds.<br><br>Unicast responses to multicast and broadcast traffic are allowed through Windows Firewall for three seconds if the responses are to the port from which the traffic was sent and are from IP addresses on the same subnet as the computer. A setting in the firewall controls this behavior, which is enabled by default. |

**Unsolicited inbound connections for applications**
**Description**
This scenario covers an application that completes a listen operation on a TCP socket or successfully binds to a specific UDP socket through Winsock. For this scenario, Windows Firewall can automatically open and close ports as needed by the application.

Some examples of tasks involving Microsoft applications that might work this way include:

- Using audio and video in MSN Messenger or Windows Messenger.
- Transferring files in MSN Messenger or Windows Messenger.
- Hosting a multiplayer game.

**Action required**
If you are developing an application that needs to listen on a port (or ports) Microsoft requests that you update your code to ask the users to indicate whether they want to allow the application to open ports in the firewall:

- If the user consents to this, then the application can use the `INetFwAuthorizedApplication` API to add itself to the AuthorizedApplications collection as Enabled.
- If the user does not consent, then the application can use the `INetFwAuthorizedApplication` API to add itself to the AuthorizedApplications collection as Disabled.

When using the `INetFwAuthorizedApplication` API to add an application to the AuthorizedApplications collection, the following values are required:

- Image File Name. This is the file that calls Winsock to listen for network traffic. This must be a fully-qualified path, but it

might contain environment variables.

- Friendly Name. This is the description for the application that will be shown to users in the Windows Firewall user interface.

For more information about the `INetFwAuthorizedApplication` API, see "INetFwAuthorizedApplication" in the Microsoft Platform Software Development Kit (SDK) on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=32000.

Windows Firewall monitors Winsock to see when applications start and stop listening on ports. As a result, ports are automatically opened and closed for applications after their entries have been enabled in the Windows Firewall exceptions list. This means that no action is required by Winsock applications to actually open and close ports in the firewall.

| **Note** |
| --- |
| An application must be running in the context of a user with Administrator rights to add itself to the Windows Firewall exceptions list.<br><br>Ports are automatically opened and closed in the firewall for allowed Winsock applications, regardless of the user context in which the applications are running.<br><br>Applications should get user consent before adding themselves to the `INetFwAuthorizedApplications` collection.<br><br>Svchost.exe cannot be added to the `INetFwAuthorizedApplications` collection. |

**Inbound connections for services using fixed ports**
**Description**
While developers are advised to use the `INetFWAuthorizedApplication` APIs for all other scenarios, the use of global port APIs in Windows Firewall is recommended for services that listen on fixed ports. Because these ports are always open, there is minimal benefit to dynamically opening the ports. Instead, users gain the ability to customize the firewall settings for these fixed ports when the global port APIs are used.

Some examples of services that require inbound connections are:

- File and printer sharing.
- UPnP architecture.
- Remote Desktop.

**Action Required**
When a service needs to listen on a fixed port, it should ask the user whether it should allow the service to open ports in the firewall. Ideally this should be done when the service is being installed.

If the user consents to this, then the service should use the `INetFwOpenPort` API to add rules to Windows Firewall for the fixed port (or ports) needed by the service. These rules should be enabled.

If the user does not consent, then the service should still use the `INetFwOpenPort` API to add rules to Windows Firewall for the fixed port or ports needed by the service. These rules, however, should not be enabled.

When using the `INetFwOpenPort` API to add a port opening to Windows Firewall, the following values are required:

- Protocol. Specifies the network protocol that is used by the service, either TCP or UDP.
- Port. This is the number of the port to be opened.
- Friendly Name. This is the description for the port opening that will be shown to users in the Windows Firewall user interface.

For more information about the `INetFwOpenPort` API, see "InetFwOpenPort" in the Platform Software Development Kit on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=35316.

When a service is disabled, it should use the `INetFwOpenPort` API to close the static ports that it opened, whenever possible. This can be easily done if it is the only service that uses the ports. If the service potentially shares the ports with other services, however, it should not close the ports unless it can verify that none of the other services are using the ports.

An application must be running in the context of a user with Administrator rights to statically open ports in Windows Firewall.

**Note**

When statically opening ports through the `INetFw` API, a service should limit itself to traffic from the local subnet whenever possible.

Services should get user consent before statically opening ports in Windows Firewall. A service should never just automatically open ports without first warning the user.

**Inbound connections on RPC and DCOM ports for system services**

**Description**

Some system services require the use of RPC ports, either through DCOM or RPC directly, for inbound connections. Because of the significant security implications when opening RPC ports, these ports are handled as a special case, and developers should try to enable RPC for system services through Windows Firewall only when absolutely necessary.

**Action required**

Windows Firewall can be configured to enable the automatic opening and closing of RPC and DCOM ports for system services. By default, however, RPC will be blocked by Windows Firewall. This means that applications that use the RPC ports to transfer data to system services will need to configure Windows Firewall appropriately. When an application needs to enable this feature, it should ask the user whether it should allow the services to open ports in the firewall. Ideally, this should be done at installation time.

If the user consents to allowing the RPC ports to be opened, then the service should use the `INetFwRemoteAdminSettings` API to open the ports that are needed by the service.

If the user does not consent to allowing the RPC ports to be opened, then the application or service should not configure Windows Firewall to allow the RPC ports.

For more information about the `INetFwRemoteAdminSettings` API, see "INetFwAuthorizedApplication" on the MSDN Web site at http://go.microsoft.com/fwlink/?linkid=32000 and, in the table of contents, click "RemoteAddresses Property of InetFwAuthorizedApplication."

**Note**

To enable or disable the automatic opening of RPC ports in Windows Firewall, an application or service must be running in the context of a user with Administrator rights.

An application or service should try to allow the RPC ports through Windows Firewall only when absolutely necessary.

If the RPC ports are already allowed, then the application or service does not need to do anything in order to function correctly. You can determine which ports are already opened using the `IsPortAllowed` API.

The RPC ports setting works only for RPC servers that run in the context of local system, network service, or local service. Ports opened by RPC servers running in other user contexts will not be enabled through this setting. Instead, those RPC servers should use the Windows Firewall exceptions list.

# Windows Media Player

Applies To: Windows Server 2003 with SP1

**What does Windows Media Player do?**
Windows Media Player is an application that provides media content, plays media files, and helps organize your stored media files.

**Who does this feature apply to?**
All users who use Windows Media Player should be aware of the changes incorporated in Windows Server 2003 Service Pack 1.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Windows Media Player 10**
**Detailed description**
Windows Media Player 10 is installed with most versions of Windows Server 2003 Service Pack 1 (it is not included with the Itanium-based versions). This version of Windows Media Player includes security fixes and new functionality.

During Windows Server 2003 Service Pack 1 installation, if you select the option to archive files, you can remove Service Pack 1 later. If you perform a new installation of Windows Server 2003 with Service Pack 1, the operating system is replaced, and Windows Media Player 10 cannot be removed. For more information, see the Windows Media Knowledge Center at on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=32062.

**Why is this change important? What threats does it help mitigate?**
Windows Media Player 10 is the most secure version of Windows Media Player and it has been updated to work with the other security enhancements contained in Windows Server 2003 Service Pack 1.

.

**What works differently?**
If you uninstall Windows Server 2003 Service Pack 1, you might need to reacquire some licenses in order to play the content that you have previously licensed. This applies if you have upgraded your computer from a member of the Windows 2000 Server or Windows Server 2003 family to Windows Server 2003 Service Pack 1, because Windows Media Player 10 handles digital content licenses differently than earlier versions.

**How do I resolve these issues?**
To ensure that your existing licensed content remains available to Windows Media Player after you remove Windows Server 2003 Service Pack 1, do one of the following:

- Before you upgrade a computer to Windows Server 2003 Service Pack 1, back up the licenses for your digital media files. (You can do this through License Management in Windows Media Player.) Then, before removing the service pack, back up any additional licenses you have acquired. After you remove the service pack, restore all of the licenses.

- After you remove Windows Server 2003 Service Pack 1, you can install Windows Media Player 10 from the Microsoft Windows Media Download Center.

# Wireless Provisioning Services (WPS)

Updated: October 13, 2010

Applies To: Windows Server 2003 with SP1

**What does Wireless Provisioning Services do?**
An increasing number of users are accessing the Internet through a growing number of public wireless networks, or wireless fidelity (Wi-Fi) hotspots. Using Wireless Provisioning Services (WPS) provides wireless users with a consistent experience and seamless connectivity to public Wi-Fi hotspots through automatic provisioning of the client and seamless roaming. WPS enables Wireless Internet Service Providers (WISPs) to use a standards-based and integrated platform to provide Wi-Fi hotspots with enhanced security that are easy to use and manage. In addition, WPS enables enterprises to easily provide guest access with enhanced security to private wireless networks.

With WPS, WISPs and enterprises can send provisioning and configuration information to mobile clients as they connect to the Internet or the corporate network. This in turn allows seamless, automatic and secure configuration of mobile clients, enabling a uniform sign-up experience in the enterprise and across different public network providers and hotspot locations.

**Who does this feature apply to?**
Wireless Provisioning Services is designed for three types of organizations:

- Hotspot Service Provider (HSP)

  HSPs deploy wireless access points in public places, such as shopping malls and airports, but HSPs are not Internet Service Providers (ISPs). Instead, the HSP contracts with one or more ISPs, and offers users one or more service plans to choose from when they want to establish an account for Internet access.

- Wireless Internet Service Provider (WISP)

  WISPS are ISPs that either deploy Wi-Fi hotspots in public places or outsource Wi-Fi hotspot services to an HSP.

- Enterprise

  Enterprises can use WPS technology to provide managed guest access on their networks.

**What new functionality is added to this feature in Windows Server 2003 Service Pack 1?**
**Wireless Provisioning Services**
**Detailed description**
Wireless Provisioning Services is an extension to the existing wireless services and user interfaces within Windows XP and Windows Server 2003. It builds on the wireless features already in Windows, such as Wireless Zero Configuration, and the wireless security features, such as Protected Extensible Authentication Protocol (PEAP) and Wi-Fi Protected Access (WPA). WPS also includes modifications to Windows Server 2003. The Windows Server 2003 Internet Authentication Service (IAS) component was modified to include guest authentication of the clients in the provisioning process.

WPS includes a provisioning service component that allows for Wireless Internet Service Providers (WISPs) and enterprises to send provisioning and configuration information to a mobile client that is trying to connect to the Internet or the corporate network. By using Wireless Provisioning Services, WISPs can offer services at multiple network locations and use multiple network names (service set identifiers, or SSIDs). After users have signed up to a WISP in one location or are preprovisioned and have downloaded the provisioning information, they can automatically connect to the Internet on subsequent occasions using the network provided by the WISP in their different hotspot locations. The Wireless Zero Configuration (WZC) service will automatically choose the correct network belonging to the WISP based on the provisioning files supplied. WSP also enables automatic and seamless roaming between different providers.

Further, when WPS is used the client computer automatically keeps the provisioning information stored on the client computer up to date. This allows the provider to change the network settings, add new locations, and so on, without disrupting the service or having users reconfigure their systems.

When a user connects his computer to a WISP and establishes an account for the first time, the following four stages occur:

- The computer discovers the WISP network at a Wi-Fi hotspot.

- The user is authenticated using a guest account and the computer is connected to the Wi-Fi network.
- The mobile client is provisioned and the user establishes an account with the WISP.
- The user is authenticated on the Wi-Fi network using the new user account credentials.

Each of these stages is discussed in detail in the following scenario.

A user arrives at a Wi-Fi hotspot with a portable computer running Windows XP with Service Pack 2 or Windows Server 2003 with Service Pack 1 and Wireless Provisioning Services. When the computer comes within range of the WISP access point beacon the following occurs:

1. The Wireless Zero Configuration (WZC) service on the client computer detects the beacon information from the access point, which is enabled with a broadcast service set identifier (SSID). The SSID is equivalent to the network name.
2. The user is informed by Windows that a wireless network is available. The user views information in Windows, including the network's friendly name. In this example, the user possesses a promotion code to use for account establishment, and proceeds by clicking **Connect**. This causes the WPS client to connect the user's computer to the wireless network using a guest account with limited privileges.

When the guest account is authenticated by the Wi-Fi network, the following occurs:

1. WZC uses 802.1x and Protected Extensible Authentication Protocol (PEAP) to connect and authenticate as guest to the WISP network through the access point, automatically passing a blank user name and password to the WISP Internet Authentication Service (IAS) server (IAS is also known as the Microsoft RADIUS server). The access point is connected to a gateway device that allows traffic from the client to pass to the provisioning services in the network to complete the sign-up process, but blocks the client from accessing the Internet.
2. The IAS server (or RADIUS server) is the PEAP authenticator and Transport Layer Security (TLS) endpoint for users who connect as guest. The TLS tunnel is created between the client and the IAS server. All subsequent messages between client and server pass through this tunnel, which traverses the access point and the gateway device.
3. Server authentication is performed when the IAS server verifies its identity to the client computer using a certificate that contains the Server Authentication purpose in Enhanced Key Usage (EKU) extensions. This certificate is issued by a public trusted root certification authority (CA) that the client computer trusts.
4. The IAS server authenticates and authorizes the user as Guest. In the Access-Accept message that the IAS server sends to the client is a container with a URL to the provisioning information. This URL provides the Wireless Provisioning Services engine running on the client, with the location of the XML master file.

When the client is provisioned and the user creates an account, the following occurs:

1. On the client computer, the Wireless Provisioning Services downloads the XML master file and sub-files from the provisioning server. The master file contains pointers to XML subfiles that control the client's progress through the process. When the XML sign-up schema is downloaded, the sign-up wizard is launched on the client to allow the user to create and pay for an account with the WISP.
2. Using the sign-up wizard on the client computer, the user steps through the process of signing up for an account. The user enters the promotion code as well as personal data such as name, address, and credit card number. The data entered by the user is converted by the Wireless Provisioning Services client into an XML document.
3. The XML document containing the user's sign-up data is sent to the Web application on the WISP provisioning server.
4. The Web application checks the promotion code entered by the user against the promotion code database (for example, a SQL Server database). If the promotion code is valid, the Web application continues processing the user's data.
5. The Web application processes the user's payment information. Once payment is verified and sign-up information is

completed successfully, the Web application reads the domain and security group information from the promotion code database and creates a user account in identity services (such as Active Directory) and adds the account to the security group. The Web application also enters the new user name in the promotion code database.

6. An XML document containing the new account credentials is sent from the WISP provisioning server to the Wireless Provisioning Services client on the client computer. The client computer uses the credentials to configure WZC and 802.1x under the name of the WISP. The connection is re-initiated with the new user account password-based credentials (user name and password).

The re-initiated connection process is as follows:

1. The Wireless Zero Configuration (WZC) service on the client computer restarts the association to the SSID for the WISP.

2. WZC finds the correct 802.11 profile which was downloaded with the other WISP information in the XML master file. WZC reassociates with the access point using the correct profile.

3. WZC uses 802.1x to start the authentication process using a combination of the Protected Extensible Authentication Protocol and the Microsoft Challenge Handshake Authentication Protocol version 2 (PEAP-MSCHAPv2) using the new account credentials passed to 802.1x by the Wireless Provisioning Services client.

4. As the client starts the authentication process with PEAP-MSCHAPv2 authentication, a TLS channel is created between the user's client computer and the WISP IAS server.

5. In the second stage of PEAP-MSCHAPv2 authentication, the WISP IAS server authenticates and authorizes the connection request against the new account in the user accounts database (for example, Active Directory). The IAS server sends an Access-Accept message to the access point. Included in the Access-Accept message are attributes that specify the user can now get access to the Internet.

6. The access point instructs the gateway device to assign the client to the logical segment network with access to the Internet.

**Why is this change important?**
Wireless Provisioning Services makes it easier to use wireless hotspots without compromising security. WPS, with Windows Server 2003 Service Pack 1, and Microsoft IAS (also known as a RADIUS server), allows users' computers to more easily discover, connect and roam between wireless hotspots with enhanced security.

- The current connection model for WISP signup and use is not secured. Most Wi-Fi hotspots are configured for open authentication and without data encryption. Users are generally required to launch a Web browser to initially sign-up to the WISP service and for subsequent logins. WSP mitigates this threat by adding encryption and authentication to the communications between the client and the wireless network.

- Browser redirection-based deployment has many usability issues. Users may not even know they have to launch their browser to get connected. Another example of what can happen is when the browser is set to use proxy settings to access the Internet and the user is connected directly to the corporate network. In this case, browser redirection does not work and the user would have to know to disable the proxy settings to connect to the hotspot. This can cause costly support calls to the WISP or the enterprise helpdesk.

- Browser based deployment is vulnerable to man-in-the-middle attacks, for example, by a malicious front-end server using a rogue access point. Users queried by this access point might unknowingly be giving away personal identification and credit card information. By eliminating the need for a Web login WSP reduces the vulnerability of WISP users to this type of attack.

- Without additional hotspot client software users cannot easily detect hotspots and do not have a unified mechanism to sign-up to them. It is not easy for users to find out information about the WISP or search for the hotspot locations for that WISP. If users sign-up at one hotspot, they are not necessarily configured to automatically use the other hotspots. In addition, there is no standard mechanism to keep their provisioning and configuration information up-to-date.

- Add-on hotspot client software can help the user access that specific WISP's network. However, add-on software can also conflict with the wireless services native to the operating system or client software from other providers, potentially causing interoperability problems, even instability of the system as they all attempt to control the wireless settings of the entire system. Updates to the WISP configuration usually require updates to the client software. For these reasons, many corporate IT departments are reluctant to deploy third party hotspot client software to their users.

- There is no standardized mechanism across WISPs to process user sign-ups and update their configurations. As a result, the user experience is fragmented and automatic and seamless roaming across providers can be difficult.

**Wireless Network Registration Wizard**
**Detailed description**
The Wireless Network Registration Wizard provides the user interface to sign-up for a wireless hotspot and guides the user through the provisioning process. The wizard builds content from provisioning information (XML files) provided by the WISP. The provisioning information can be dynamically downloaded or preinstalled on the client system. Preinstallation can be provided by an OEM for new systems, by the IT department within an organization, or from a WISP Web site. The WISP owns and creates the provisioning information and drives the users' sign-up and provisioning experience. The following example presents a simple Wireless Network Registration Wizard experience where the user has prepaid for an access code. The XML schema and wizard are flexible and can enable more complex sign-up experiences.

First, the user can either right-click the wireless network icon in the notification area and then click **View Available Wireless Networks**, or the user can respond to the notification message in the notification area that indicates availability of a new wireless network in range. When **Choose a wireless network** appears, the user selects a new wireless network and places that network on the preferred networks list.

The user then selects a network name (an SSID) and clicks **Connect** to connect to the wireless network. With a WPS-based Wi-Fi hotspot, the client detects that there is more provisioning information in form of XML files that is available about the network and the provider. It then confirms with the user whether the provisioning information should be downloaded. With a non-WPS network, the experience would be the same as with Windows XP today: either the users are prompted for a security key when connecting to a secure network or the users are warned that the network they are trying to connect to is unsecured, and they are asked if they still want to connect to it.

After the download is complete, the Wireless Network Registration Wizard automatically launches and guides the user through the sign-in process. The first screen displays a customized logo (or banner) and content from the provider.

The subsequent screens may include selecting a subscription plan, entering credit card information, personal information and so on. In this example there is just one plan and the user is asked to enter a prepaid or promotional code to get access to the network. Next, Wi-Fi Hotspot Deployment displays information about the selected plan, such as the terms of the service agreement and privacy statement.

On the last screen, the wizard asks the users for their connectivity preferences for this connection. These default preferences can be set by the provider but can be overridden by the user. For example, if the users select a monthly subscription with unlimited data, they probably want to always connect to the network automatically whenever in range. If the users choose a "pay-as-you-go" plan, they probably want to control when to connect and choose a manual connection option as their preference.

The second option determines whether the client keeps the provisioning information automatically up to date. For example, if the provider adds new network names, adds new locations, or changes the network or security settings, the client can automatically update the information without any user interaction required while connected to the network.

On subsequent visits to hotspots made available by the provider or by their roaming partners in the same or different locations, if automatic connection is selected, all the user has to do is to turn the mobile computer back on or resume operations from standby, and the user is automatically connected. When connected, instead of showing a cryptic network name or SSID in the **Choose wireless network** dialog box (which opens from the **View Available Wireless Networks** notification window), a friendly name of the provider will be shown, along with a logo of the provider.

From this dialog box, users can also search for available hotspot locations or view the help and support information provided by the WISP. Both the help and hotspot location information is downloaded as part of the provisioning information. The location information can be searched and viewed online or offline.

**What existing functionality is changing in Windows Server 2003 Service Pack 1?**
The wireless user interface has changed – a new **View Available Wireless Networks** dialog box will replace the existing dialog box.

**Do I need to change my code to work with Windows Server 2003 Service Pack 1?**
Wireless Provisioning Service does not require any changes to existing applications. There are two new APIs with WPS. One of the new APIs provides for adding to and queries through the XML data on the computer. This API can be used to preprovision the client from the WISP Web site by the user (using a standalone application), by OEMs, or IT departments.

**Additional Resources**
For more information about WPS, see

1. Deploying Wireless Provisioning Services (WPS) Technology, available in Word format on the Microsoft Download Center, at http://go.microsoft.com/fwlink/?LinkId=203315.

2. Using the Wireless Provisioning Services (WPS) Technology Authoring Tool, available in Word format on the Microsoft Download Center, at http://go.microsoft.com/fwlink/?LinkId=203316.

# .NET Framework version 1.1 for 64-bit operating systems

Applies To: Windows Server 2003 with SP1

**What does the .NET Framework do?**
The .NET Framework is a new computing platform designed to simplify application development in the highly distributed environment of the Internet. The .NET Framework has several main components: the common language runtime, the .NET Framework class library, and the runtime hosts. The common language runtime is the foundation of the .NET Framework. It manages code execution and provides core services such as memory management, thread management, and remote execution. The .NET Framework class library is a comprehensive, object-oriented collection of reusable classes that you can use to develop a wide range of applications, including ASP.NET applications and XML Web services. The .NET Framework also provides several runtime hosts, including Windows Forms and ASP.NET, which work directly with the runtime to provide a scalable, server-side environment for managed code.

In the previous release of the 64-bit versions of the Microsoft Windows Server 2003 operating systems and Microsoft Windows XP Professional x64 Edition operating system the .NET Framework was not supported. In the 64-bit versions of Windows Server 2003 Service Pack 1 and Windows XP Professional, the .NET Framework is supported. The Microsoft .NET Framework 1.1 is built into all products in the Windows Server 2003 family except for the 64-bit versions.

The 32-bit version of .NET Framework 1.1 is supported by 64-bit versions of Windows Server operating systems and can be installed for 32-bit applications running on 64-bit versions of Windows operating systems (WOW64).

To install .NET Framework 1.1, visit Windows Update and select the .NET Framework 1.1 package or see "Microsoft .NET Framework Version 1.1 Redistributable Package" at the Microsoft Download Center Web site at http://go.microsoft.com/fwlink/?LinkId=17153. To install the service pack, visit Windows Update or see "Microsoft .NET Framework 1.1 Service Pack 1" at the Microsoft Download Center Web site at http://go.microsoft.com/fwlink/?LinkId=39058.

**Important performance and scalability information for Itanium-based systems**
If a 32-bit version of the .NET Framework is installed on 64-bit Itanium-based systems, applications created for the 32-bit version of the Framework will bind and run against it. Therefore, applications created with the Microsoft .NET Framework 1.1 run only in a 32-bit process within the WOW64 compatibility environment. Due to the design of x86 emulation and the WOW64 subsystem for the Itanium processor family applications are restricted to execution on one processor.

Single processor execution and x86 emulation reduce the performance and scalability of 32-bit .NET Framework applications running on Itanium-based systems. We recommend that applications using the .NET Framework 1.1 be used for interactive, client applications. We do not recommend this environment for .NET Framework 1.1 applications that demand high performance or scalability, such as high-load ASP.NET applications. We suggest that application developers instead evaluate the .NET Framework 2.0, which includes native 64-bit support for Itanium-based systems, for increased performance and scalability.

**Who does this feature apply to?**
This feature applies to users with applications written to use the .NET Framework 1.1 and also to application developers developing .NET Framework 1.1 applications that will be run on both 64-bit and 32-bit operating systems.

# Appendices

Applies To: Windows Server 2003 with SP1

**Appendix A: Document History**

| Release Date | Changes to Document |
|---|---|
| October 6. 2004 | First version of document released |
| December 6. 2004 | Added new sections: Access-based Enumeration, Active Directory, ADPrep.exe, DCDiag.exe, Ntdsutil.exe, Security Account Manager (SAM), Device\PhysicalMemory Object, Kernel patch protection for x64-based operating systems, Remote Access Quarantine, Remote Installation Services (RIS) for 64-bit Operating Systems, Setup<br><br>Revised sections: Data Execution Prevention, DCOM, Internet Explorer features, Windows Firewall |
| April 18, 2005 | Added new sections: Distributed File System (DFS) in Windows Server 2003 Service Pack 1, Distributed Transaction Coordinator, Internet Information Services (IIS) in Windows Server 2003 Service Pack 1, .NET Framework for x64-based operating systems, Terminal Services in Windows Server 2003 Service Pack 1<br><br>Revised sections: Access-based Enumeration, Data Execution Prevention, DCOM Security Enhancements, Post-Setup Security Updates, Remote Installation Services (RIS) for 64-bit operating systems, Windows Firewall |

**Appendix B: Group Policy Administrative Templates**

Many operating system components have added support for Group Policy administrative templates, which support many new settings. These new settings have been created in response to customer feedback.

Microsoft has published a reference spreadsheet that lists Group Policy settings described in Administrative Template (.adm) files that are included with Windows Server 2003 Service Pack 1. To download the reference spreadsheet, see "Group Policy Settings Reference for Windows Server 2003 with Service Pack 1" on the Microsoft Download Center at http://go.microsoft.com/fwlink/?LinkId=22031.

# Windows Server 2003 Service Pack 1 Installation and Deployment Guide

Updated: June 8, 2005

Applies To: Windows Server 2003 R2

Introduction to Service Pack 1 (SP1)

Before You Deploy SP1

Planning Your Deployment

The Standalone Installation

The Integrated Installation

Command-Line Options for Installing SP1

Uninstalling SP1

Symbols for Debugging Service Packs

Additional Resources

**Introduction to Service Pack 1 (SP1)**

This guide explains how you can:

- **Deploy Microsoft® Windows Server™ 2003 Service Pack 1 (SP1) to multiple computers** that are already running the Windows Server 2003 operating systems. If you have only one server to update, you can see the Readme for Windows Server 2003 Service Pack 1 (on the Microsoft TechCenter Web site) instead.

- **Integrate SP1 with Windows Server 2003** for deploying to multiple computers running an earlier version of Windows® or with no operating system installed.

- **Uninstall SP1** from computers.

This guide does not explain:

- **How to combine SP1 with other updates for Windows Server 2003**. For information about how to do this, see Microsoft Windows Server 2003 Service Pack 1 Installing and Deploying Updates (on the Microsoft TechCenter Web site).

- **New SP1 functionality**. For important information about functional changes to SP1 that you should understand before you deploy SP1, review the information that applies to your setup on the Microsoft TechCenter Web site.

| Note |
| --- |
| You cannot install SP1 on any x64-based versions of Windows Server 2003. For more information about these versions, see Windows Server 2003 x64 on the Microsoft Web site. |

- **How to deploy SP1 by using Software Update Services (SUS)**

  For details about using SUS, see Windows Server System on the Microsoft Web site.

**Before You Deploy SP1**

Before you deploy SP1, you should review the information about the service pack on the Microsoft TechCenter Web site so that you can:

- Understand what functionality and security technologies SP1 includes and how you can implement them in your

environment.

- Find out how to plan, prepare, test, and troubleshoot your SP1 deployment.

- Read other essential installation information, and check minimum hard disk requirements in the Readme for Windows Server 2003 Service Pack 1 (on the Microsoft TechCenter Web site).

**List of updates**
For information about updates and fixes included in SP1, see article 824721, "Windows Server 2003 Service Pack 1 List of Updates," in the Microsoft Knowledge Base.

**Release notes**
Before you install SP1, see article 889101, "Release Notes for Windows Server 2003 Service Pack 1," in the Microsoft Knowledge Base.

**Files and programs in SP1**
You can obtain installation files to deploy SP1 to multiple computers from either the SP1 CD or the Microsoft Download Center.

For 32-bit versions of Windows Server 2003 (which run on x86-based computers), the SP1 installation file is named WindowsServer2003-KB889101-SP1-x86-*LLL*.exe, where *LLL* is the language version of SP1. For example, ENU represents the English-language version.

For Itanium-based versions of Windows Server 2003, the SP1 installation file is named WindowsServer2003-KB889101-SP1-ia64-*LLL*.exe.

You can update Itanium-based versions with SP1 for only English, German, Japanese, and French locales.

The instructions and examples throughout this document use the name of the installation file for 32-bit versions (unless a particular difference between 32-bit and Itanium-based installations must be called out).

**Contents of the SP1 CDs**
For each language version, two CDs are available to update Windows Server 2003 operating systems with SP1: one for 32-bit versions of Windows Server 2003 and one for Itanium-based versions. The CD for Itanium-based versions is labeled as such.

Each SP1 CD contains the following files:

- A service pack installation file

- The Deploy.cab file. This is a compressed file that contains a collection of tools and accompanying online Help. (See Deploy.chm and Ref.chm when you expand Deploy.cab.) It is located on the SP1 CD in the \Support\Tools folder. Deploy.cab is not automatically loaded when you install SP1.

- The Support.cab file. This is a compressed file that also contains a collection of tools and online Help. It is located in the \Support\Tools folder. Technical support personnel and network administrators can use the updated support tools in this file to manage networks and troubleshoot problems. Support.cab is not automatically loaded when you install SP1.

**Download Center**
You can update multiple servers by downloading SP1 installation files from the Microsoft Download Center. You can download installation files for 32-bit versions or Itanium-based versions of Windows Server 2003.

Because downloading SP1 installation files takes a substantial amount of time, we recommend that you save the file on your computer. This way, if you must restart the installation or reinstall SP1, you will not need to download the file again. Because the installation file is very large, if your computer has more than one hard disk, you should save the file on a disk other than your system disk.

**Planning Your Deployment**
To ensure a successful deployment, you should review the information presented in Before You Deploy SP1.

After you have reviewed this information, you must complete the following set of planning tasks:

- Choose an installation method.

- Remove all prerelease versions of SP1 from your servers.
- Determine whether you want to disable antivirus software during installations from the CD.
- Identify the deployment tools and files.
- Determine update and upgrade options.
- Check space requirements.
- Test and troubleshoot the deployment in your environment.
- Review the post-installation information near the end of this guide.

For detailed information about deployment-planning tasks and strategies, see the Windows Server 2003 Deployment Guide (on the Microsoft TechCenter Web site). This information can help you get started, including describing how to create a deployment plan and how to run a pilot project.

**Choosing an installation method**
You can either:

- Deploy SP1 on a network to multiple servers that are already running Windows Server 2003. (Standalone Installation)
- Integrate a Windows Server 2003 operating system with SP1, and then install the operating system and SP1 together on multiple servers using one procedure. This type of installation is also known as "slipstreaming." You can either install an integrated version on a server that does not have an operating system, or you can use the integrated version to upgrade computers that are running previous versions of Windows to Windows Server 2003 with SP1 (following the same path you would use to upgrade those computers to Windows Server 2003).
- Follow the instructions in the Windows Server 2003 Service Pack 1 Installing and Deploying Updates (on the Microsoft TechCenter Web site) to combine SP1 with an installation of Windows Server 2003, with other updates, or with both the operating system and other updates, and then install them together using one procedure.

You can perform a standalone or integrated installation from a shared distribution folder on a network. Even if you decide to do this, we recommend storing SP1 source files locally.

If you want to save disk space, you can extract the files from the service pack installation file. With this method, Windows accesses the distribution folder whenever it requires a service pack file, such as when Windows File Protection must restore a corrupted file or when an optional component is being configured. This step saves disk space on local computers because, if source files for the service pack are required, the installation will point to the distribution folder for the folder called ServicePackFiles instead of creating this folder locally.

**Important**

Because the service pack source files are stored remotely on the network, this installation method is suitable only for computers that are permanently connected to the network. For example, this method is not suitable for updating laptop computers.

You must use a shared distribution folder that was created specifically for SP1. Do not reuse a folder that was set up for a previous service pack. Shared distribution folders for service pack source files must be permanent to ensure that all of the files that a computer might need to replace are available.

For more information about moving the shared distribution folder, see article 271484, "Files and Folders Are Added to Your System After Service Pack Is Installed," in the Microsoft Knowledge Base.

**Removing prerelease versions of SP1**
Unless you have a supplemental support agreement with Microsoft, you must uninstall any prerelease versions of SP1 before you proceed. Microsoft does not support installing this version over the release candidate or beta versions of SP1.

**Antivirus software and installing the service pack**

| **Important** |
| --- |
| Antivirus software is a critical part of keeping a computer secure. But the time that it takes for the software to scan files on your system can add significantly to the time required to install the service pack: as much as an hour or more on slower systems. Disabling your antivirus software before you install the service pack eliminates this extra installation time. If you disable your antivirus software before you install the service pack, be sure that you understand the risks involved, and be sure to enable the antivirus software after you install the service pack. |

**Checking space requirements**

Check the system requirements for installing SP1 in the article 892807, "Hard Disk Space Requirements for Windows Server 2003 Service Pack 1" in the Microsoft Knowledge Base.

**Overview of the deployment tools and files**

After you select your installation method, review the corresponding scenario in The Standalone Installation or The Integrated Installation later in this guide. This section will help you identify the tools and files that you need for your deployment.

Depending on your environment, you might need one or more of the following deployment tools and files:

- **Microsoft Windows Installer**

  Windows Installer is a Windows component that standardizes and simplifies how you install and manage software programs (such as the service pack) on multiple computers. You can use this installation service to manage the installation, modification, repair, and removal of programs. Because Windows Installer facilitates consistency in your deployments, it enables you to manage shared resources, customize installation processes, make decisions about application usage, and resolve configuration problems.

- **The Unattend.txt answer file** (for integrated installations only)

  The Unattend.txt answer file identifies how Windows Server 2003 Setup interacts with the distribution folders and files that you create and provides information about your preinstallation requirements. This answer file also supplies Setup with all of the information that you are prompted to provide during a typical Windows Server 2003 installation.

  You can create or modify the Unattend.txt file by using either a text editor or Setup Manager. Make sure that only the system administrator has Write access to this file.

  For more information, see the Unattend.txt topic in the Microsoft Windows Preinstallation Reference Help (Ref.chm) in Deploy.cab in the \Support\Tools folder on your SP1 CD.

- **Microsoft Systems Management Server**

  Microsoft Systems Management Server (SMS) provides a variety of tools to help you deploy the service pack in your organization. With SMS 2003, you can automatically update servers in your organization with the new service pack.

  You can allow administrators to run the service pack installation whenever they like, or you can schedule the service pack installation to run at a specific time.

The following resources provide more detailed information about specific deployment tools and files.

- Windows Server 2003 Deployment Kit (on the Microsoft TechCenter Web site).

- Article 892778, "Updated System Preparation tool for Windows Server 2003 Service Pack 1," in the Microsoft Knowledge Base.

- The Microsoft Windows Corporate Deployment Tools User's Guide (Deploy.chm) and the Microsoft Windows Preinstallation Reference Help (Ref.chm) in Deploy.cab in the \Support\Tools folder on your CD.

- The Windows Support Tools Help (Suptools.chm) in Support.cab in the \Support\Tools folder on your CD. This Help file describes the support tools and gives examples of how to use them.

- The Release Notes (Readme.htm) for Windows Support Tools for Microsoft Windows Server 2003, which is located in the \Support\Tools folder on your CD.

- Article 892777, "Windows Server 2003 Service Pack 1 Support Tools," in the Microsoft Knowledge Base.

**Testing the deployment in your computing environment**
Although Microsoft has a high degree of confidence in SP1, it is not possible to test all hardware configurations and applications that might be present in all environments where you might install SP1.

We therefore recommend that you test the service pack in your computing environment before you deploy it to all of your servers.

Testing the service pack can include the steps described in following procedure, but might need to include more steps, depending on your environment.

**To test the service pack in your environment**

1. Your test environment should include a cross-section of the types of computers on which you want to deploy the service pack. Make sure that the test computers are equipped with the software and the hardware devices that are typically used in your organization.

2. Install the service pack on each test computer just as you would in the environment where you plan to use the service pack. Make sure that you complete each of the following tasks as appropriate for your environment:

    - Update test computers that are running Windows Server 2003 to Windows Server 2003 with SP1.

    - Upgrade test computers that are running Windows NT Server 4.0 and Windows 2000 Server to Windows Server 2003 with SP1.

    - Install Windows Server 2003 with SP1 onto test computers that have no other operating system installed (that is, perform a "clean installation").

3. Verify that the software and hardware continue to work as expected for a variety of scenarios.

If you are installing Windows Server 2003 for the first time in your organization, you might want to set up a pilot group to test your deployment and verify whether it works in your environment as expected.

**The Standalone Installation**
During the standalone installation, the service pack is installed on a computer that is already running Windows Server 2003. When you run the Update.exe program to install SP1, it installs the updated system files and makes the necessary registry changes. After the computer is restarted and the post-boot processes have completed, the installation is complete, and the operating system runs with an updated file set.

This section describes four scenarios for installing the service pack.

- Scenario 1: Installing the service pack so that computers use local source files for the service pack (recommended)

- Scenario 2: Installing the service pack so that computers share remote source files for the service pack

- Scenario 3: Using Systems Management Server (SMS) to install the service pack

- Scenario 4: Using Windows Installer and Group Policy to install the service pack

| **Important** |
| --- |
| If a system file on a computer becomes corrupted or must be replaced for some other reason, you must have the source files for that service pack to replace that system file. |

You can distribute the service pack through several types of media, including CD-ROMs, shared folders on networks, and Web downloads. Because this guide is intended for corporate audiences, it focuses on using shared distribution folders on networks, which is the most common distribution medium for this audience.

**Svcpack.log file creation**
When you run a standalone installation, the Update.exe program creates a log file named Svcpack.log in systemroot. This log file contains the following information:

- The command line that initiated the Update.exe program.
- A list of the files that the Update.exe program copied to your computer.
- Error messages if any errors were encountered.
- The command-line options that were used to install the service pack.

**Scenario 1: Installing the service pack so that computers use local source files for the service pack (recommended)**
By using this method, you can set up a shared distribution folder on a network for the service pack installation file. (The 32-bit version of this file is called WindowsServer2003-KB889101-SP1-x86-*LLL*.exe.) If you set up a shared distribution method, you can run the service pack installation from a central location and then store source files for the service pack locally.

To install SP1 from a shared folder, copy the service pack installation file to the folder from which you want to install SP1. You can download the SP1 installation file from the Microsoft Download Center, or you can copy it from the SP1 CD:

- WindowsServer2003-KB889101-SP1-x86-*LLL*.exe.
- WindowsServer2003-KB889101-SP1-ia64-*LLL*.exe.

When you run WindowsServer2003-KB889101-SP1-x86-*LLL*.exe, the updated system files are extracted to the local machine. By default, Update.exe then automatically installs the updated system files and makes the necessary changes in the registry. After the computer is restarted, the installation is complete, and Windows Server 2003 runs with an updated file set.

Unless you have a supplementary support agreement with Microsoft, you must uninstall any prerelease versions of SP1 before you proceed. Microsoft does not support the installation of this version over the release candidate or beta versions of SP1.

| **Note** |
| --- |
| In the following procedure, *Drive*: represents the drive letter of the network or computer where your distribution folder is located. |

**To update servers by installing SP1 from a shared folder so that computers use local source files for the service pack (recommended)**

1. Connect to the network or computer on which you want to create the distribution folder.
2. In the shared folder on the network, create a distribution folder for the service pack.

   For example:

   To install SP1 for a Windows Server 2003 operating system, create a distribution folder named WS2003SP1 by typing the following:

   **mkdir** *Drive*:**\WS2003SP1**

   (In the example, *Drive:* represents the drive where you want to place the distribution folder.)
3. Copy WindowsServer2003-KB889101-SP1-x86-*LLL*.exe from the SP1 CD or download it from the Microsoft Download Center into the distribution folder.
4. To verify that you have assigned appropriate permissions to users who are installing the service pack, do the following:

a. Navigate to the appropriate folder, right-click it, and then click **Properties**.

b. Click the **Sharing** tab, and then click **Share This Folder**.

c. In **Share Name**, type a name for the folder.

d. Click **Permissions**, and then assign permissions that allow users to install the service pack from this folder.

e. If you are using an NTFS file system partition, click the **Security** tab, confirm that the permissions listed there do not conflict with those on the **Sharing** tab, and then click **OK**.

5. To install the service pack from the distribution folder (in this example, the folder is named WS2003SP1), at the command prompt, type the following:

   *****ServerName***\WS2003SP1\WindowsServer2003-KB889101-SP1-x86-***LLL***.exe**

   You can include command-line options as needed. For example, if you want to install updates immediately after you install SP1, specify the **/Z** option in the installation command. This option prevents your computer from restarting automatically after SP1 is installed.

6. Follow the instructions in the Setup Wizard.

7. After the installation is complete, do one of the following:

   - If you do not want to install additional updates right after the service pack installation, restart the computer immediately.

   - If you want to install additional updates, install them before you restart your computer. If you use this approach, SP1 and the updates will become fully operational at the same time.

8. After you restart the computer, restart the antivirus software if you disabled it.

| **Important** |
| --- |
| SP1 will not be fully operational until you restart your computer. |

**# Scenario 2: Installing the service pack so that computers share remote source files for the service pack**
Use this method to set up a shared distribution folder on a network, and then install the service pack from the shared folder onto computers that are already running Windows Server 2003.

With this method, source files for the service pack are stored in the shared distribution folder rather than on local computers.

| **Important** |
| --- |
| Because the source files for the service pack are stored remotely on the network, this method is suitable only for computers that are permanently connected to the network. For example, this method is not suitable for updating laptop computers. |

You must use a shared distribution folder that was created specifically for SP1. Do not reuse a folder that was set up for a previous service pack. Shared distribution folders for service pack source files must be permanent to ensure that all of the files that a computer might need to replace are available.

If you want the installation to use source files from the distribution folder, you must first extract them from the installation file. This method saves disk space on local computers because, if source files for the service pack are required, the installation will point to the distribution folder for the folder called ServicePackFiles instead of creating this folder locally. The ServicePackFiles folder is needed whenever the operating system requires a service pack file, such as when Windows File Protection must restore a corrupted file, or when an optional component is being configured.

For more information about moving the shared distribution folder, see article 271484, "Files and Folders Are Added to Your System After Service Pack Is Installed," in the Microsoft Knowledge Base.

| **Note** |
| --- |
| In the following procedure, *Drive:* represents the drive letter of the network or computer where your distribution folder is located. |

**To install the service pack so that computers share remote source files for the service pack**

1. Connect to the network or computer on which you want to create the distribution folder.

2. In the shared folder on the network, create a distribution folder for the service pack. For example, to create a distribution folder named WS2003SP1, type the following at the command prompt:

   **mkdir** *Drive*:**\WS2003SP1**

3. To extract files to the shared distribution folder, type the following at the command prompt:

   **WindowsServer2003-KB889101-SP1-x86-***LLL***.exe /X:***Path*

   where *Path* is the location of the shared distribution folder.

   If you use **/U** (for unattended), no confirmation dialog box appears after the files have been extracted.

4. For each computer that you plan to update, back up the files and close programs before you continue (unless you plan to force programs to close during the installation).

5. To install the service pack from the shared distribution folder, run Update.exe instead of the installation file (for example, WindowsServer2003-KB889101-SP1-x86-*LLL*.exe). For example, to install the service pack from a distribution folder named WS2003SP1, type the following at the command prompt:

   *Drive***:\WS2003SP1\i386\Update\Update.exe.**

   You can use the same command-line options for Update.exe as you would for the installation file.

6. The installation continues as described in Scenario 1 earlier in this section.

We recommend that you restart the computer immediately to complete the installation after Update.exe has completed.

If you want to install updates, critical updates, or security updates, see the Guide for Installing and Deploying Updates for Microsoft Windows Server 2003 Service Pack 1 (on the Microsoft TechCenter Web site).

If you disabled your antivirus software, enable it again after you restart the computer.

| **Important** |
| --- |
| SP1 will not be fully installed until you restart your computer. |

**# Scenario 3: Using SMS to install the service pack**

This scenario explains how to use Microsoft Systems Management Server (SMS) to install the service pack from a shared distribution folder on a network. This installation method installs the service pack on SMS servers that are already running Windows Server 2003.

This scenario assumes that you have an understanding of SMS and a working knowledge of software distribution.

| **Important** |
| --- |
| To perform this type of installation, your computer must be running SMS 2.0 with Service Pack 5, SMS 2003, or SMS 2003 with Service Pack 1. |

**To use SMS to install the service pack**

1. Create the SMS package by importing the package definition file for the service pack. In the package, provide the path to the source files for the service pack.

2. Distribute the SMS package to the distribution points.

3. Create the advertisement to notify SMS servers that the service pack is available.

For details about deploying SP1 using SMS, see article 894712, "How to install Windows Server 2003 Service Pack 1 (SP1) by using Systems Management Server," in the Microsoft Knowledge Base.

**# Scenario 4: Using Windows Installer and Group Policy to install the service pack**
This scenario explains how to use Windows Installer to install the service pack from a shared distribution folder on a network. This method installs the service pack on servers that are already running Windows Server 2003.

To use this method, you should have a thorough understanding of Windows Installer and a working knowledge of Group Policy and Active Directory. For more information about Windows Installer, Group Policy, and Active Directory, see the Windows Server 2003 Deployment Guide (on the Microsoft TechCenter Web site).

**# Using Windows Installer**
The Windows Installer package file (Update.msi) contains all of the information that Windows Installer requires to install or remove the service pack and to run Setup.

This package file describes the relationships between service pack components and resources. It also contains an installation database from which you can view a summary (known as a summary information stream) of the properties that the installation program uses. To view this summary, right-click the installation database, and then click **Properties**.

You must use the machine-assigned distribution method with Update.msi. No other methods are available.

| **Important** |
| --- |
| We recommend that you use the installation file WindowsServer2003-KB889101-SP1-x86-*LLL*.exe or WindowsServer2003-KB889101-SP1-ia64-*LLL*.exe when deploying SP1 at the command prompt. (*LLL* represents the language code; for example, ENU represents English). If you use Update.msi to distribute service packs, you must use a server-based (machine-assigned) Group Policy object (GPO) only. User-based Group Policy deployments are not supported with Update.msi. For more information, see article 278503, "Best Practices for Using Update.msi to Deploy Service Packs," in the Microsoft Knowledge Base. |

To upgrade servers to SP1, you must join them to the same domain as the server where the Windows Installer (MSI) file resides. After you assign the package, Windows Installer automatically installs the service pack the next time that the server is started (as long as it is connected to the network).

| **Note** |
| --- |
| Only a network administrator or someone who is logged on to a local server as an administrator can remove the assigned software. |

**# Assigning Service Pack 1 to Servers**
The procedure in this section explains how to assign the service pack to servers that are managed by a GPO. For your installation, you might want to associate the GPO with a new Active Directory container.

**To use Group Policy to assign the service pack**

1. Create a shared network distribution folder.

2. Create a GPO for SP1 deployments.

3. Deploy the SP1 Update.msi from the shared distribution folder as machine-assigned. Do not deploy it as a user deployment.

   When the servers are restarted, they are updated to SP1.

| **Important** |
| --- |
| Check the properties of each server to ensure that the update has completed. You might need to restart each server more than once to complete the update. |

For general information about how to apply your software deployment policy to users who are outside the boundaries of organization units, see article 324750 "How To Assign Software to a Specific Group By Using a Group Policy in the Windows Server 2003 Family," in the Microsoft Knowledge Base.

**The Integrated Installation**

You should perform the integrated installation of Windows Server 2003 with SP1 on computers that do not have an operating system or that are running an earlier version of Windows, such as Windows 2000. You would use this method if you already purchased Windows Server 2003 and want to apply the service pack and the operating system at the same time.

When you perform an integrated installation, you install the operating system and the service pack simultaneously. This means that you do not need to perform separate installations of the operating system and the service pack.

To perform an integrated installation, first use the **/integrate** option to update Windows Server 2003 with SP1 installation files in a shared distribution folder. After you do this, run Windows Server 2003 Setup. During the integrated installation process, Windows Server 2003 Setup installs the operating system with the service pack already applied.

The path that you use to upgrade previous versions of Windows to Windows Server 2003 with SP1 is the same path you would use to upgrade to Windows Server 2003.

To complete the procedure for integrating Windows Server 2003 with SP1, you must use a computer that is already running a Windows Server 2003 or Windows XP operating system.

| **Note** |
| --- |
| In the following procedure, *Drive:* represents the drive letter of the network or computer where your distribution folder is located. |

**Spslpsrm.log file creation**

The Update.exe program creates a log file, named Spslpsrm.log, for integrated installations. This log file is created in *systemroot* and contains the following information:

- The command line that initiated the Update.exe program.
- A list of the files that the Update.exe program copied to your computer.
- Error messages if any errors were encountered.
- The command-line options that were used to install the service pack.

**Scenario 1: To create an integrated installation of the service pack with Windows Server 2003**

1. Connect to the network or computer on which you want to create the distribution folder.
2. In the shared folder on the network, create a distribution folder for the Windows Server 2003 installation files.

   For example:

   - To install SP1 with a 32-bit version of Windows Server 2003, create a distribution folder named WS2003\x86 by typing the following:

     **mkdir** *Drive***:\WS2003\x86**

   - To install SP1 with a 64-bit version of Windows Server 2003, create a distribution folder named WS2003\64bit by

typing the following:

**mkdir** *Drive***:\WS2003\64bit**

| **Important** |
| --- |
| Ensure that only system administrators have full access to this folder. Other users should have only Read and Execute permissions. |

3. To verify that you have assigned appropriate permissions to users who are installing the service pack, do the following:

   a. Navigate to the appropriate folder, right-click it, and then click **Properties**.

   b. Click the **Sharing** tab, and then click **Share This Folder**.

   c. In **Share Name**, type a name for the folder.

   d. Click **Permissions**, and then assign permissions that allow users to install the service pack from this folder.

   e. If you are using an NTFS file system partition, click the **Security** tab, confirm that the permissions listed there do not conflict with those on the **Sharing** tab, and then click **OK**.

4. Insert your Windows Server 2003 product CD or DVD into the CD-ROM drive, and then copy the contents of the CD to the distribution folder that you created in step 2.

   For example, to copy the installation files and folders from the Windows Server 2003 product CD in the CD-ROM drive (D:) to the distribution folder named WS2003\x86 on the E: drive, you would type the following:

   **xcopy /E D:\ E:\WS2003\x86**

5. Remove the product media from the CD-ROM drive, and then insert the SP1 CD. Be sure to use the correct SP1 CD (for either 32-bit or Itanium-based versions of Windows Server 2003).

6. Do one of the following:

   - To apply the source files for the service pack to the installation files for a 32-bit version of Windows Server 2003 in the folder named WS2003\x86, type the following:

     **WindowsServer2003-KB889101-SP1-x86-***LLL***.exe /integrate:***Drive***:\WS2003\x86**

   - To apply the source files for the service pack to the installation files for an Itanium-based version of Windows Server 2003 in the folder named WS2003\64bit, type the following:

     **WindowsServer2003-KB889101-SP1-ia64-***LLL***.exe /integrate:***Drive***:\WS2003\64bit**

   For a list of additional command-line options, see Command-Line Options for Installing SP1.

7. Service pack files are extracted and then applied to the operating system files to update your shared distribution folder. You can either use the files from this network shared folder to make a CD (32-bit versions only) to upgrade your servers, or you can customize Setup for Windows Server 2003 as necessary. For more information about how to customize Setup, you can view Help by entering the following command from the shared distribution folder:

   **\i386\winnt32.exe /?**

8. You can now deploy Windows Server 2003 with SP1 to your computers from the shared distribution folder in either

attended or unattended Setup mode. During the standard installation process, Setup for Windows Server 2003 (Winnt.exe or Winnt32.exe) installs the updated operating system with the service pack already applied.

| **Important** |
| --- |
| When you run the command given in Step 6, the Update.exe program automatically creates a Svcpack.log file in systemroot on the computer that is running the Update.exe program. If you plan to update more than one operating system from this computer, rename the Svcpack.log file after you update each version. This step ensures that you do not overwrite the current log file when you update additional operating systems. |

**Scenario 2: Using RIS to install Windows Server 2003 integrated with the service pack**

This section explains how to use Remote Installation Services (RIS) to install Windows Server 2003 operating systems integrated with the service pack. However, this section does not explain how to set up RIS. For more information about RIS, see Remote Installation Services (on the Microsoft TechCenter Web site).

**Types of RIS images**

RIS supports two types of operating system images: CD-based images (images created by using RISetup) and Remote Installation Preparation (RIPrep) images.

Using the CD-based option is similar to setting up a server operating system directly from the Windows Server 2003 product CD, except that the source files reside on a RIS server. You can create a RIPrep image from a server that is running Windows Server 2003 with SP1 and that is configured with applications and settings that you specify. You can then deploy this image to other similar servers connected to the network.

**Adding a CD-based image for an operating system that is integrated with a service pack to a RIS server**

After you install RIS, perform the following steps to add an image of Windows Server 2003 with SP1 to your RIS server.

**To copy Windows Server 2003 with SP1 to your RIS server**

1. Create an integrated installation of Windows Server 2003 with SP1. For more information, see Scenario 1: Creating an installation of Windows Server 2003 integrated with the service pack earlier in this guide.

2. To create an image, click **Start**, click **Run**, and then type the following:

   **risetup.exe -add**

3. The Remote Installation Services Setup Wizard appears. Follow the instructions in the wizard. When the **Installation Source Files Location page** prompts you for the image source, enter the path to the shared folder that contains the integrated installation that you created in Step 1.

4. A box appears showing the progress of the installation. After the RISetup image is complete, you can install the image on each server as described in Remote Installation Services (on the Microsoft TechCenter Web site).

**Updating existing RIPrep images to SP1**

If you want to add additional programs or settings to your integrated installation image, you must have a CD–based image of Windows Server 2003 with SP1 on your RIS server. (For more information, see the preceding section, Adding a CD-based image for an operating system that is integrated with a service pack to a RIS server.)

**To update existing RIPrep images**

1. Use RIS to install the RISetup image on your computer.

2. Add the additional programs and settings that you want to include in the image.

3. Run RIPrep to create an image on the RIS server.

   For instructions on how to run RIPrep on RIS servers running Windows Server 2003, see Remote Installation Services and Automating and Customizing Installations (on the Microsoft TechCenter Web site).

4. You can now deploy your RIPrep image to other servers. For details about how to perform this task, see Remote

Installation Services (on the Microsoft TechCenter Web site).

| Note |
| --- |
| You cannot use the **/integrate** option to integrate SP1 directly into an existing CD-based image or a RIPrep image. |

**Command-Line Options for Installing SP1**

You can define the way SP1 is installed by typing one or more of the following command-line options when you run the installation file (for example, WindowsServer2003-KB889101-SP1-x86-*LLL*.exe) or Update.exe. You can precede the options with either a forward slash (/) or a hyphen (-). The options are not case-sensitive.

| Command-line option | Description |
| --- | --- |
| **/?**<br>or<br>**/Help** | Displays help text. |
| **/D:** *FolderName* | Back up to a specified folder the files that are required to remove the service pack.<br>If you back up files but do not specify a folder, the default location is:<br>$ntservicepackuninstall$<br>Any location that you specify must be on the local drive. |
| **/ER** | Enables extended return codes that return a detailed error message if the update installation fails. For more information, see the white paper, The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components, on the Microsoft Web site. |
| **/F** | After the installation is complete, you must close all open applications before you restart the computer. This option forces applications to close without saving files. You can use this option with other command-line options, except **/integrate**, **/L**, and **/Z**. |
| **/Forcerestart** | Restarts the computer after the update installation is complete. This option follows standard shutdown behavior. It does not force applications to close. |
| **/integrate:** *Path* | Integrates this software update into the path that you specify. Be sure to provide the absolute path to the installation files for your operating system. |
| **/L** | Lists installed updates. |
| **/N** | We do not recommend this option.<br>Does not back up files for removing SP1. An entry for SP1 does not appear in Add or Remove Programs if you use this option. |
| **/O** | Overwrites OEM files without prompting. |
| **/Q**<br>or<br>**/Quiet** | Uses quiet mode. Shows no user interface during SP1 installation. This is the same as unattended mode, except that the user interface is hidden. No prompts will appear during the installation process. |
| **/U**<br>or<br>**/Passive** | Uses unattended Setup mode and default SP1 options. Requires no user interaction during the installation of the updates and shows only critical errors and a progress bar. |

| | |
|---|---|
| **/Z**<br>or<br>**/Norestart** | Does not restart the computer after the installation is completed. |

**Command-Line Options for Installing the Service Pack Only**

The following table identifies additional command-line options that only the installation program for the service pack supports.

| Command-line option | Description |
|---|---|
| **/X** | Extracts service pack files without starting Update.exe. You are prompted to provide the path for the folder in which you want the extracted service pack installation files to be placed. |
| **/U /X:** *FolderName* | Extracts service pack files and places them in the *FolderName* folder without prompting and without starting Update.exe. |

| **Important** |
|---|
| SP1 will not be fully functional until you restart your computer. |

**Qfecheck.exe**

For more information about the Qfecheck.exe program, see the following articles in the Microsoft Knowledge Base:

- 282784: "Qfecheck.exe Verifies the Installation of Windows 2000 and Windows XP Updates"
- 304864: "Qfecheck Hotfix Tool Reports False Need to Reinstall Freshly Installed Updates"

Although these articles were written for other Windows operating systems, they also apply to updates for Windows Server 2003.

**Uninstalling SP1**

If you created backup files when you installed SP1, you can use Add or Remove Programs or the command prompt to remove SP1 at any time and restore your computer to its previous state.

You can uninstall SP1 only if it was installed as an update to an existing operating system. You cannot remove SP1 if you installed it as part of an integrated installation. In this case, you must uninstall the entire operating system together with SP1.

**To remove SP1 using a command prompt**

1. Open a command prompt and type:

   **%systemroot%\$NtServicePackUninstall$\spuninst**

2. Type **Spuninst.exe /***Option*. Replace *Option* with any of the options in the following table.

3. Press ENTER to continue, and then follow the instructions that appear on your screen.

| Option | Description |
|---|---|
| **/U** | Removes the service pack in unattended mode. If you use this option, only critical error prompts appear while you uninstall SP1. |
| **/Q** | Removes SP1 in quiet mode, which is the same as unattended mode except that the user interface is hidden. If you use this option, no prompts appear while you uninstall SP1. |
| **/Z** | Does not restart the computer after you uninstall SP1. |
| **/F** | Forces other applications to close when the computer restarts after you uninstall SP1. |

**Important**

If you choose to remove SP1, a dialog box displays a list of the applications that you installed after you installed SP1. If you continue to remove SP1, these applications might not work correctly.

Multiple descriptions of some applications might appear instead of a single generic description. You should ignore these additional descriptions.

**Symbols for Debugging Service Packs**

If you are a system administrator (someone who diagnoses problems on computers that are running Windows Server 2003), we recommend that you download the symbol files for debugging service packs. However, you do not need to install these files for your computer to run properly.

If you want to debug Windows Server 2003 with SP1, you must first download and install the symbols for debugging Windows Server 2003 from the download page on the Internet, and then you must add symbols for debugging SP1 to the same folder. For more information, see Debugging Tools for Windows — Overview at the Microsoft Web site.

You can download symbols for debugging SP1 from one of the following locations:

- From the Download Windows Symbol Packages page on the Microsoft Web site.
- On demand from the Internet Symbol Server. For more information about using the Internet Symbol Server, see Debugging Tools and Symbols: Getting Started on the Microsoft Web site.
- The English version of the Windows Server 2003 Service Pack 1 CD, which includes the symbols package. The package (Symbols.exe) is in the \Support\Symbols folder on the service pack CD. The symbols package is included only on the English version of the service pack CD, but this package is language-independent and can be downloaded for debugging any Windows Server 2003 locale.

**Note**

When you install SP1, the current versions of the symbol files overwrite any previous versions that are in the symbol installation folder.

**Additional Resources**

- For information about Windows Server 2003 and SP1, see the Microsoft TechCenter Web site.
- The Microsoft Knowledge Base provides updated information about the Windows Server 2003 operating systems, SP1, and other Microsoft products.
- For the most up-to-date information about supported hardware, see the hardware compatibility information at the Windows Server Catalog Web site.
- To obtain the most recent product updates, see the Windows Update Web site.

# Windows Server 2003 Service Pack 1 Installing and Deploying Updates

Updated: March 28, 2005

Applies To: Windows Server 2003 R2

About this Guide

What Is an Update?

The Standalone Update Installation

The Combination Installation

Installing SP1 and updates with Windows Server 2003

Removing Updates

Copyright

**About this Guide**

This guide was formerly called "Hotfix Deployment and Installation Guide."

This guide is geared for system administrators who are installing software updates on Microsoft® Windows Server™ 2003 Service Pack 1 (SP1).

Unless specified, this guide uses the term "update" to refer to any software update, including an update rollup, service pack, feature pack, critical update, security update, or hotfix that improves or fixes a software product that is released by Microsoft Corporation. For definitions of each of these types of software updates, see article 824684, "Description of the standard terminology that is used to describe Microsoft software updates," in the Microsoft Knowledge Base.

This guide includes technical information, procedures, and recommendations for installing updates on multiple computers in a small business or corporate environment. This includes installing updates separately or in combination with Windows Server 2003, with or without a service pack.

If you want to deploy either the standalone version of SP1 or the version of SP1 that is integrated with the operating system, see the Windows Server 2003 Service Pack 1 Installation and Deployment Guide (on the Microsoft TechCenter Web site).

Although this guide includes some basic operating system information, it assumes that you have a working knowledge of Windows Server 2003 and update installations. This guide is designed to complement formal training and other sources of information, such as the Windows Server 2003 Help documentation, not to replace them.

Although updates are available for both 32-bit (x86) and 64-bit versions of Windows Server 2003, throughout this guide, all examples will use the format for 32-bit updates.

**What Is an Update?**

An update is a file or collection of files that you can apply to your operating system to correct a specific problem. You can install updates separately from the operating system or in combination with Windows Server 2003, with or without a service pack.

An update is an executable (.exe) file. When you install an update, backup files are automatically created so you can remove the update later if you want to. The installation process also copies the new files to specific folders and updates registry settings.

Windows Server 2003 update files are named according to the following convention:

- For the 32-bit (x86) versions of the Windows Server 2003 operating systems:

  WindowsServer2003-KB######-x86-*LLL*.exe

- For the Itanium-based versions of the Windows Server 2003 operating systems

  WindowsServer2003-KB######-ia64-*LLL*.exe

- For the x64-based versions of the Windows Server 2003 operating systems:

WindowsServer2003-KB######-x64-*LLL*.exe

The symbols ###### represent the Microsoft Knowledge Base article number that explains the details about the update, and *LLL* represents the language version of the update.

Updates are self-installing. There are two main types of update installations:

- The standalone update installation

  Use this to install Windows updates on computers that are already running Windows Server 2003.

- The combination installation

  Use this to perform an unattended installation of Windows updates in combination with an installation of Windows Server 2003, SP1, or both.

| **Important** |
| --- |
| Updates are applied only to software that is already installed. If you remove a component and later reinstall it, you must reinstall any updates that apply to that component. In addition, if you add further components to your computer that require this update, you must reinstall the update for it to apply to the new component.<br><br>However, if you install updates by installing SP1, the updates are applied to all components that you add or reinstall. You would not need to reinstall SP1. |

**The Standalone Update Installation**

During the standalone update installation, Windows updates are applied to a computer that is already running Windows Server 2003. When you run the update program, it automatically installs updated system files and makes the necessary registry changes. After the computer is restarted, the installation is complete, and the operating system runs with an updated file set.

You can install the updates by running one of the update program files listed previously, which extracts the update files and runs the Update.exe installation program. Update.exe then checks the service pack version that you are currently using. If the service pack version was released before the updates, and the language is the same, Update.exe automatically installs the updates. If your service pack version was released after the updates, the installation is not completed, and an error message appears stating that the version of the updates is incorrect.

For more information about Update.exe, see the white paper, "Inside Update.exe - The Package Installer for Windows and Windows Components," on the Microsoft Web site.

| **Note** |
| --- |
| If your service pack version was released after the updates and you were completing an unattended installation using either the **/U** (unattended setup) or **/Q** (quiet setup) option, the installation does not continue and no message appears. For more information about command-line options, see Command-line options for the update package, later in this document. |

If the language of the updates does not match the language that you selected for your Windows Server 2003 operating system, Setup is interrupted. If there are no conflicts with the language version, Setup continues with the installation, and Update.exe registers the updates under the following registry keys:

- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Updates\Server2003\SP2\KB######

- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Hotfix\KB######

During the installation, information for removing the updates is stored in a hidden folder named %systemroot%\$NtUninstallKB######$. For information about removing updates, see Removing Updates later in this document.

**Methods for installing updates**
There are several methods that you can choose from to install an update, such as:

- Run Update.exe manually using a combination of installation options.
- Use Systems Management Server (SMS).
- Use Windows Installer.

You can deploy updates to multiple computers on a network by using a shared network distribution folder or by downloading the updates from the Web. Because this guide is intended primarily for corporate users, the procedures in the following section apply to the distribution of updates on a shared network. This is the most common way of distributing updates in a corporate environment.

The instructions in the rest of this section explain how to install updates on computers that are already running Windows Server 2003.

**Using Qchain.exe**
Windows Server 2003 updates have Qchain.exe functionality built in as part of Update.exe. This means that you can install SP1, and then install any number of post–SP1 updates without having to restart the computer between installations.

If multiple updates replace the same file, Update.exe ensures that the correct version of the file is retained. If you install multiple updates, be sure to use the **/Z** option that is described in "Command-line options for the update package," the next section in this guide.

**Command-line options for the update package**

| **Command-line option** | **Description** |
|---|---|
| **/?**<br>or<br>**/Help** | Displays help text. |
| **/ER** | Enables extended return codes that return a detailed error message if the update installation fails. For more information, see the white paper, "Inside Update.exe - The Package Installer for Windows and Windows Components," on the Microsoft Web site. |
| **/F** | Forces other applications to close after you install the update package and before you restart the computer. |
| **/Forcerestart** | Restarts the computer after the update installation is complete. This option follows standard shutdown behavior. It does not force applications to close. |
| **/integrate:** *path* | Integrates this software update into the path you specify. Be sure to provide the absolute path to your operating system source files. |
| **/L** | Lists installed updates. |
| **/N** | Does not back up files for removing updates. An entry for the update does not appear in **Add or Remove Programs** if you use this option. |
| **/O** | Overwrites OEM files without prompting. |
| **/Q**<br>or<br>**/Quiet** | Uses quiet mode. Shows no user interface during the installation of the updates. This is the same as unattended mode, except that the user interface is hidden. No prompts will appear during the installation process. |

| | |
|---|---|
| **/U**<br>or<br>**/Passive** | Uses unattended Setup mode. Requires no user interaction during the installation of the updates and shows only critical errors and a progress bar. |
| **/Z**<br>or<br>**/Norestart** | Does not restart the computer after the installation is completed. |

**Installing updates on computers running Windows Server 2003**

To install an update on a single computer, run the update program, WindowsServer2003-KB######-x86-*LLL*.exe, on that computer.

If you want to install the update on more than one computer, you can create a distribution folder for the update on the network. The following procedure describes how to install one or more updates using this method.

| **Important** |
|---|
| You must install SP1 either in combination with or before you install updates released after SP1. Installing more recently released updates before you install SP1 can cause problems with your system. |

| **Note** |
|---|
| For the following procedure, *Drive*:\ represents the drive of the network or computer on which your distribution folder is located. |

**To install an update by running the Update.exe program**

1. Connect to the network or computer on which you want to create the distribution folder.
2. In the shared network distribution folder, create a distribution folder for the update files.

   For example, to create a distribution folder named Update, type the following:

   **mkdir** *Drive***:\Update**

3. Copy the Windows Server 2003 Update.exe program to the distribution folder that you created in Step 2. For example, to copy the SP1 Update.exe program to the distribution folder named Update, type the following:

   **xcopy C:\WindowsServer2003-KB** ###### **-x86-** *LLL* **.exe** *Drive* **:\Update**

4. To install the update from the shared network distribution folder, run the WindowsServer2003-KB######-x86-*LLL*.exe program.

   For example, to install the update from the distribution folder named Update, type the following:

   *Drive* **:\Update\WindowsServer2003-KB** ###### **-x86-** *LLL* **.exe**

5. To ensure that your updates take effect, restart your computer after you finish installing all of the updates.

| **Note** |
|---|
| The WindowsServer2003-KB######-x86-*LLL*.exe file supports the same command-line options as Update.exe. You can use the command-line options that are described in the table that precede this procedure. |

**Installing several updates together**

You can group multiple updates together in a batch file and install them as a unit. This makes it unnecessary for you to restart your computer after you install each update. The update installer provides options that you can use when performing this type of installation.

The following code sample is a batch file that installs updates and ensures that the correct files are replaced after the computer is restarted.

```
@echo off
setlocal
set PATHTOFIXES=Drive:\update
%PATHTOFIXES%\WindowsServer2003-KB######-x86-LLL.exe /quiet /norestart
%PATHTOFIXES%\WindowsServer2003-KB######-x86-LLL.exe /quiet /norestart
%PATHTOFIXES%\WindowsServer2003-KB######-x86-LLL.exe /quiet /norestart
```

**Important**

To ensure that the updates that you installed take effect, restart the computer if the batch file does not automatically restart it for you. If you want your computer to restart automatically, in the last update that you install, replace the option **/norestart** with the option **/forcerestart**.

**The Combination Installation**

The combination installation uses both the update installation and integrated installation processes to install SP1 with one or more of the following:

- Windows Server 2003
- Windows Server 2003 updates
- Additional Microsoft and non-Microsoft software that might be included on the SP1 CD

**Note**

An integrated installation is one in which the operating system and the service pack are installed together as a single installation.

For a combination installation, you can include the components that you want to install as entries in the Svcpack.inf file, along with the updates. You can also choose to install SP1 at the same time.

This section provides instructions for using unattended Setup mode to simultaneously install Windows Server 2003 and updates.

**Installing SP1 and updates with Windows Server 2003**

This section explains how to perform a combination installation that includes SP1 and post–SP1 updates integrated with Windows Server 2003 in a shared distribution folder on a network. A combination installation makes it unnecessary for you to perform separate installations of Windows Server 2003, SP1, and the Windows Server 2003 updates.

If you want to install Windows Server 2003 with updates, you must use this method. This process installs the updates during Windows Server 2003 Setup.

**Preparing for the combination installation**

Before you deploy the installation of Windows Server 2003 and the Windows Server 2003 updates across a network, you must copy the Windows Server 2003 and Windows Server 2003 update installation files to a shared distribution folder and complete the steps described in the following procedure, "To create and set up the required folders and files for Windows Server 2003."

If you are an original equipment manufacturer (OEM) and you plan to install additional OEM files (such as device driver, application, or component files) on the destination computers, create a \$1 subfolder within the \$OEM$ subfolder. The \$1 subfolder corresponds to *systemdrive*, which is the destination drive for the Windows Server 2003 installation.

**Note**

In the following procedure, *Drive***:** represents the drive name of the network or computer where your distribution folder is located.

**To create and set up the required folders and files for Windows Server 2003**

1. Connect to the network or computer on which you want to create the distribution folder.
2. Create a distribution folder by typing the following (using the appropriate drive letter):

**mkdir** *Drive* **:\WServer2003DIST**

3. Use the command **xcopy** to copy the files and subfolders from the integrated installation product CD or DVD that includes Windows Server 2003 and SP1 to the *Drive*:\WServer2003DIST folder.

   For example, if D is your CD-ROM drive, type the following:

   **xcopy /E /I /V D:** *Drive* **:\WServer2003DIST**

4. Use the **/integrate** option to run the update that you want to install by typing the following:

   **WindowsServer2003-KB** ###### **-x86-** *LLL* **.exe /integrate: Drive:\WServer2003DIST**

   Repeat this step for each update you want to include your deployment.

| **Important** |
| --- |
| If you want to include SP1 *and* updates in your deployment of Server 2003, and you do not have a version of the operating system that includes SP1, first you must integrate Windows Server 2003 with SP1 as described in the Service Pack Deployment Guide. Then you can integrate the updates. If you integrate the updates before SP1, you will not be able to include SP1 afterwards. |

For more information about how to integrate updates, see article 828930, "How to integrate software updates into your Windows installation source files," in the Microsoft Knowledge Base.

**Deploying the combination installation**

You can deploy the installation of the Windows Server 2003 updates and the Windows Server 2003 operating system to multiple computers from a shared distribution folder on a network. During the standard installation process, Windows Server 2003 Setup installs the operating system and applies the updates.

### To deploy the installation

1. Verify that the installation and executable files for the Windows Server 2003 updates and Windows Server 2003 exist in your distribution folder.

2. Customize Windows Server 2003 Setup as necessary. For more information about customizing Windows Server 2003 Setup, see the Winnt32.exe command syntax topic in the Microsoft Windows Server 2003 Professional Resource Kit Documentation on the Windows Deployment and Resource Kits Web site.

3. Run Windows Server 2003 Setup. This deploys the installation of the Windows Server 2003 updates and Windows Server 2003 to multiple computers from the shared distribution folder.

| **Note** |
| --- |
| For more information about the preceding procedure, see the Microsoft Windows Corporate Deployment Tools User's Guide (Deploy.chm) included in Deploy.cab in the \Support\Tools folder on your SP1 CD. |

**Removing Updates**

You can remove an update for Windows Server 2003 at a command prompt or by using **Add or Remove Programs** in **Control Panel**.

If you want to remove updates, you must remove them in the reverse order in which they were installed. So, you must remove the most recently installed update first. For example, assume that you installed **UpdateA** before you installed **UpdateB**. To return your computer to its state before the installation of **UpdateA**, you must remove **UpdateB** before you remove **UpdateA**. You should follow this reverse order when you uninstall updates because some updates share files.

| **Important** |
| --- |

If you try to remove the updates in the wrong order, a warning appears that lists all of the updates and programs that have been installed since you installed the update that you are trying to remove. The warning names the update you are trying to remove and warns you that if you continue, the programs listed might not run correctly. Click **No** if you do not want to remove the update and if you prefer to remove the programs and updates that are listed before you continue. Otherwise, click **Yes**.

You cannot remove updates that were installed by using the combination installation method unless you reinstall the operating system. Reinstalling the operating system overwrites the updates.

**To remove an update at the command line**

1. Specify this location at the command line:

   **%systemroot%\$NtUninstallKB** ###### **$\spuninst**

2. Type **Spuninst.exe /***option*. Replace *option* with any of the following options:

| Option | Description |
|---|---|
| **/U** | Removes the update in unattended mode. If you use this option, only critical error prompts appear while you uninstall the update. |
| **/Q** | Removes the update in quiet mode, which is the same as unattended mode except that the user interface is hidden. If you use this option, no prompts appear while you uninstall the update. |
| **/Z** | Does not restart the computer after the process of uninstalling the update is complete. |
| **/F** | Forces other applications to close when the computer restarts after uninstalling the update. |

**To remove an update for Windows Server 2003 by using Add or Remove Programs**

1. Open **Control Panel**.
2. Click **Add or Remove Programs**.
3. Select the **Show updates** check box.
4. Click the update that you want to remove, and then click **Change or Remove**.
5. Follow the instructions that appear on your screen

**Introduction to Service Pack 1 (SP1)**

This document provides important information about Microsoft® Windows Server™ Service Pack 1 (SP1). SP1 contains updates that can help improve the security, reliability, and performance of your operating system. We recommend that you install SP1 because it includes updates that can improve how some programs run with Windows Server 2003 operating systems.

It is important to read this document before you install SP1. This document explains how to install SP1, and it provides specific information that might apply to your setup.

You can install SP1 to update the following versions of Windows Server 2003 operating systems:

- Windows Server 2003, Standard Edition
- Windows Server 2003, Enterprise Edition
- Windows Server 2003, Datacenter Edition
- Windows Server 2003, Web Edition
- Itanium-based versions of Windows Server 2003

**Note**

If you are running Windows Server 2003, Datacenter Edition, contact your OEM before you install SP1. OEMs are required to test Windows Server 2003, Datacenter Edition with service packs, such as SP1. If you subscribe to updates from your OEM, they should provide you with SP1 and provide or direct you to updated adapter drivers and utilities. They should also provide a custom HAL if your system requires such additional items. It is not possible to update the x64 versions of Windows Server 2003. For information about support for these products, contact your OEM, and see the Windows Server 2003 x64 Web site.

**Components of SP1**

SP1 contains updates and additional functionality for Windows Server 2003. You can read about these changes on the Microsoft TechCenter Web site. Help and Support Center has also been updated for SP1. For information about new functionality, see the updated version of Help and Support Center posted on the Microsoft TechCenter Web site. You can update Itanium-based versions of Windows Server 2003 with SP1 only for English, German, Japanese, and French locales.

**List of updates**

For information about updates and fixes included in SP1, see the article 824721, "Windows Server 2003 Service Pack 1 List of Updates," in the Microsoft Knowledge Base.

**Installation Options**
You can install SP1 from the CD, the Microsoft Download Center, or from the Windows Update Web site.

For 32-bit versions (x86) of Server 2003, the name of the SP1 installation file is WindowsServer2003-KB889101-SP1-x86-*LLL*.exe

The examples throughout this document use the 32-bit name for the SP1 installation file.

For Itanium-based versions of Windows Server 2003, the name of the SP1 installation file is WindowsServer2003-KB889101-SP1-ia64-*LLL*.exe, where *LLL* is the language version of SP1. For example, ENU represents the English-language version.

You can update Itanium-based versions with SP1 for only English, German, Japanese, and French locales.

**Using the CD to install SP1**
You can use the CD to install SP1 onto a single server, or follow the instructions in the Windows Server 2003 Service Pack 1 Installation and Deployment Guide (on the Microsoft TechCenter Web site) to deploy SP1 to multiple servers on a network.

There are two SP1 CDs available to update Windows Server 2003 operating systems with SP1: one for 32-bit versions of the Windows Server 2003 operating system, and one for Itanium-based versions of the Windows Server 2003 operating system. The CD for Itanium-based operating systems is labeled as such.

**Using the Web to install SP1**
There are two options available for installing SP1 from the Web.

| **Important** |
| --- |
| During the download, check the URL of the Web site to ensure that you are downloading files from Microsoft. |

**Windows Update**
You can use Windows Update to install SP1 on a single server running a 32-bit version of Windows Server 2003. You can update Itanium-based versions with SP1 only by using the CD or by downloading it from the Microsoft Download Center.

**Download Center**
You can update a single server or multiple servers by downloading SP1 from the Microsoft Download Center. You can choose to download SP1 for 32-bit (x86) versions or Itanium-based versions of the Windows 2003 operating system.

Because downloading the SP1 installation takes a substantial amount of time, we recommend that you save the SP1 installation file on your computer. This way, if you must restart the installation or reinstall SP1, you will not need to download the installation file again. Because the SP1 installation file is very large, if your computer has more than one hard disk, you should save WindowsServer2003-KB889101-SP1-x86-*LLL*.exe on a disk other than your system disk.

**Deploying SP1 to Multiple Servers**
You can obtain SP1 installation files from the SP1 CD or from the Download Center. Follow the instructions in the Windows Server 2003 Service Pack 1 Installation and Deployment Guide (on the Microsoft TechCenter Web site) and do one of the following:

- Deploy SP1 to multiple servers on a network that are already running Windows Server 2003 operating systems.
- Integrate a Windows Server 2003 operating system with SP1, and then install the operating system and SP1 together on multiple servers using one procedure. This type of procedure is also known as "slipstreaming."

Follow the instructions in the Windows Server 2003 Service Pack 1 Installing and Deploying Updates (on the Microsoft TechCenter Web site) to combine SP1 with an installation of Windows Server 2003, updates, or both the operating system and updates, and install them together using one procedure.

**Release Notes**
Before you install SP1, see article 889101, "Release Notes for Windows Server 2003 Service Pack 1." The information in this section will also help you prepare for your installation of SP1.

**Microsoft .NET Framework version 1.1**
The Microsoft .NET Framework is included in all of the 32-bit versions of the Windows Server 2003 operating systems. It is not included in 64-bit versions of the Windows Server 2003 operating systems.

The 32-bit version of .NET Framework 1.1 is supported by 64-bit versions of Windows Server operating systems and can be installed for 32-bit applications running on 64-bit versions of Windows operating systems (WOW64).

To install .NET Framework 1.1, see "Microsoft .NET Framework Version 1.1 Redistributable Package" at the Microsoft Download Center Web site. To install .NET Framework version 1.1 Service Pack 1, see "Microsoft .NET Framework 1.1 Service Pack 1" at the Microsoft Download Center Web site.

**Important performance and scalability information**
If a 32-bit version of the Microsoft .NET Framework is installed on the 64-bit Itanium-based systems, applications created for the 32-bit version of the .NET Framework will bind and run against it. Therefore, applications created with the .NET Framework version 1.1 run only in a 32-bit process within the WOW64 compatibility environment. Due to the design of x86 emulation for Itanium processors and the WOW64 subsystem, applications are restricted to execution on one processor.

Single processor execution and x86 emulation reduce the performance and scalability of 32-bit .NET Framework applications running on Itanium-based systems. We recommend that applications using the .NET Framework version 1.1 be used for interactive, client applications. With .NET Framework applications that demand high performance and scalability, such as high-load ASP.NET applications, we do not recommend this environment. We suggest that application developers instead evaluate the .NET Framework version 2.0, which includes 64-bit support for Itanium-based systems, for increased performance and scalability.

**Dell OpenManage support for Windows Server 2003 SP1**
In order to support the new enhancements and features in Windows Server 2003 SP1, Dell plans to release Dell OpenManage version 4.4, including Dell Server Assistant version 8.6, to fully support SP1. For current customers who are running Dell OpenManage version 4.3 or earlier, go to the Dell Web site for Dell OpenManage and Service Pack 1 upgrade and deployment information.

| **Note** |
| --- |
| Web addresses can change, so you might be unable to connect to the Web site mentioned here. |

**Before You Install SP1**
You can install SP1 only on a computer that is running a Windows Server 2003 operating system.

Before you install SP1, review the following information about Windows Server 2003 SP1.

1. Review the planning and deployment information for Windows Server 2003 SP1, available on the Microsoft TechCenter Web site.

   Because SP1 includes enhanced security, increased reliability, and a simplified administration, we recommend that you review these functionality changes and how they can affect your server setup before you deploy SP1. For example, SP1 includes the Security Configuration Wizard (SCW) that you can use to create security templates for servers based on their roles. Before you deploy SP1, you should determine how to incorporate SCW into your deployment process. An overview of this and other information you should know before you deploy SP1 is included in "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1" on the Microsoft TechCenter Web site.

2. Check the system requirements for installing SP1 in the article, 892807, "Hard Disk Space Requirements for Windows Server 2003 Service Pack 1" in the Microsoft Knowledge Base.

3. Review article 824721, “Windows Server 2003 Service Pack 1 List of Updates” in the Microsoft Knowledge Base to find out about updates and fixes included in SP1.

4. Unless you have a supplemental support agreement with Microsoft, you must uninstall any prerelease versions of SP1 before you proceed. Microsoft does not support the installation of this version over the release candidate or beta versions of SP1.

5. Fully back up your servers. Your backup should include all data and configuration information that is necessary for that computer to function. It is important to perform a backup of configuration information for servers, especially those that provide network infrastructure, such as Dynamic Host Configuration Protocol (DHCP). When you perform the backup, be sure to include the boot and system partitions and the System State. Another way to back up configuration information is to create a backup set for Automated System Recovery.

6. If you are not connected to a network or the Internet, and you want to minimize the installation time for the SP1 update, you can choose to disable your antivirus software. You can usually do this by right-clicking your antivirus-software icon (which typically appears in the bottom right-hand corner of the computer screen), and clicking **Disable**. Be sure to enable the antivirus software again after you install SP1. Do this only if you are installing from the CD.

| **Important** |
| --- |
| Antivirus software is a critical part of keeping a computer secure, but the time that it takes for the software to scan files on your system can add significantly to the time required to install the service pack—as much as an hour or more on slower systems.<br><br>Disabling your antivirus software before you install the service pack eliminates this extra installation time.<br><br>If you disable your antivirus software before you install the service pack, be sure that you are aware of the risks involved, and be sure to enable it after the service pack is installed. |

**Installing SP1 from the CD**

The SP1 CD contains the program, WindowsServer2003-KB889101-SP1-x86-*LLL*.exe, which is a self-extracting executable file that contains the source files for SP1. The CD also includes tools for advanced users, technical support staff, and administrators.

**To install SP1 from the CD**

1. To install SP1, you must be logged on to the computer as an administrator.
2. Insert the SP1 CD into your CD-ROM drive. It might take a few moments for the installation document to display. This document is titled, "Installing Microsoft Windows Server 2003 Service Pack 1."

   If this document does not automatically open when you insert the CD, open it using the following steps:

   a. Click **Start**, and then click **Run**.

   b. Type the following, and then press ENTER:

      **D:Srsp1.cmd**

      D is the drive letter associated with your CD-ROM drive.
3. To complete a default installation (recommended), in "Installing Microsoft Windows Server 2003 Service Pack 1," look for the link to install SP1 and click that link to begin. Otherwise, to customize your installation, use the command line. To view command-line options for a customized installation, type:

   **WindowsServer2003-KB889101-SP1-x86-** *LLL* **.exe /?**
4. If the Setup Wizard prompts you to run WindowsServer2003-KB889101-SP1-x86-*LLL*.exe or to save it to disk, click **Run this program from its current location**, and then click **OK**.
5. Follow the instructions in the Setup Wizard.
6. During the installation, backup files are created by default so you can remove SP1 later if you want to. If you install from the command line, you can choose not to back up files by using the option **/N**. We do not recommend this option. If you install from the user interface, the Setup wizard allows you to choose where you want to create backup files.
7. After the installation is complete, restart your computer, and then turn on the antivirus software if you disabled it for the installation.

| **Important** |
| --- |
| If you choose not to create backup files, you will be unable to remove SP1. |

**Uninstalling SP1**

If you chose to create backup files when you installed SP1, you can use **Add or Remove Programs** or the command prompt

to remove SP1 at any time and restore your computer to its previous state.

It is only possible to uninstall SP1 if it was installed as an update to an existing operating system. It is not possible to remove SP1 if you installed it as part of an integrated installation. In this case, you can only uninstall the entire operating system together with SP1.

**To remove SP1 using a command prompt**

1. Open a command prompt and type:

   **%systemroot%\$NtServicePackUninstall$\spuninst**

2. Type **Spuninst.exe /***option*. Replace *option* with any of the options in the following table.

3. Press ENTER to continue, and then follow the instructions that appear on your screen.

| Option | Description |
|---|---|
| **/U** | Removes the service pack in unattended mode. If you use this option, only critical error prompts appear while you uninstall SP1. |
| **/Q** | Removes SP1 in quiet mode, which is the same as unattended mode except that the user interface is hidden. If you use this option, no prompts appear while you uninstall SP1. |
| **/Z** | Does not restart the computer after the process of uninstalling SP1 is complete. |
| **/F** | Forces other applications to close when the computer restarts after uninstalling SP1. |

**Important**

If you choose to remove SP1, a dialog box displays a list of the applications that you installed after you installed SP1. If you continue to remove SP1, these applications might not work correctly.

Multiple descriptions of some applications might appear instead of a single generic description. You should ignore these additional descriptions.

**Additional Resources**

- For information about Windows Server 2003 and SP1, see the Microsoft TechCenter Web site.
- The Microsoft Knowledge Base provides updated information about the Windows Server 2003 operating systems, SP1, and other Microsoft products.
- For the most up-to-date information about supported hardware, see the hardware compatibility information at the Windows Server Catalog Web site.
- To obtain the latest product updates, see the Windows Update Web site.

# Windows Server 2003 Service Pack 2 Technical Library

Applies To: Windows Server 2003 with SP2

The technical library includes documentation, tools, and other resources to help you evaluate, plan, deploy, and manage Windows Server 2003 Service Pack 2 on the servers in your organization.

**Evaluating and planning**

- Readme for Windows Server 2003 Service Pack 2
- What's New in Windows Server 2003 Service Pack 2
- Release Notes for Microsoft Windows Server 2003 Service Pack 2

**Testing and deploying**

- Windows Server 2003 Service Pack 2 Installation and Deployment Guide
- Installing and Deploying Updates for Microsoft Windows Server 2003

For more information, see http://go.microsoft.com/fwlink/?LinkID=64780.

# What's New in Windows Server 2003 Service Pack 2

Applies To: Windows Server 2003 with SP2

This document outlines some changes in functionality between earlier versions of the Microsoft® Windows Server® 2003 and Microsoft Windows® XP Professional x64 Edition operating systems, and Windows Server 2003 with Service Pack 2 (SP2) and Windows XP Professional x64 Edition with SP2. Examples and details are provided for several of the technologies that are experiencing the biggest changes.

Unless otherwise specified, these notes apply to the following versions and editions:

- Windows Server 2003 with SP2
- Windows Server 2003 R2 with SP2
- Windows Server 2003 x64 Editions with SP2
- Windows Server 2003 R2 x64 Editions with SP2
- Windows Server 2003 for Itanium-based Systems with SP2
- Windows XP Professional x64 Edition with SP2

**Clustering**

A new event log event has been created to address certain situations in which the Cluster service account becomes excessively restricted by domain policy.

The new event ID is 1239. The event text includes troubleshooting information. You can also refer to article 871236 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkID=69284) for further information.

**Data access components**

XmlLite is new with Windows Server 2003 SP2. XmlLite is a fast, low-level, native XML parser with a small memory footprint. For more information, including the Programmer's Guide and API reference, see the MSDN Web site (http://go.microsoft.com/fwlink/?LinkID=69285).

**Distributed systems**

New options have been added to the Dcdiag.exe Domain Name System (DNS) tests. These new options are **/x** and **/xsl:xslfile.xsl** or **/xsl:xsltfile.xslt**. They generate XML tags when the tests are run with the /test:dns option. You can use this new output mechanism to more easily parse the verbose log that the DNS tests generate.

To direct the XML output file to XMLLog.xml, use the **/x** option. For example:

**dcdiag /test:dns /v /e /x:XMLLog.xml**

Note: The **/x**: option only works with the **/test:dns** option.

To add the processing instructions that reference the specified style sheet, use the **/xsl:xslfile.xsl** or **/xsl:xsltfile.xslt** option. For example:

**dcdiag /test:dns /v /e /x:XMLLog.xml; /xsl:xslfile.xsl**

**dcdiag /test:dns /v /e /x:XMLLog.xml; /xsl:xsltfile.xslt**

Note: The **/xsl:xslfile.xsl** or **/xsl:xsltfile.xslt** option only works with the **/test:dns /x:XMLLog.xml** option.

**File systems**

Icacls.exe is an upgrade of the Cacls.exe tool in Windows Server 2003 SP2, and can be used to reset the access control lists (ACLs) on files from Recovery Console, and to back up ACLs. Also, unlike Cacls.exe, Icacles.exe correctly propagates the creation of inherited ACLs and changes to them.

**Microsoft Message Queuing**

The default storage limit for message queuing has been changed to 1 gigabyte (GB). If you choose to have a storage limit of more than 1 GB, you can change the storage limit setting in Microsoft Management Console (MMC) on the **General** tab of

Message Queuing Properties.

**Networking and communications**

- This version of Windows Server 2003 SP2 includes an update that enables you to simplify the creation and maintenance of Internet Protocol security (IPsec) policy. This update enables you to use an IPsec "Simple Policy". For most environments, the installation of this update allows you to reduce the number of IPsec filters that are required for a Server Isolation deployment or for a Domain Isolation deployment. You can reduce the number of IPsec filters from many hundreds of filters to only two filters. For more information about this update for Windows Server 2003 and Windows XP, see article 914841 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkID=69286).

- Group Policy support for non-broadcasting networks and Wi-Fi Protected Access 2 (WPA2) settings has been added to the Windows wireless client in Windows Server 2003 SP2. This update allows the Windows wireless client to accept additional wireless Group Policy configuration options. These new settings include support for WPA2 parameters and non-broadcast networks.

- The Windows wireless client now supports WPA2, which enables you to take advantage of high levels of standards-based connection and encryption security. New security features include:

    - Non-broadcast network profiles are now marked with a flag to improve the security of the Windows wireless client.

    - Windows will not automatically connect to a peer-to-peer network, even if it has been automatically saved in the preferred network list. You must manually connect to a peer-to-peer network profile.

**Windows Deployment Services**

Starting with this version of Windows Server 2003 with SP2, Remote Installation Services is replaced by Windows Deployment Services. You can use Windows Deployment Services to set up new computers through a network-based installation without having to be physically present at each computer and without having to install directly from DVD media. For more information about Windows Deployment Services, see the Windows Deployment Services Update Step-by-Step Guide (http://go.microsoft.com/fwlink/?LinkID=69289).

# Windows Server 2003 Service Pack 2 Installation and Deployment Guide

Updated: February 19, 2009

Applies To: Windows Server 2003 with SP2

This guide is for system administrators who are installing Microsoft® Windows Server® 2003 operating systems with Service Pack 2 (SP2). It includes technical information, procedures, and recommendations for installing SP2 on multiple computers in a small business or corporate environment. Although this guide includes some basic operating system information, it assumes that you have a working knowledge of Windows Server 2003.

This guide does *not* explain:

- **How to combine SP2 with other updates for Windows Server 2003**. For information about how to do this, see "Installing and Deploying Updates for Microsoft Windows Server 2003" (http://go.microsoft.com/fwlink/?LinkID=64779).
- **New functionality in SP2**. For important information about functional changes to SP2, see "What's New in Windows Server 2003 Service Pack 2" (http://go.microsoft.com/fwlink/?LinkID=62452).
- **How to deploy SP2 by using Windows Server Update Services (WSUS)**. For more information, see the WSUS Web site (http://go.microsoft.com/fwlink/?LinkID=94242).

**Obtain the installation files**

You can install SP2 from the SP2 CD or from the Web. To order an SP2 CD, see the Microsoft TechNet Web site (http://go.microsoft.com/fwlink/?LinkId=78087). To download the installation files, see the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=78088).

Because downloading SP2 installation files takes a substantial amount of time, we recommend that you save the files on your computer. This way, you can reinstall or repair the installation without downloading the file again. You should ensure that there is enough disk space on your hard disk drive before starting the download.

The installation file is named one of the following. XXX stands for the type of operating system (for example x86) and LLL stands for the language (for example ENU).

- WindowsServer2003-KB914961-SP2-XXX-LLL.exe
- WindowsServer2003.WindowsXP-KB914961-SP2-XXX-LLL.exe

**Plan your deployment**

This section includes information about how to plan your SP2 deployment, including pre-deployment tasks, testing the deployment, and additional resources.

**Pre-deployment tasks**

Before you install SP2, do the following:

- **Review the following documentation.**
  - Article 914962 in the Microsoft Knowledge Base for a list of the updates included in this service pack (http://go.microsoft.com/fwlink/?LinkId=74380).
  - "Release Notes for Windows Server 2003 Service Pack 2" for a list of the known issues with this version of SP2 (http://go.microsoft.com/fwlink/?LinkId=74381).
  - "Installing and Deploying Updates for Microsoft Windows Server 2003" for information about combining this service pack with other updates (http://go.microsoft.com/fwlink/?LinkID=64779).
- **Check the disc space requirements.** See article 926029 in the Microsoft Knowledge Base

(http://go.microsoft.com/fwlink/?LinkId=74454).

- **Back up your servers**. Your backup should include all data and configuration information that is necessary for that server to function. It is important to perform a backup of configuration information for servers, especially those that provide network infrastructure, such as Dynamic Host Configuration Protocol (DHCP). When you perform the backup, be sure to include the boot and system partitions and the system state. Another way to back up configuration information is to create a backup set for Automated System Recovery.

- **Disconnect UPS devices.** If you have an uninterruptible power supply (UPS) connected to your destination computer, disconnect the connecting serial cable before running Setup. Setup automatically attempts to detect devices connected to serial ports, and UPS equipment can cause problems with the detection process.

- **Disable your antivirus software.** If you are not connected to a network or the Internet and you want to minimize the installation time, you can disable your antivirus software. The time that it takes for the antivirus software to scan each file can add significant time to the installation (an hour or more on slower computers). Be sure to enable the antivirus software after you install SP2.

- **Uninstall prerelease versions of SP2.** Unless you have a supplementary support agreement with Microsoft, you must uninstall any prerelease versions of SP2 before you proceed. Microsoft does not support upgrading to this version from any prerelease version.

- **Close all open programs.**

**Testing the deployment**

We recommend that you test SP2 in your computing environment before you deploy it to all of your servers. If you are installing Windows Server 2003 for the first time, you should set up a pilot group to test your deployment and verify that the deployment works as expected. For more detailed information about testing your deployment and creating a pilot program, see the Windows Server 2003 Deployment Guide (http://go.microsoft.com/fwlink/?LinkId=44319). To test the deployment, do the following:

1. Create a test environment. Make sure that the test computers contain the operating systems, software, and the hardware devices that are used in your organization.

2. Install the service pack on each test computer. As needed, test the following scenarios:

    - Update computers that are running Windows Server 2003.

    - Update computers that are running Windows Server 2003 with SP1.

    - Update computers that are running Windows Server 2003 R2.

    - Upgrade test computers that are running Windows NT® Server 4.0 and Windows 2000 Server.

    - Perform a clean installation—that is, install Windows Server 2003 with SP2 onto computers that do not have an operating system.

3. Verify that the software and hardware perform as expected in each scenario.

**Additional resources**

The following resources contain detailed information that can help you plan your deployment.

- Windows Server 2003 Deployment Guide (http://go.microsoft.com/fwlink/?LinkId=44319).

- Article 926028 in the Microsoft Knowledge Base: "Updated System Preparation Tool for Windows Server 2003 Service Pack 2." This article contains instructions on how to use the Sysprep tool to deploy system images (http://go.microsoft.com/fwlink/?LinkId=78090).

- Deploy.cab and Support.cab. These are compressed files that contain a collection of tools and online **Help**. Technical support personnel and network administrators can use these updated support tools to manage networks and troubleshoot problems. These files are located on the SP2 CD in the \Support\Tools folder and on the Microsoft Download Center.

    - To download Deploy.cab, search the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=78088) for "Windows Server 2003 Service Pack 2 Deployment Tools."

    - To download Support.cab, search the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=78088) for "Windows Server 2003 Service Pack 2 Support Tools." Support.cab is included in the WindowsServer2003-KB914961-SupportTools-XXX-LLL.exe file.

- Article 926027 in the Microsoft Knowledge Base: "Windows Server 2003 Service Pack 2 Support Tools" (http://go.microsoft.com/fwlink/?LinkId=78091).

- Qfecheck.exe.Qfecheck.exe is a command-line tool that gives network administrators increased ability to track and verify installed hotfixes. For more information about the Qfecheck.exe program, see article 282784 in the Microsoft Knowledge Base: "Qfecheck.exe Verifies the Installation of Windows 2000 and Windows XP Updates" (http://go.microsoft.com/fwlink/?LinkId=44323). Although this article was written for other operating systems, it also applies to Windows Server 2003.

**Installation options**
You have two installation options:

- Standalone installation. Deploys SP2 to servers that are already running Windows Server 2003.

- Integrated installation. Integrates SP2 into Windows Server 2003, and then installs the operating system and SP2 simultaneously. You can use the integrated installation to upgrade servers and to perform clean installations on servers that do not have an operating system. For more information about creating an integrated version, see "Installing and Deploying Updates with Microsoft Windows Server 2003" (http://go.microsoft.com/fwlink/?LinkID=64779).

To perform these installations, first copy the installation files to a network share. Then extract the SP2 source files either to either each computer locally or to a network share (to save disk space on each computer).

When you extract the files to a network share, it is called a UNC install. For UNC installs, each computer uses the files on the network share to install the software. UNC installs are only suitable for computers that are permanently connected to the network because the service pack source files are stored remotely. For example, you should not use this method for updating laptop computers because if connectivity is lost during the installation, the computer may be left in an unusable state. In addition, you must use a network share that was created specifically for SP2 so that the source files are always available for computers. If you need to move a shared distribution folder, see article 271484 in the Microsoft Knowledge Base: "Files and Folders Are Added to Your System After Service Pack Is Installed" (http://go.microsoft.com/fwlink/?LinkId=9273).

**The standalone installation**
In a standalone installation, you install the service pack on computers that already have an operating system. The service pack installation is not complete until the computer is restarted. When you run a standalone installation, Update.exe creates a log file named Svcpack.log in the %systemroot% directory.

There are four scenarios for installing the standalone service pack:

- Scenario 1: Installing SP2 using local source files

- Scenario 2: Installing SP2 using source files that are located on a network share

- Scenario 3: Installing SP2 using Systems Management Server (SMS)

- Scenario 4: Installing SP2 using Windows Installer (Update.msi) and Group Policy

**Scenario 1: Installing SP2 using local source files**
First set up a shared distribution folder for the service pack installation file. Then to install the service pack, save the installation files locally on each computer.

### To install SP2 using installation files that are saved locally on each computer

1. Connect to the network or computer where you want to create the distribution folder.
2. In the shared folder, create a distribution folder for the service pack. For example, to create a distribution folder named WS2003SP2, type **mkdir Drive:\WS2003SP2** at the command prompt(Drive: represents the drive where you want to store the distribution folder).
3. Copy WindowsServer2003-KB914961-SP2-XXX-LLL.exe into the distribution folder.
4. To verify that you have assigned appropriate permissions to users who are installing the service pack:
   a. Navigate to the appropriate folder, right-click it, and then click **Properties**.
   b. Click the **Sharing** tab, and then click **Share This Folder**.
   c. In **Share Name**, type a name for the folder.
   d. Click **Permissions**, and then assign permissions that allow users to install the service pack from this folder.
   e. If you are using an NTFS file system partition, click the **Security** tab, confirm that the permissions listed there do not conflict with those on the **Sharing** tab, and then click **OK**.
5. To install the service pack at the command prompt, type the following using the desired command-line options:

   **\\ServerName\WS2003SP2\WindowsServer2003-KB914961-SP2-XXX-LLL.exe**
6. Follow the instructions in the Setup Wizard.
7. After the installation is complete, if you want to install additional updates, install them before you restart your computer.
8. Restart the computer and then restart the antivirus software if you disabled it.

**Scenario 2: Installing SP2 using source files that are located on a network share**
To install SP2 from the network, first extract the installation files to a shared distribution folder. Then install SP2 on each computer using these files.

### To install the service pack using a network share

1. Connect to the network or computer where you want to create the distribution folder.
2. In the shared folder, create a distribution folder. For example, to create a distribution folder named WS2003SP2, type **mkdir Drive:\WS2003SP2** at the command prompt (Drive: represents the drive where you want to store the distribution folder).
3. To extract the files to the distribution folder, type the following at the command prompt, where *Path* is the location of the distribution folder:

   **WindowsServer2003-KB914961-SP2-XXX-LLL.exe /X:Path**
4. For each computer that you plan to update, back up the files and close programs before you continue (unless you plan to force programs to close during the installation).
5. To install the service pack from the shared distribution folder, run Update.exe. For example, to install from a distribution folder named WS2003SP2, type the following at the command prompt using the desired command-line options:

   **Drive:\WS2003SP2\i386\Update\Update.exe**
6. Follow the instructions in the Setup Wizard.
7. After Update.exe has completed, restart the computer to complete the installation. SP2 will not be fully installed until you

restart your computer.

8. If you disabled your antivirus software, enable it after you restart the computer.

**Scenario 3: Installing SP2 using Systems Management Server (SMS)**
This scenario explains how to use Microsoft Systems Management Server (SMS) to install the service pack from a shared folder. You can use this method to install the service pack on SMS servers that are already running Windows Server 2003.

This scenario assumes that you have an understanding of SMS and a working knowledge of software distribution. For more information about deploying SP2 using SMS, see article 926030 in the Microsoft Knowledge Base: "How to Install Windows Server 2003 Service Pack 2 (SP2) by Using Systems Management Server" (http://go.microsoft.com/fwlink/?LinkId=78092).

### To use SMS to install the service pack

1. Ensure that your computer is running SMS 2003 with Service Pack 1 or Service Pack 2.

2. Create the SMS package by importing the package definition file for the service pack. In the package, provide the path to the source files for the service pack.

3. Distribute the SMS package to the distribution points.

4. Create the advertisement to notify SMS servers that the service pack is available.

**Scenario 4: Installing SP2 using Windows Installer (Update.msi) and Group Policy**
This scenario explains how to install SP2 from a shared folder using the Windows Installer package file (Update.msi). You can use this method to install the service pack on servers that are already running an operating system.

Update.msi contains all of the required information to install or remove the service pack. This file defines the relationships between service pack binary files. It also contains an installation database where you can view a summary of the properties that the installation program uses. To view this summary, right-click the installation database, and then click **Properties**. You must use the machine-assigned distribution method with Update.msi.

Before you begin, please note:

- To use this method, you should have a thorough understanding of Windows Installer and a working knowledge of Group Policy and Active Directory. For more information about Windows Installer, Group Policy, and Active Directory, see the Windows Server 2003 Deployment Guide (http://go.microsoft.com/fwlink/?LinkId=44319).

- For general information about how to apply your software deployment policy to users who are outside the boundaries of organization units, see article 324750 in the Microsoft Knowledge Base: "How To Assign Software to a Specific Group By Using a Group Policy in the Windows Server 2003 Family" (http://go.microsoft.com/fwlink/?LinkId=43972).

- We recommend that you use the SP2 installation file (for example, WindowsServer2003-KB914961-SP2-XXX-LLL.exe) when deploying SP2 at the command prompt. If you use Update.msi to distribute service packs, you must use a server-based ("machine-assigned") Group Policy object (GPO) only. User-based Group Policy deployments are not supported with Update.msi. For more information, see article 278503 in the Microsoft Knowledge Base: "Best Practices for Using Update.msi to Deploy Service Packs" (http://go.microsoft.com/fwlink/?LinkId=28711).

**#Assigning Service Pack 2 to servers using Group Policy**
This procedure explains how to assign the service pack to servers that are managed by a Group Policy object (GPO). For your installation, you might want to associate the GPO with a new Active Directory container. Only a network administrator or someone who is logged on to a local server as an administrator can remove the assigned software.

### To use Group Policy to assign SP2

1. Ensure that the server you want to update is joined to the same domain as the server where Update.msi resides.

2. Create a shared network distribution folder.

3. Create a GPO for SP2 deployments.

4. Deploy Update.msi from the shared distribution folder as "machine-assigned." Do not deploy it as a user deployment.

5. Restart each server. When you restart each server, it is updated to SP2. You should check the properties of each server to ensure that the update has completed. You might need to restart each server more than once to complete the update.

**The integrated installation**
You should perform the integrated installation if you want to install SP2 and Windows Server 2003 at the same time. To perform this type of installation, first use the **/integrate**option to update Windows Server 2003 with the SP2 installation files. To do this, you need to use a computer that is already running a Windows Server 2003 or Windows XP operating system.

After you have the integrated version, you can run Windows Server 2003 Setup. The Update.exe program creates a log file (named Spslpsrm.log) for integrated installations. This log file is created in the %systemroot% directory. If you plan to update more than one operating system from this computer, rename the Svcpack.log file after you update each version. Otherwise Update.exe will overwrite this file.

This section describes three scenarios for installing the integrated installation.

- Scenario 1: Creating an integrated installation
    - For Windows Server 2003
    - For Windows Server 2003 R2
- Scenario 2: Using RIS to install an integrated installation
- Scenario 3: Using Windows Deployment Services to install an integrated installation

**Scenario 1: Creating an integrated installation**
This section contains instructions for creating integrated installations of SP2 with Windows Server 2003 and Windows Server 2003 R2.

**For Windows Server 2003**
**To create an integrated installation of Windows Server 2003 with SP2**

1. Connect to the network or computer where you want to create the distribution folder.
2. Create the shared folder and ensure that only system administrators have full access to this folder. (Other users should have only Read and Execute permissions.)
3. In the shared folder, create a distribution folder for the Windows Server 2003 installation files. For example, to create a distribution folder named WS2003\x86, type:

   **mkdir Drive:\WS2003\x86**
4. To verify that you have assigned appropriate permissions to users who are installing the service pack:
    a. Navigate to the appropriate folder, right-click it, and then click **Properties**.
    b. Click the **Sharing** tab, and then click **Share This Folder**.
    c. In **Share Name**, type a name for the folder.
    d. Click **Permissions**, and then assign permissions that allow users to install the service pack from this folder.
    e. If you are using an NTFS file system partition, click the **Security** tab, confirm that the permissions listed there do not conflict with those on the **Sharing** tab, and then click **OK**.
5. Insert your Windows Server 2003 product disc into the CD-ROM drive and copy the contents to the distribution folder. For example, to copy the contents in the CD-ROM drive (D:) to the distribution folder named WS2003\x86 on the E: drive, type:

   **xcopy /E D:\ E:\WS2003\x86**
6. Remove the Windows Server 2003 product disc, and insert the SP2 CD.
7. Apply the source files for the service pack to the installation files. For example, for a 32-bit version of Windows Server 2003, in the folder named WS2003\x86, type:

**WindowsServer2003-KB914961-SP2-XXX-LLL.exe /integrate:Drive:\WS2003\x86**

8. Service pack files are extracted and then applied to the operating system files to update your shared distribution folder. You can either use the files from this folder to make a CD (32-bit versions only) to upgrade your servers, or you can customize Setup for Windows Server 2003 as necessary. For more information about how to customize Setup, view **Help** by typing **i386\winnt32.exe /?** at the command prompt in theshared distribution folder.

9. You can now deploy Windows Server 2003 with SP2 to your computers from the shared folder in either attended or unattended Setup mode.

**For Windows Server 2003 R2**

This section applies only if you have the first release of Windows Server 2003 R2 where disc 1 contains Windows Server 2003 with Service Pack 1. If the product discs that you have do not specify which service pack is included, the discs contain Windows Server 2003 with SP1. If you have the second release of Windows Server 2003 R2 where disc 1 contains Windows Server 2003 with SP2, you do not need to integrate disc 1 and SP2 because disc 1 already contains SP2.

**To create an integrated installation of Windows Server 2003 R2 and SP2**

1. Connect to the network or computer where you want to create the distribution folder.

2. Create the shared folder and ensure that only system administrators have full access to this folder. (Other users should have only Read and Execute permissions.)

3. In the shared folder, create a distribution folder for the Windows Server 2003 R2 disc 1 installation files. For example, to create a distribution folder named WS2003\x86\CD1, type:

   **mkdir Drive:\WS2003\x86\CD1**

4. To verify that you have assigned appropriate permissions to users who are installing the service pack:

   a. Navigate to the appropriate folder, right-click it, and then click **Properties**.

   b. Click the **Sharing** tab, and then click **Share This Folder**.

   c. In **Share Name**, type a name for the folder.

   d. Click **Permissions**, and then assign permissions that allow users to install the service pack from this folder.

   e. If you are using an NTFS file system partition, click the **Security** tab, confirm that the permissions listed there do not conflict with those on the **Sharing** tab, and then click **OK**.

5. Insert disc 1 into the CD-ROM drive, and copy the contents to the distribution folder. For example, to copy the contents in the CD-ROM drive (D:) to the distribution folder named WS2003\x86\CD1 on the E: drive, type:

   **xcopy /E D:\ E:\WS2003\x86\CD1**

6. Remove the Windows Server 2003 R2 disc 1, and insert the SP2 CD.

7. Apply the source files for the service pack to the installation files. For example, for a 32-bit version of Windows Server 2003 in the folder named WS2003\x86\CD1, type:

   **WindowsServer2003-KB914961-SP2-XXX-LLL.exe /integrate:Drive:\WS2003\x86\CD1**

8. Service pack files are extracted and then applied to the operating system files to update your shared distribution folder. You can either use the files from this folder to make a CD (32-bit versions only) to upgrade your servers, or you can customize Setup for Windows Server 2003 as necessary. For more information about how to customize Setup, view **Help** by typing **i386\winnt32.exe /?** at the command prompt in theshared distribution folder.

9. Insert your Windows Server 2003 R2 disc 2 into the CD-ROM drive, and copy the contents to the distribution folder. For example, to copy the contents in the CD-ROM drive (D:) to the distribution folder named WS2003\x86\CD2 on the E: drive, type:

   **xcopy /E D:\ E:\WS2003\x86\CD2**

10. Apply the source files for the service pack to the installation files. For example, for a 32-bit version of Windows Server 2003 in the folder named WS2003\x86\CD2, type:

    **WindowsServer2003-KB914961-SP2-XXX-LLL.exe /integrate:Drive:\WS2003\x86\CD2**

11. You can now deploy the integrated version of disc 1 and the installation files for disc 2 to your computers from the shared folder in either attended or unattended Setup mode.

**Scenario 2: Using RIS to install an integrated installation**
This section explains how to use Remote Installation Services (RIS) to install an integrated version of Windows Server 2003 with SP2. However, this section does not explain how to set up RIS. For more information about RIS, see Remote Installation Services (http://go.microsoft.com/fwlink/?LinkId=36940).

RIS supports two types of operating system images:

- CD-based images (images created by using RISetup)
- Remote Installation Preparation (RIPrep) images.

The CD-based option is similar to setting up a server operating system directly from the Windows Server 2003 product CD, except that the source files reside on a RIS server. You can create a RIPrep image from a server that is running Windows Server 2003 with SP2, and you can then deploy this image to other similar servers that are connected to the network.

**Creating a CD-based (RISetup) image to add to a RIS server**
After you install RIS, perform the following steps to create the image and then add the image to your RIS server.

**To create an image of Windows Server 2003 with SP2 and add it to your RIS server**

1. Create an integrated version of the operating system with SP2. For more information, see Scenario 1.
2. To create an image, click **Start**, click **Run**, and then type:

   **risetup.exe /add**

3. The Remote Installation Services Setup Wizard appears. Follow the instructions in the wizard. When the **Installation Source Files Location page** prompts you for the image source, enter the path to the shared folder that contains the integrated version that you created in Step 1.
4. A box appears showing the progress of the installation. After the RISetup image is complete, you can install the image on each server as described in Remote Installation Services on the Microsoft TechCenter Web site (http://go.microsoft.com/fwlink/?LinkId=36940).

**Creating a Remote Installation Preparation (RIPrep) image to deploy to other servers**
If you want to add additional programs or settings to your integrated installation image, you must have a CD–based image of Windows Server 2003 with SP2 on your RIS server. Note that you cannot use the **/integrate** option to integrate SP2 directly into an existing CD-based image or a RIPrep image.

**To update existing RIPrep images**

1. Use RIS to install the RISetup image on your computer.
2. Add the additional programs and settings that you want to include in the image.
3. Run RIPrep to create an image on the RIS server. For instructions on how to run RIPrep on RIS servers running Windows Server 2003, see:
   - Remote Installation Services (http://go.microsoft.com/fwlink/?LinkId=36940)
   - Automating and Customizing Installations (http://go.microsoft.com/fwlink/?LinkId=44324)
4. You can now deploy your RIPrep image to other servers.

**Scenario 3: Using Windows Deployment Services to install an integrated installation**
This section explains how to use Windows Deployment Services to install an integrated version of Windows Server 2003 with

SP2. However, this section does not explain how to set up Windows Deployment Services. For more information, see the documentation that is included with the tool and the Windows Deployment Services Update Step-by-Step Guide (http://go.microsoft.com/fwlink/?LinkId=66145).

You can also deploy SP2 by using RIS functionality from a Windows Deployment Services Server. For example, first ensure that the server is in either Legacy or Mixed mode. Then follow the procedures in Scenario 2 to deploy SP2. To check the operating mode that you are in, run **WDSUTIL /get-server /show:config**. The output will contain a line with the mode that you are in. For example, "WDS operational mode: Mixed."

To add an image of Windows Server 2003 with SP2 to your Windows Deployment Services server, you must first create a .wim install image. Install images are built from reference installations of the Windows operating system and are deployed when Windows Deployment Services is used to install Windows. A reference installation may be a standard Windows installation or may be configured for a specific environment or use prior to creating the image.

**To create an install image**

1. Create a reference computer that contains Windows Server 2003, SP2, and any programs and settings that you want to include in the image.
2. Download the updated deployment tools (Deploy.cab). To do this, search the Microsoft Download Center for "Windows Server 2003 Service Pack 2 Deployment Tools" (http://go.microsoft.com/fwlink/?LinkId=78088).
3. From a command prompt on the reference computer, change directories to the directory that contains the updated version of Sysprep.exe (which is included in Deploy.cab). For more information about using this tool, see article 926028 in the Microsoft Knowledge Base: "Updated System Preparation Tool for Windows Server 2003 Service Pack 2" (http://go.microsoft.com/fwlink/?LinkId=78090).
4. Type **sysprep.exe /reseal /reboot**.
5. When the reference computer reboots, press **F12**.
6. In **Windows Boot Manager**, choose to boot to the appropriate capture image.
7. On the **Image Capture Wizard** welcome page, click **Next**.
8. On the **Image Capture Source** page, use the **Volume to Capture** drop-down menu to choose the appropriate volume, and then provide a name and description for the image. Click **Next** to continue.
9. On the **Image Capture Destination** page, click **Browse** and browse to the location where you want to store the captured image.
10. In the **Filename** text box, type a name for the image using the .WIM file name extension, and then click **Save**.
11. Click **Upload image to WDS server**.
12. Type the name of the Windows Deployment Services server and click **Connect**.
13. If prompted for credentials, provide a user name and password for an account with sufficient privilege to connect to the Windows Deployment Services server.
14. Using the drop-down **Image Group** menu, choose an image group in which to store the image.
15. Click **Finish**.

**Command-line options**

You can use the following options to define the way SP2 is installed. You can use the following options through Update.exe or when you run the installation file (for example, **WindowsServer2003-KB914961-SP2-XXX-LLL.exe**). You can precede the following options with a forward slash (/) or a hyphen (-). The options are not case-sensitive.

| **Note** |
| --- |
| You can also use the /Log and /Verbose options. For more information, see "The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components" (http://go.microsoft.com/fwlink/?LinkId=42759). |

| Command-line option | Description |
| --- | --- |
| **/D:Path** | Backs up the files that are required to remove the service pack to *Path*. Any location that you specify must be on the local drive. If you back up files but do not specify a folder, the default location is:<br><br>$ntservicepackuninstall$ |
| **/ER** | Enables extended codes that return a detailed error message if the update installation fails. For more information, see "The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components" (http://go.microsoft.com/fwlink/?LinkId=42759). |
| **/F**<br><br>or<br><br>**/Forceappsclose** | Forces other applications to close after you install the update package and before the computer is restarted. You cannot use this option with **/integrate**, **/L**, and **/Z**. |
| **/Forcerestart** | Restarts the computer after the installation is complete, even if a restart is not required to complete the installation. This option does not force applications to close. |
| **/Integrate:Path** | Integrates the SP2 source files into the path you specify. Be sure to provide the absolute path to your operating system source files. This option is the same as the **/S** option that was used by previous installers. |
| **/L** | Lists installed updates. |
| **/N**<br><br>or<br><br>**/Nobackup** | Does *not* create backup files during setup. We do not recommend this option because backup files allow you to remove SP2 in the future. An entry for SP2 does not appear in **Add or Remove Programs** if you use this option. |
| **/O**<br><br>or<br><br>**/Overwriteoem** | Overwrites OEM files without prompting. |
| **/Promptrestart** | If a restart is required, a dialog box notifies the user that a restart is required to complete setup. Intended for use with /Quiet. |
| **/Q**<br><br>or<br><br>**/Quiet** | Uses quiet mode. This mode shows no user interface during the installation of the updates. This is the same as unattended mode, except that the user interface is hidden. No prompts will appear during the installation process. |
| **/U**<br><br>or<br><br>**/Passive** | Installs the service pack in unattended mode. Only critical error prompts and a progress bar will appear during the installation. By default, the program invokes the **/Warnrestart** option. |
| **/Warnrestart: [Seconds]** | If a restart is required, a dialog box notifies the user that the computer will restart in the specified seconds. The user can click **Cancel** or **Restart Now**. The default is 60 seconds. |
| **/X**<br><br>or<br><br>**/Extract** | Extracts service pack files without starting Update.exe. You are prompted to provide the path for the folder in which you want the extracted service pack installation files to be placed. For more information, see "The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components" (http://go.microsoft.com/fwlink/?LinkId=42759). |
| **/Z**<br><br>or<br><br>**/Norestart** | Does not restart the computer after the installation is complete, even if a restart is required to complete the installation. |

| | |
|---|---|
| **/?**<br>or<br>**/Help** | Displays Help. |

**Uninstalling SP2**

It is possible to uninstall SP2 only if it was installed as an update to an existing operating system. It is not possible to remove only SP2 if you installed it as part of an integrated installation. In addition, you can only uninstall the last service pack that you installed. For example, if you install SP1 and then you install SP2, you can only uninstall SP2.

By default, backup files are created during the installation so you can remove SP2. Unless you specified the /nobackup option when installing SP2, then you can remove SP2 using **Add or Remove Programs** or the command prompt.

If you remove SP2, a dialog box displays a list of the applications that you installed after you installed SP2. If you continue, these applications might not work correctly. Multiple descriptions of some applications might appear instead of a single generic description. You can ignore these additional descriptions.

**To remove SP2 using a command prompt**

1. Open a command prompt, type the following, and then press ENTER (*Option* can be any option listed in the following table):

   %systemroot%\$NtServicePackUninstall$\spuninst\Spuninst.exe /*Option*

2. Follow the instructions that appear on your screen.

| Option | Description |
|---|---|
| **/F**<br>or<br>**/Forceappsclose** | Forces applications to close when the computer restarts. |
| **/Q**<br>or<br>**/Quiet** | Removes SP2 in quiet mode, which is the same as unattended mode except that the user interface is hidden and no prompts appear. |
| **/U**<br>or<br>**/Passive** | Removes the service pack in unattended mode. Only critical error prompts appear while SP2 is being uninstalled. |
| **/Z**<br>or<br>**/Norestart** | Does not restart the computer after the process of uninstalling SP2 is complete. |
| **/?**<br>or<br>**/Help** | Displays Help. |

**Debugging symbols**

If you want to debug the operating system, first download and install the symbols for debugging Windows Server 2003, and then add the symbols for debugging SP2 to the same folder. When you install SP2, the current versions of the symbol files overwrite any previous versions that are in the symbol installation folder. For more information, see Debugging Tools for Windows—Overview (http://go.microsoft.com/fwlink/?LinkId=30565).

You can download symbols for debugging SP2 from one of the following locations:

- The Download Windows Symbol Packages page on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkID=30539).

- On demand from the Internet Symbol Server. For more information about using the Internet Symbol Server, see "Debugging Tools and Symbols: Getting Started" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=30524).

- The English version of the SP2 CD. This CD contains the symbols package (Symbols.cab) in the \Support\Symbols folder. This package is language-independent and can be downloaded for debugging any Windows Server 2003 locale.

**Additional resources**

- For information about SP2, see the Microsoft TechCenter Web site (http://go.microsoft.com/fwlink/?LinkId=78093).

- The Microsoft Knowledge Base provides updated information about the Windows Server 2003 operating systems, SP2, and other Microsoft products (http://go.microsoft.com/fwlink/?LinkId=4441).

- For the most up-to-date information about supported hardware, see the hardware compatibility information at the Windows Server Catalog Web site (http://go.microsoft.com/fwlink/?LinkId=16906).

- To obtain the most recent product updates, see the Windows Update Web site (http://go.microsoft.com/fwlink/?LinkId=22377).

# Installing and Deploying Updates for Microsoft Windows Server 2003

Applies To: Windows Server 2003 with SP2

**About this guide**
This guide is for system administrators who are installing software updates on Microsoft® Windows Server® 2003. It includes technical information, procedures, and recommendations for installing updates on multiple computers in a small business or corporate environment. Although this guide includes some basic operating system information, it assumes that you have a working knowledge of Windows Server 2003 and update installations. All of the examples in this guide use the format for 32-bit updates.

If you want to deploy the standalone version of a service pack or the service pack that is integrated with the operating system, see the Windows Server 2003 Service Pack Installation and Deployment Guide that applies to your service pack. (For example, the guide for Service Pack 2 is located at http://go.microsoft.com/fwlink/?LinkID=64780.)

**What is an update?**
This guide uses the term "update" to refer to any software update, including an update rollup, service pack, feature pack, critical update, security update, or hotfix that is released by Microsoft Corporation. For descriptions of the standard terminology that is used to describe Microsoft software updates, see article 824684 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=43258).

Although this guide uses update as a broad term, it is important that you know the following differences between hotfixes and service packs:

- Hotfixes can be un-installed in the order they are installed.
- Only the last installed service pack can be uninstalled.
- Hotpatch command-line options are valid only for hotfixes, not for service packs.

You can install updates separately from the operating system or in combination with Windows Server 2003 (with or without a service pack). When you install an update, backup files are automatically created so you can remove the update later if you want to. The installation process also copies the new files to specific folders and updates registry settings.

| **Important** |
| --- |
| Updates are applied only to software that is already installed. For example, if you remove a component and later reinstall it, you must reinstall updates that apply to that component. In addition, if you further add components to your computer that require this update, you must reinstall the update for it to apply to the new component. |

Windows Server 2003 update files are named according to the following format: WindowsServer2003-KB######-XXX-LLL.exe. The symbols###### represent the Microsoft Knowledge Base article that explains the details about the update, XXX represents the version of the operating system (for example, x86), and LLL represents the language version of the update.

Updates are self-installing. There are two main types of update installations:

- The standalone update installation  Use this installation to update computers that are already running Windows Server 2003.
- The combination installation  Use this unattended installation to install an update in combination with an installation of Windows Server 2003, a service pack, or both.

**The standalone update installation**
During the standalone update installation, updates are applied to a computer that is already running an operating system. When you run the update program, it installs updated system files and makes the necessary registry changes. The installation is complete after the computer is restarted.

You can install the updates by running the WindowsServer2003-KB######-XXX-LLL.exe file, which extracts the update files

and runs Update.exe. Update.exe registers the updates under the following registry keys:

- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Updates\Server2003\SP2\KB######
- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Hotfix\KB######

For more information about Update.exe, read this white paper about the package installer for Windows and Windows components (http://go.microsoft.com/fwlink/?LinkId=42759).

During the installation, information for removing the updates is stored in a hidden folder named %systemroot%\$NtUninstallKB######$. For information, see Removing updates.

**Using Qchain.exe**
Windows Server 2003 updates have Qchain.exe functionality built in as part of Update.exe. This means that you can install the service pack, and then install any number of updates without having to restart the computer between installations.

If multiple updates replace the same file, Update.exe ensures that the correct version of the file is retained. If you install multiple updates, be sure to use the **/Z** option so the computer does not restart after each update.

**Command-line options for the update package**
To customize your installation, you can use the following command-line options with WindowsServer2003-KB######-x86-LLL.exe and Update.exe.

| **Note** |
| --- |
| If your service pack version was released after the updates and you were completing an unattended installation using either the **/U** (unattended setup) or **/Q** (quiet setup) option, the installation does not continue and no message appears. |

| **Command-line option** | **Description** |
| --- | --- |
| **/ER** | Enables extended codes that return a detailed error message if the update installation fails. For more information, see "The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components" (http://go.microsoft.com/fwlink/?LinkId=42759). |
| **/F**<br>or<br>**/Forceappsclose** | Forces other applications to close after you install the update package and before the computer is restarted. You cannot use this option with **/integrate**, **/L**, and **/Z**. |
| **/Forcerestart** | Restarts the computer after the installation is complete, even if a restart is not required to complete the installation. This option does not force applications to close. |
| **/Integrate:Path** | Integrates this software update into the path you specify. Be sure to provide the absolute path to your operating system source files. This option is the same as the **/S** option that was used by previous installers. |
| **/L** | Lists installed updates. |
| **/N**<br>or<br>**/Nobackup** | Does *not* create backup files during setup. We do not recommend this option because backup files allow you to remove SP2 in the future. An entry for the update does not appear in **Add or Remove Programs** if you use this option. |
| **/O**<br>or<br>**/Overwriteoem** | Overwrites OEM files without prompting. |

| | |
|---|---|
| **/Q**<br>or<br>**/Quiet** | Uses quiet mode. This mode shows no user interface during the installation of the updates. This is the same as unattended mode, except that the user interface is hidden. No prompts will appear during the installation process. |
| **/U**<br>or<br>**/Passive** | Installs the update in unattended mode. Only critical error prompts and a progress bar will appear during the installation. By default, the program invokes the **/Warnrestart** option. |
| **/Z**<br>or<br>**/Norestart** | Does not restart the computer after the installation is complete, even if a restart is required to complete the installation. |
| **/?**<br>or<br>**/Help** | Displays Help. |

**Installing updates on multiple computers**

Although there are several methods that you can use to install an update (like using Systems Management Server or Windows Installer), the following procedure outlines how to run Update.exe manually using a distribution folder.

| **Important** |
|---|
| You must install the service pack either in combination with or before you install updates that were released after the service pack. Installing more recently released updates before you install the service pack can leave the system in an unstable state. |

**To install an update by running Update.exe**

1. Connect to the network or computer on which you want to create the distribution folder.
2. In the shared distribution folder, create a folder for the update files. For example, to create a distribution folder named Update, type the following (using the appropriate drive letter):

   mkdir *Drive*:\Update

3. Copy the Windows Server 2003 Update.exe program to the distribution folder that you created in Step 2. For example, to copy the Update.exe program to the distribution folder named Update, type:

   xcopy C:\WindowsServer2003-KB######-x86-LLL.exe *Drive*:\Update

4. To install the update from the distribution folder, run the WindowsServer2003-KB######-x86-*LLL*.exe program. For example, to install the update from the distribution folder named Update, type:

   *Drive*:\Update\WindowsServer2003-KB######-x86-LLL.exe

5. To ensure that your updates take effect, restart your computer after you finish installing all of the updates.

**Installing several updates together**

You can group multiple updates together in a batch file and install them as a unit. In this case, you do not need to restart your computer after you install each update. The update installer provides options that you can use when performing this type of installation. The following code is a sample batch file that installs updates and ensures that the correct files are replaced after the computer is restarted.

```
@echo off
setlocal
set PATHTOFIXES=Drive:\update
%PATHTOFIXES%\WindowsServer2003-KB######-x86-LLL.exe /quiet /norestart
%PATHTOFIXES%\WindowsServer2003-KB######-x86-LLL.exe /quiet /norestart
%PATHTOFIXES%\WindowsServer2003-KB######-x86-LLL.exe /quiet /norestart
```

| **Important** |
| --- |
| To ensure that the updates that you installed take effect, restart the computer if the batch file does not automatically restart it for you. If you want your computer to restart automatically, in the last update that you install, replace the option **/Norestart** with the option **/Forcerestart**. |

**The combination installation**

The combination installation uses the update installation and integrated installation processes to install a service pack with one or more of the following:

- Windows Server 2003
- Other updates (such as feature packs, critical updates, or hotfixes)
- Additional Microsoft and non-Microsoft software that might be included on a service pack CD

For a combination installation, you can include the components that you want to install as entries in the Svcpack.inf file along with the updates. You can also choose to install the service pack at the same time. This section provides instructions for using unattended setup mode to simultaneously install Windows Server 2003 and updates.

**Installing a service pack and updates with Windows Server 2003**

This section explains how to perform a combination installation from a distribution folder. This option installs a service pack and updates that are integrated with Windows Server 2003. A combination installation makes it unnecessary for you to perform separate installations of Windows Server 2003, a service pack, and the updates because it installs all of them together.

**Preparing for the combination installation**

Before you deploy the installation of Windows Server 2003 and the updates across a network, you must copy Windows Server 2003 and the update installation files to a shared folder and complete the steps described in To create and set up the required folders and files for Windows Server 2003.

If you are an original equipment manufacturer (OEM) and you plan to install additional OEM files (such as device driver, application, or component files), create a \$1 subfolder within the \$OEM$ subfolder. The \$1 subfolder corresponds to %systemdrive%, which is the destination drive for the Windows Server 2003 installation.

| **Important** |
| --- |
| If you want to include a service pack *and* updates in your deployment of Windows Server 2003, first you must integrate Windows Server 2003 with the service pack as described in the Windows Server 2003 Service Pack Installation and Deployment Guide that applies to your service pack. (For example, the guide for Service Pack 2 is located at http://go.microsoft.com/fwlink/?LinkID=64780.) Then you can integrate the updates, which will support the service pack. |

For more information about how to integrate updates, see article 828930 in the Microsoft Knowledge Base about how to integrate software updates into your Windows installation source files (http://go.microsoft.com/fwlink/?LinkId=42761).

**To create and set up the required folders and files for Windows Server 2003**

1. Connect to the network or computer on which you want to create the distribution folder.
2. Create a distribution folder by typing the following at the command prompt (using the appropriate drive letter):

   mkdir *Drive*:\WServer2003DIST
3. Use the command **xcopy** to copy the files and subfolders from the integrated installation product disc that includes Windows Server 2003 and the service pack to the *Drive*:\WServer2003DIST folder.

   For example, if D is your CD-ROM drive, type:

   xcopy /E /I /V D:\ *Drive*:\WServer2003DIST
4. Use **/Integrate** to run the update that you want to install by typing the following:

   WindowsServer2003-KB######-x86-LLL.exe /integrate: *Drive*:\WServer2003DIST

5. Repeat this step for each update you want to include your deployment.

**Deploying the combination installation**

You can deploy the integrated installation of Windows Server 2003 and the updates to multiple computers from a distribution folder. During the standard installation process, Setup installs the operating system and applies the updates.

| **Note** |
| --- |
| For more information about the following procedure, see the Microsoft Windows Corporate Deployment Tools User's Guide (Deploy.chm) included in Deploy.cab in the \Support\Tools folder on your service pack CD. |

### To deploy the installation

1. Verify that the installation and executable files for Windows Server 2003 and the updates exist in your distribution folder.
2. Customize Windows Server 2003 Setup as necessary. For more information about customizing Windows Server 2003 Setup, see the **Winnt32.exe** command syntax topic in the Microsoft Windows Server 2003 Professional Resource Kit Documentation on the Windows Deployment and Resource Kits Web site (http://go.microsoft.com/fwlink/?LinkId=40616).
3. Run Windows Server 2003 Setup. This deploys the installation of Windows Server 2003 and the updates to multiple computers from the distribution folder.

**Removing updates**

You can remove an update for Windows Server 2003 at a command prompt or by using **Add or Remove Programs** in **Control Panel**. If you want to remove updates, you must remove them in the reverse order of installation (that is, you must remove the most recently installed update first). For example, if you installed UpdateA before you installed UpdateB, you will need to remove UpdateB first to return your computer to its original state. This is because some updates share files.

| **Note** |
| --- |
| You cannot remove updates that were installed using the combination installation method. |

### To remove an update at the command prompt

1. Specify this location at the command prompt:

   %systemroot%\$NtUninstallKB######$\spuninst\

2. Type "Spuninst.exe */option*". Replace *option* with any of the following options:

| Option | Description |
| --- | --- |
| **/U**<br>or<br>**/Passive** | Removes the update in unattended mode.<br>(If you use this option, only critical error prompts appear while you uninstall the update.) |
| **/Q**<br>or<br>**/Quiet** | Removes the update in quiet mode.<br>(This is the same as unattended mode except that the user interface is hidden. If you use this option, no prompts appear while you uninstall the update.) |
| **/Z**<br>or<br>**/Norestart** | Does not restart the computer after the process of uninstalling the update is complete. |

| | |
|---|---|
| **/F**<br>or<br>**/Forceappsclose** | Forces other applications to close when the computer restarts after uninstalling the update. |
| **/?**<br>or<br>**/Help** | Displays Help. |

**To remove an update for Windows Server 2003 by using Add or Remove Programs**

1. Open **Control Panel**.
2. Click **Add or Remove Programs**.
3. Select the **Show updates** check box.
4. Click the update that you want to remove, and then click **Change or Remove**.
5. Follow the instructions that appear on your screen.

# Readme for Windows Server 2003 Service Pack 2

Applies To: Windows Server 2003 with SP2

This document contains information that you should know before you install Microsoft® Windows Server® 2003 Service Pack 2 (SP2). There are three versions of SP2: one for 32-bit operating systems, one for Itanium-based operating systems, and one for x64-based operating systems. SP2 contains the latest collection of updates to help improve the security, reliability, and performance of the following operating systems:

- 32-bit versions of Microsoft Windows Server 2003
- Itanium-based versions of Microsoft Windows Server 2003
- x64-based versions Microsoft Windows Server 2003
- Windows Server 2003 R2 Editions
- KN versions of Windows Server 2003 R2
- Windows® XP Professional x64 Edition

| **Note** |
| --- |
| If you are running Windows Server 2003, Datacenter Edition, and subscribe to the Windows High Availability Support Program through a qualified original equipment manufacturer (OEM), do not install this service pack. Instead, you should contact your OEM for the service pack, updated adapter drivers, utilities, a custom hardware abstraction layer (HAL) if needed, and support. OEMs are required to test Windows Server 2003 Datacenter Edition with service packs. If you do not subscribe to this program, you can continue installing this service pack. |

**Before you install**

Before you install SP2:

- **Review the following documentation.**
  - Article 914962 in the Microsoft Knowledge Base, for a list of the updates included in this service pack (http://go.microsoft.com/fwlink/?LinkId=74380).
  - "Release Notes for Windows Server 2003 Service Pack 2" (http://go.microsoft.com/fwlink/?LinkId=74381), for a list of the known issues with this version of SP2.
  - "Installing and Deploying Updates for Microsoft Windows Server 2003" (http://go.microsoft.com/fwlink/?LinkID=64779), for information about combining this service pack with other updates.
  - "Windows Server 2003 Service Pack 2 Installation and Deployment Guide" (http://go.microsoft.com/fwlink/?LinkID=64780), for more deployment options.
- **Check the disc space requirements.** See article 926029 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=74454).
- **Back up your servers**. Your backup should include all data and configuration information that is necessary for that server to function. It is important to perform a backup of configuration information for servers, especially those that provide network infrastructure, such as Dynamic Host Configuration Protocol (DHCP). When you perform the backup, be sure to include the boot and system partitions and the system state. Another way to back up configuration information is to create a backup set for Automated System Recovery.
- **Disconnect UPS devices.** If you have an uninterruptible power supply (UPS) connected to your destination computer, disconnect the connecting serial cable before running Setup. Setup automatically attempts to detect devices connected to

serial ports, and UPS equipment can cause problems with the detection process.

- **Disable your antivirus software.** If you are not connected to a network or the Internet and you want to minimize the installation time, you can disable your antivirus software. The time that it takes for the antivirus software to scan each file can add significant time to the installation: as much as an hour or more on slower computers. Be sure to enable the antivirus software after you install SP2.

- **Uninstall prerelease versions of SP2.** Unless you have a supplementary support agreement with Microsoft, you must uninstall any prerelease versions of SP2 before you proceed. Upgrading to this version from any prerelease version is not supported.

- **Close all open programs.**

**How to install SP2 from the Web**

You can install SP2 from:

- **Windows Update:** You can use Microsoft Update to install SP2 on a single server running Windows Server 2003. You can update Itanium-based versions with SP2 only by using the CD or by downloading it from the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=77236).

- **Microsoft Download Center:** You can download SP2 from the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=77236). We recommend that you save the SP2 installation file locally on the computer. Then if you have to restart the installation or reinstall SP2, you will not need to download the installation file again. Because the SP2 installation file is very large, if your computer has more than one hard disk, save the installation file on a disk other than your system disk.

**Deploying SP2 to multiple servers**

You can use the SP2 installation files to deploy SP2 to multiple servers that are already running one of the supported operating systems. And you can use the SP2 files to integrate a Windows Server 2003 operating system with SP2 and then install the operating system and SP2 together on multiple servers. This procedure is known as "slipstreaming." For more information, see:

- Installing and Deploying Updates for Windows Server 2003 (http://go.microsoft.com/fwlink/?LinkID=64779)

- Windows Server 2003 Service Pack 2 Installation and Deployment Guide (http://go.microsoft.com/fwlink/?LinkID=64780)

**Command-line options**

You can define the way SP2 is installed by typing one or more of the following command-line options when you run the installation .exe file. You can precede the options with either a forward slash (/) or a hyphen (-). The options are not case-sensitive.

| **Note** |
|---|
| You can also use the **/Log** and **/Verbose** options. For more information, see "The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components" (http://go.microsoft.com/fwlink/?LinkId=42759). |

| Command-line option | Description |
|---|---|
| **/D:Path** | Backs up the files that are required to remove the service pack to *Path*. Any location that you specify must be on the local drive. If you back up files but do not specify a folder, the default location is:<br><br>$ntservicepackuninstall$ |

| | |
|---|---|
| **/ER** | Enables extended codes that return a detailed error message if the update installation fails. For more information, see "The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components" (http://go.microsoft.com/fwlink/?LinkId=42759). |
| **/F**<br>or<br>**/Forceappsclose** | Forces other applications to close after you install the update package and before the computer is restarted. You cannot use this option with **/integrate**, **/L**, and **/Z**. |
| **/Forcerestart** | Restarts the computer after the installation is complete, even if a restart is not required to complete the installation. This option does not force applications to close. |
| **/Integrate:Path** | Integrates the SP2 source files into the path you specify. Be sure to provide the absolute path to your operating system source files. This option is the same as the **/S** option that was used by previous installers. |
| **/L** | Lists installed updates. |
| **/N**<br>or<br>**/Nobackup** | Does *not* create backup files during setup. We do not recommend this option because backup files allow you to remove SP2 in the future. An entry for SP2 does not appear in **Add or Remove Programs** if you use this option. |
| **/O**<br>or<br>**/Overwriteoem** | Overwrites OEM files without prompting. |
| **/Promptrestart** | If a restart is required, a dialog box notifies the user that a restart is required to complete setup. Intended for use with /Quiet. |
| **/Q**<br>or<br>**/Quiet** | Uses quiet mode. This mode shows no user interface during the installation of the updates. This is the same as unattended mode, except that the user interface is hidden. No prompts will appear during the installation process. |
| **/U**<br>or<br>**/Passive** | Installs the service pack in unattended mode. Only critical error prompts and a progress bar will appear during the installation. By default, the program invokes the **/Warnrestart** option. |
| **/Warnrestart: [Seconds]** | If a restart is required, a dialog box notifies the user that the computer will restart in the specified seconds. The user can click **Cancel** or **Restart Now**. The default is 60 seconds. |
| **/X**<br>or<br>**/Extract** | Extracts service pack files without starting Update.exe. You are prompted to provide the path for the folder in which you want the extracted service pack installation files to be placed. For more information, see "The Package Installer (Formerly Called Update.exe) for Microsoft Windows Operating Systems and Windows Components" (http://go.microsoft.com/fwlink/?LinkId=42759). |
| **/Z**<br>or<br>**/Norestart** | Does not restart the computer after the installation is complete, even if a restart is required to complete the installation. |
| **/?**<br>or<br>**/Help** | Displays Help. |

**Uninstalling SP2**

It is possible to uninstall SP2 only if it was installed as an update to an existing operating system. It is not possible to remove

only SP2 if you installed it as part of an integrated installation. In addition, you can only uninstall the last service pack that you installed. For example, if you install SP1 and then you install SP2, you can only uninstall SP2.

By default, backup files are created during the installation so you can remove SP2. Unless you specified the /nobackup option when installing SP2, then you can remove SP2 using **Add or Remove Programs** or the command prompt.

| **Important** |
| --- |
| If you remove SP2, a dialog box displays a list of the applications that you installed after you installed SP2. If you continue, these applications might not work correctly. Multiple descriptions of some applications might appear instead of a single generic description. You can ignore these additional descriptions. |

**To remove SP2 using a command prompt**

1. Open a command prompt, type the following, and then press ENTER (*Option* can be any option listed in the following table):

   %systemroot%\$NtServicePackUninstall$\spuninst\Spuninst.exe /*Option*

2. Follow the instructions that appear on your screen.

| Option | Description |
| --- | --- |
| **/F**<br>or<br>**/Forceappsclose** | Forces applications to close when the computer restarts. |
| **/Q**<br>or<br>**/Quiet** | Removes SP2 in quiet mode, which is the same as unattended mode except that the user interface is hidden and no prompts appear. |
| **/U**<br>or<br>**/Passive** | Removes the service pack in unattended mode. Only critical error prompts appear while SP2 is being uninstalled. |
| **/Z**<br>or<br>**/Norestart** | Does not restart the computer after the process of uninstalling SP2 is complete. |
| **/?**<br>or<br>**/Help** | Displays Help. |

**Additional resources**

- For more information about Windows Server 2003 SP2, see the Microsoft TechCenter Web site (http://go.microsoft.com/fwlink/?LinkID=64780)

- For the most up-to-date information about supported hardware, see the hardware compatibility information at the Windows Server Catalog Web site (http://go.microsoft.com/fwlink/?LinkID=62603)

- To obtain the latest product updates, see the Microsoft Update Web site (http://go.microsoft.com/fwlink/?LinkID=54836)

# Release Notes for Microsoft Windows Server 2003 Service Pack 2

Applies To: Windows Server 2003 with SP2

These release notes address late-breaking issues and information about the Microsoft® Windows Server® 2003 operating systems with Service Pack 2 (SP2) and Microsoft Windows® XP Professional x64 Edition operating system with SP2. Unless otherwise specified, these notes apply to the following operating systems:

- Windows Server 2003 with SP2
- Windows Server 2003 R2 with SP2
- x64-based versions of Windows Server 2003 with SP2
- x64-based versions of Windows Server 2003 R2 with SP2
- Itanium-based versions of Windows Server 2003 with SP2
- Windows XP Professional x64 Edition with SP2

**Additional information**

- For information about issues that have been resolved in Windows Server 2003 with SP2, see article 914962 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82243).
- For information about Windows Server 2003 SP2 support tools, see article 926027 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82244).
- For information about how to obtain the latest service pack, see article 889100 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82245).
- To obtain an updated version of the System Preparation tool for Windows Server 2003 SP2, see article 892778 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82247).

**Active Directory**

If you are running the initial version of Active Directory Application Mode (ADAM) that was available as a download, you will not be able to directly update the computer to Windows Server 2003 Service Pack 2 (SP2). If you do so, the ADAM instances may stop functioning.

**Preventing the issue**

To prevent this, do one of the following before you update the computer to Windows Server 2003 SP2:

- Download and install Windows Server 2003 Active Directory Application Mode Service Pack 1 (ADAM SP1). Follow the instructions provided in Microsoft Knowledge Base article 902838 (http://go.microsoft.com/fwlink/?LinkId=82253). Then, install Windows Server 2003 SP2.
- If you have the first release of Windows Server 2003 R2, then update ADAM as follows. (Disc 1 contains SP1. If the product discs that you have do not specify which service pack is included, then the discs contain SP1.)

    1. Install both disks.
    2. Update the ADAM instances by installing ADAM using **Add/Remove Windows Components** in **Add or Remove Programs** in Control Panel.

3. Install Windows Server 2003 SP2.

**Correcting the issue**
If you have already installed Windows Server 2003 SP2 (for example, from Windows Update or by using Update.exe) without first updating ADAM, you can correct this issue with the following procedure:

### To repair ADAM

1. Uninstall Windows Server 2003 SP2.
2. Download and install ADAM SP1 by following the instructions provided in Microsoft Knowledge Base article 902838 (http://go.microsoft.com/fwlink/?LinkID=82253).
3. Reinstall Windows Server 2003 SP2.

**Updating ADAM**
If you have already installed the integrated version of Windows Server 2003 with SP2 (for example, if you installed Disc 1 of the second release of Windows Server R2, which contains SP2), and you did not update ADAM first, the ADAM instances will continue to function properly.

However, you can update ADAM by doing one of the following:

- Download and install ADAM SP1 by following the instructions provided in Microsoft Knowledge Base article 902838 (http://go.microsoft.com/fwlink/?LinkID=82253).
- Install Windows Server 2003 R2 Disc 2, and then install ADAM by using the **Add/Remove Windows Components** in Control Panel.

| **Note** |
| --- |
| For more information about the options for upgrading to the second release of Windows Server 2003 R2, see the upgrade diagram in Upgrading When You Have the SP2 Version of Windows Server 2003 R2 (http://go.microsoft.com/fwlink/?LinkId=85407). |

**Installation**
This release note applies to you if you are upgrading to SP2 from a computer running SP1 or installing a different edition of Windows Server 2003 with SP2 on a computer already running SP2.

If you are installing SP2 on a computer running SP1, to ensure that certain applications and components (such as Windows .NET Framework 2.0) function properly, install SP2 by using Microsoft Update (http://go.microsoft.com/fwlink/?LinkId=85856).

If you are installing a different edition of SP2 on a computer already running SP2 (for example, if you are installing Windows Server 2003, Enterprise Edition with SP2 on a computer running Windows Server 2003, Standard Edition with SP2), there is no workaround. If any applications or components stop functioning, you may need to reinstall them.

**Internet Explorer**
You do not need to uninstall Internet Explorer 7 prior to installing Windows Server 2003 SP2.

If you have previously installed Internet Explorer 7 on a computer running Windows Server 2003 with SP1 and are now installing Windows Server 2003 SP2 using Microsoft Update, the downloadable SP2 update from the Microsoft Download Center, or the SP2 update CD, your computer will retain Internet Explorer 7 as expected.

If you have previously installed Internet Explorer 7 on a computer running Windows Server 2003 with SP1 and are now installing the integrated version of Windows Server 2003 SP2 (that is, the full operating system integrated with the service pack), the computer will have Internet Explorer 6 as the default browser in Windows Server 2003 SP2. You will need to reinstall Internet Explorer 7.

For more information about options for installing Windows Server 2003 SP2, see http://go.microsoft.com/fwlink/?LinkId=85899.

**Microsoft Management Console**
If you start certain snap-ins for Microsoft Management Console 3.0 and then subsequently uninstall Windows Server 2003 SP2, you may not be able to start some or all of the snap-ins in Microsoft Management Console 2.0 afterwards. If

this occurs, remove all the files in the %APPDATA%\Microsoft\MMC\ folder.

**Migration**
If you use Active Directory Migration Tool (ADMT) version 2.0 to migrate Windows 2000 Professional domain accounts between computers that are running Windows Server 2003 SP1 or Windows Server 2003 SP2, you may encounter an "RPC server unavailable" error message.

To avoid this, download and use Active Directory Migration Tool version 3.0 from http://go.microsoft.com/fwlink/?LinkID=68791.

**Printing**
To avoid interrupting print services, schedule the installation of Windows Server 2003 SP2 for a time when the print spooler will not be in high demand.

For more details about interruption to printing, see article 832219 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82276).

**Scheduled tasks**
If you uninstall Windows Server 2003 SP2, scheduled tasks may subsequently fail because of the loss of administrative credentials. To verify that this issue is the cause of tasks failing, check the Task Scheduler log for error 0x8004130f.

**Preventing the issue**
To avoid this issue, ensure that you stop the Task Scheduler service before you uninstall Windows Server 2003 SP2.

A hotfix for this issue is available in article 933550 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=85408). The hotfix only applies to certain configurations and scenarios, so be sure to read the hotfix documentation carefully.

**Correcting the issue**
If your scheduled tasks have already failed as a result of this issue, you can restore them by re-entering the appropriate administrative credentials for each task using the Task Scheduler.

**Windows Small Business Server 2003**
Before you install Windows Server 2003 SP2 on a computer running Windows Small Business Server 2003 (Windows SBS), see article 939421 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=93765).

**Windows Media Player**
If you uninstall Windows Server 2003 SP2, you may not be able to access some Windows Media content that is protected by Digital Rights Management. If this occurs, you can restore access by doing the following:

| Operating system | Action |
|---|---|
| All Windows Server 2003 versions | Reinstall Service Pack 2 |
| Windows XP Professional x64 Edition | Do either of the following:<br>• Reinstall Service Pack 2<br>• Install Windows Media Player 11 |

For more detailed information about this issue, see article 932542 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=83575).

**Copyright**

# Comparison of Windows Server 2003 Editions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following table describes features supported by the Microsoft® Windows Server™ 2003 operating system, and illustrates which editions of the operating system support which features.

● = Feature included

◒ = Feature partially supported

○ = Feature not included

| Category | Feature and Description | Standard Edition | Enterprise Edition | Datacenter Edition | Web Edition |
|---|---|---|---|---|---|
| Hardware Specifications | **64-bit Support for Intel Itanium-based Computers**(1)<br>Support for 64-bit processing delivers far higher scalability than 32-bit file servers by providing a greatly enlarged virtual address space and paged pool area, the ability to handle increased numbers of users and connections, and increased hardware reliability through predictive error checking and notification of failures. | ○ | ● | ● | ○ |
| Hardware Specifications | **Hot Add Memory**(2, 3)<br>Hot Add Memory allows ranges of memory to be added to a computer and made available to the operating system and applications as part of the normal memory pool. This does not require rebooting the computer and involves no downtime. This feature only operates on servers that have hardware support for adding memory while the server is operating. Most existing servers do not have such hardware support and can be damaged if memory is installed while the power is on. It is recommended that you consult your server operator's manual for more information. | ○ | ● | ● | ○ |
| Hardware Specifications | **Non-Uniform Memory Access**(3)<br>As processor clock rates continue to increase and put pressure on processor bus architectures, scaling is addressed by implementing multiple processor buses. This can result in an architecture consisting of processors and memory arranged in smaller subsystems called nodes. Processor access time to memory in other nodes is longer than access time to memory in the same node. This results in Non-Uniform Memory Access (NUMA) across the system. The longer access times to other nodes can degrade software performance. The operating system attempts to limit degradation by scheduling threads from the same process on processors that are in the same node, and allocating all memory requests within the same node as the processor making the request. In addition, an API is included to make NUMA architecture information available to application software. These features ensure that memory accesses are local to a node wherever possible, and limit software degradation caused by the NUMA architecture. | ○ | ● | ● | ○ |

| | | | | | |
|---|---|---|---|---|---|
| Hardware Specifications | **Datacenter Program**<br><br>The Datacenter Program provides customers with an integrated hardware, software, and service offering, delivered by Microsoft and qualified server vendors such as original equipment manufacturers (OEMs). | ○ | ○ | ● | ○ |
| Hardware Specifications | **2-GB RAM Maximum**<br><br>RAM facilitates improved system scalability and performance. The more RAM added to a server beyond minimum requirements, the more memory available for applications to use. Designed for building and hosting Web applications, Web pages, and XML Web services, Windows Server 2003, Web Edition supports new systems with up to 2 GB of RAM. | ○ | ○ | ○ | ● |
| Hardware Specifications | **4-GB RAM Maximum**<br><br>RAM facilitates improved system scalability and performance. The more RAM added to a server beyond minimum requirements, the more memory available for applications to use. Designed for small organizations and departmental use, Windows Server 2003, Standard Edition supports new systems with up to 4 GB of RAM. | ● | ○ | ○ | ○ |
| Hardware Specifications | **32-GB RAM Maximum**<br><br>RAM facilitates improved system scalability and performance. The more RAM added to a server beyond minimum requirements, the more memory available for applications to use. Designed for demanding enterprise applications, Windows Server 2003, Enterprise Edition supports new systems with up to 32 GB of RAM. | ○ | ● | ○ | ○ |
| Hardware Specifications | **64-GB RAM Maximum**(4)<br><br>RAM facilitates improved system scalability and performance. The more RAM added to a server beyond minimum requirements, the more memory available for applications to use. Designed for mission-critical applications, the 32-bit version of Windows Server 2003, Datacenter Edition supports up to 64 GB of RAM on x86-based computers. The 64-bit version of Windows Server 2003, Enterprise Edition supports systems with up to 64 GB of RAM. | ○ | ◒ | ● | ○ |
| Hardware Specifications | **512-GB RAM Maximum**(5)<br><br>RAM facilitates improved system scalability and performance. The more RAM added to a server beyond minimum requirements, the more memory available for applications to use. The 64-bit version of Windows Server 2003, Datacenter Edition supports systems with up to 512 GB of RAM. | ○ | ○ | ◒ | ○ |

| | | | | | |
|---|---|---|---|---|---|
| Hardware Specifications | **2-Way Symmetric Multiprocessing**<br>The Windows Server 2003 family supports single or multiple CPUs that conform to the symmetric multiprocessing (SMP) standard. Using SMP, the operating system can run threads on any available processor, which makes it possible for applications to use multiple processors when additional processing power is required to increase the capability of a system. New features include SMP locking performance, improved registry performance, and increased Terminal Server sessions. Designed for building and hosting Web applications, Web pages, and XML Web services, Windows Server 2003, Web Edition supports new systems with up to two-way SMP. | ● | ● | ○ | ● |
| Hardware Specifications | **4-Way Symmetric Multiprocessing**<br>The Windows Server 2003 family supports single or multiple CPUs that conform to the symmetric multiprocessing (SMP) standard. Using SMP, the operating system can run threads on any available processor, which makes it possible for applications to use multiple processors when additional processing power is required to increase the capability of a system. New features include SMP locking performance, improved registry performance, and increased Terminal Server sessions. Designed for small organizations and departmental use, Windows Server 2003, Standard Edition supports new systems with up to four-way SMP. | ● | ● | ○ | ○ |
| Hardware Specifications | **8-Way Symmetric Multiprocessing**<br>The Windows Server 2003 family supports single or multiple CPUs that conform to the symmetric multiprocessing (SMP) standard. Using SMP, the operating system can run threads on any available processor, which makes it possible for applications to use multiple processors when additional processing power is required to increase the capability of a system. New features include SMP locking performance, improved registry performance, and increased Terminal Server sessions. Designed for demanding enterprise applications, Windows Server 2003, Enterprise Edition supports new systems with up to eight-way SMP. This includes the 64-bit edition of Windows Server 2003, Enterprise Edition. | ○ | ● | ● | ○ |
| Hardware Specifications | **32-Way Symmetric Multiprocessing**<br>The Windows Server 2003 family supports single or multiple CPUs that conform to the symmetric multiprocessing (SMP) standard. Using SMP, the operating system can run threads on any available processor, which makes it possible for applications to use multiple processors when additional processing power is required to increase the capability of a system. New features include SMP locking performance, improved registry performance, and increased Terminal Server sessions. Designed for mission-critical applications, Windows Server 2003, Datacenter Edition supports new systems with 8-way to 32-way SMP. This includes the 64-bit edition of Windows Server 2003, Datacenter Edition. | ○ | ○ | ● | ○ |

| | | | | | |
|---|---|---|---|---|---|
| Hardware Specifications | **64-Way Symmetric Multiprocessing**<br><br>The Windows Server 2003 family supports single or multiple CPUs that conform to the symmetric multiprocessing (SMP) standard. Using SMP, the operating system can run threads on any available processor, which makes it possible for applications to use multiple processors when additional processing power is required to increase the capability of a system. New features include SMP locking performance, improved registry performance, and increased Terminal Server sessions. Designed for mission-critical applications, Windows Server 2003, Datacenter Edition supports new systems with up to 64-way SMP. The support for over 32 processors is only available with the 64-bit edition of Windows Server 2003, Datacenter Edition.<br><br>Microsoft also offers a 128-way SKU for Windows Server 2003, Datacenter Edition so Windows can run on a 128-processor computer. However, the largest partition supported would be 64 processors. | ○ | ○ | ● | ○ |
| Directory Services | **Active Directory® Directory Service**<br><br>Active Directory is the directory service for Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. It stores information about objects on the network and makes this information easy for administrators and users to find and use. Active Directory uses a structured data store as the basis for a logical, hierarchical organization of directory information. | ● | ● | ● | ◒ |
| Directory Services | **Microsoft Identity Integration Server Support**<br><br>Microsoft Identity Integration Server (MIIS) is a centralized service that stores and integrates identity information from multiple directories in an organization. The goal of this metadirectory is to provide an organization with a unified view of all known identity information about users, applications, and network resources. A metadirectory solves important business issues that result from having information stored in multiple, disparate data repositories throughout an organization. MIIS is available via Microsoft Consulting Services (MCS) or via an MIIS partner engagement. | ○ | ● | ● | ○ |
| Security Services | **Internet Connection Firewall**<br><br>Internet Connection Firewall (ICF) provides Internet security in the form of a firewall. Designed for use in the home and small business, ICF provides protection on computers directly connected to the Internet. This feature is available for LAN or dial-up networks, virtual private networks (VPNs), and Point-to-Point Protocol over Ethernet (PPPoE) connections. It also prevents scanning of ports and resources (such as file and printer shares) from external sources. | ● | ● | ○ | ○ |

| | | | | | |
|---|---|---|---|---|---|
| Security Services | **Public Key Infrastructure, Certificate Services, and Smart Cards**<br><br>By using Certificate Services and certificate management tools, you can deploy your own public key infrastructure (PKI). With a PKI, you can implement standards-based technologies, such as smart card logon capabilities, client authentication through Secure Sockets Layer (SSL) and Transport Layer Security (TLS), secure e-mail, digital signatures, and secure connectivity using Internet Protocol security (IPSec). By using Certificate Services, you can set up and manage certification authorities (CAs) that issue and revoke X.509 v3 certificates. This means that you do not have to depend on commercial client authentication services, although you can integrate commercial client authentication into your PKI if you choose. | ◒ | ● | ● | ◒ |
| Terminal Services | **Remote Desktop for Administration**<br><br>With Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode), you can administer a computer from virtually any computer on your network. Based on Terminal Services technology, Remote Desktop for Administration is specifically designed for server management. | ● | ● | ● | ● |
| Terminal Services | **Terminal Server**<br><br>Terminal Server lets you deliver Windows-based applications — or the Windows desktop itself — to virtually any computing device, including those that cannot run Windows. For example, a user can access a virtual Windows XP Professional desktop and x86-based Windows applications from hardware that cannot run the software locally. Terminal Server provides this capability for both Windows-based and non–Windows-based client devices. When a user runs an application on Terminal Server, all of the application execution takes place on the server, and only keyboard, mouse, and display information traverses the network.<br><br>**Note**<br><br>• Terminal Server mode is not included on computers running Microsoft Windows Server 2003, Web Edition; however, Remote Desktop for Administration is available on Windows Server 2003, Web Edition. | ● | ● | ● | ○ |
| Terminal Services | **Terminal Server Session Directory**<br><br>Terminal Server Session Directory allows users to easily reconnect to a disconnected session in a load-balanced Terminal Server farm. Session Directory is compatible with the Windows Server 2003 Network Load Balancing service, and is supported by third-party external load-balancer products from manufacturers such as F5 Networks (formerly F5 Labs) and Radware.<br><br>**Note**<br><br>• The Session Directory Service runs on all editions of Windows Server 2003; however, to participate in a Session Directory, the server must be running Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition (including the 64- bit editions of the Windows Server 2003 family). | ○ | ● | ● | ○ |

| | | | | | |
|---|---|---|---|---|---|
| Clustering Technologies | **Network Load Balancing**<br><br>Previously known as Windows NT Load Balancing Service (WLBS), Network Load Balancing distributes incoming TCP/IP traffic among multiple servers. Your clustered applications, especially Web server applications, can handle more traffic, provide higher availability, and provide faster response times. | ● | ● | ● | ● |
| Clustering Technologies | **Cluster Service**<br><br>A cluster is a group of independent computers, called nodes, that work together to run a common set of applications and provide high availability. If one node on the cluster fails, the application can be failed over to the next node. Server clusters of up to eight nodes are available only in Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition. | ○ | ● | ● | ○ |
| Communications and Networking Services | **Virtual Private Network Support**<br><br>You can give users ready access to your organization's network even when they are out of the office — and reduce the cost of this access — by implementing a virtual private network (VPN). The VPN connection creates a secure tunnel across the Internet into the private network. There are two types of VPN technologies in the Windows Server 2003 family: Point-to-Point Tunneling Protocol (PPTP), which employs user-level Point-to-Point Protocol (PPP) authentication methods and Microsoft Point-to-Point Encryption (MPEE) for data encryption; and Layer Two Tunneling Protocol (L2TP) with Internet Protocol security (IPSec). L2TP employs user-level PPP authentication methods and computer-level certificates with IPSec for data encryption. On Windows Server 2003, Web Edition and Windows Server 2003, Standard Edition, you can create up to 100 PPTP ports and up to 100 L2TP ports. However, Windows Server 2003, Web Edition, can accept only one VPN connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections via the ports. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000. Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition support unlimited concurrent users. | ● | ● | ● | ◒ |
| Communications and Networking Services | **Internet Authentication Service**<br><br>Internet Authentication Service (IAS) is the Microsoft implementation of a Remote Authentication Dial-in User Service (RADIUS) server and proxy. As a RADIUS server, IAS performs centralized connection authentication, authorization, and accounting for many types of network access including wireless, authenticating switch, and remote access dial-up and virtual private network (VPN) connections. As a RADIUS proxy, IAS forwards authentication and accounting messages to other RADIUS servers. You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range. | ● | ● | ● | ○ |

| | | | | | |
|---|---|---|---|---|---|
| Communications and Networking Services | **Network Bridge**<br><br>Network Bridge provides an easy way for you to connect different LAN segments, allowing users to bridge connections between different computers and devices on their network, even when they connect to the network through different methods. Network bridge is supported in Windows Server 2003, Standard Edition and Windows Server 2003, Enterprise Edition. | ● | ● | ○ | ○ |
| Communications and Networking Services | **Internet Connection Sharing**<br><br>By using the Internet Connection Sharing (ICS) feature of Network Connections, you can connect your home network or small office network to the Internet. For example, you might have a home network that connects to the Internet through a dial-up connection. By enabling ICS on the computer that uses the dial-up connection, you can provide network address translation (NAT), addressing, and name resolution services for all the computers on your network. | ● | ● | ○ | ○ |
| Communications and Networking Services | **IPv6**<br><br>Internet Protocol version 6 (IPv6) is a suite of Internet standard protocols that will become the next generation of network layer protocols for the Internet. IPv6 is designed to solve many of the problems of the current version of IP (known as IPv4) with regard to address depletion, security, autoconfiguration, extensibility, and more. | ● | ● | ● | ● |
| File and Print Services | **Distributed File System**<br><br>Distributed File System (DFS) is enhanced for Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition by allowing multiple DFS roots on a single server. You can use this feature to host multiple DFS roots on a single server, reducing administrative and hardware costs of managing multiple namespaces and multiple replicated namespaces. Using Active Directory, DFS shares can be published as volume objects and administration can be delegated. Windows Server 2003, Standard Edition supports only one DFS root. DFS is partially supported in Windows Server 2003, Web Edition, where it is possible to access DFS files and act as a node in DFS tree, but only 10 concurrent incoming server message block (SMB) connections are permitted. | ● | ● | ● | ◒ |
| File and Print Services | **Encrypting File System**<br><br>Encrypting File System (EFS) complements other access controls and provides an additional level of protection for your data. EFS runs as an integrated system service on all disks (including clustered disks), making it easy to manage, difficult to attack, and transparent to the user. | ● | ● | ● | ● |
| File and Print Services | **Shadow Copies for Shared Folders**<br><br>Shadow Copy Restore (Previous Versions) provides point-in-time copies for network folders. Users can easily access previous versions of their files through Windows Explorer by right-clicking a file or folder. | ● | ● | ● | ● |

| | | | | | |
|---|---|---|---|---|---|
| File and Print Services | **Removable Storage**<br><br>Removable Storage makes it easy to track your removable storage media (tapes and optical discs) and to manage the hardware libraries (such as changers and jukeboxes) that contain them. Because removable optical discs and tapes are less expensive per megabyte than hard disks, Removable Storage and Remote Storage can decrease your costs. | ● | ● | ● | ● |
| File and Print Services | **Remote Storage**<br><br>Remote Storage uses criteria that you specify to automatically copy little-used files to removable media. If hard disk space drops below specified levels, Remote Storage removes the cached file content from the disk. If the file is needed later, the content is automatically recalled from storage. Remote Storage now supports migration to magneto-optical media. Remote Storage is not available in Windows Server 2003, Standard Edition or Windows Server 2003, Web Edition. | ○ | ● | ● | ○ |
| File and Print Services | **Fax Service**<br><br>Fax Service lets users send and receive faxes by using a modem or a fax board. You can also send faxes by using your network. You can print to fax from any application, send a cover page, and track and monitor fax activity. New wizards simplify configuration and fax sending. Also, developers can write applications using the new fax APIs to automatically send faxes from their applications. | ● | ● | ● | ○ |
| File and Print Services | **Services for Macintosh**<br><br>Services for Macintosh provides Macintosh users with access to files stored on a computer running Windows Server 2003. The file server is accessible over TCP/IP networks and over AppleTalk networks. Print services allow Macintosh clients to print to Windows NT or Windows 2000–based print shares via the AppleTalk protocol. In addition to the print server, there is a 300 dpi PostScript RIP engine that allows Macintosh-generated PostScript print jobs to be sent to non-PostScript printers, such as inkjet printers. | ● | ● | ● | ○ |
| Management Services | **IntelliMirror® Management Technologies**<br><br>To help reduce costs, administrators need high levels of control over portable and desktop systems. IntelliMirror management technologies provide this control on client systems running Windows 2000 Professional or Windows XP Professional. You can use IntelliMirror to define policies based on business roles, group memberships, and locations. With these policies, Windows 2000 Professional desktops and Windows XP Professional desktops are automatically reconfigured to meet a specific user's requirements each time that user logs on to the network, regardless of where the user logs on. | ● | ● | ● | ◒ |

| | | | | | |
|---|---|---|---|---|---|
| Management Services | **Group Policy Results**<br><br>Group Policy Results allows administrators to see the effect a Group Policy setting has on a targeted user or computer. Included in the Group Policy Management Console, Group Policy Results provides administrators with a powerful and flexible base-level tool to plan, monitor, and troubleshoot Group Policy.<br><br>Group Policy Results uses Windows Management Instrumentation (WMI), making the information available to administrators via the console and directly to other management applications via WMI. | ● | ● | ● | ◒ |
| Management Services | **Windows Management Instrumentation Command Line**<br><br>Windows Management Instrumentation (WMI) provides unified access to the management functions of local and remote systems. By adding command-line access to WMI, administrators can directly access these management functions and create queries based on this data. You can monitor local and remote Windows Server 2003 and Windows XP systems directly, to view results through the command line or to retrieve the management data in XML format and processed into built-in or custom XSL output formats. WMI follows the specifications of the industry-standard Common Information Model (CIM) defined by the Distributed Management Task Force (DMTF). | ● | ● | ● | ● |
| Management Services | **Remote OS Installation**<br><br>Remote OS Installation uses Group Policy, Remote Installation Services, and Pre-Boot eXecution Environment (PXE) server hardware to re-image a server with a clean install of a Windows Server 2003–based environment. This feature can also be used to re-image Windows 2000 and Windows XP desktops.<br><br>Administrators can use Remote OS Installation and IntelliMirror together to simplify the task of exchanging or bringing new computers into the network environment:<br><br>• Remote OS Installation can establish a full initial working set image directly to the computer hardware.<br><br>• IntelliMirror can restore policy-based settings for data, settings, and software use.<br><br>Used together with IntelliMirror or on its own, Remote OS Installation can increase the efficiency of computer management in your organization while simplifying the task of maintaining corporate-standard environments on Windows-based servers and desktops. | ● | ● | ● | ● |
| Management Services | **Remote Installation Services**<br><br>You can use Remote Installation Services (RIS) to create automated installation images of operating systems or of complete computer configurations. You can then make these installation images available to users at client computers. You can also specify which RIS server will provide installations to a given client computer. The client computers must support remote booting with the Pre-Boot eXecution Environment (PXE) ROM, or they must be started with a remote-startup floppy disk. | ● | ● | ● | ○ |

| | | | | | |
|---|---|---|---|---|---|
| Management Services | **Windows System Resource Manager**<br><br>Windows System Resource Manager (WSRM) provides resource management and enables the allocation of resources, including processor and memory resources, among multiple processes based on business priorities. An administrator sets targets for the amount of hardware resources that running applications or users (typically in a Terminal Server environment) are allowed to consume. It also creates utilization accounting records for management, service level agreement (SLA) tracking, and enabling charge-backs. | ○ | ● | ● | ○ |
| .NET Application Services | **.NET Framework**(2)<br><br>The .NET Framework enables your developers to create great Web applications with the help of ASP.NET and other technologies. It also helps them build the same type of applications they design and develop today. The .NET Framework is language-neutral; virtually any programming language can target it. Developers can build .NET-based applications and services in a number of languages, including Visual C++, Visual Basic .NET, JScript, and Visual C#. Integrated into the Windows Server 2003 family, the .NET Framework is the infrastructure for .NET. The .NET Framework incorporates the common language runtime and a unified set of class libraries that include Windows Forms, ADO.NET, ASP.NET, and other capabilities. The .NET Framework provides a fully managed, protected, and feature-rich application execution environment, simplified development and deployment, and seamless integration with a wide variety of programming languages. | ● | ● | ● | ● |
| .NET Application Services | **Internet Information Services 6.0**<br><br>Internet Information Services (IIS) 6.0 is a full-featured Web server that provides the foundation for the Windows Server 2003 family and existing Web-based applications and XML Web services. IIS 6.0 offers dedicated application mode, which runs all application code in an isolated environment. IIS 6.0 also supports Web gardens, in which a set of equivalent processes on a computer each receive a share of the requests normally served by a single process, achieving better multiprocessor scalability. | ● | ● | ● | ● |
| .NET Application Services | **ASP.NET**(2)<br><br>ASP.NET is the engine for Web-based applications and XML Web services. It brings rapid application development to the server. Part of the class library in the .NET Framework, ASP.NET pages use a compiled, event-driven programming model that improves performance and enables the separation of application logic and user interface. | ● | ● | ● | ● |

| | | | | | |
|---|---|---|---|---|---|
| .NET Application Services | **Enterprise UDDI Services**<br><br>Universal Description, Discovery, and Integration (UDDI) is an industry specification for publishing and locating information about Web services. Some products in the Windows Server 2003 family include UDDI Services, a Web service that provides UDDI capabilities for use within an enterprise or across organizations. UDDI Services is not included with Windows Server 2003, Web Edition. In addition, Windows Server 2003, Standard Edition, supports only stand-alone installations of UDDI Services. Distributed installation support is available with Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition. In a stand-alone installation of UDDI Services, both the UDDI Web server component and the UDDI database component are installed on a single server. In a distributed installation, UDDI components are distributed across multiple servers. | ● | ● | ● | ○ |
| Multimedia Services | **Windows Media® Services**<br><br>Windows Media Services provide streaming audio and video over corporate intranets and the Internet. In Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, Windows Media Services delivers advanced streaming functionality such as multicasting, wireless network support, Internet authentication, server plug-ins, and cache/proxy APIs. | ◒ | ● | ● | ○ |

([1]) Applies to 64-bit versions only.

([2]) Not supported in 64-bit versions of Windows Server 2003.

([3]) Might be limited by lack of support by OEM hardware.

([4]) Both the 32-bit version of Windows Server 2003, Datacenter Edition and the 64-bit version of Windows Server 2003, Enterprise Edition support up to 64 GB of RAM.

([5]) The 64-bit version of Windows Server 2003, Datacenter Edition supports up to 512 GB of RAM.

# Printer Connectivity Technical Overview

Updated: March 28, 2003

Applies To: Windows Server 2003 with SP1

Network printing connectivity has a substantial impact on the performance and scalability of Microsoft® Windows® print servers in two main areas. The first of these are the options available for connecting client workstations to a print server. The second area of impact is the printer port type used to de-spool print jobs from the server to the print device. This paper provides a technical examination of network and local printer ports types available to Windows Server 2003, and the value of Standard Port Monitor to a high performance print serving environment.

**In This White Paper**

Client-Server Connection

Printer Port Selection

Network Printer Ports

Local Printer Ports

Internet Printing Protocol (IPP)

Summary of Printer Connectivity Technical Overview

# Client-Server Connection

Updated: March 28, 2003

Applies To: Windows Server 2003 with SP1

Windows clients typically connect to a print server through a remote procedure call (RPC) or SMB service. RPC connections are the preferred connection type, as they support the enhanced Point-and-Print features. SMB connections are associated primarily with Windows 98 and earlier systems. It is also possible to connect from Microsoft Windows NT®–based clients by creating a local printer port that is redirected to the printer share on a Windows print server. HTTP offers another possible connection type from a client to a server. Windows 2000 and Windows Server 2003 implement version 1.0 of the Internet Printing Protocol (IPP) standard. This protocol allows a client to view printers and their status as well as connect to shared printers and submit jobs using the HTTP print provider.

# Printer Port Selection

Updated: March 28, 2003

Applies To: Windows Server 2003 with SP1

Windows Server 2003 provides built-in support for the following network port types:

- Standard TCP/IP port monitor
- LPR print monitor
- AppleTalk print monitor
- HTTP print provider

| **Note** |
| --- |
| The Hewlett-Packard printer port is not available in Windows Server 2003. |

Windows Server 2003 also supports the following local printer ports:

- USB 1.0 and 2.0
- Parallel (IEEE 1284)
- IrDA
- IEEE1394
- Serial port
- SCSI print

Internet printing support was added in Windows 2000 Server as well. Although there are client-side and server-side pieces involved, we'll discuss this topic based on the full scenario rather local vs. network.

Additionally, some printer manufactures choose to provide their own local or network printer port type.

# Network Printer Ports

Updated: March 28, 2003

Applies To: Windows Server 2003 with SP1

**Standard TCP/IP Port Monitor**

For network-connected print devices, the standard TCP/IP port monitor is the best choice. Standard port monitor is the successor to line printer remote (LPR), that has been widely adopted as the de facto standard in network printing for the past several years. Standard port monitor is faster, more scalable, and bidirectional. In contrast, LPR is limited in all of these areas. Although Windows NT 4 and later provided registry modifications to help extend the capabilities of LPR printing, these changes do not compare with the benefits of using standard port monitor.

Standard port monitor uses TCP/IP as the transport protocol, which makes it the preferred port monitor in Windows Server 2003. Standard port monitor also uses the Simple Network Management Protocol (SNMP) to configure and monitor the printer status.

Standard port monitor sends documents to a printer using either the RAW or LPR printing protocols. Together, these protocols support most current TCP/IP printers.

| **Note** |
| --- |
| Do not confuse these print protocols with the transport protocols such as TCP/IP or Data Link Control (DLC). |

The RAW protocol is the default for most print devices. To send a RAW-formatted job, the print server opens a TCP stream to the printer's network interface. For many devices this will be port 9100. When the TCP/IP port is created, Windows uses SNMP to query the device for its object identifier according to RFC 1759 (Printer MIB). If the device returns a value the system file, tcpmon.ini, is parsed for a match. If the printer manufacturer has provided special configuration information for the particular device, it is created with the configuration settings in place. For example, some external print server interfaces support multiple printers (for example, the Hewlett Packard JetDirect EX with three parallel port connections). The manufacture can use different ports to designate which printer a job should be submitted to (for example, 9102 for port 1, 9103 for port 2; and so on). This ability is helpful for print server interfaces that require the use of specific port names, such as PASS on some IBM network printers.

Standard port monitor can be configured to comply more closely with the LPR standard (RFC 1179). Specifically, you can use the **Configure Port** button in the **Server Properties, Ports** tab to enable byte counting. This setting can be helpful if a line printer daemon (LPD) requires an accurate byte count to be sent, which is compliant with the RFC.

By default, standard port monitor deviates from the LPR standard in two ways:

- First, standard port monitor does not conform to the RFC 1179 requirement that the source TCP port lie between port 721 and port 731. Standard port monitor uses ports from the general, unreserved pool of ports (ports 1024 and above).

- Second, the LPR standard states that print jobs must include information about the size of the job the port monitor sends. Sending a print job with job size information requires that the port monitor spool the job twice, once to determine size, and once to send the job to the spooler. Spooling the job only once improves printing performance, so standard port monitor sends the job to the spooler without determining the actual job size, and claims the job is a default size, regardless of the job's actual size.

The table below compares the standard TCP/IP port monitor to the LPR port monitor.

| **LPR (RFC 1179 Compliant)** | **Standard TCP/IP Port Monitor** |
| --- | --- |
| Limited to 721–731 source ports | Source ports from ephemeral ports (9100 default) |
| Four-minute timeout per port | No source port timeout |
| Unidirectional—single error status reporting | Uses SNMP for rich status and error reporting |
| Control file requires double spooling for accurate byte count | Single-file spooling enabled by default. (configurable through Port Properties) |

| | |
|---|---|
| Prints to destination port 515 | Prints to destination port 515 in LPR mode |

**LPR**
Although Windows Server 2003 uses the standard TCP/IP Port monitor by default for a network printer, it still supports LPR/LPD printing for interoperability with legacy systems and RFC-compliant LPR/LPD clients and devices.

An LPR utility lets an application on one computer print to a spooler on a remote computer. The receiving component is called a line printer daemon (LPD). The LPR/LPD combination was developed for UNIX computers but is widely used for many operating systems. Both utilities are included in Print Services for UNIX.

**Default Data Types**
Print Services for UNIX sets the print data type when it sends the document to the spooler. This type is derived from the control command included in a print job from an LPR client. It might be necessary to change the default data type at the client to avoid processing PCL or PostScript print jobs as TEXT format when they are actually in RAW format.

If the control command is *f* or *p*, the data type is TEXT, and the spooler edits the document file to print correctly. If the command is *l*, the data type is RAW, and no editing is done. If the command is *o*, the document is already formatted in PostScript code and is assigned the RAW data type.

Some UNIX systems usually send the f command by default, resulting in the following symptoms:

- Output includes PCL or PostScript code
- Extended characters are printed incorrectly
- Printer's default font is used
- Extra page is printed at the end

You can make a registry entry to force Windows 2000 to process the data as RAW format. For more information, see the following Knowledge Base articles:

- Q150930, “LPD Server Adds and Print Control Codes”
- Q168457, “Configuring Individual Printers to Passthrough LPR Print Jobs”
- Q243729, “Preventing Print Spooler CR or LF to CR/LF Character Translation”

LPR must include an accurate byte count in the control file, but it cannot get it from the local print provider. After LPRMON receives a document from the local print provider, it spools it a second time as a temporary file in the System32 subfolder, finds the size of that file, and sends the size to the LPD print server. The standard TCP/IP port monitor does not adhere to this RFC requirement and sends a very large byte count to the LPD to begin printing. After the job is complete, it simply closes the connection. This step reduces the spool time and disk I/O by eliminating the temporary spool file creation.

The LPR protocol does not return a detailed error status report. If there is a problem, the message is always ERROR and Windows reports ”Printer Error.” As discussed above, through the use of SNMP and the standard printer MIB (RFC 1759), the standard TCP/IP port provides much more detailed error reporting.

Almost all current printer models are compatible with the standard TCP/IP port monitor. In most cases, Print Services for UNIX (LPR/LPD) is required only for interoperability with other computer systems that require strict compliance with the LPR/LPD RFC (1179). Some LPD servers require only the accurate byte count as specified in the RFC. For these systems, simply configuring the standard TCP/IP port with the **LPR Byte Counting Enabled** option eliminates any errors. Microsoft recommends using the standard TCP/IP port whenever possible for performance and status monitoring.

**AppleTalk**
**To install Apple Talk protocol**

1. From Control Panel, select Add or Remove Programs and then select Add or Remove Windows Components
2. Select Other Network File and Print Services, and then click Details

3. Then select Optional Windows Component Print Server for Macintosh. Print Server for Macintosh

This option allows the server to receive jobs from Macintosh clients and print to devices that use the AppleTalk protocol.

When creating an AppleTalk printer port, you are prompted to capture the port. If you capture the AppleTalk print device, it accepts print jobs exclusively from this print server. This option can be helpful in providing tighter device management and control. For a higher level of interoperability or in a mixed environment with multiple servers or clients printing to the device, the port should not be captured, which enables a job-based connection.

In addition, when Printer Services for Macintosh is installed, Macintosh clients can connect to printer shares on a Windows print server. These printers can be locally connected to the server or connected through any support network port, such as standard port monitor, LPR, and so forth.

# Local Printer Ports

Updated: March 28, 2003

Applies To: Windows Server 2003 with SP1

**USB Printing**
Windows Server 2003 supports printing to Universal Serial Bus (USB) printers. USB consists of an external bus architecture for connecting USB-capable peripheral devices to a host computer, as well as a communication protocol that supports serial data transfers between a host system and USB-capable peripherals.

**Parallel Port**
Support for parallel port printing was enhanced in the release of Windows XP and Windows Server 2003. Traditionally, parallel port devices did not benefit from the introduction of Plug and Play several years ago. Windows XP and Windows Server 2003 perform periodic polling of the parallel port to provide an experience similar but not identical to Plug and Play. USB and IEEE 1394 are fully Plug-and-Play aware and should be used whenever printing performance and system performance are important. Parallel printing is slower and more CPU-intensive than these other local printing options.

**IrDA**
Infrared Data Association (IrDA) is a system of exchanging information between computers using infrared transmissions that do not require a cable connection. IrDA can occur between any two devices that support IrDA (such as computers and printers). Windows Server 2003 supports printing using IrDA.

IrDA is a point-to-point protocol based on TCP/IP and WinSock application programming interfaces (APIs). Typically, IrDA printers support Plug and Play, automatically installing the driver if it is available on the workstation. Additionally, the Add Printer Wizard may be used by selecting the IrDA port under **Available Ports**.

Connectivity Capacities:

| Technology | Variant | Speed |
|---|---|---|
| Parallel (1284) | (Centronics) | 250 Kbps |
| | ECP/EPP | 3–5 Mbps |
| IrDA | | 4 Mbps |
| FireWire (1394) | (up to 63 devices) | 400 Mbps |
| USB | 1.0 | 12 Mbps |
| | 2.0 | 480 Mbps |
| Bluetooth | | 2–3 Mbps |

**IEEE 1394**
Windows Server 2003 supports the IEEE 1394 bus, which is designed for high-bandwidth devices, such as digital camcorders, digital cameras, digital VCRs, and storage devices. IEEE 1394 is a serial protocol supporting speeds ranging from 100 to 400 megabits per second (Mbps), depending on the implementation. It provides a high-speed Plug and Play-capable bus that eliminates the need for peripheral devices to have their own power supply, and provides support for asynchronous data transfer.

You can connect up to 63 devices to one IEEE 1394 bus and interconnect up to 1,023 buses to form a very large network with more than 64,000 devices. Each device can have up to 256 terabytes of memory addressable over the bus. A built-in mechanism ensures equal access to the bus for all devices.

Because of the very high data transfer rates that IEEE 1394 can handle, it is ideal for scanning or printing large, high-resolution data.

# Internet Printing Protocol (IPP)

Updated: March 28, 2003

Applies To: Windows Server 2003 with SP1

Windows 2000 Server introduced support for the Internet Printing Protocol 1.0 specification. Windows Server 2003 continues this support for the 1.0 standard. There are two main components to IPP:

- Web-based printer management
- Internet printing

**Web-based Printer Management**

Web-based printer management is very simple to use. The only prerequisite is that IIS be installed and running on the print server. It is on by default for Windows 2000 Server versions and can be installed as an optional component on Windows 2000 Professional. Web-based printer management can be configured on Windows Server 2003 by using the IIS Lockdown Wizard and selecting the **Enable Active Server Pages** and **Enable Internet Printing** check boxes. When a printer is created and shared, it becomes available for management through the Internet browser. To access the Web-based feature, use the following URL, substituting your print server's computer name for *printserver*:

http://*printserver*/printers

Users must have adequate permissions in order to pause printers, purge print jobs, and so on. Most Windows clients in use today have built-in support for IPP or can download IPP support from the Microsoft Web site (http://www.microsoft.com). When a client has IPP support installed, they can view and connect to printers from within their Web browser. Microsoft strongly recommends the use of this technology, particularly for corporations that want to deploy a Web-based solution for finding and connecting to printers.

| **Note** |
| --- |
| Windows XP provides support for Web-based management of locally hosted printers by default. In the future, this option might be disabled by default—as is true for Windows Server 2003 — and enabled by a process similar to the IIS Lockdown Wizard used on the Windows Server 2003 family of products. |

**Internet Printing**

When a user connects to a printer through the Web-based printer management, one of two things can happen: Either Windows creates an IPP printer connection using an HTTP port, or Windows creates an RPC "true-connect" printer connection.

**HTTP Printer Connection Through Web Browser**

If the client's Internet Explorer security settings for the print server are set to medium or higher, Windows creates an IPP printer connection using an HTTP port. Because this technology requires the installation of a local printer queue (unlike a true Point-and-Print connection, which uses RPC), the client must have either **Administrator** or **Power User** status with the added **Load and unload driver** privilege on the local machine. (On Windows 2000 Server, this connection also works if the client has only Power User privilege.)

This solution is recommended only for Internet sites–specifically, untrusted sites viewed by a browser in which the security settings must be set to medium or higher. This type of printing works very well to print data in one location on a page at another location that does not share security or network infrastructure. However, HTTP printer connections are more limited than RPC true-connections (described below) in a Windows printing environment, as they do not support enhanced metafile (EMF) features.

**RPC Printer Connection Through Web Browser – Preferred Method**

If the client's Internet Explorer settings are set to medium-low or lower, when the client chooses the **connect** option in a Web browser, Windows automatically creates an RPC true-connect printer connection. True-connect, or UNC, connections have many benefits over true IPP printer connections and should be used for intranet printing (local to the company) where the security setting in Internet Explorer can be set to medium-low safely. True-connect connections are supported through the Windows remote spooler, which is where the vast majority of future Microsoft innovation will be—in the RPC printer connection rather than the IPP printer connection state.

For additional information about RPC connections, see the "Point and Print Technical Overview" at

http://www.microsoft.com/printserver.

# Summary of Printer Connectivity Technical Overview

Updated: March 28, 2003

Applies To: Windows Server 2003 with SP1

Use Standard TCP/IP Printer Ports and connect using Windows 2000 or later clients by using RPC instead of TCP/IP. (Named Pipes implementation)

Using the portconv.vbs script or Print Migrator 3.0 or later lets you easily convert existing LPR ports to standard TCP/IP ports.

Microsoft is evaluating the standard TCP/IP port support for SNMP through the standard printer MIB (management information base). In future releases, it might be possible to extend the implementation to include even more status and error reporting. Other new technologies such as Universal Plug & Play (UPnP) along with printer driver enhancements will enable a new era of device installation and management for future enterprise printing environments.

# Introduction (Using Clustering for a Highly Available Web Site: An Example)

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

High availability, high reliability and high performance are important objectives for Web sites. This white paper describes in detail how Microsoft uses Network Load Balancing to achieve these objectives for its own Microsoft.com Web site. You can use information in this document to help you achieve similar goals for your own Web site.

This white paper discusses the Network Load Balancing (NLB) clusters that support the Microsoft.com Web site. It provides detailed information about hardware, software, and Network Load Balancing configurations, and also reasons why the configurations were chosen. This white paper includes a list of best practices for using Network Load Balancing, as well as information about several operational procedures that Microsoft uses to help make its Web site highly reliable and highly available. Web site administrators can use Microsoft.coms implementation as an example for their own Network Load Balancing implementation.

| **Note** |
| --- |
| This is the first of two white papers that describe the use of clustering at Microsoft. The second white paper, which is called Using Clustering with Exchange 2003: An Example, describes how the internal IT department at Microsoft has implemented server clusters to manage their Exchange servers. This white paper is available at the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=18652). |

**Focus: Network Load Balancing Clusters**

The primary focus of this white paper is on the Network Load Balancing clusters that the Microsoft.com Web site uses. Other aspects of Microsoft.com, such as the domain structure and the Active Directory configuration, are only described to the extent that they affect the clustering implementations.

**Use This White Paper as an Example Only**

The information in this white paper about the Network Load Balancing clusters that are used by the Microsoft.com Web site is presented as an example. The actual steps and configuration for computers and devices in your own network will be different. This document shows only the configuration that specifically relates to the objectives described later in this document. This document does not cover other procedures and devices that are required in a production environment.

# Topics Discussed in This White Paper (Using Clustering for a Highly Available Web Site: An Example)

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

# Microsoft.com Objectives

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This document describes how Microsoft uses Network Load Balancing and related operational procedures to achieve the following technical and business objectives for the Microsoft.com Web site:

- **High availability**. Provide Web site content that is always available to users.
- **Efficiency**. Deliver Web content to users quickly, regardless of the number of concurrent sessions.
- **Scalability**. Allow system administrators to add additional servers as necessary in a way that is transparent to users.
- **Ease of maintenance**. Allow system administrators to maintain the Web site easily through a process that is transparent to users.

These objectives apply to the set of Network Load Balancing clusters described in this white paper. These objectives are similar to those of most Web sites. Therefore, the clustering implementations presented here should be valuable to businesses with similar goals.

# Reasons for Using Network Load Balancing

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Microsoft uses Network Load Balancing to help achieve its technical and business objectives for the Microsoft.com Web site. This section discusses specific features that Network Load Balancing offers that help Microsoft.com achieve these objectives.

This white paper discusses the set of Network Load Balancing clusters at Microsoft.com that are running IIS 6.0. This set of clusters consists of six Network Load Balancing clusters. Each of these clusters has 10 servers running IIS.

Network Load Balancing provides improved performance, the ability to add additional servers as necessary, and the ability to perform maintenance on any of the servers without any customer impact or hardware configuration changes. By using the combination of Network Load Balancing and multiple, redundant clusters, Microsoft.com can add and remove clusters with minimal customer impact.

The following is a detailed list of Network Load Balancing features:

- **Scalability**
  - Network Load Balancing can load balance requests for individual TCP/IP requests across the cluster.
  - Network Load Balancing can load balance multiple server requests, from the same client or from several clients across multiple hosts in the cluster.
- **High availability**
  - Network Load Balancing can automatically detect and recover from a failed or offline computer.
  - Network Load Balancing can automatically rebalance the network load when hosts are added or removed.
- **Manageability**
  - Network Load Balancing can specify the load-balancing behavior for a single IP port or group of ports using port management rules.
- **Ease of use**
  - Network Load Balancing is installed as a standard Windows networking driver component.
  - Network Load Balancing requires no hardware changes to enable and run.
  - Network Load Balancing allows clients to access the cluster with a single logical Internet name and virtual IP address (also known as the cluster IP address) while retaining individual names for each computer. This feature can be used for administration purposes.
  - Network Load Balancing allows server applications to run in a Network Load Balancing cluster without requiring modification.
  - Network Load Balancing can be configured to automatically add a failed host to the cluster after it is brought back online. The added host will then be able to start handling new server requests from clients.
  - Network Load Balancing allows system administrators to take computers offline for preventive maintenance without disturbing cluster operations on the other hosts.

**Reason for Using Multiple Clusters**

In addition to Network Load Balancing, Microsoft.com uses multiple clusters to make the Web site easier to maintain. For

example, if an entire virtual IP (VIP) begins to experience problems, administrators can stop routing traffic to that entire cluster altogether (a process external to Network Load Balancing). Administrators can then perform maintenance or corrective procedures on the software and equipment associated with the failed VIP while the other VIPs continue to respond to Internet client requests.

For more information about the design and architecture of the Network Load Balancing clusters and individual hosts, see Microsoft.com Cluster Overview Diagram, Set of Network Load Balancing Clusters Running IIS 6.0, and Network Load Balancing Host Diagram later in this document. For details on the hardware and software used in this cluster, as well as the configuration of the hardware and software used to take advantage of these features, see Configuration of the Network Load Balancing Clusters at Microsoft.com later in this document.

# Microsoft.com Cluster Overview Diagram

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Diagram 1 is a general overview of how three sets of clusters work together to support the Microsoft.com Web site. This white paper describes the Network Load Balancing clusters of Web servers. This set of clusters consists of six clusters. Each of these clusters is made up of 10 servers running IIS 6.0.

**Diagram 1**

# Set of Network Load Balancing Clusters Running IIS 6.0

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Diagram 2 depicts the Network Load Balancing clusters of Web servers that support the Microsoft.com Web site. This set of clusters consists of six Network Load Balancing clusters. Each cluster has 10 servers running IIS 6.0.

**Diagram 2**

Each of the six clusters has a unique virtual IP address (VIP). However, all six of these clusters are addressable by the URL www.microsoft.com. Internet traffic is initially routed to one of the six VIPs by round robin. Round robin is a simple mechanism used by DNS servers to share and distribute loads for network resources. Here, round robin is used to rotate the order of VIPs that are used in response to a query from the Internet to www.microsoft.com.

Each host within each of the six clusters has two network adapters: the cluster adapter, which connects to the Internet and is bound to one of the VIPs, and the management adapter, which connects to the Microsoft corporate network by a perimeter network. All 10 of the hosts in each individual cluster have the same VIP that is bound to the hosts cluster adapter (shown by the red line). In contrast, the blue line represents the set of 10 unique IP addresses (one for each host in the cluster) that are bound to its management adapter. For more information about the two network adapters, see Diagram 3.

For more information about the design considerations and configuration details of these Network Load Balancing Clusters, see Reasons for Using Network Load Balancing, earlier in this document, and Configuration of the Network Load Balancing Clusters at Microsoft.com later in this document.

# Network Load Balancing Host Diagram

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Diagram 3 depicts the network-adapter configuration for each Network Load Balancing host. These hosts make up the Network Load Balancing clusters of Web servers for the Microsoft.com Web site.

**Diagram 3**

This set of clusters consists of six individual Network Load Balancing clusters. Each cluster has 10 hosts. Each host in the cluster has two network adapters. The cluster adapter, or front-end adapter (labeled FE by the administrators at Microsoft.com), is attached to the Internet. The management adapter, or back-end adapter (labeled BE by the administrators at Microsoft.com), is attached to the Microsoft corporate network.

The FE adapter is bound to both the virtual IP address (VIP) and a unique dedicated IP address (DIP). All Internet traffic comes through the FE adapter by using the VIP. The DIP on this adapter is typically used only by ClusterSentinel, which is the cluster management and monitoring tool used by Microsoft.com. Other traffic that is intended specifically for a particular host is addressed to the BE adapter.

The BE adapter on each host has a unique static IP address and is used for cluster and host management traffic, which typically originates from the Microsoft corporate network.

For more information about the design consideration and configuration details of Network Load Balancing Cluster 1, see Reasons for Using Network Load Balancing, earlier in this document, and Configuration of the Network Load Balancing Clusters at Microsoft.com later in this document.

# Configuration of the Network Load Balancing Clusters at Microsoft.com

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section describes the details of the hardware, software, and Network Load Balancing configurations of the clusters of Web servers that support the Microsoft.com Web site. Because the purpose of this document is to focus on the details of the clustering implementations, only limited information is provided regarding general network hardware configuration and other configuration settings that are not specifically related to Network Load Balancing. However, each Network Load Balancing setting is discussed in depth.

- For information about hardware configuration, see Hardware Configuration for Network Load Balancing Hosts.
- For information about the software configuration, see Software Configuration for Network Load Balancing Hosts.
- For information about the Network Load Balancing configuration, see Network Load Balancing Configuration.

**Hardware Configuration for Network Load Balancing Hosts**

Each host in the Network Load Balancing clusters at Microsoft.com has the same hardware. The servers are Compaq ProLiant ML570s (7U) with the following standard hardware:

| | |
|---|---|
| **Processors** | 4 x Pentium III XEON 700 Mhz; 1-MB cache processors |
| **Memory** | 2 GB, 100 Mhz SDRAM |
| **Controller** | Smart array controller 5302/64: PCI; 64-bit/66 MHz; 2-channel; U160; 64-MB cache |
| **Hard disk drives** | 10 x 18.2 GB hot-plug; 15K RPM drives<br>2 x 36.4 GB hot-plug; 15K RPM drives |
| **Network adapters** | 2 x NC3134 Fast Ethernet network adapters; 32/64-bit PCI; 33/66 MHz; dual-base 10/100 |
| **Power supply** | Hot-plug redundant power supply |

**Explanation**

This hardware provides the necessary processor capacity for unexpected spikes in Web-site traffic at Microsoft.com. At the time of this writing, these are currently some of the fastest four-processor computers available. With 2 gigabytes (GB) of memory, the computers can handle several IIS 6.0 processes at once, in addition to providing plentiful caching capacity.

**Storage Configuration for Each Host**

Each host has the following storage configuration:

- 120-GB content capacity
- 34-GB logging capacity
- Virtual disk 1: RAID-1 mirrored system volume that contains the operating system and applications
- Virtual disk 2: RAID-1 mirrored logging volume that contains IIS log files
- Virtual disk 3: RAID-5 striped content volume that contains all Web content

**Storage configuration for each host**

**Diagram 4**

Diagram 4 shows the storage configuration for each host. Each host has 12 physical disks, which are configured into three virtual disks. Virtual disks 1 and 2 are RAID-1 configurations and the third is a RAID-5 configuration. Virtual disk 3 (RAID-5) is distributed across a two-channel RAID controller.

**Explanation**

Microsoft.com implemented this storage configuration for each host to achieve high capacity and redundancy. Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, support RAID-0, RAID-1, and RAID-5 configurations. The purpose of RAID-1 and RAID-5 configurations is to guard against the loss of data in the event of a catastrophic hard-disk failure. Microsoft.com used RAID-1 and RAID-5 configurations to provide the required fault tolerance at a minimum cost.

The virtual disks and hard disks were split across two channels because of the limitations of hard disk space. Although each RAID channel can only accommodate six hard disks, each server has space for 12. Therefore, these are split between two channels.

This design is a compromise between minimizing cost and optimizing performance. With only two channels and a single controller to use, Microsoft.com chose to put the Web content on a single channel and therefore, had to put the operating system and the IIS logs together on the other channel. The ideal high-availability solution, which includes storing the mirrored volumes on separate channels, requires additional hardware costs.

**Software Configuration for Network Load Balancing Hosts**

Each host in the Network Load Balancing clusters at Microsoft.com has the following software:

- Windows Server 2003, Enterprise Edition
- IIS 6.0
- Microsoft Operations Manager (MOM)

**Network Adapters**

Each server has two network adapters installed. The cluster adapter is labeled FE (by Microsoft.com administrators) for front-end. The management adapter is labeled BE for back-end.

The network adapters have the following:

| | **"FE" network adapter** | **"BE" network adapter** |
|---|---|---|
| **Protocols** | Internet protocol (TCP/IP)<br><br>Network monitor driver | Internet protocol (TCP/IP)<br><br>Network monitor driver |
| **Clients** | Network Load Balancing | Client for Microsoft networks<br><br>File and printer sharing for Microsoft networks |
| **IP address** | Static virtual IP address (VIP)<br><br>Static dedicated IP address (DIP) | Static IP address |

**Explanation**

The adapters are labeled for easy identification. The FE adapter is the cluster adapter, which is used for Internet traffic, while the

BE adapter is the management adapter, which is used for content replication and administration. As a best practice, you should use two network adapters in all Network Load Balancing implementations. In this case, the two network adapters provide additional security by physically separating the Internet traffic from the perimeter network (also known as the screened subnet) traffic. Also, they address the restriction that a Network Load Balancing cluster that is operating in unicast mode cannot distinguish among single adapters on individual hosts. Therefore, to make communication among cluster hosts possible, each cluster host must have at least two network adapters.

**TCP/IP Configuration**

- Each network adapter is given a static IP address and a static DNS server address. The static IP address on the FE adapter is known as the dedicated IP address (DIP).
- In addition to the DIP, the FE adapter also has the virtual IP address (also known as the cluster IP address, or VIP), which is used by all Internet clients connecting to Microsoft.com.
- NetBIOS is disabled on the FE adapter through the advanced TCP/IP **Properties** dialog box.

**Explanation**
Each adapter that is bound to Network Load Balancing (in this case the FE adapter on each host) has a dedicated IP address (DIP) in addition to the virtual IP address (see Diagram 5). The dedicated IP address must be a static IP address that is unique for each host. The DIP cannot be a DHCP address. The DIP is only used to allow remote connections to a specific host through the Network Load Balancing Adapter. Traffic addressed to the DIP is never load balanced.

Be aware that you should always enter the dedicated IP address first in TCP/IP properties, before the virtual IP address.

**Diagram 5**

Network Load Balancing references the dedicated IP address (DIP) only when a single network adapter is used to handle both client-to-cluster traffic and other network traffic that must go specifically to the dedicated IP address; for example, Telnet access to a specific host within the cluster. At Microsoft.com, the DIP is primarily used by ClusterSentinel. All other administrative communication, such as content replication, occurs through the BE adapter.

Communication over the direct hosting port, as well as other ports that are considered unnecessary, is restricted by router access control lists (ACLs). The NetBIOS is disabled on the FE adapter in order to provide a secondary layer of protection to protect against malicious activity behind the ACLs. However, even with the NetBIOS disabled, direct hosting of Server Message Block (SMB) traffic is still active. For more information about direct hosting, see article 204279, Direct Hosting of SMB Over TCP/IP, in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=4441).

**Network Load Balancing Configuration**
This section describes the parameters that are configured for the Network Load Balancing clusters as a whole, the parameters that are specific to each host in the Network Load Balancing cluster, and the port rules that control how the cluster functions.

**Cluster Parameters**
These parameters appear on the **Cluster Parameters** tab that is available when you configure or view Network Load Balancing properties. These parameters must be set identically on each host of the cluster. The easiest way to achieve this is to use Network Load Balancing Manager when implementing and configuring the hosts.

| Configuration setting | Explanation |
|---|---|

| | |
|---|---|
| Network Load Balancing is enabled on the network adapter labeled FE. | Network Load balancing is only enabled on the FE adapter because the BE adapter is used exclusively for administrative network traffic and communication among the hosts. The BE adapters also handle content replication across the hosts. The BE adapter does not handle any cluster traffic from clients. |
| **IP address** is set to the IP address of the cluster (the VIP). In this document, these addresses are 0.0.0.x.* See Set of Network Load Balancing Clusters Running IIS 6.0 (Diagram 2) and the Network Load Balancing Host Diagram (Diagram 3), earlier in this document, for more information.<br><br>**Subnet mask** is set to the subnet mask of the cluster's IP address.<br><br>* These are not the actual Microsoft.com VIPs. | Note that each cluster has only one virtual IP address. Microsoft.com has not used the Virtual Cluster feature of Windows Server 2003, Enterprise Edition, which allows you to enable multiple virtual IP addresses for each cluster. |
| **Unicast** is selected. | Unicast mode is typically the preferred cluster operation mode. While multicast mode can sometimes be used as an alternative and does offer certain advantages, it is not supported by all routers and often presents additional complexity. Unicast mode with multiple adapters is a model that is suitable for a cluster such as the one described in this document, in which ordinary network communication among cluster hosts is necessary or desirable and a second management adapter is available for that communication. |
| **Remote control** is enabled. | Remote control is enabled to allow the administrators to use ClusterSentinel for controlling the cluster. |

**Note**

Although used at Microsoft.com, the remote control option is generally discouraged because it presents significant security exposures including the possibility of data tampering, denial of service and information disclosure. We strongly recommend that sites use other remote management tools such as Network Load Balancing Manager or Windows Management Instrumentation (WMI) instead of remote control. If you choose to enable remote control, it is vital that you restrict access by specifying a strong remote control password. In addition to the password, it is also imperative that you use a firewall to protect the Network Load Balancing UDP control ports (the ports receiving remote control commands) to shield them from outside intrusion (see Diagram 6). By default, these are ports 1717 and 2504 at the virtual IP address. Microsoft.com has implemented these safeguards.

**Diagram 6:**

**Host Parameters**

These parameters appear on the **Host Parameters** tab that is available when you configure Network Load Balancing. Some of these parameters are unique for each host, but in most cases are identical across all of the hosts in the cluster.

| Configuration setting | Explanation |
|---|---|

| | |
|---|---|
| **Priority (Unique Host ID)** is set to the host ID that the particular server represents in the cluster. | The **Priority (Unique Host ID)** determines which host handles certain cluster traffic. The host with the lowest numerical priority among the current members of the cluster handles all of the cluster's network traffic that is not covered by a port rule. Each host must have a different **Priority** value. If Network Load Balancing Manager is used to configure the hosts, Network Load Balancing Manager will ensure that each host has a unique priority. |
| **Initial host state** is set to stopped and the **Remain suspended** check box is not selected. | **Initial host state** is set to **stopped** to allow the Microsoft.com administrators to perform a variety of tests on the host once it is restarted after a shutdown, but prior to allowing it to rejoin the cluster. This allows the administrators to ensure that the host is operating properly before it is included in the Network Load Balancing rotation. |
| **Dedicated IP address** and **Subnet mask** are set to the IP address and subnet mask of the FE network adapter. | Once again, it is important to distinguish between the dedicated IP address (the DIP), which is configured on this tab, and the virtual IP address (VIP), which is the cluster's IP address and is configured on the **Cluster Parameters** tab. If you use Network Load Balancing Manager to configure your cluster, the dedicated IP address parameter will already contain the correct address. The addresses configured on this tab (and the **Cluster Parameters** tab) are assigned to the FE network adapter. |

**Port Rules**

Port rules are set up to control how each port handles network traffic addressed to the cluster. The number and type of rules must be exactly the same for each host in the cluster. We recommend that you use Network Load Balancing Manager to configure port rules. If you are using Network Load Balancing Manager, when you add additional hosts, they will automatically inherit the cluster port rules from the initial host. If you are not using Network Load Balancing Manager and a host attempts to join the cluster with a different number of rules, or with different rules from the other hosts, it is not accepted as part of the cluster. The rest of the cluster then continues to handle the traffic as before. At the same time, a message is entered into the Windows event log.

Be aware that all network traffic that is addressed to the cluster and is not governed by port rules is handled by the host with the highest host priority among the current members of the cluster. This single host handles all of the cluster network traffic not governed by a port rule, with another host taking over the traffic only in the event that the highest priority host fails or goes offline. This default behavior ensures that Network Load Balancing does not affect cluster network traffic for ports that you do not specifically manage with the Network Load Balancing load-balancing mechanisms. It also provides high availability for handling your cluster network traffic.

**Port Rules Configured at Microsoft.com**

Microsoft.com has only two port rules configured:

- Port range: 80 to 80
    - Virtual IPs: all
    - Protocols: TCP
    - Filtering mode: multiple hosts
    - Affinity: none
    - Load weight: equal
- Port range: 443 to 443
    - Virtual IPs: all
    - Protocols: TCP
    - Filtering mode: multiple hosts
    - Affinity: none

- Load weight: equal

**Explanation**

The **port range** that is specified in each of the rules includes only ports that are handled by the cluster's virtual IP address (VIP). Therefore, they are the only ports handling traffic managed by Network Load Balancing. Be aware, however, that this does not prevent network traffic from being sent to and from each host's dedicated IP address (DIP) or other ports on the VIP. Microsoft.com has used router access control lists (ACLs) to manage this kind of traffic. You can also disable the remaining ports by creating port rules that include all remaining ports, and then using the **Disable** setting in the **Port Rules Configuration** dialog box. While this configuration provides additional protection for the host, do not use port rules as a substitute for a firewall.

Microsoft.com does not make use of virtual clusters in this document, thus the port rules are configured as global port rules by choosing **All** for the virtual IP address.

TCP is the only type of traffic that this cluster handles.

Setting the **filtering mode** to **multiple hosts** allows all of the hosts in the cluster to handle network traffic for the associated port rule. This filtering mode provides scaled performance and fault tolerance by distributing the network load among multiple hosts. You can specify whether the load is equally distributed among the hosts or that each host handle a specified load weight. Microsoft.com has specified **equal load weight** for each host.

**Affinity** is set to **None**, which specifies that multiple connections from the same client IP address can be handled by different cluster hosts (that is, there is no client affinity).

| **Note** |
| --- |
| Although not used by Microsoft.com, Class C or single affinity is typically recommended for Secure Sockets Layer (SSL) transmissions on port 443 to make the most efficient use of server resources. SSL connections are associated with a particular session ID, which (within a specified time constraint) can be reused when communicating with a particular host. If the client computer presents the session ID to a different host, the session will be rejected and a new session will be negotiated. (This process is transparent to the user). The negotiation requires additional host resources and increases the server overhead. Therefore, if you use Class C or single affinity, you can minimize how often the session must be renegotiated. |

This concludes the configuration section of this document. As described earlier, information provided here is meant to cover only those settings directly related to the Network Load Balancing implementation at Microsoft.com. Other software and hardware details that are necessary for a production Web site have not been described.

# Cluster Monitoring

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section discusses the tools that the administrators at the Microsoft.com Web site use to monitor the condition and configuration of their clusters and cluster hosts. Microsoft Operations Manager (MOM) is installed on each server running IIS and is used to monitor event logs and run scripts remotely. In addition to MOM, Microsoft.com uses a variety of other tools for monitoring and reporting including ClusterSentinel, HTTP Monitoring Tool, Data Center Warehouse, and RMS. Microsoft developed these four monitoring tools for use within the company. However, other commercially available products, such as Microsoft Application Center, provide similar functionality.

**ClusterSentinel**
ClusterSentinel is a tool used to monitor and control the Network Load Balancing cluster hosts. Microsoft.com administrators use ClusterSentinel to:

- Determine and report the state of the Network Load Balancing cluster hosts, such as converged or suspended.
- Manually control cluster hosts by using Network Load Balancing commands, such as **Stop**, **Start**, **Drain** and **Drainstop**.
- Monitor and report on application health. If an application is determined to be having problems on a particular host, that host will automatically be removed from the cluster.

ClusterSentinel traffic is handled by the dedicated IP address on the FE network adapter on the cluster hosts. For more information about the network adapters configured in this cluster, see Network Load Balancing Host Diagram earlier in this document.

Network Load Balancing Manager, a new feature in the Windows Server 2003 family of products, can be used for the first two of the tasks performed by ClusterSentinel. Network Load Balancing Manager does not, however, have the ability to monitor application condition.

**HTTP Monitoring Tool**
HTTP Monitoring Tool (HTTPMon) is a Resource Kit utility that is included in Microsoft Windows NT 4.0 and in the *Microsoft Windows 2000 Resource Kit*. HTTPMon is a multithreaded tool that monitors HTTP activity on your servers and can notify you if there are changes in the amount of activity. You can also configure it to automatically remove a host from a Network Load Balancing cluster depending on the availability of specific applications, such as IIS, or the availability of a particular Web site.

HTTPMon runs through a series of remote application level tests and collects information from each server every 30 seconds, looking for failures in the application layer, which are more common than system failures, but much harder to detect. Application-layer problems can range from IIS being overloaded by requests, to an application not responding and requiring a server reboot. HTTPMon looks for errors consistent with RFC 1945. For example, a status code of 200 indicates successful performance, while a status code of 500 indicates a server error. The results of the tests are stored in a SQL database.

If HTTPMon determines that a server is having problems at the application layer (for example, with IIS), HTTPMon directs Network Load Balancing to remove the host from the cluster. One minute later, HTTPMon checks again to see if the server has recovered. If it has, the server is returned to service. If the server still does not respond, a technician is alerted to attend to the computer, determine the nature of the problem so it can be corrected, and bring it back online.

**Data Center Warehouse**
The Data Center Warehouse (DCW) is a tool that compiles all of the information from ClusterSentinel, HTTPMon and a variety of performance monitors, such as ASP requests per second, and presents the data on a single Web page. It displays a global view of each server and cluster. Administrators can then review the information collected in its entirety or they can limit their view to only certain error conditions, such as servers with failing applications or well-functioning servers that are not active in the cluster.

| Host05 | 0 | 0 | 0 | 0 | 275 | 0 | 1 | 0 | 0 | N/A | N/A | 12 | 12 | Bad | 0 | Suspended |
| Host06 | 74 | 0 | 0 | 0 | 3222 | 0 | 6 | 49 | 2044 | N/A | N/A | 12 | 12 | Good | 200 | Converged |
| Host07 | 84 | 0 | 0 | 0 | 3183 | 0 | 6 | 48 | 1997 | N/A | N/A | 20 | 20 | Good | 200 | Converged |

**Figure 1:**

Figure 1 shows the type of information available in DCW.

**RMS**

RMS is another application used to monitor software configuration. RMS compares the configuration of the cluster and each cluster host to a predefined, standard configuration. The standard configuration includes information such as registry settings, program versions, IIS metadata, operating systems versions, and service packs that are installed. If differences are found between the actual cluster or host and the predefined configuration, Microsoft Operations Manager (MOM) is used to push that information to a SQL database.

By retaining and monitoring the data collected by all of these tools, Microsoft.com can quickly address current problems and also use the historical availability reports to monitor and track trends that might indicate future problems.

# Network Load Balancing Best Practices (Using Clustering for a Highly Available Web Site: An Example)

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Microsoft.com Web site implements many of the following best practices, as illustrated throughout this document. Additional best practices have also been included. Web site administrators should review these practices to ensure that they are using Network Load Balancing most effectively.

**Properly Secure the Network Load Balancing Hosts and the Load-Balanced Applications.**

- Network Load Balancing does not provide additional security for the load-balanced hosts and cannot be used as a firewall. Therefore, it is important to properly secure the load-balanced applications and hosts. To find out about security procedures for your applications, see the documentation for each particular application. For example, if you are using Network Load Balancing to load balance a cluster of servers running Internet Information Services (IIS), follow the procedures and guidelines for securing IIS. To view the IIS product documentation, install IIS, open the IIS User Interface (the IIS snap-in), and then click **Help**.

- To avoid interference from unauthorized heartbeat packets, you must physically protect the Network Load Balancing subnet from intrusion by unauthorized computers and devices.

- If you use the optional host list with Network Load Balancing Manager, ensure that only users in the local Administrators group have access to the host list file.

**Use Two or More Network Adapters in Each Cluster Host Whenever Possible. Two Network Adapters, However, are not Required.**

- If the cluster is operating in unicast mode (the default), Network Load Balancing cannot distinguish among single adapters on individual hosts. Therefore, to make communication among cluster hosts possible, each cluster host must have at least two network adapters.

- Although you are able to configure Network Load Balancing on more than one network adapter, make sure that you install Network Load Balancing on only one adapter (called the cluster adapter) if you use a second network adapter to address this best practice.

**Use Only the TCP/IP Network Protocol on the Cluster Adapter.**

- Do not add any other protocols (for example, IPX) to this adapter.

**Use Network Load Balancing Manager to Configure Options.**

- You can configure many Network Load Balancing options using either Network Load Balancing Manager or the **Network Load Balancing Properties** dialog box that you can access through **Network Connections**. However, Network Load Balancing Manager is the preferred method. We recommend that you do not use both Network Load Balancing Manager and **Network Connections** together to change Network Load Balancing properties. Also, you should not use two instances of Network Load Balancing Manager to configure the same cluster.

**Do not Enable Network Load Balancing Remote Control.**

- The Network Load Balancing remote control option presents many security risks, including the possibility of data tampering, denial of service and information disclosure. We strongly recommend that you do not enable remote control. Instead, use Network Load Balancing Manager or other remote management tools such as Windows Management Instrumentation (WMI).

  If you choose to enable remote control, it is vital that you restrict access by specifying a strong remote control password.

It is also imperative that you use a firewall to protect the Network Load Balancing UDP control ports (the ports that receive remote control commands) to shield them from outside intrusion (see Diagram 7). By default, these are ports 1717 and 2504 at the virtual IP address. Use remote control only from a secure, trusted computer within your firewall.

**Diagram 7**

**Enable Network Load Balancing Manager Logging.**

- You can configure Network Load Balancing Manager to log each Network Load Balancing Manager event. This log can be very useful for troubleshooting problems or errors when using Network Load Balancing Manager. Enable Network Load Balancing Manager logging by clicking **Log Settings** in the Network Load Balancing Manager **Options** menu. Select the **Enable logging** check box and specify a name and location for the log file.

  The Network Load Balancing Manager log file contains potentially sensitive information about the Network Load Balancing cluster and hosts, so it must be properly secured. By default, the log file inherits the security settings of the directory in which it is created, so you might have to change the explicit permissions on the file to restrict read and write access to those individuals who do not need full control of the file. Be aware that the individual using Network Load Balancing Manager does require full control of the log file.

**Verify that the Configuration Options for Cluster Parameters, Port Rules and Host Parameters are Set as Follows:**

- Make sure that all hosts in a cluster have identical cluster parameters and port rules for each unique virtual IP address.

  Each unique virtual IP address must be configured with the same port rules for every host that services that virtual IP address. However, if you have multiple virtual IP addresses configured on a host, each of those virtual IP addresses can have a different set of port rules.

- Verify that port rules are set for all ports that are used by the load-balanced application. For example, FTP uses port 20, port 21, and ports 102465535.

- Verify that the dedicated IP address is unique for each host and that the virtual IP address is added to each cluster host.

- If fragmentation of the network traffic is a possibility and you are using **UDP** or **Both** (UDP and TCP/IP) for your protocol setting, verify that the affinity setting is set to **Single** or **Class C**.

**Verify that any Load-Balanced Application is Started on all Cluster Hosts on which the Application is Installed.**

- Network Load Balancing does not start or stop applications.

**Verify that the Configuration Options for Dedicated IP Address and Virtual IP Address are Set as Follows:**

- Make sure that the virtual IP address (VIP) and, optionally the DIP, are entered during Setup in the **Network Load Balancing Properties** dialog box and also in the **Internet Protocol (TCP/IP) Properties** dialog box. Make sure that the addresses are the same in both places. This is most easily achieved by using Network Load Balancing Manager to create and manage your cluster.

  If you omit this step, the cluster will converge and appear to be working properly, but the cluster host will not accept and handle cluster traffic.

For more information about convergence, you can view Help and Support Center topics on the Web in the Product Documentation for Windows Server 2003 section of the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=4299). You can also open Help and Support Center on a computer running a product in the Windows Server 2003 family by clicking **Start**, and then clicking **Help and Support**. Look for the topics on Network Load Balancing, which can be found by navigating to Availability and Scalability\Windows Clustering\Network Load Balancing or searching Help.

- Verify that the DIP (if present) is always listed first (before the virtual IP address) in the **Internet Protocol (TCP/IP) Properties** dialog box. This ensures that responses to connections that originate from a host will return to the same host.

- Verify that both the dedicated IP address and the virtual IP address are static IP addresses. They cannot be DHCP addresses.

**Ensure that All Hosts in a Cluster Belong to the Same Subnet and that the Clusters Clients are Able to Access this Subnet.**

**Perform Moves of a Cluster Host According to the Following Guidelines:**

- If you move a cluster host from one cluster to another on the same subnet by changing the virtual IP address, first remove Network Load Balancing and remove the virtual IP address from TCP/IP. Then, re-enable Network Load Balancing after changing the IP address. This will prevent you from experiencing an IP address conflict.

**Verify that all Cluster Hosts are Operating in Either Unicast or Multicast Mode, but not Both.**

- All network adapters within a cluster must be configured identically with regards to unicast or multicast.

**Do not Enable Network Load Balancing on a Computer that is Part of a Server Cluster.**

- Network Load Balancing can interfere with network adapters used by server clusters. Microsoft does not support the same computer being a host in a Network Load Balancing cluster and also being a node within a server cluster.

**Avoid Uninstalling Network Load Balancing.**

- There is typically no need to uninstall this feature. Network Load Balancing is an integral part of the products in the Windows Server 2003 family and does not need to be installed or uninstalled separately.

# Summary (Using Clustering for a Highly Available Web Site: An Example)

Updated: September 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Microsoft.com Web sites use of Network Load Balancing is a typical implementation of this clustering technology, so it serves as a useful example. Web site administrators can use the details of Microsoft.coms host, cluster and port rule configuration as an example for their own Network Load Balancing implementation. Web site administrators should also review the Best Practices section closely to ensure that they are using Network Load Balancing most effectively.

# Step-by-Step Guide for Setting Up IPv6 in a Test Lab

Updated: July 27, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides detailed information about how you can use five computers to create a test lab with which to configure and test IPv6 with the Microsoft® Windows® XP Professional with Service Pack 2 (SP2) operating system and the 32-bit versions of the Windows Server™ 2003 with Service Pack 1 (SP1) operating system. These step-by-step instructions take you through the configuration required for setting up IPv6 in the test lab.

| **Note** |
| --- |
| The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the desired functionality. This configuration is neither designed to reflect best practices nor is it designed to reflect a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed only to work on a separate test lab network. |

**Setting up the IPv6 infrastructure**

The infrastructure for the IPv6 test lab network consists of five computers performing the following services:

- A computer running Windows Server 2003 with SP1, Standard Edition, that is used as a Domain Name System (DNS) server. This computer is named DNS1.
- A computer running Windows XP Professional with SP2 that is used as a client. This computer is named CLIENT1.
- A computer running Windows Server 2003 with SP1, Standard Edition, that is used as a router. This computer is named ROUTER1.
- A computer running Windows Server 2003 with SP1, Standard Edition, that is used as a router. This computer is named ROUTER2.
- A computer running Windows XP Professional with SP2 that is used as a client. This computer is named CLIENT2.

The following figure shows the configuration of the IPv6 test lab.

In the preceding figure, there are three network segments:

- Subnet 1 uses the private IP subnet prefix of 10.0.1.0/24 and global subnet prefix of 2001:DB8:0:1::/64.
- Subnet 2 uses the private IP subnet prefix of 10.0.2.0/24 and global subnet prefix of 2001:DB8:0:2::/64.
- Subnet 3 uses the private IP subnet prefix of 10.0.3.0/24 and global subnet prefix of 2001:DB8:0:3::/64.

All computers on each subnet are connected to a separate common hub or Layer 2 switch. The two router computers, ROUTER1 and ROUTER2, have two network adapters installed.

For the IPv4 configuration, each computer is manually configured with the appropriate IP address, subnet mask, default gateway, and DNS server IP address. For the IPv6 configuration, link-local addresses are used initially. Dynamic Host Configuration Protocol (DHCP) and Windows Internet Name Service (WINS) servers are not used.

The configuration of the lab routing infrastructure goes through three phases.

1. IPv4 routing. This phase demonstrates IPv4 connectivity and the automatic configuration of IPv6 local-link addresses - similar to Automatic Private IP Addressing (APIPA).

2. IPv6 routing. This phase demonstrates all test lab nodes can be reached by using IPv6 traffic.

3. ISATAP routing. ISATAP is an address assignment and automatic tunneling technology that is used to provide unicast IPv6 connectivity between IPv6/IPv4 hosts over an IPv4 intranet. This phase removes IPv6 connectivity for Subnet 2 and Subnet 3 and restores it using ISATAP.

The following sections describe how to configure each of the computers in the test lab with the basic IPv6 infrastructure. To create this test lab, configure the computers in the order presented.

**Consider using Virtual PC or Virtual Server**
Microsoft Virtual PC or Virtual Server allow you to create the computer lab used in this document using only one physical computer. After the virtual lab is configured, you can switch between the five virtual computers needed for this lab with the click of a button. For more information, see the following resources:

- Virtual PC 2004 Product Information (http://go.microsoft.com/fwlink/?LinkId=69217)

- Virtual Server Product Information (http://go.microsoft.com/fwlink/?LinkId=69220)

- Do More With Less: Exploring Virtual Server 2005 (http://go.microsoft.com/fwlink/?LinkId=69221)

- TechNet Webcast: Virtual Server 2005 - Setting Up a Virtual Test and Development Environment—Level 200 (http://go.microsoft.com/fwlink/?LinkId=69222)

**DNS1**
DNS1 is a computer running Windows Server 2003 with SP1, Standard Edition. It is providing DNS Server services for the testlab.microsoft.com DNS domain. To configure DNS1 for this service, perform the following steps.

**Configure DNS1 to provide DNS Services**

1. Install Windows Server 2003 with SP1, Standard Edition, as a standalone server. Set the Administrator password.

2. After restarting, log on as Administrator.

3. Configure the TCP/IP protocol with the IP address of 10.0.1.2, the subnet mask of 255.255.255.0, and the default gateway of 10.0.1.1.

**Install the DNS Server service**

1. Open Windows Components Wizard. To open the Windows Components Wizard, click **Start**, click Control Panel, double-click **Add or Remove Programs**, and then click **Add/Remove Windows Components**.

2. In **Components**, select the **Networking Services** check box, and then click **Details**.

3. In **Subcomponents of Networking Services**, select the **Domain Name System (DNS)** check box, click **OK**, and then click **Next**.

4. If prompted, in **Copy files from**, type the full path to the distribution files, and then click **OK**.

Define a forward lookup zone named testlab.microsoft.com that allows dynamic updates.

**Define a forward lookup zone**

1. Open DNS. To open DNS, click **Start**, select **Administrative Tools**, and then click **DNS**.

2. In the console tree, click and then right-click the DNS server **DNS1**, and then click **New Zone** to run the New Zone Wizard.

3. On the **Welcome to the New Zone Wizard** page, click **Next**.

4. On the **Zone Type** page, the option to create a primary zone is selected by default. Click **Next**.

5. On the **Forward or Reverse Lookup Zone** page, the option to create a forward lookup zone is selected by default. Click **Next**.

6. On the **Zone Name** page, type **testlab.microsoft.com** in **Zone name**. Click **Next**.

| **Note** |
| --- |
| The domain name testlab.microsoft.com is used here for example purposes only. You can use any domain name in your test lab configuration. |

7. On the **Zone File** page, the new zone file name, **testlab.microsoft.com.dns**, is automatically derived from the zone name entered on the previous page, as shown in the following figure. Click **Next**.

8. On the **Dynamic Update** page, select **Allow both nonsecure and secure dynamic updates**. Click **Next**.

9. Click **Next**. On the **Completing the New Zone Wizard** page, click **Finish**.

### Install IPv6

- On DNS1, at the command prompt, type:

  **netsh interface ipv6 install**

#### CLIENT1

CLIENT1 is a computer that is being used as a client.

### Configure CLIENT1 as a client computer

1. Install Windows XP Professional with SP2 as a workgroup computer. Set the Administrator password.

2. After restarting, log on as Administrator.

3. At the command prompt, install the IPv6 protocol by typing:

   **netsh interface ipv6 install**

4. Configure the TCP/IP protocol with the IP address of 10.0.1.3, the subnet mask of 255.255.255.0, a default gateway of 10.0.1.1, and the DNS server IP address of 10.0.1.2.

5. Append the DNS suffix **testlab.microsoft.com**. Click **Start**, click **Control Panel**, click **Network and Internet**

**Connections**, and then click **Network Connections**. Right-click the network connection that you want to configure, and then click **Properties**. On the **General** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**. Click **Advanced**, and then click the **DNS** tab. Add **testlab.microsoft.com** to the list of DNS suffixes, as show in the following dialog box:

Windows Firewall is automatically turned on in Windows XP Professional with SP2. You need to configure an exception to allow CLIENT2 to ping CLIENT1.

**Configure Windows to allow communication between client computers**

1. Click **Start**, point to **Control Panel**, and then click **Security Center**.
2. Click **Windows Firewall**, and then in the **Windows Firewall** dialog box, click the **Advanced** tab.
3. Click **Settings** for **ICMP**, and then click **Allow incoming echo request**.
4. Click **OK** twice to close **Windows Firewall**.

**ROUTER1**

ROUTER1 is a computer that is being used as a router between Subnet 1 and Subnet 2.

**Configure ROUTER1 as a router**

1. Install Windows Server 2003 with SP1, Standard Edition, as a workgroup computer. Set the Administrator password.
2. After restarting, log on as Administrator.
3. At the command prompt, install the IPv6 protocol by typing:

   **netsh interface ipv6 install**

4. In **Control Panel-Network Connections**, rename the LAN connection connected to Subnet 1 to **Subnet 1 Connection** and rename the LAN connection connected to Subnet 2 to **Subnet 2 Connection**.
5. For **Subnet 1 Connection**, configure the TCP/IP protocol with the IP address of 10.0.1.1, the subnet mask of 255.255.255.0, and the DNS server IP address of 10.0.1.2.
6. For **Subnet 2 Connection**, configure the TCP/IP protocol with the IP address of 10.0.2.1, the subnet mask of 255.255.255.0, and a default gateway of 10.0.2.2.
7. Start the registry editor (Regedit.exe) and set HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\\IPEnableRouter to 1.

This step enables IPv4 routing between Subnet 1 and Subnet 2.

8. Restart the computer.

**ROUTER2**
ROUTER2 is a computer that is being used as a router between Subnet 2 and Subnet 3.

**Configure ROUTER2 as a router**

1. Install Windows Server 2003 with SP1, Standard Edition, as a workgroup computer. Set the Administrator password.
2. After restarting, log on as Administrator.
3. At the command prompt, install the IPv6 protocol by typing:

   **netsh interface ipv6 install**

4. Open Network Connections, and rename the LAN connection connected to Subnet 2 to **Subnet 2 Connection**, and rename the LAN connection connected to Subnet 3 to **Subnet 3 Connection**.
5. For **Subnet 2 Connection**, configure the TCP/IP protocol with the IP address of 10.0.2.2, the subnet mask of 255.255.255.0, and a default gateway of 10.0.2.1.
6. For **Subnet 3 Connection**, configure the TCP/IP protocol with the IP address of 10.0.3.1 and the subnet mask of 255.255.255.0.
7. Start the registry editor (Regedit.exe) and set HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\IPEnableRouter to 1.

   This step enables IPv4 routing between Subnet 2 and Subnet 3.

8. Restart the computer.

**CLIENT2**
CLIENT2 is a computer that is being used as a client.

**Configure CLIENT2 as a client computer**

1. Install Windows XP Professional with SP2 as a workgroup computer. Set the Administrator password.
2. After restarting, log on as Administrator.
3. At the command prompt, install the IPv6 protocol by typing:

   **netsh interface ipv6 install**

4. Configure the TCP/IP protocol with the IP address of 10.0.3.2, the subnet mask of 255.255.255.0, a default gateway of 10.0.3.1, and the DNS server IP address of 10.0.1.2, and append the DNS suffix **testlab.microsoft.com**.
5. Verify the integrity of the IPv4 routing infrastructure by pinging 10.0.1.3 from the CLIENT2 computer. On CLIENT2, type the following command:

   **ping 10.0.1.3**

   You should be able to successfully ping CLIENT1.

**Link-local addresses**
Link-local addresses, identified by the beginning address block FE80, are equivalent to APIPA IPv4 addresses autoconfigured on computers running current Microsoft Windows operating systems using the 169.254.0.0/16 prefix. One of the most useful aspects of IPv6 is its ability to automatically configure itself without the use of a stateful configuration protocol, such as Dynamic Host Configuration Protocol for IPv6 (DHCPv6). By default, an IPv6 node configures a link-local address for each interface. Link-local addresses are used by nodes when communicating with neighboring nodes on the same link (a network segment bounded by routers). The scope of a link-local address is the local link. An IPv6 router never forwards link-local traffic beyond the link.

**Link-local ping**
At this point in the lab configuration, only IPv4 traffic across the subnets is routed through an IPv4 routing infrastructure. However, you should be able to successfully ping neighboring link-local addresses. After the lab is configured to route IPv6

traffic, you will be able to successfully ping using global addresses.

**Determine and ping the link-local address of CLIENT1 from DNS1**

1. On CLIENT1, type the **ipconfig** command to obtain the link-local address and interface index of the interface named Local Area Connection.

In this example, the link-local address is FE80::203:FFFF:FEE1:2A73 and the interface index is 5.

2. On DNS1, type the **ipconfig** command to obtain the interface index of the interface named Local Area Connection.

   In this example, the interface index of Local Area Connection is 4.

3. On DNS1, ping the IPv6 link-local address of CLIENT1. You must use the interface index of the sending interface, the Local Area Connection interface of DNS1. For example, using the example configuration in step 1:

   **ping FE80::203:FFFF:FEE1:2A73%4**

   A successful ping demonstrates that CLIENT1 and DNS1 are neighbors on the same link.

**Creating a static IPv6 routing infrastructure**

Configure a static IPv6 routing infrastructure so that all test lab nodes can be reached by using IPv6 traffic.

**Create a static IPv6 routing infrastructure**

1. On ROUTER1, type the **ipconfig** command to obtain the link-local addresses of the interfaces connected to Subnet 1 Connection and Subnet 2 Connection.

```
Command Prompt

C:\Documents and Settings\Administrator>ipconfig

Windows IP Configuration

Ethernet adapter Subnet 1 Connection:

   Connection-specific DNS Suffix  . :
   IP Address. . . . . . . . . . . . : 10.0.1.1
   Subnet Mask . . . . . . . . . . . : 255.255.255.0
   IP Address. . . . . . . . . . . . : fe80::203:ffff:fee1:fa74%4
   Default Gateway . . . . . . . . . :

Ethernet adapter Subnet 2 Connection:

   Connection-specific DNS Suffix  . :
   IP Address. . . . . . . . . . . . : 10.0.2.1
   Subnet Mask . . . . . . . . . . . : 255.255.255.0
   IP Address. . . . . . . . . . . . : fe80::203:ffff:fefc:fa75%5
   Default Gateway . . . . . . . . . : 10.0.2.2

Tunnel adapter Teredo Tunneling Pseudo-Interface:

   Connection-specific DNS Suffix  . :
```

For this example, the information is as follows:

Subnet 1 Connection - FE80::203:FFFF:FEE1:FA74

Subnet 2 Connection - FE80::203:FFFF:FEFC:FA75

2. On ROUTER2, type the **ipconfig** command to obtain the link-local addresses of the interfaces connected to Subnet 2 Connection and Subnet 3 Connection.

```
Command Prompt

C:\Documents and Settings\Administrator>ipconfig

Windows IP Configuration

Ethernet adapter Subnet 2 Connection:

   Connection-specific DNS Suffix  . :
   IP Address. . . . . . . . . . . . : 10.0.2.2
   Subnet Mask . . . . . . . . . . . : 255.255.255.0
   IP Address. . . . . . . . . . . . : fe80::203:ffff:fee0:fa76%4
   Default Gateway . . . . . . . . . : 10.0.2.1

Ethernet adapter Subnet 3 Connection:

   Connection-specific DNS Suffix  . :
   IP Address. . . . . . . . . . . . : 10.0.3.1
   Subnet Mask . . . . . . . . . . . : 255.255.255.0
   IP Address. . . . . . . . . . . . : fe80::203:ffff:fefd:fa77%5
   Default Gateway . . . . . . . . . :

Tunnel adapter Teredo Tunneling Pseudo-Interface:

   Connection-specific DNS Suffix  . :
```

For this example, the information is as follows:

Subnet 2 Connection - FE80::203:FFFF:FEE0:FA76

Subnet 3 Connection - FE80::203:FFFF:FEFD:FA77

3. On ROUTER1, type the following commands:

   a. **netsh interface ipv6 set interface "Subnet 1 Connection" forwarding=enabled advertise=enabled**

   b. **netsh interface ipv6 set interface "Subnet 2 Connection" forwarding=enabled advertise=enabled**

      Steps a. and b. configure the Subnet 1 and 2 Connection interfaces to route (forward IPv6 packets not addressed to them) and advertise subnet prefixes (for address autoconfiguration).

   c. **netsh interface ipv6 add route 2001:db8:0:1::/64 "Subnet 1 Connection" publish=yes**

   d. **netsh interface ipv6 add route 2001:db8:0:2::/64 "Subnet 2 Connection" publish=yes**

      Steps c. and d. add routes to the IPv6 routing table corresponding to the subnet prefix for Subnet 1 and 2 and configures the router to advertise these routes in Router Advertisement messages.

e. **netsh interface ipv6 add route ::/0 "Subnet 2 Connection" nexthop=** *ROUTER2AddressOnSubnet2* **publish=yes**

Step e. adds the default route to the IPv6 routing table and configures the router to advertise itself as a default router in the Router Advertisement messages.

In the preceding command, *ROUTER2AddressOnSubnet2* represents the link-local address assigned to the Subnet 2 Connection interface on ROUTER2. For example, using the connection in this lab the command would be:

**netsh interface ipv6 add route ::/0 "Subnet 2 Connection" nexthop= FE80::203:FFFF:FEE0:FA76 publish=yes**

4. On ROUTER2, type the following commands:

   a. **netsh interface ipv6 set interface "Subnet 2 Connection" forwarding=enabled advertise=enabled**

   b. **netsh interface ipv6 set interface "Subnet 3 Connection" forwarding=enabled advertise=enabled**

   c. **netsh interface ipv6 add route 2001:db8:0:2::/64 "Subnet 2 Connection" publish=yes**

   d. **netsh interface ipv6 add route 2001:db8:0:3::/64 "Subnet 3 Connection" publish=yes**

   e. **netsh interface ipv6 add route ::/0 "Subnet 2 Connection" nexthop=** *ROUTER1AddressOnSubnet2* **publish=yes**

   In the preceding command, *ROUTER1AddressOnSubnet2* represents the link-local address assigned to the Subnet 2 Connection interface on ROUTER1. For example, using the connection in this lab the command would be:

   **netsh interface ipv6 add route ::/0 "Subnet 2 Connection" nexthop= FE80::203:FFFF:FEFC:FA75 publish=yes**

**Global addresses**

At this point, you have now created static IPv6 routes with global subnet prefixes. Global addresses are equivalent to the IPv4 public address space. Unlike link-local addresses, global addresses are not automatically configured and must be assigned either through stateless or stateful address configuration processes. You can determine which address is the global address by the "ff:fe" portion of the public address in the sixth and seventh blocks of the address, indicating an EUI-64-based interface ID. The Extended Unique Identifier (EUI)-64 address is a newer 64-bit MAC address.

**Global ping**

**Verify the IPv6 routing structure**

1. On CLIENT1, type the **ipconfig** command to check for a new global IPv6 address.

   In this example, the CLIENT1 global address is 2001:DB8:0:1:203:FFFF:FEE1:2A73.

2. On CLIENT2, type the following commands:

   **ping** *CLIENT1GlobalAddress*

**tracert -d** *CLIENT1GlobalAddress*

In this example, the CLIENT1 global address is 2001:DB8:0:1:203:FFFF:FEE1:2A73.

A successful ping and tracert demonstrates that IPv6 static routes have been created and are functioning.

3. You can view the entries in the ROUTER1 neighbor cache for CLIENT1 and ROUTER2, by typing the following on ROUTER1:

   **netsh interface ipv6 show neighbors**

**Using name resolution**

To resolve host names to IPv6 addresses, you must first configure DNS. On DNS1, create an AAAA record for CLIENT2 with the DNS name client2.testlab.microsoft.com for its global IPv6 address using the IPv6 Host resource record type.

**Configure DNS to resolve names to IPv6 addresses**

1. On DNS1, click **Start**, select **Administrative Tools**, and then click **DNS**.
2. In the console tree, click and then right-click **testlab.microsoft.com** in the **Forward Lookup Zones** folder, and then click **Other New Records**.
3. Click **IPv6 Host (AAAA)**, and then click **Create Record**.
4. In the **Host** text box type **client1**, and then in the **IP version 6 host address** text box, enter the IPv6 global address for CLIENT1.

   In this example, the CLIENT1 global address is 2001:DB8:0:1:203:FFFF:FEE1:2A73.

5. Click **OK**, and then click **Done** to add the new IPv6 host record to the zone.
6. On CLIENT 2, type the following command:

   **ping client1**

   A successful ping demonstrates that host names can resolve to IPv6 addresses.

**Configuring the test lab to use ISATAP**

ISATAP is an address assignment and automatic tunneling technology that is used to provide unicast IPv6 connectivity between IPv6/IPv4 hosts on an IPv4 intranet, which are also known as ISATAP hosts. ISATAP is described in RFC 4214. More information about ISATAP can be found in the IPv6 Transition Technologies white paper (http://go.microsoft.com/fwlink/?LinkId=67210). By default, the IPv6 protocol for Windows XP Professional with SP2 and Windows Server 2003 with SP1, Standard Edition, configures a link-local ISATAP address on the Automatic Tunneling Pseudo-Interface for each IPv4 address assigned to a computer.

To configure global ISATAP addresses, or to communicate beyond the logical subnet defined by the IPv4 intranet, you need an ISATAP router. An ISATAP router performs the following functions:

- Advertises its presence and address prefixes, enabling global ISATAP addresses to be configured.
- Optionally forwards IPv6 packets between ISATAP hosts on the IPv4 intranet and IPv6 hosts beyond it.

An ISATAP router is typically configured to perform both functions, but can perform either individually. Most often, an ISATAP router acts as the forwarder between ISATAP hosts on an IPv4 intranet and IPv6 hosts on an IPv6-enabled portion of an intranet.

To demonstrate the use of an ISATAP router between IPv6 and IPv4 intranets, the following steps first separate the lab into a portion that has IPv4 and IPv6 connectivity and another that has IPv4 connectivity only. Then, ROUTER1 is configured as an ISATAP router so that hosts on the IPv4-only portion of the intranet can communicate with hosts on the IPv6-enabled portion of the intranet.

To do this, we will disable IPv6 forwarding and advertising on the Subnet 2 Connection interface of ROUTER1 and both interfaces of ROUTER2. This emulates an intranet in which a portion is IPv6-enabled (Subnet 1) and a portion is not (Subnet 2 and Subnet 3).

**Configure the test lab to use ISATAP**

1. Disable forwarding and advertising on the Subnet 2 Connection interface of ROUTER1 and ROUTER2.

   a. On ROUTER1, at the command prompt, type:

      **netsh interface ipv6 set interface "Subnet 2 Connection" forwarding=disabled advertise=disabled**

   b. On ROUTER2, at the command prompt, type:

      **netsh interface ipv6 set interface "Subnet 2 Connection" forwarding=disabled advertise=disabled**

2. Disable forwarding and advertising on the Subnet 3 Connection interface. On ROUTER2, at the command prompt, type:

   **netsh interface ipv6 set interface "Subnet 3 Connection" forwarding=disabled advertise=disabled**

3. Renew CLIENT2 configuration to remove the global address and route. On CLIENT2, type the following command:

   **netsh interface ipv6 renew**

4. Ping CLIENT1 from CLIENT2. On CLIENT2, type the following command:

   **ping** *CLIENT1GlobalAddress*

   or

   **ping client1**

   In this example, the CLIENT1 global address is 2001:DB8:0:1:203:FFFF:FEE1:2A73.

   This Ping command fails because there is no longer IPv6 connectivity between CLIENT2 and CLIENT1.

5. Configure ROUTER1 as an ISATAP router advertising the 2001:DB8:0:10::/64 route to the logical ISATAP subnet consisting of Subnet 2 and Subnet 3.

   a. On ROUTER1, enable forwarding and advertising on the Automatic Tunneling Pseudo-Interface, using the following commands:

      **netsh interface ipv6 isatap set router 10.0.2.1**

      **netsh interface ipv6 set interface "Automatic Tunneling Pseudo-Interface" forwarding=enabled advertise=enabled**

   b. On ROUTER1, add a route for the subnet prefix of the logical subnet of the IPv4 intranet to the Automatic Tunneling

Pseudo-Interface and configure it to be published. Use the following command:

**netsh interface ipv6 add route 2001:db8:0:10::/64 "Automatic Tunneling Pseudo-Interface" publish=yes**

6. Add an ISATAP address (A) resource record to the DNS server for the IPv4 address of 10.0.2.1.

   a. On DNS1, click **Start**, select **Administrative Tools**, and then click **DNS**.

   b. In the console tree, click and then right-click **testlab.microsoft.com** in the **Forward Lookup Zones** folder, and then click **New Host (A)**.

   c. In the **Name** text box, type **ISATAP**, and in the **IP address** text box, type **10.0.2.1**, as shown in the following figure.

   d. Click **Add Host**, click **OK**, and then click **Done** to add the new host record to the zone.

7. Renew the CLIENT2 configuration to recognize the ISATAP router IPv4 address of ROUTER1 and obtain an ISATAP address with the global prefix of 2001:DB8:0:10::/64. On CLIENT2, type the following command:

   **netsh interface ipv6 renew**

8. Ping CLIENT1 from CLIENT2. On CLIENT2, type the following command:

   **ping** *CLIENT1GlobalAddress*

   or

   **ping client1**

   In this example, the CLIENT1 global address is 2001:DB8:0:1:203:FFFF:FEE1:2A73.

   This ping command succeeds because IPv6 connectivity using ISATAP now exists between CLIENT2 and CLIENT1. On the link between CLIENT1 and ROUTER1, the IPv6 traffic is encapsulated as IPv4 packets.

| **Note** |
| --- |
| It may take a few minutes for IPv6 connectivity between CLIENT2 and CLIENT1 to be established. You may need to restart CLIENT2 and run **netsh interface ipv6 renew** on CLIENT1. |

**Conclusion**

This guide described the steps required to configure IPv6 in a test lab with five computers. It also described how to use ISATAP to provide IPv6 connectivity between IPv6/IPv4 hosts on an IPv4-only portion of an intranet and IPv6 hosts on an IPv6-enabled portion of an intranet.

# Step-by-Step Guide for Setting Up VPN-based Remote Access in a Test Lab

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides detailed information about how you can use five computers to create a test lab with which to configure and test virtual private network (VPN) remote access with the Microsoft® Windows® XP Professional operating system with Service Pack 2 (SP2) and the 32-bit versions of the Microsoft Windows Server™ 2003 operating system with Service Pack 1 (SP1). These instructions are designed to take you step-by-step through the configuration required for a Point-to-Point Tunneling Protocol (PPTP) connection, a Layer Two Tunneling Protocol (L2TP) with Internet Protocol security (L2TP/IPsec) connection, and a VPN connection that uses certificate-based Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication.

| **Note** |
| --- |
| The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to show the desired functionality clearly. This configuration is designed to reflect neither best practices nor a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed to work only on a separate test lab network. |

**Setting Up the Test Lab for PPTP, L2TP/IPsec, and EAP-TLS Remote Access VPN Connections**

The infrastructure for the VPN test lab network consists of five computers performing the following services:

- A computer running Windows Server 2003 with SP1, Enterprise Edition, named DC1 that is acting as a domain controller, a Domain Name System (DNS) server, a Dynamic Host Configuration Protocol (DHCP) server, and a certification authority (CA).
- A computer running Windows Server 2003 with SP1, Standard Edition, named IAS1 that is acting as a Remote Authentication Dial-In User Service (RADIUS) server.
- A computer running Windows Server 2003 with SP1, Standard Edition, named IIS1 that is acting as a Web and file server.
- A computer running Windows Server 2003 with SP1, Standard Edition, named VPN1 that is acting as a VPN server. VPN1 has two network adapters installed.
- A computer running Windows XP Professional with SP2 named CLIENT1 that is acting as a VPN client.

The following diagram shows the configuration of the VPN test lab.

There is a network segment representing a corporate intranet and a network segment representing the Internet. All computers on the corporate intranet are connected to a common hub or Layer 2 switch. All computers on the Internet are connected to a separate common hub or Layer 2 switch. Private addresses are used throughout the test lab configuration. The private network of 172.16.0.0/24 is used for the intranet. The private network of 10.0.0.0/24 is used for the simulated Internet. Windows

Firewall is set up and configured on the RADIUS server (IAS1), the Web and file server (IIS1), and the client computer (CLIENT1). Windows Firewall should not be turned on or configured on either the domain controller (DC1) or the VPN server (VPN1). In addition, the Windows Firewall/Internet Connection Sharing (ICS) service should be disabled on VPN1.

IIS1 obtains its IP address configuration using DHCP. CLIENT1 uses DHCP for its IP address configuration; however, it is also configured with an alternate IP configuration so that it can be placed on either the intranet network segment or the simulated Internet. All other computers have a manual IP address configuration. There are no Windows Internet Name Service (WINS) servers present.

To reconstruct this test lab, configure the computers in the order presented, beginning with the PPTP-based remote access VPN connection. Additional sections of this guide describe L2TP/IPsec-based and EAP-TLS-based remote access VPN connections.

**PPTP-based Remote Access VPN Connections**

The following sections describe how to set up and configure each of the computers in the test lab for a PPTP-based remote access VPN connection. PPTP is typically used when there is no public key infrastructure (PKI) to issue computer certificates that are required for L2TP/IPsec connections.

**DC1**

DC1 is a computer running Windows Server 2003 with SP1, Enterprise Edition, that is providing the following services:

- A domain controller for the example.com Active Directory® domain.
- A DNS server for the example.com DNS domain.
- A DHCP server for the intranet network segment
- The enterprise root certification authority (CA) for the example.com domain.

| **Note** |
| --- |
| Windows Server 2003 with SP1, Enterprise Edition, is used so that autoenrollment of user certificates for EAP-TLS authentication can be configured. This is described in the "EAP-TLS-based Remote Access VPN Connections" section of this guide. |

**Configure DC1**

1. Install Windows Server 2003 with SP1, Enterprise Edition, as a stand-alone server.
2. Configure the TCP/IP protocol with the IP address of 172.16.0.1 and the subnet mask of 255.255.255.0.

**Configure DC1 as a domain controller**

1. To start the Active Directory Installation Wizard, click **Start**, click **Run**, type **dcpromo**, and then click **OK**.
2. In the **Welcome to the Active Directory Installation Wizard** dialog box, click **Next**.
3. In the **Operating System Compatibility** dialog box, click **Next**.
4. Verify that **Domain controller for a new domain** option is selected, and then click **Next**.
5. Verify that **Domain in a new forest** is selected, and then click **Next**.
6. Verify that **No, just install and configure DNS on this computer** is selected, and then click **Next**.
7. On the **New Domain Name** page, type **example.com**, and then click **Next**.
8. On the **NetBIOS Domain Name** page, confirm that the Domain NetBIOS name is **EXAMPLE**, and then click **Next**.
9. Accept the default **Database and Log Folders** directories, as shown in the following figure, and then click **Next**.

10. In the **Shared System Volume** dialog box, shown in the following figure, verify that the default folder location is correct. Click **Next**.

11. On the **Permissions** page, verify that the **Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems** check box is selected, as shown in the following figure. Click **Next**.

12. On the **Directory Services Restore Mode Administration Password** page, leave the passwords blank, and then click

**Next**.

13. Review the information that appears on the **Summary** page, and then click **Next**.

14. On the **Completing the Active Directory Installation Wizard** page, click **Finish**.

15. When prompted to restart the computer, click **Restart Now**.

**Raise the domain functional level**

1. Open the **Active Directory Domains and Trusts** snap-in from the **Administrative Tools** folder, and then right-click the domain computer **dc1.example.com**.

2. Click **Raise Domain Functional Level**, select **Windows Server 2003** on the **Raise Domain Functional Level** page, and then click **Raise**, as shown in the following figure.

**Install and configure DHCP**

1. In Control Panel, double-click **Add or Remove Programs**, and then install DHCP as a Networking Services component.

2. Open the **DHCP** snap-in from the **Administrative Tools** folder.

3. Click **Action**, and then click **Authorize** to authorize the DHCP service.

4. In the console tree, right-click **dc1.example.com**, and then click **New Scope**.

5. On the **Welcome** page of the New Scope Wizard, click **Next**.

6. On the **Scope Name** page, type **CorpNet** in **Name**. This is shown in the following figure.

7. Click **Next**. On the **IP Address Range** page, type **172.16.0.10** in **Start IP address**, **172.16.0.100** in **End IP address**, and **24** in **Length**. This is shown in the following figure.

8. Click **Next**. On the **Add Exclusions** page, click **Next**.

9. On the **Lease Duration** page, click **Next**.

10. On the **Configure DHCP Options** page, click **Yes, I want to configure DHCP options now**. This is shown in the following figure.

11. Click **Next**. On the **Router (Default Gateway)** page, click **Next**.

12. On the **Domain Name and DNS Servers** page, type **example.com** in **Parent domain**. Type **172.16.0.1** in **IP address**, and then click **Add**. This is shown in the following figure.

13. Click **Next**. On the **WINS Servers** page, click **Next**.

14. On the **Activate Scope** page, click **Yes, I want to activate this scope now**. This is shown in the following figure.

15. Click **Next**. On the **Completing the New Scope Wizard** page, click **Finish**.

**Install Certificate Services**

1. In Control Panel, double-click **Add or Remove Programs**, and then install the Certificate Services component as an enterprise root CA with the name **Example CA**.

2. Select **Enterprise root CA**, as shown in the following figure, and then click **Next**.

3. Type **Example CA** for the **Common name for this CA**, as shown in the following figure, and then click **Next**.

4. Click **Next** to accept the default **Certificate Database Settings** shown in the following figure.

5. Click **Finish**.

**Add computers, users, and groups to the domain**

1. Open the Active Directory Users and Computers snap-in.
2. In the console tree, open **example.com**.
3. Right-click **Users**, point to **New**, and then click **Computer**.
4. In the **New Object - Computer** dialog box, type **IAS1** in **Computer name**. This is shown in the following figure.

5. Click **Next**. In the **Managed** dialog box, click **Next**. In the **New Object - Computer** dialog box, click **Finish**.
6. Use steps 3 through 5 to create additional computer accounts with the following names: **IIS1**, **VPN1**, and **CLIENT1**.
7. In the console tree, right-click **Users**, point to **New**, and then click **User**.
8. In the **New Object - User** dialog box, type **VPNUser** in **First name**, and type **VPNUser** in **User logon name**. This is shown in the following figure.

9. Click **Next**.
10. In the **New Object - User** dialog box, type a password of your choice in **Password** and **Confirm password**. Clear the **User must change password at next logon** check box and select the **Password never expires** check box. This is shown in the following figure.

11. In the **New Object** - **User** dialog box, click **Finish**.

12. In the console tree, right-click **Users**, point to **New**, and then click **Group**.

13. In the **New Object - Group** dialog box, type **VPNUsers** in **Group name**, and then click **OK**. This is shown in the following figure.

14. In the details pane, double-click **VPNUsers**.

15. Click the **Members** tab, and then click **Add**.

16. In the **Select Users, Contacts, Users, or Groups** dialog box, type **vpnuser** in **Enter the object names to select**. This is shown in the following figure.

17. Click **OK**. In the **Multiple Names Found** dialog box, click **OK**. The VPNUser user account is added to the VPNUsers group. This is shown in the following figure.

18. Click **OK** to save changes to the VPNUsers group.

**IAS1**

IAS1 is a computer running Windows Server 2003 with SP1, Standard Edition, that is providing RADIUS authentication, authorization, and accounting for VPN1.

**Configure IAS1 as a RADIUS server**

1. Install Windows Server 2003 with SP1, Standard Edition, as a member server named IAS1 in the example.com domain.
2. For the intranet local area connection, configure the TCP/IP protocol with the IP address of 172.16.0.2, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1.
3. In Control Panel, double-click **Add or Remove Programs**, and then install Internet Authentication Service as a Networking Services component.
4. Open the Internet Authentication Service snap-in from the **Administrative Tools** folder.
5. Right-click **Internet Authentication Service**, and then click **Register Server in Active Directory**. When the **Register Internet Authentication Server in Active Directory** dialog box appears, click **OK**. This is shown in the following figure.

6. In the console tree, right-click **RADIUS Clients**, and then click **New RADIUS Client**.
7. On the **Name and Address** page of the New RADIUS Client wizard, for **Friendly name**, type **VPN1**. In **Client address (IP or DNS)**, type **172.16.0.4**. This is shown in the following figure.

8. Click **Next**. On the **Additional Information** page of the New RADIUS Client wizard, for **Shared secret**, type a shared secret for VPN1, and then type it again in **Confirm shared secret**. This is shown in the following figure.

9. Click **Finish**.

10. In the console tree, right-click **Remote Access Policies**, and then click **New Remote Access Policy**.

11. On the **Welcome to the New Remote Access Policy Wizard** page, click **Next**.

12. On the **Policy Configuration Method** page, type **VPN remote access to intranet** in **Policy name**. This is shown in the following figure.

13. Click **Next**. On the **Access Method** page, select **VPN**. This is shown in the following figure.

14. Click **Next**. On the **User or Group Access** page, click **Group**. This is shown in the following figure.

15. Click **Add**. In the **Select Groups** dialog box, click **Locations**, select **example.com** as the location, and then click **OK**.

16. Type **vpnusers** in **Enter the object names to select**. This is shown in the following figure.

17. Click **OK**. The VPNUsers group in the example.com domain is added to the list of groups on the **User or Group Access** page. This is shown in the following figure.

18. Click **Next**. On the **Authentication Methods** page, the **Microsoft Encrypted Authentication version 2 (MS-CHAPv2)** authentication protocol is selected by default. This is shown in the following figure.

19. Click **Next**. On the **Policy Encryption Level** page, clear the **Basic encryption** and **Strong encryption** check boxes, leaving only **Strongest encryption** selected. This is shown in the following figure.

20. Click **Next**. On the **Completing the New Remote Access Policy** page, click **Finish**.

**Configure Windows Firewall on IAS1**

1. In Control Panel, double-click **Windows Firewall**.
2. In the **Windows Firewall** dialog box, click the **Exceptions** tab.
3. Click **Add Port**, and in the **Add a Port** dialog box add the following port exceptions:

| **Note** |
|---|
| You must click **Add Port** on the **Exceptions** tab for each port exception. |

| Name | Port Number | Protocol |
|---|---|---|
| Legacy RADIUS | 1645 | UDP |
| Legacy RADIUS | 1646 | UDP |
| RADIUS Accounting | 1812 | UDP |
| RADIUS Authentication | 1813 | UDP |

4. Verify that the four port exceptions that you added are selected on the **Exceptions** tab, as shown in the following example.

5. Click the **Advanced** tab, and then click **Settings** for **Security Logging**.

6. In the **Log Setting** dialog box, select **Log dropped packets** and **Log successful connections**. Note the path and file name in **Name**.

   The log file allows you to see where connection errors occur, as well as which source and destination ports the errors occurred on. This log file should provide you with the information needed in case you need to add more ports to the exception list.

7. Click **OK** twice to close Windows Firewall.

**IIS1**

IIS1 is a computer running Windows Server 2003 with SP1, Standard Edition, and Internet Information Services (IIS). It is providing Web and file server services for intranet clients. To configure IIS1 as a Web and file server and to configure Windows Firewall on IIS1, perform the following steps.

**Configure IIS1 as a Web and file server**

1. Install Windows Server 2003 with SP1, Standard Edition, as a member server named IIS1 in the example.com domain.

2. In Control Panel, double-click **Add or Remove Programs**, and then install Internet Information Services (IIS) as a subcomponent of the Application Server component in the Windows Components Wizard.

3. On IIS1, use Windows Explorer to create a new share for the root folder of drive C using the share name ROOT with the default permissions.

4. To determine whether the Web server is working correctly, run Internet Explorer on IAS1. If the Internet Connection Wizard prompts you, configure Internet connectivity for a LAN connection. In Internet Explorer, in **Address**, type **http://IIS1.example.com/iisstart.htm**. You should see a message saying the Web site is under construction.

5. To determine whether file sharing is working correctly, on IAS1, click **Start**, click **Run**, type **\\IIS1\ROOT**, and then click **OK**. You should see the contents of the root folder of drive C on IIS1.

**Configure Windows Firewall on IIS1**

1. In Control Panel, double-click **Windows Firewall**.

2. In the **Windows Firewall** dialog box, click the **Exceptions** tab.

3. Select **File and Print Sharing**, and then click **Add Program**.

4. In the **Add a Program** dialog box, select **Internet Explorer**, and then click **OK**.
5. Click **Add a Port**.
6. In the **Add a Port** dialog box, type **World Wide Web Publishing Service** for the **Name**, type **80** for the **Port number**, select **TCP** as the type of traffic processed by the port, and then click **OK**.
7. Verify that **File and Print Sharing**, **Internet Explorer**, and **World Wide Web Publishing Service** are all selected in the **Exceptions** dialog box, and then click the **Advanced** tab.
8. Click **Settings** for **Security Logging**.
9. In the **Log Setting** dialog box, select **Log dropped packets** and **Log successful connections**. Note the path and file name in **Name**.
10. Click **OK** twice to close Windows Firewall.

**VPN1**
VPN1 is a computer running Windows Server 2003 with SP1, Standard Edition, that is providing VPN server services for Internet-based VPN clients.

**Configure the VPN server**

1. Install Windows Server 2003 with SP1, Standard Edition, as a member server named VPN1 in the example.com domain.
2. Open the **Network Connections** folder.
3. For the intranet local area connection, rename the connection to **CorpNet**. For the Internet local area connection, rename the connection to **Internet**. This is shown in the following figure.

4. Configure the TCP/IP protocol for the CorpNet connection with the IP address of 172.16.0.4, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1.
5. Configure the TCP/IP protocol for the Internet connection with the IP address of 10.0.0.2 and the subnet mask of 255.255.255.0.

Windows Firewall and Routing and Remote Access cannot run simultaneously on VPN1. If Windows Firewall is turned on, you will need to turn it off; if the Windows Firewall/Internet Connection Sharing (ICS) service has started or is set to automatic before you configure Routing and Remote Access, you must disable it.

**Disable the Windows Firewall/Internet Connection Sharing (ICS) service**

1. Click **Administrative Tools**, and then click **Services**.
2. In the **Services** details pane, right-click **Windows Firewall/Internet Connection Sharing (ICS)** service, and then click **Properties**.
3. If the service **Startup Type** is either **Automatic** or **Manual**, change it to **Disabled**.
4. Click **OK** to close the **Windows Firewall/Internet Connection Sharing (ICS)** dialog box, and then close the **Services**

page.

**Configure Routing and Remote Access**

1. Run the **Routing and Remote Access** snap-in from the **Administrative Tools** folder.
2. In the console tree, right-click **VPN1**, then and click **Configure and Enable Routing and Remote Access**.
3. On the **Welcome to the Routing and Remote Access Server Setup Wizard** page, click **Next**.
4. On the **Configuration** page, **Remote access (dial-up or VPN)** is selected by default. This is shown in the following figure.

5. Click **Next**. On the **Remote Access** page, select **VPN**. This is shown in the following figure.

6. Click **Next**. On the **VPN Connection** page, click the **Internet** interface in **Network** interfaces. This is shown in the following figure.

7. Click **Next**. On the **IP Address Assignment** page, **Automatically** is selected by default. This is shown in the following figure.

8. Click **Next**. On the **Managing Multiple Remote Access Servers** page, click **Yes, set up this server to work with a RADIUS server**. This is shown in the following figure.

9. Click **Next**. On the **RADIUS Server Selection** page, type **172.16.0.2** in **Primary RADIUS server** and the shared secret in **Shared secret**. This is shown in the following figure.

10. Click **Next**. On the **Completing the Routing and Remote Access Server Setup Wizard** page, click **Finish**.

11. You are prompted with a message describing the need to configure the DHCP Relay Agent. This is shown in the following figure.

12. Click **OK**.

13. In the console tree, open **VPN1 (local)**, then **IP Routing**, and then **DHCP Relay Agent**. Right-click **DHCP Relay Agent**, and then click **Properties**.

14. In the **DHCP Relay Agent Properties** dialog box, type **172.16.0.1** in **Server address**. This is shown in the following figure.

15. Click **Add**, and then click **OK**.

**CLIENT1**

CLIENT1 is a computer running Windows XP Professional with SP2 that is acting as a VPN client and gaining remote access to intranet resources across the simulated Internet.

**Configure Client1 as a VPN client for a PPTP connection**

1. Connect CLIENT1 to the intranet network segment.
2. On CLIENT1, install Windows XP Professional with SP2 as a member computer named CLIENT1 of the example.com domain.

| **Note** |
| --- |
| Installing Windows XP Professional with SP2 also installs and automatically turns on Windows Firewall. Leave Windows Firewall turned on for this scenario. You will not need to configure any port or program exceptions. |

3. Add the VPNUser account in the example.com domain to the local Administrators group.
4. Log off and then log on using the VPNUser account in the example.com domain.
5. In Control Panel, open the **Network Connections** folder, obtain properties on the Local Area Network connection, and then obtain properties on the Internet protocol (TCP/IP).
6. Click the **Alternate Configuration** tab, and then click **User configured**.
7. In **IP address**, type **10.0.0.1**. In **Subnet mask**, type **255.255.255.0**. This is shown in the following figure.

8. Click **OK** to save changes to the TCP/IP properties. Click **OK** to save changes to the Local Area Network connection.
9. Shut down the CLIENT1 computer.
10. Disconnect CLIENT1 from the intranet network segment, and connect it to the simulated Internet network segment.
11. Restart CLIENT1 and log on using the VPNUser account.
12. On CLIENT1, in Control Panel, open the **Network Connections** folder.
13. In **Network Tasks**, click **Create a new connection**.
14. On the **Welcome to the New Connection Wizard** page of the New Connection Wizard, click **Next**.
15. On the **Network Connection Type** page, click **Connect to the network at my workplace**. This is shown in the following figure.

16. Click **Next**. On the **Network Connection** page, click **Virtual Private Network connection**. This is shown in the following figure.

17. Click **Next**. On the **Connection Name** page, type **PPTPtoCorpnet** in **Company Name**. This is shown in the following figure.

18. Click **Next**. On the **VPN Server Selection** page, type **10.0.0.2** in **Host name or IP address**. This is shown in the following figure.

19. Click **Next**. On the **Connection Availability** page, click **Next**.

20. On the **Completing the New Connection Wizard** page, click **Finish**. The **Connect PPTPtoCorpnet** dialog box appears. This is shown in the following figure.

21. Click **Properties**, and then click the **Networking** tab.

22. On the **Networking** tab, in **Type of VPN**, click **PPTP VPN**. This is shown in the following figure.

23. Click **OK** to save changes to the **PPTPtoCorpnet** connection. The **Connect PPTPtoCorpnet** dialog box appears.

24. In **User name**, type **example\VPNUser**. In **Password**, type the password you chose for the VPNUser account.

25. Click **Connect**.

26. When the connection is complete, run Internet Explorer.

27. If prompted by the Internet Connection Wizard, configure it for a LAN connection. In **Address**, type **http://IIS1.example.com/iisstart.htm**. You should see a message saying the Web page is under construction.

28. Click **Start**, click **Run**, type **\\IIS1\ROOT**, and then click **OK**. You should see the contents of the local drive (drive C) on IIS1.

29. Right-click the **PPTPtoCorpnet** connection, and then click **Disconnect**.

**L2TP/IPsec-based Remote Access VPN Connections**

L2TP/IPsec-based remote access VPN connections require computer certificates on the VPN client and the VPN server. L2TP/IPsec is typically used when there are stronger requirements for security and a public key infrastructure (PKI) is in place to issue computer certificates to VPN clients and servers.

**DC1**

**Configure DC1 for autoenrollment of computer certificates**

1. Open the Active Directory Users and Computers snap-in.
2. In the console tree, double-click **Active Directory Users and Computers**, right-click the **example.com** domain, and then click **Properties**.
3. On the **Group Policy** tab, click **Default Domain Policy**, and then click **Edit**.
4. In the console tree, open **Computer Configuration**, open **Windows Settings**, open **Security Settings**, open **Public Key Policies**, and then open **Automatic Certificate Request Settings**. This is shown in the following figure.

5. Right-click **Automatic Certificate Request Settings**, point to **New**, and then click **Automatic Certificate Request**.
6. On the **Welcome to the Automatic Certificate Request Setup Wizard** page, click **Next**.
7. On the **Certificate Template** page, click **Computer**. This is shown in the following figure.

8. Click **Next**. On the Completing the **Automatic Certificate Request Setup Wizard** page, click **Finish**. The Computer certificate type now appears in the details pane of the Group Policy Object Editor snap-in. This is shown in the following

figure.

9. Type **gpupdate** at a command prompt to update Group Policy on DC1.

**VPN1**

**Update Group Policy on VPN1**

- To immediately update Group Policy and request a computer certificate, type **gpupdate** at a command prompt.

After updating VPN1 with the new certificates you need to stop and restart the IPsec Policy Agent and Routing and Remote Access services.

**Restart IPsec Policy Agent and Routing and Remote Access**

1. Click **Start**, point to **Administrative Tools**, and then click **Services**.
2. In the details pane, point to **IPSEC Services**, point to **Action**, and then click **Restart**.
3. In the details pane, point to **Routing and Remote Access**, point to **Action**, and then click **Restart**.

**CLIENT1**

To obtain a computer certificate on CLIENT1 and then configure an L2TP/IPsec-based remote access VPN connection, perform the following steps.

**Obtain a computer certificate and configure an L2TP/IPsec-based remote access VPN connection**

1. Shut down the CLIENT1 computer.
2. Disconnect CLIENT1 from the simulated Internet network segment, and connect it to the intranet network segment.
3. Restart CLIENT1 and log on using the VPNUser account. The computer and user Group Policy is automatically updated.
4. Shut down CLIENT1.
5. Disconnect CLIENT1 from the intranet network segment, and connect it to the simulated Internet network segment.
6. Restart CLIENT1 and log on using the VPNUser account.
7. On CLIENT1, in Control Panel, open the **Network Connections** folder.
8. In **Network Tasks**, click **Create a new connection**.
9. On the **Welcome to the New Connection Wizard** page of the **New Connection Wizard**, click **Next**.
10. On the **Network Connection Type** page, click **Connect to the network at my workplace**. This is shown in the following figure.

11. Click **Next**. On the **Network Connection** page, click **Virtual Private Network connection**. This is shown in the following figure.

12. Click **Next**. On the **Connection Name** page, type **L2TPtoCorpnet** in **Company Name**. This is shown in the following figure.

13. Click **Next**. On the **Public Network** page, click **Do not dial the initial connection**. This is shown in the following figure.

14. Click **Next**. On the **VPN Server Selection** page, type **10.0.0.2** in **Host name or IP address**. This is shown in the following figure.

15. Click **Next**. On the **Connection Availability** page, click **Next**.

16. On the **Completing the New Connection Wizard** page, click **Finish**. The **Connect L2TPtoCorpnet** dialog box appears. This is shown in the following figure.

17. Click **Properties**, and then click the **Networking** tab.

18. On the **Networking** tab, in **Type of VPN**, click **L2TP IPSec VPN**. This is shown in the following figure.

19. Click **OK** to save changes to the **L2TPtoCorpnet** connection. The **Connect L2TPtoCorpnet** dialog box appears.

20. In **User name**, type **example\VPNUser**. In **Password**, type the password you chose for the VPNUser account.

21. Click **Connect**.

22. When the connection is established, run the Web browser.

23. In **Address**, type **http://IIS1.example.com/iisstart.htm**. You should see a message saying the Web site is under construction.

24. Click **Start**, click **Run**, type **\\IIS1\ROOT**, and then click **OK**. You should see the contents of the local drive (drive C) on IIS1.

25. Right-click the **L2TPtoCorpnet** connection, and then click **Disconnect**.

**EAP-TLS-based Remote Access VPN Connections**

EAP-TLS-based remote access VPN connections require a user certificate on the VPN client and a computer certificate on the IAS server. EAP-TLS is for authenticating your VPN connection with the most secure user-level authentication protocol. Locally installed user certificates, enabled in the following steps, make it easier to set up a test lab. In a production environment, it is

recommended that you use smart cards, rather than locally installed user certificates, for EAP-TLS authentication.

**DC1**

**Configure DC1 for autoenrollment of user certificates**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, double-click **Certificate Templates**, click **Close**, and then click **OK**.
4. In the console tree, click **Certificate Templates**. All of the certificate templates will be displayed in the details pane. This is shown in the following figure.

5. In the details pane, click the **User** template.
6. On the **Action** menu, click **Duplicate Template**.
7. In the **Template display name** box, type **VPNUser**.
8. Verify that the **Publish Certificate in Active Directory** check box is selected. This is shown in the following figure.

9. Click the **Security** tab.
10. In the **Group or user names** list, click **Domain Users**.

11. In the **Permissions for Domain Users** list, select the **Read**, **Enroll,** and **Autoenroll** check boxes so that these permissions are allowed. This is shown in the following figure.

12. Click the **Subject Name** tab.

13. Clear the **Include E-mail name in subject name** and **E-mail name** check boxes. Because you did not configure an e-mail name for the VPNUser user account, you must clear these check boxes to allow a user certificate to be issued. This is shown in the following figure.

14. Click **OK**.

15. Open the **Certification Authority** snap-in from the **Administrative Tools** folder.

16. In the console tree, open **Certification Authority**, open **Example CA**, and then open **Certificate Templates**. This is shown in the following figure.

17. On the **Action** menu, point to **New**, and then click **Certificate Template to Issue**.

18. Click **VPNUser**. This is shown in the following figure.

19. Click **OK**.

20. Open the Active Directory Users and Computers snap-in.

21. In the console tree, double-click **Active Directory Users and Computers**, right-click the example.com domain, and then click **Properties**.

22. On the **Group Policy** tab, click **Default Domain Policy**, and then click **Edit**.

23. In the console tree, open **User Configuration**, open **Windows Settings**, open **Security Settings**, and then open **Public Key Policies**. This is shown in the following figure.

24. In the details pane, double-click **Autoenrollment Settings**.

25. Click **Enroll certificates automatically**. Select the **Renew expired certificates, update pending certificates, and remove revoked certificates** check box. Select the **Update certificates that use certificate templates** check box. This is shown in the following figure.

26. Click **OK**.

**IAS1**

**Configure IAS1 with a computer certificate for EAP-TLS authentication**

1. Restart IAS1 to ensure that IAS1 has autoenrolled a computer certificate.

2. Open the Internet Authentication Service snap-in.

3. In the console tree, click **Remote Access Policies**.

4. In the details pane, double-click **VPN remote access to intranet**. The **VPN remote access to intranet Properties** dialog box appears. This is shown in the following figure.

5. Click **Edit Profile**, and then click the **Authentication** tab. This is shown in the following figure.

6. On the **Authentication** tab, click **EAP Methods**. The **Select EAP Providers** dialog box appears. This is shown in the following figure.

7. Click **Add**. The **Add EAP** dialog box appears. This is shown in the following figure.

8. Click **Smart Card or other certificate**, and then click **OK**.

9. Click **Edit**. The **Smart Card or other Certificate Properties** dialog box appears. This is shown in the following figure.

10. The properties of the computer certificate issued to the IAS1 computer are displayed. This step verifies that IAS1 has an acceptable computer certificate installed to perform EAP-TLS authentication. Click **OK**.

11. Click **OK** to save changes to EAP providers. Click **OK** to save changes to the profile settings.

12. When prompted to view help topics, click **No**. Click **OK** to save changes to the remote access policy.

These configuration changes will allow the **VPN remote access to intranet** remote access policy to authorize VPN connections using the EAP-TLS authentication method.

**CLIENT1**

**Obtain a user certificate on CLIENT1, and then configure an EAP-TLS-based remote access VPN connection**

1. Shut down the CLIENT1 computer.

2. Disconnect CLIENT1 from the simulated Internet network segment, and connect it to the intranet network segment.

3. Restart CLIENT1 and log on using the VPNUser account. The computer and user Group Policy is automatically updated.

4. Shut down CLIENT1.
5. Disconnect CLIENT1 from the intranet network segment, and connect it to the simulated Internet network segment.
6. Restart CLIENT1 and log on using the VPNUser account.
7. On CLIENT1, in Control Panel, open the **Network Connections** folder.
8. In **Network Tasks**, click **Create a new connection**.
9. On the **Welcome to the New Connection Wizard** page of the New Connection Wizard, click **Next**.
10. On the **Network Connection Type** page, click **Connect to the network at my workplace**.
11. Click **Next**. On the **Network Connection** page, click **Virtual Private Network** connection.
12. Click **Next**. On the **Connection Name** page, type **EAPTLStoCorpnet** in **Company Name**.
13. Click **Next**. On the **Public Network** page, click **Do not dial the initial connection**.
14. Click **Next**. On the **VPN Server Selection** page, type **10.0.0.2** in **Host name or IP address**.
15. Click **Next**. On the **Connection Availability** page, click **Next**.
16. On the **Completing the New Connection Wizard** page, click **Finish**. The **Connect EAPTLStoCorpnet** dialog box appears. This is shown in the following figure.

17. Click **Properties**, and then click the **Security** tab.
18. On the **Security** tab, click **Advanced**, and then click **Settings**. The **Advanced Security Settings** dialog box appears.
19. In the **Advanced Security Settings** dialog box, click **Use Extensible Authentication Protocol (EAP)**. This is shown in the following figure.

20. Click **Properties**. In the **Smart Card or other Certificate Properties** dialog box, click **Use a certificate on this computer**. This is shown in the following figure.

21. Click **OK** to save changes to the **Smart Card or Other Certificate** dialog box. Click **OK** to save changes to the **Advanced Security Settings**. Click **OK** to save changes to the **Security** tab. The connection is immediately initiated using the installed user certificate. The first time you try to connect, it may take several attempts to successfully make a connection.

22. When the connection is successful, run the Web browser.

23. In **Address**, type **http://IIS1.example.com/iisstart.htm**. You should see a message saying the Web site is under construction.

24. Click **Start**, click **Run**, type **\\IIS1\ROOT**, and then click **OK**. You should see the contents of the local drive (drive C) on IIS1.

25. Right-click the **EAPTLStoCorpnet** connection, and then click **Disconnect**.

**Summary**

This guide described in detail the steps required to configure secure VPN remote access using PPTP, L2TP/IPsec, and EAP-TLS

in a test lab with five computers simulating an organization intranet and the Internet.

# Step-by-Step Guide for Setting Up a PPTP-based Site-to-Site VPN Connection in a Test Lab

Updated: April 15, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides an example with detailed information about how you can use five computers in a test lab environment to configure and test a Point-to-Point Tunneling Protocol (PPTP)-based site-to-site VPN connection using any 32-bit version of the Microsoft® Windows Server™ 2003 operating system with Service Pack 1 (SP1) as well as the Microsoft Windows® XP Professional operating system with Service Pack 2 (SP2).

You can use this example deployment to learn about Windows Server 2003 with SP1 site-to-site VPN functionality before you deploy a site-to-site VPN connection in a production environment. This test lab configuration simulates a deployment of a PPTP-based site-to-site VPN connection between the Seattle and New York offices of an organization.

| **Note** |
| --- |
| The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the functionality. This configuration is designed to reflect neither best practices nor a recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed to work only on a separate test lab network. |

**Setting Up the Test Lab**

The infrastructure for a PPTP-based site-to-site VPN deployment test lab network consists of five stand-alone computers performing the roles shown in Table 1. Each computer is part of a workgroup. None of the computers are joined to a domain.

In this test lab scenario, Windows Firewall is installed and turned-on automatically on the client computers running Windows XP Professional with SP2. You will configure a Windows Firewall exception on CLIENT1, allowing communication between the two client computers. On the three computers with Windows Server 2003 with SP1, Standard Edition, Windows Firewall is automatically installed, but it is not turned-on by default. On these computers, Windows Firewall will remain turned-off. In addition, the Windows Firewall/Internet Connection Sharing (ICS) service should be disabled on each of these computers.

**Table 1 Test Lab Computer Setup**

| Computer | Role |
| --- | --- |
| CLIENT1 running Windows XP Professional with SP2 | • Client computer |
| ROUTER1 running Windows Server 2003 with SP1, Standard Edition | • VPN Server<br>• Answering router |
| INTERNET running Windows Server 2003 with SP1, Standard Edition | • Internet router |
| ROUTER2 running Windows Server 2003 with SP1, Standard Edition | • VPN server<br>• Calling router |
| CLIENT2 running Windows XP Professional with SP2 | • Client computer |

In addition to these five computers, the test lab also contains four hubs (or Layer 2 switches):

- A hub that connects the Seattle office (CLIENT1) to the answering router (ROUTER1).
- A hub that connects the New York office (CLIENT2) to the calling router (ROUTER2).

- A hub that connects the answering router (ROUTER1) to the Internet router (INTERNET).
- A hub that connects the calling router (ROUTER2) to the Internet router (INTERNET).

| **Note** |
| --- |
| Because there are only two computers on each subnet, the hubs can be replaced by Ethernet crossover cables. |

The configuration of this test lab is shown in the following figure:

The IP addresses for the test lab configuration are shown in Tables 2, 3, and 4.

**Table 2 IP Addresses for the Seattle Office Subnet**

| Computer/Interface | IP Addresses |
| --- | --- |
| CLIENT1 | 172.16.4.3 |
| ROUTER1 (to the Seattle intranet) | 172.16.4.1 |

**Table 3 IP Addresses for the Internet Subnets**

| Computer/Interface | IP Addresses |
| --- | --- |
| ROUTER1 (to the Internet) | 10.1.0.2 |
| INTERNET (to ROUTER1, the answering router) | 10.1.0.1 |
| ROUTER2 (to the Internet) | 10.2.0.2 |
| INTERNET (to ROUTER2, the calling router) | 10.2.0.1 |

**Table 4 IP Addresses for the New York Office Subnet**

| Computer/Interface | IP Addresses |
| --- | --- |
| ROUTER2 (To the New York intranet) | 172.16.56.1 |
| CLIENT2 | 172.16.56.3 |

Configure your test lab by performing the following tasks:

1. Configure the client computers in the Seattle and New York offices.
2. Configure the computers performing as the answering and calling routers.
3. Configure the computer performing as the Internet router.

**Configuration for CLIENT1**

CLIENT1 is a client on the Seattle office subnet, running Windows XP Professional with SP2.

### Configure TCP/IP properties

1. Open **Network Connections**, right-click the network connection you want to configure, and then click **Properties**.
2. On the **General** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.

3. Click **Use the following IP address**, type **172.16.4.3** for the **IP address**, type **255.255.255.0** for the **Subnet mask**, and then type **172.16.4.1** for the **Default gateway**.

Installing Windows XP Professional with SP2 turns on Windows Firewall by default. You will need to configure port exceptions on the firewall allowing for communication between CLIENT1 and CLIENT2.

**Configure Windows Firewall on CLIENT1**

1. Click **Start**, point to **Control Panel**, and then click **Security Center**.
2. Click **Windows Firewall**, and then in the **Windows Firewall** dialog box, click the **Advanced** tab.
3. Click **Settings** for **ICMP**, and then click **Allow incoming echo request**.
4. Click **OK** twice to close **Windows Firewall**.

**Configuration for CLIENT2**

CLIENT2 is a client on the New York office subnet, running Windows XP Professional with SP2. Installing Windows XP Professional with SP2 turns on Windows Firewall by default. However, because CLIENT2's only role is as a calling computer, Windows Firewall does not need to be enabled with any exceptions. Leave the default Windows Firewall settings on CLIENT2.

**Configure TCP/IP properties**

1. Open **Network Connections**, right-click the network connection you want to configure, and then click **Properties**.
2. On the **General** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
3. Click **Use the following IP address**, and then type **172.16.56.3** for the **IP address**, type **255.255.255.0** for the **Subnet mask**, and then type **172.16.56.1** for the **Default gateway**.

**Configuration for the Answering and Calling Routers**

This section describes the setup for the routers in the test lab. For information about configuring routing and remote access for the answering router (ROUTER1) and the calling router (ROUTER2), see "Configuring a PPTP-based Site-to-Site VPN Connection" in this guide.

**ROUTER1**

ROUTER1 is a computer on the Seattle office subnet, running Windows Server 2003 with SP1, Standard Edition. ROUTER1 is acting as the answering router.

**Configure TCP/IP properties**

1. Open **Network Connections**, right-click the network connection you want to configure, and then click **Properties**.
2. On the **General** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
3. Configure the IP address and subnet mask with the following values:
   a. On the **To the Internet** interface, type **10.1.0.2** for the **IP address**, type **255.255.0.0** for the **Subnet mask**, and then type **10.1.0.1** for the **Default gateway**.
   b. On the **To the Seattle intranet** interface, type **172.16.4.1** for the **IP address**, type **255.255.255.0** for the **Subnet mask**. Leave the **Default gateway** clear.

Windows Firewall and Routing and Remote Access cannot run simultaneously on VPN1. If Windows Firewall is turned on, you will need to disable it. If the Windows Firewall/Internet Connection Sharing (ICS) service has started or is set to automatic before configuring Routing and Remote Access, you must disable it.

**Disable the Windows Firewall/Internet Connection Sharing (ICS) service**

1. Click **Administrative Tools**, and then click **Services**.
2. In the **Services** details pane, right-click **Windows Firewall/Internet Connection Sharing (ICS)** service, and then click **Properties**.
3. If the service **Startup Type** is either **Automatic** or **Manual**, change it to **Disabled**.
4. Click **OK** to close the **Windows Firewall/Internet Connection Sharing (ICS)** dialog box, and then close the **Services**

page.

#### ROUTER2

ROUTER2 is a computer on the New York office subnet, running Windows Server 2003 with SP1, Standard Edition. ROUTER2 is acting as the calling router.

**Configure TCP/IP properties**

1. Open **Network Connections**, right-click the network connection you want to configure, and then click **Properties**.
2. On the **General** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
3. Configure the IP address and subnet mask with the following values:
    a. On the **To the Internet** interface, type **10.2.0.2** for the **IP address**, type **255.255.0.0** for the **Subnet mask**, and then type **10.2.0.1** for the **Default gateway**.
    b. On the **To the Seattle intranet** interface, type **172.16.56.1** for the **IP address**, type **255.255.255.0** for the **Subnet mask**. Leave the **Default gateway** empty.

As with ROUTER1, you must turn off Windows Firewall on ROUTER2 and disable the Windows Firewall/ICS service.

**Disable the Windows Firewall/Internet Connection Sharing (ICS) service**

1. Click **Administrative Tools**, and then click **Services**.
2. In the **Services** details pane, right-click **Windows Firewall/Internet Connection Sharing (ICS)** service, and then click **Properties**.
3. If the service **Startup Type** is either **Automatic** or **Manual**, change it to **Disabled**.
4. Click **OK** to close the **Windows Firewall/Internet Connection Sharing (ICS)** dialog box, and then close the **Services** page.

#### Configuration for the Internet Router

INTERNET is a computer running Windows Server 2003 with SP1, Standard Edition.

**Configure TCP/IP properties**

1. Open **Network Connections**, right-click the network connection you want to configure, and then click **Properties**.
2. On the **General** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
3. Configure the IP address and subnet mask with the following values:
    a. On the **To Router1** interface, type **10.1.0.1** for the **IP address**, and then type **255.255.0.0** for the **Subnet mask**.
    b. On the **To Router2** interface, type **10.2.0.1** for the **IP address**, and then type **255.255.0.0** for the **Subnet mask**.
4. Click **Administrative Tools**, and then click **Routing and Remote Access** to open the Routing and Remote Access Microsoft Management Console (MMC) snap-in.
5. In the Routing and Remote Access snap-in, right-click **INTERNET (local)** in the console tree, and then click **Configure and Enable Routing and Remote Access**.
6. The Routing and Remote Access Server Setup Wizard opens. Click **Next**.
7. On the **Configuration** page, select **Custom configuration**, as shown in the following figure.

8. Click **Next**. On the **Custom Configuration** page, select **LAN routing**, as shown in the following figure.

9. Click **Next**. On the **Completing the Routing and Remote Access Server Setup** page, click **Finish**, and then click **Yes** to start the service.

Make sure that Windows Firewall is turned off and that the Windows Firewall/Internet Connection Sharing (ICS) service is disabled.

**Disable the Windows Firewall/Internet Connection Sharing (ICS) service**

1. Click **Administrative Tools**, and then click **Services**.
2. In the **Services** details pane, right-click **Windows Firewall/Internet Connection Sharing (ICS)** service, and then click **Properties**.
3. If the service **Startup Type** is either **Automatic** or **Manual**, change it to **Disabled**.
4. Click **OK** to close the **Windows Firewall/Internet Connection Sharing (ICS)** dialog box, and then close the **Services** page.

**Verify the routing infrastructure**

1. On **ROUTER1**, ping the IP address 10.2.0.2. This should be successful.
2. On **CLIENT2**, ping the IP address 172.16.4.3. This should be unsuccessful because CLIENT1 cannot be reached by

CLIENT2 across the simulated Internet until the site-to-site VPN connection is created.

**Configuring a PPTP-based Site-to-Site VPN Connection**
To create a PPTP-based VPN connection, perform the following tasks:

1. Configure VPN on the answering router.
2. Configure the demand-dial interface on the answering router.
3. Configure VPN on the calling router.
4. Configure the demand-dial interface on the calling router.
5. Confirm remote access policy configuration on the answering and calling routers.
6. Initiate the VPN connection.
7. Test the VPN connection.

**Configure VPN on the answering router (ROUTER1)**

1. On **ROUTER1**, click **Administrative Tools**, and then click **Routing and Remote Access**.
2. In Routing and Remote Access, right-click **ROUTER1 (local)** in the console tree, and then click **Configure and Enable Routing and Remote Access**.
3. The **Routing and Remote Access Server Setup Wizard** appears. Click **Next**.
4. On the **Configuration** page, select **Remote access (dial-up or VPN)**, as shown in the following figure.

5. Click **Next**. On the **Remote Access** page, select **VPN**, as shown in the following figure.

6. Click **Next**. On the **VPN Connection** page, select **To the Internet**, and then verify that the **Enable security on the selected interface by setting up static packet filters** check box is selected, as shown in the following figure.

7. Click **Next**. On the **IP Address Assignment** page, select **From a specified range of addresses**, as shown in the following figure.

8. Click **Next**. On the **Address Range Assignment** page, click **New**, as shown in the following figure.

9. In the **New Address Range** dialog box, do the following:

   a. In the **Start IP address** box, type **172.16.100.1**.

   b. In the **End IP address** box, type **172.16.100.2**.

   c. In the **Number of Addresses** box, accept the displayed value of **2**, as shown in the following figure.

10. Click **OK**. On the **Address Range Assignment** page, click **Next**.

11. On the **Managing Multiple Remote Access Servers** page, select **No, use Routing and Remote Access to authenticate connection requests**, as shown in the following figure.

12. Click **Next**. On the **Completing the Routing and Remote Access Server Setup** page, click **Finish**.

13. Click **OK** to close the message box prompting you to configure the DHCP Relay Agent. For this scenario the DHCP Relay Agent will not be configured.

**Configure the demand-dial interface on the answering router (ROUTER1)**

1. In the Routing and Remote Access snap-in, expand **ROUTER1**, and then right-click **Network Interfaces**.

2. Click **New Demand-dial Interface** to open the Demand-Dial Interface Wizard, and then click **Next**.

3. On the **Interface Name** page, type **VPN_NewYork**, as shown in the following figure. The interface name must match the user account name of the calling router.

4. Click **Next**. On the **Connection Type** page, select **Connect using virtual private networking (VPN)**, as shown in the following figure.

5. Click **Next**. On the **VPN Type** page, select **Point-to-Point Tunneling Protocol (PPTP)**, as shown in the following figure.

6. Click **Next**. On the **Destination Address** page, type **10.2.0.2** in the **Host name or IP address** box, as shown in the following figure.

7. Click **Next**. On the **Protocols and Security** page, do the following:

   a. Select **Route IP packets on this interface**.

   b. Select **Add a user account so a remote router can dial in**, as shown in the following figure.

8. Click **Next**. On the **Static Routes for Remote Networks** page, click **Add**, as shown in the following figure.

9. In the **Static Route** dialog box, do the following:

   a. In the **Destination** box, type **172.16.56.0**.

   b. In the **Network Mask** box, type **255.255.255.0**.

   c. In the **Metric** box, accept the displayed value **1**, as shown in the following figure.

10. Click **OK**. On the **Static Routes for Remote Networks** page, click **Next**.

11. On the **Dial In Credentials** page, type a password for the **VPN_NewYork** user account, and then retype the password in the **Confirm password** box. The **User name** box is automatically populated with the value **VPN_NewYork**.

12. Click **Next**. On the **Dial Out Credentials** page, do the following:

    a. In the **User name** box, type **VPN_Seattle**.

    b. In the **Domain** box, type **ROUTER2**.

    c. In the **Password** box, type a password for the **VPN_Seattle** user account.

    d. In the **Confirm password** box, retype the password for the **VPN_Seattle** user account, as shown in the following figure.

13. Click **Next**. On the last **Demand-Dial Interface Wizard** page, click **Finish**.
14. Click **OK** to close the message box prompting you to configure the DHCP Relay Agent. For this scenario the DHCP Relay Agent will not be configured.

**Configure VPN on the calling router (ROUTER2)**

1. On **ROUTER2**, click **Administrative Tools**, and then click **Routing and Remote Access**.
2. In Routing and Remote Access, right-click **ROUTER2 (local)** in the console tree, and then click **Configure and Enable Routing and Remote Access**.
3. The Routing and Remote Access Server Setup Wizard appears. Click **Next**.
4. On the **Configuration** page, select **Remote access (dial-up or VPN)**, and then click **Next**.
5. On the **Remote Access** page, select **VPN**, and then click **Next**.
6. On the **VPN Connection** page, select **To the Internet**, verify that the **Enable security on the selected interface by setting up static packet filters** check box is selected, and then click **Next**.
7. On the **IP Address Assignment** page, select **From a specified range of addresses**, click **Next**, and then on the **Address Range Assignment** page, click **New**.
8. In the **New Address Range** dialog box, do the following:
   a. In the **Start IP address** box: type **172.56.200.1**.
   b. In the **End IP address** box, type **172.56.200.2**.
   c. In the **Number of Addresses** box, accept the displayed value of **2**, and then click **OK**.
9. On the **Address Range Assignment** page, click **Next**.
10. On the **Managing Multiple Remote Access Servers** page, select **No, use Routing and Remote Access to authenticate connection requests**. Click **Next**.
11. On the **Completing the Routing and Remote Access Server Setup** page, click **Finish**.
12. Click **OK** to close the message box prompting you to configure the DHCP Relay Agent.

**Configure the demand-dial interface on the calling router (ROUTER2)**

1. In the Routing and Remote Access snap-in, expand **ROUTER2 (local)**, and then right-click **Network Interfaces**.
2. Click **New Demand-dial Interface** to open the Demand-dial Interface Wizard. To complete the Demand-Dial Interface

Wizard, click **Next**.

3. On the **Interface Name** page, type **VPN_Seattle**. The interface name must match the user account name of the answering router. Click **Next**.
4. On the **Connection Type** page, select **Connect using virtual private networking (VPN)**. Click **Next**.
5. On the **VPN Type** page, select **Point-to-Point Tunneling Protocol (PPTP)**. Click **Next**.
6. On the **Destination Address** page, type **10.1.0.2**, and then click **Next**.
7. On the **Protocols and Security** page, do the following:
   a. Select **Route IP packets on this interface**.
   b. Select **Add a user account so a remote router can dial in**, and then click **Next**.
8. On the **Static Routes for Remote Networks** page, click **Add**.
9. In the **Static Route** dialog box, do the following:
   a. In the **Destination** box, type **172.16.4.0**.
   b. In the **Network Mask** box, type **255.255.255.0**.
   c. In the **Metric** box, accept the displayed value **1**, and then click **OK**.
10. On the **Static Routes for Remote Networks** page, click **Next**.
11. On the **Dial In Credentials** page, type the password for the **VPN_Seattle** user account, and then retype the password in the **Confirm password** box. The **User name** box is pre-populated with the value **VPN_Seattle**. Click **Next**.
12. On the **Dial Out Credentials** page, do the following:
    a. In the **User name** box, type **VPN_NewYork**.
    b. In the **Domain** box, type **ROUTER1**.
    c. In the **Password** box, type the password for the **VPN_NewYork** user account created on **ROUTER1**.
    d. In the **Confirm password** box, retype the password for the **VPN_NewYork** user account, and then click **Next**.
13. On the last **Demand-Dial Interface Wizard** page, click **Finish**.

**Confirm the remote access policy configuration on the answering and calling routers**

1. On **ROUTER2**, in Routing and Remote Access, click **Remote Access Policies**.
2. In the details pane, right-click **Connections to Microsoft Routing and Remote Access server**, and then click **Properties**.
3. On the **Settings** tab, select **Grant remote access permission**, and then click **OK** to save changes.
4. Repeat steps 1 through 3 on **ROUTER1**.

Initiate the VPN connection by performing the following steps on ROUTER2.

**Initiate the VPN connection**

1. On **ROUTER2**, in the console tree of the Routing and Remote Access snap-in, click **Network Interfaces**.
2. In the details pane, right-click **VPN_Seattle**, and then click **Connect**.
3. Confirm that the connection state of **VPN_Seattle** is connected.

**Test the VPN connection**

1. On **CLIENT2**, at the command prompt, type **ping 172.16.4.3**.

   This is the IP address for CLIENT1. Pinging CLIENT1 from CLIENT2 will test whether the Seattle subnet is now reachable.

2. To confirm that the packets crossed the VPN connection, at the command prompt, type **tracert 172.16.4.3**. Note that you must use the IP address of CLIENT1, rather than its computer name, because a DNS server is not configured in this test lab scenario.

   Results that are similar to the following indicate that the connection is working.

```
Tracing route to 172.16.4.3 over a maximum of 30 hops:
     1    <1 ms    <1 ms    <1 ms  [172.16.56.1]
     2     1 ms    <1 ms    <1 ms  [172.56.200.2]
     3     1 ms     1 ms     1 ms  [172.16.4.3]
Trace complete.
```

| **Note** |
| --- |
| 172.16.56.1 is the IP address of the ROUTER2 interface that connects to the New York intranet. 172.56.200.2 is the IP address that ROUTER2 assigned to ROUTER1. The presence of this IP address in the Tracert output indicates that packets are moving across the site-to-site VPN connection. 172.16.4.3 is the IP address of CLIENT1. |

**Summary**

The preceding tasks describe how to configure a PPTP-based site-to-site VPN connection in a test lab with five computers. These five computers simulate two remote sites using VPN to connect over the Internet.

# Alerter (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Alerter

**Executable Name:** svchost.exe -k LocalService

**Log On As:** LocalService

**Description:** The Alerter service notifies selected users and computers of administrative alerts.

Use the Alerter service to send alert messages to specified users that are connected on your network.

Alert messages warn users about security, access, and user session problems. Alert messages are sent as messages from a server to a user's computer. The Messenger service must be running on the user's computer for the user to receive alert messages.

If this service is stopped or disabled, applications that use the NetAlertRaise or NetAlertRaiseEx APIs will be unable to notify a user or computer (by a message box from the messenger service) that the administrative alert took place.

*See also* **Messenger**.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Workstation

**The following system components depend on this service:** None

**Port Numbers used:**

TCP: 2869, dynamic

UDP: 1900

# Application Layer Gateway Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ALG

**Executable Name:** ALG.EXE

**Log On As:** LocalService

**Description:** This subcomponent of the Internet Connection Sharing (ICS) / Internet Connection Firewall (ICF) service provides support for independent software vendors (ISVs) to write protocol plug-ins that allow their proprietary network protocols to pass through the firewall and work behind ICS. Application Layer Gateway plug-ins have the power to open ports and change data (such as ports and IP addresses) embedded in packets. File Transfer Protocol (FTP) is the only network protocol that has a plug-in shipping with Windows Server 2003 Standard Edition and Windows Server 2003 Enterprise Edition.

The service listens for outgoing FTP traffic from an FTP client. It extracts the port that the FTP client is expecting to receive data from and creates an appropriate dynamic port mapping for the FTP data channel

If this service is disabled, the Internet Connection Firewall and Internet Connection Sharing service will not start. The ALG service will start when set to manual if the Internet Connection Firewall and Internet Connection Sharing service is started.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

None

**The following system components depend on this service:**

Internet Connection Firewall (ICF) / Internet Connection Sharing (ICS)

**IP Port Numbers used:**

TCP: 21, dynamically allocated

# Application Management (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** AppMgmt

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Provides software installation services, such as Assign, Publish, and Remove. This service processes requests to enumerate, install, and remove applications deployed via a corporate network. When you click Add in Add/Remove Programs on a computer joined to a domain, the program calls this service to retrieve the list of your deployed applications. The service is also called when you use Add/Remove Programs to install or remove an application, and in cases when a component (such as the shell or Component Object Model (COM)), makes an install request for an application to handle a file extension, COM class, or ProgID that is not present on the computer. The service is started by the first call made to it—it does not terminate once started.

If this service is disabled, deployed application information will not be retrieved nor will this information appear with Add/Remove Programs, Add New Programs. No programs are available on the network will be displayed in the Add programs from your network dialog box. Stopping this service is not possible once started. This service must be disabled to prevent it from starting if not required.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:** None

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# ASP .NET State Service

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Aspnet_state

**Executable Name:** aspnet_state.exe

**Log On As:** Network Service

**Description:** ASP State Service provides support for out-of-process session states for ASP. ASP has a concept of session state – a listing of values associated with the client session is accessible from ASP pages through the Session property. There are three options provided to store session data: In process; SQL database; and out-of-process. The ASP State Service stores session data out-of-process. The service communicates with ASP using sockets.

If this service is stopped or disabled, out of process requests will not be processed.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed Through:** Add/Remove Windows Components, Application Server, ASP.NET

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:** None

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 42424

# Automatic Updates (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Wuauserv

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Enables the download of updates from Microsoft's Windows Update Web site.

This service keeps your computer up-to-date automatically with the latest updates, drivers and enhancements from Microsoft. You no longer have to search for critical updates and information; Windows Update delivers them directly to your computer if configured. Windows recognizes when you are online and uses your Internet connection to search for downloads from the Windows Update page on the Microsoft Web site. A message appears on your desktop to let you know when new updates are available.

The Automatic Update feature can be turned off through the Systems setting in the Control Panel or by right mouse clicking My Computer and selecting Properties.

You can also use the MMC Group Policy Object Editor snap in administrative template to configure an intranet server to host updates from the Microsoft Update Web sites. This setting lets you specify a server on your network to function as an internal update service. The Automatic Updates client will search this service for updates that apply to the computers on your network.

Stopping or disabling this service has no effect on the rest of the operating system. The user will have to update their computer manually from the Windows Update Web site located at http://v4.windowsupdate.microsoft.com/en/default.asp.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Installed By:** Default

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:** None

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 80

# Background Intelligent Transfer Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** BITS

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Use Background Intelligent Transfer Service (BITS) to transfer files asynchronously between a client and an HTTP server. BITS is a background file transfer mechanism and queue manager. Requests to the BITS service are submitted and the files are transferred uses idle network bandwidth so that other network related activities, such as browsing, are not affected.

BITS suspends the transfer if a connection is lost or if the user logs off. BITS persists transfer information while the user is logged off, across network disconnects, and during machine restarts. When the user logs on, BITS resumes the user's transfer job.

BITS uses a queue to manage file transfers. You can prioritize transfer jobs within the queue and specify whether the files are transferred in the foreground or background. Background transfers are optimal in that BITS uses idle network bandwidth to transfer the files and will increase or decrease the rate (throttle) at which files are transferred based on the amount of idle network bandwidth available. If a network application begins to consume more bandwidth, BITS decreases its transfer rate to preserve the user's interactive experience.

BITS provides one foreground and three background priority levels that you can use to prioritize transfer jobs. Higher priority jobs preempt lower priority jobs; whereas, jobs at the same priority level share transfer time (round-robin scheduling prevents a large job from blocking the transfer queue). Lower priority jobs do not receive transfer time until all higher priority jobs are complete or in an error state.

The BITS service can be demand started when set to manual and the first job is submitted. When all outstanding jobs are completed, the BITS service will stop.

When stopped: If the service is stopped, features such as Automatic Update, and MSN Explorer will be unable to automatically download programs and other information until the BITS service has started.

When disabled: If this service is disabled, any services that explicitly depend on this service will fail to transfer files if they do not have a fail safe mechanism to transfer files directly through other methods such as Internet Explorer.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Installed By:** Default

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 80

# Certificate Service

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** CertSvc

**Executable Name:** CERTSVC.EXE

**Log On As:** LocalSystem

**Description:** Part of the core operating system that enables a business to act as if its own certificate authority (CA), and issue and manage digital certificates for applications such as Secure/Multipurpose Internet Mail Extensions (S/MIME), Secure Sockets Layer (SSL), Encrypting File System (EFS), IP Security (IPSEC), and smartcard log on.

If this service is stopped or disabled, certificate requests will not be accepted and the Certificate Revocation Lists (CRLs) and delta CRLs will not be published. If this service is paused or stopped long enough for CRLs to expire, validation of existing certificates will fail.

For more information about S/MIME and SSL, see "Certificate Services" in the Windows Server Distributed Services Guide.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition.

**Installed through:** Add/Remove Windows Components, Certificate Service

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:** None

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 1117

# Client Service for NetWare (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NWCWorkstation

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalService

**Description:** Provides access to files and directories as well as resources on NetWare networks.

With Client Service for Netware, you can access file and print resources on Netware Servers that are running Novell Directory Services (NDS) or bindery security (Netware versions 3.x or 4.x) from your computer.

The Client Service for Netware does not support the IP protocol and therefore cannot be used to interoperate with NetWare 5.x in an IP-only environment. To do this, you must load the IPX protocol onto the Netware 5.x server, or use a redirector that is compatible with Netware Core Protocol (NCP) and supports native IP.

If this service is stopped or disabled, access to file and print resources on NetWare networks will no longer function unless the Novell Client for NetWare is installed.

**Available on:** Windows XP Home Edition; Windows XP Professional Edition; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add-on via Network Connections, Client

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:** None

**The following system components depend on this service:** None

**IP Port Numbers used:**

UDP: 213 (IPX Over IP)

# Clipbook (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ClipSrv

**Executable Name:** clipsrv.exe

**Log On As:** LocalSystem

**Description:** Enables the Clipbook Viewer to create and share "pages" of data to be viewed by remote computers.

This service depends on the (NetDDE) Network Dynamic Data Exchange service to create the actual file shares that other computers can connect to, while the Clipbook application and service allow users to create the pages of data to share.

This service is disabled by default. When this service is disabled and Clipbrd.exe is launched, Clipbrd.exe can still be used to view the local Clipboard (where data is stored when a user highlights text and then goes to the **Edit** menu and selects **Copy**, or types **Ctrl+C**).

**Available on:** Windows XP Home Edition; Windows XP Professional Edition; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Installed by:** Default

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Network DDE

Network DDE DSDM

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# Cluster Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ClusSvc

**Executable Name:** Clussvc.exe

**Log On As:** Domain account specified when cluster service is configured

**Description:** Server clusters provide high availability and scalability for mission-critical applications such as databases, messaging systems, and file and print services. If one of the nodes in a cluster becomes unavailable either due to planned downtime for maintenance or unplanned downtime due to failure of a node, the operating system or an application, another node takes over to provide the service to the end-user—a process known as failover. When failover occurs, users who are accessing the cluster service continue to access the service, and are unaware that it is now being provided from a different server (node).

Supports for up to 8-node server clusters in both Enterprise Server and Datacenter Server, however, a cluster cannot be made up of nodes running both Windows Server 2003 Enterprise Server and Windows Datacenter Server, they must all be running either Enterprise server or Datacenter server. A server cluster can be operated with some nodes running Windows 2000 and others running Windows Server as part of a rolling upgrade scenario.

**Server clusters can be set up as one of three different configurations:**

- Single node server clusters can be configured with, or without, external cluster storage devices. For single node clusters without an external cluster storage device, the local disk is configured as the cluster storage device. Single node configurations can be used to develop cluster aware applications or can be used in production to provide the local health monitoring and restart capabilities to applications.

- Single quorum device server clusters have two or more nodes and are configured so that every node is attached to one or more cluster storage devices. The cluster configuration data is stored on a single cluster storage device known as the quorum disk.

- Majority node set server clusters have two or more nodes where the nodes may or may not be attached to one or more cluster storage devices. The cluster configuration data is stored on multiple disks across the cluster and the Cluster service makes sure that this data is kept consistent across the different disks.

If this service is stopped or disabled, the cluster service itself and any applications or services hosted by the cluster service will be stopped.

**Available on:** Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Not started until the first node of a cluster is configured.

**This service depends on the following system components:**

Network Connections

Remote Procedure Call

Windows Time

Network Cluster Driver

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 3343

UDP: 1204, 1094, 2036, 2008, 3343

# COM+ Event System

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** EventSystem

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Provides automatic distribution of events to subscribing COM (Component Object Model) components. COM+ Events extend the COM+ programming model to support late-bound events or method calls between the publisher or subscriber and the event system. Instead of repeatedly polling the server, the event system notifies interested parties as information becomes available.

COM+ Events handle most of the event semantics for the publisher and subscriber. Publishers offer to publish event types, and subscribers request event types from specific publishers. Subscriptions are maintained outside both the publisher and subscriber and are retrieved when needed. This simplifies the programming model. The subscriber does not need to contain the logic for building subscriptions—building a subscription is as easy as building a COM component. The life cycle of the subscription is separate from that of either the publisher or the subscriber. Subscriptions can be built prior to either the subscriber or publisher being made active.

If the service is disabled, you will be prompted to also stop the SENS (System Event Notification) service as well since SENS is dependent upon this service and logon and log off notifications will not occur and other inbox applications, such as Volume Snapshot service, will not work correctly.

**Available on:** Windows XP, Home Edition; Windows XP, Professional Edition; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:**

System Event Notification

DHCP Server

COM+ System Application

**IP Port Numbers used:** None

# COM+ System Application

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** COMSysApp

**Executable Name:** dllhost.exe /Processid:{02D4B3F1-FD88-11D1-960D-00805FC79235}

**Log On As:** LocalSystem

**Description:** The COM+ system application hosts COM+ services and manages COM+ application configuration and tracking.

COM+ applications will not work if the COM+ system application is disabled, also you will not be able to administer anything to do with COM+ or OLE registrations on the system.

If you disable the MS DTC (Microsoft Distributed Transaction) service, any COM+ system applications will fail because this service needs local transactions to maintain its state.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

# Computer Browser (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Browser

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Maintains an up-to-date list of computers on your network, and supplies the list to programs that request it. The Computer Browser service is used by Windows-based computers that need to view network domains and resources. Computers designated as browsers maintain browse lists, which contain all shared resources used on the network. Earlier versions of Windows applications, such as My Network Places, the NET VIEW command, and the Microsoft Windows NT Explorer, all require browsing capability.

There are several different roles a computer may perform in a browsing environment. Under some conditions (such as failure or shutdown of a computer designated for a specific browser role) browsers—or potential browsers—may change to a different role of operation. Windows NT assigns the following special roles to computers running the Computer Browser service:

- **Domain Master Browser** - Used only in domain environments. By default, the DC (domain controller) for a domain operates in this role. The domain master browser collects and maintains the master browse list of available servers for its domain, in addition to any names for other domains and workgroups used in the network. It also distributes and synchronizes the master browse list for master browsers on other subnets that have computers belonging to the same domain.

- **Master Browser** - Collects and maintains the list of available network servers in its subnet. The master browser fully replicates its listed information with the domain master browser to obtain a complete browse list for the network, and distributes it to backup browsers located on the same subnet.

- **Backup Browser** - The backup browser receives a copy of the browse list from the master browser for its subnet, and distributes it to other computers upon request.

- **Potential Browser** - Capable of becoming a backup browser when instructed to by the subnet's master browser, the potential browser operates similarly to a non-browser under normal conditions.

- **Nonbrowser** - A nonbrowser is configured so it cannot become a browser, and it does not maintain a browse list. It can operate as a browse client, requesting browse lists from other computers operating as browsers on the same subnet. When the Computer Browser service is turned off there is no mechanism to discover other computers to populate the My Network Places, and so on.

If this service is stopped or disabled, computer browsing features will not be available.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Server

Workstation

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 139

UDP: 137(browsing requests of NETBIOS over TCP/IP), 138 (browsing datagram responses of NetBios over TCP/IP)

# Cryptographic Services (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** CryptSvc

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Provides key management services for your computer. The Cryptographic Service is comprised of three management services: Catalog Database Service, Protected Root Service, and Key Service.

- Catalog Database Service - This part of the service is responsible for adding, removing, and looking up catalog files. Catalog files are used to bulk sign all the files in the operating system. So, this service is used by Windows File Protection (WFP), Driver Signing, and setup to verify signed files.

- Protected Root Service - This part of the service is responsible for adding and removing Trusted Root Certification Authority certificates for the current user. It displays a service message box with the certificate's name and thumbprint. If the user clicks OK, the certificate is added to or removed from the current user's list of trusted root authorities. Only Local System has write access to this list. If this part of the service is turned off, the current user will not be able to add or remove Trusted Root Certificate Authority certificates.

- Key Service - This part of the service allows administrators to enroll for certificates on behalf of the local machine account. To that end, it provides several pieces of functionality required for enrollment -- enumeration of available Certification Authorities, enumeration of available machine templates, the ability to create and submit a certificate request in the local machine context, and so on. Only administrators may enroll on behalf of the local machine account.

If this service is disabled, administrators will not be able to enroll for machine certificates and auto enrollment will not be able to automatically acquire the default set of machine certificates. Also, WFP and driver signing will not be able to check the signatures of the operating system files.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

# DHCP Client (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Dhcp

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** NetworkService

**Description:** Dynamic Host Configuration Protocol (DHCP) Client manages network configuration by registering and updating IP addresses and Domain Name Server (DNS) names for your computer. You do not have to manually change the IP settings when a client, such as a roaming user, wanders throughout the network. The client is automatically given a new IP address regardless of the subnet it reconnects to—as long as a DHCP server is accessible from each of those subnets. There is no need to manually configure settings for DNS or Windows Internet Name Service (WINS). The DHCP server can give these settings to the client, as long as the DHCP server has been configured to issue such information. To enable this option on the client, simply select the Obtain DNS Server Address Automatically option button. There are no conflicts caused by duplicate IP addresses.

If this service is stopped or disabled, you will not be able to obtain an IP address from a DHCP Server and you will have to configure a static IP address on the local machine. If this service is set to manual it will not demand start.

See also **DHCP Server**, **Manage Your Server**, **Configure Your Server**.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

UDP: 67, 68, 1029

# DHCP Server (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** DHCPServer

**Executable Name:** tcpsvcs.exe

**Log On As:** LocalSystem

**Description:** The DHCP Server service allocates IP addresses and allows the advanced configuration of network settings such as DNS servers, WINS servers to DHCP clients automatically.

DHCP uses a client-server model. The network administrator establishes one or more DHCP servers that maintain TCP/IP configuration information and provide it to clients. The server database includes the following:

- Valid configuration parameters for all clients on the network.
- Valid IP addresses maintained in a pool for assignment to clients, plus reserved addresses for manual assignment.
- Duration of a lease offered by the server. The lease defines the length of time for which the assigned IP address can be used.

Dynamic Host Configuration Protocol (DHCP) is an IP standard designed to reduce the complexity of administering address configurations by using a server computer to centrally manage IP addresses and other related configuration details used on your network. The Windows Server family provides the DHCP service, which enables the server computer to perform as a DHCP server and configure DHCP-enabled client computers on your network as described in the current DHCP draft standard, RFC 2131.

DHCP includes the Multicast Address Dynamic Client Assignment Protocol (MADCAP) which is used to perform multicast address allocation. When registered clients are dynamically assigned IP addresses through MADCAP, they can participate efficiently in the data stream process, such as for real-time video or audio network transmissions.

With a DHCP server installed and configured on your network, DHCP-enabled clients can obtain their IP address and related configuration parameters dynamically each time they start and join your network. DHCP servers provide this configuration in the form of an address-lease offer to requesting clients. With a DHCP server installed and configured on your network, DHCP-enabled clients can obtain their IP address and related configuration parameters dynamically each time they start and join your network. DHCP servers provide this configuration in the form of an address-lease offer to requesting clients.

If the DHCP Server service is stopped or disabled off, DHCP clients will not automatically receive IP addresses or network settings. See also **DHCP Client**, **Configure Your Server**, **Manage Your Server**.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

# Distributed File System (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** DFS

**Executable Name:** dfssvc.exe

**Log On As:** LocalSystem

**Description:** The Distributed File System (DFS) service manages logical volumes distributed across a local or wide area network. DFS is a single hierarchical file system, the contents of which are distributed across the network. DFS provides a logical tree structure for file system resources that may be anywhere on the network. Since the DFS tree is a single point of reference, regardless of the actual location of the underlying resources, you can access network resources based on a meaningful representation of the data. You no longer need to know and specify the actual physical location of files distributed across the network.

If the DFS service is stopped or disabled, users will be unable to access network data through the logical namespace and any attempt to configure a DFS root using the MMC DFS snap in will result in an RPC error. In order to for users to access the data, users will need to know the names of all the servers and shares in the namespace, and access each of these targets independently.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default

**Startup type:** Automatic

**Service status:** Started

UDP: None

# Distributed Link Tracking Client (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Trkwrks

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Maintains links between the NTFS file system files within a computer or across computers in a network domain. The DLT Client service ensures that shortcuts and OLE (Object Linking and Embedding) links continue to work after the target file is renamed or moved. When a shortcut to a file on an NTFS v5 volume is created, distributed link tracking stamps a unique object identifier (ID) into the target file, known as the link source. Information about the object ID is also stored within the referring file, known as the link client.

Distributed link tracking can use this object ID to locate the link source file in any combination of the following scenarios that occur within a Windows domain:

- The link source file is renamed.
- The link source file is moved to another folder on the same volume or to a different volume on the same computer.
- The link source file is moved from one NTFS volume to another within the same domain. (The NTFS volumes must be on computers running Windows 2000 or later. The NTFS volumes cannot be on removable media.)
- The computer containing the link source file is renamed.
- The shared network folder containing the link source file is renamed.
- The volume containing the link source file is moved to another computer within the same domain.

Distributed link tracking also attempts to maintain links even when they do not occur within a domain, such as cross-domain, within a workgroup, or on a single computer that is not connected to a network. Links can always be maintained in these scenarios when a link source is moved within a computer, or when the network shared folder on the link source computer is changed. Typically, links can be maintained when the link source is moved to another computer, though this form of tracking is less reliable over time.

Distributed link tracking uses different services for client and server:

- The DLT Client service runs on all Windows 2000-based or later computers. In non-networked computers, the DLT Client service performs all activities related to link tracking.
- The DLT Server service runs on Windows 2000 Server or later domain controllers. The service maintains information relating to the movement of link source files. Because of this service and the information it maintains, links within a domain are more reliable than those outside a domain. For computers that run in a domain, the DLT Client service takes advantage of this information by communicating with the DLT Server service.

| **Note** |
| --- |
| The DLT Client service monitors activity on NTFS volumes and stores maintenance information in a file called Tracking.log, which is located in a hidden folder called System Volume Information at the root of each volume. This folder is protected by permissions that allow only the system to have access to it. The folder is also used by other Windows services, such as Indexing Service.<br><br>If the DLT Client service is disabled, you won’t be able to track links. Likewise, users on other computers won’t be able to track links for documents on your computer. |

*See also* **Distributed Link Tracking Server**.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# Distributed Link Tracking Server (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** TrkSrv

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The distributed link tracking server runs on each domain controller in a domain. The service accepts notifications of file and volume moves from the tracking service on a computer and allows the distributed link tracking client to query a link source's current location.

This server service maintains information in the DC about volumes and files which have been moved. The information on moves cannot grow above a certain size and it is automatically removed if it becomes unnecessary.

The distributed link-tracking services are available only on NTFS, and are only available for link sources on NTFS 5.0 and later volumes. Thus if a link source is moved to a FAT volume, or if a link source is moved to a computer running Windows NT 4.0, the tracking information is lost. Additionally, if a link source is moved even between NTFS 5.0 volumes, but the computer performing the move is running an earlier version of Windows NT or Windows 95/98/Me, the link tracking information is lost. When the link tracking information is lost, no harm is done to the link-source file itself, it is simply not trackable by the distributed link-tracking services.

Links to files on removable media are not maintained. Also, the tracking service does not recognize a new NTFS volume until the system is rebooted. A new volume might become available because of repartitioning, reformatting a FAT volume to NTFS, or connecting a new external drive. The service accepts notifications of file and volume moves from the tracking service on a computer and allows the distributed link tracking client to query a link source's current location.

If the DLT server service is stopped or disabled, links maintained by the DLT Client service will be unreliable. The "NtfsDisableDomainLinkTracking" policy should be enabled in the File system policy group to prevent DLT clients from repeatedly trying to reach the disabled service.

*See also* **Distributed Link Tracking Client**.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

# Distributed Transaction Coordinator (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MSDTC

**Executable Name:** msdtc.exe

**Log On As:** NetworkService

**Description:** Coordinates transactions that are distributed across multiple computer systems and/or resource managers, such as databases, message queues, file systems, or other transaction-protected resource managers. The Distributed Transaction Coordinator is necessary if transactional components are going to be configured through Component Services (COM+). It is also required for transactional queues in Message Queuing (MSMQ) and Microsoft SQL Server operations that span multiple systems.

Stopped or disabling this service prevents the transactions described above from occurring.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

Security Accounts Manager

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# DNS Client (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Dnscache

**Executable Name:** svchost.exe -k NetworkService

**Log On As:** NetworkService

**Description:** The Domain Name System (DNS) client service resolves and caches DNS names. The DNS client service must be running on every computer that will perform DNS name resolution. The ability to resolve DNS names is crucial for locating domain controllers in Active Directory domains. The DNS client service is also critical for locating devices identified using DNS name resolution.

The DNS Client service running on Windows implements the following features:

- System-wide caching

  Resource records (RRs) from query responses are added to the client cache as applications query DNS servers. This information is then cached for a set Time to Live (TTL) and can be used again to answer subsequent queries.

- RFC-compliant negative caching support

  In addition to caching positive query responses from DNS servers (which contain resource record information in the answered reply), the DNS Client service also caches negative query responses. A negative response results when a resource record for the queried name does not exist.

  Negative caching prevents the repeating of additional queries for names that do not exist, which can adversely affect client system performance. Any query information negatively cached is kept for a shorter period of time than is used for positive query responses; by default, no more than 5 minutes. This avoids continued negative caching of stale information if the records later become available.

  Negative caching is a new DNS standard specification defined in RFC 2308. For more information, refer to this RFC. For more information on obtaining RFCs, see TCP/IP RFCs.

- Avoidance of unresponsive DNS servers

  The DNS Client service uses a server search list, ordered by preference. This list includes all preferred and alternate DNS servers configured for each of the active network connections on the system. Windows rearranges these lists based on the following criteria:

  - Preferred DNS servers are given first priority.
  - If no preferred DNS servers are available, then alternate DNS servers are used.
  - Unresponsive servers are removed temporarily from these lists.

If the DNS client service is stopped or disabled on your computer, you may not be able to locate the domain controllers of the Active Directory domains and will no longer be able to locate the devices identified using DNS names.

*See also* **DNS Server**.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

TCP/IP Protocol Driver

IPSEC Driver

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 53

# DNS Server (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** DNS

**Executable Name:** dns.exe

**Log On As:** LocalSystem

**Description:** Enables DNS name resolution by answering queries and update requests for DNS names. Presence of the DNS servers is crucial for locating devices identified using DNS names and locating domain controllers in Active Directory. If there is no authoritative DNS for a particular portion of the namespace, then locating devices in that portion of the namespace will fail. Not having the authoritative DNS server for the DNS namespace used to resolve Active Directory domains results in an inability to locate the domain controllers for such domain.

If this service is stopped or disabled, DNS name or device resolution will not be reliable.

*See also* **DNS Client**, **Configure Your Server**, **Manage Your Server**.

# Error Reporting Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ERSvc

**Executable Name:** svchost.exe –k netsvcs

**Log On As:** LocalSystem

**Description:** The Error Reporting Service provides an infrastructure for collecting, storing and reporting kernel mode, operating system and application faults to Microsoft. Error reporting helps Microsoft track and address errors. You can configure error reporting to send Microsoft specific error information and to generate reports for operating system errors, Windows component errors or program errors. An operating system error causes the computer to display a blue screen with error codes. A program or component error causes the program or component to stop working.

If you have an Internet connection, you can report these errors directly to Microsoft. You can configure error reporting to respond to program errors in one of two ways: as soon as an error occurs, the error reporting dialog box can prompt any user to send the error to Microsoft, or the next time an administrator logs on, the error reporting dialog box can prompt the administrator to send the error report to Microsoft.

Windows treats operating system errors and unplanned shutdowns differently from the way it does program errors. When operating system errors or unplanned shutdowns occur, Windows writes the error information to a log file. The next time an administrator logs on, the error reporting dialog box prompts them to report the error.

When you send an error report to Microsoft over the Internet, you provide technical information that programming groups at Microsoft use to enhance future versions of the product. This data is used for quality control purposes only and is not used for tracking individual users or installations for any marketing purpose. If information is available to help you solve the problem, Windows displays an Error Reporting dialog box with a link to that information.

Alternatively, if your organization has configured Group Policy, administrators in your information technology (IT) department can use Corporate Error Reporting to collect and report to Microsoft only those errors that they think are important. Administrators configure workstations and servers for Corporate Error Reporting by enabling the Report Errors policy setting and configuring the Corporate upload file path to the local file server where the Corporate Error Reporting tool is installed. When errors occur, they are automatically redirected to this file server. Administrators can then review the error information, identify the important data, and submit it to Microsoft using the Corporate Error Reporting tool. You can download the Corporate Error Reporting tool from the Office XP Resource Kit Web site (http://www.microsoft.com/office/).

If error reporting is stopped or disabled, users will not be given the option to report errors. If Display Error Notification is enabled, users will still get a message indicating that a problem occurred, but will not have the option to report this information to Microsoft or a local network share.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

TCP: 80

# Event Log (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Eventlog

**Executable Name:** services.exe

**Log On As:** LocalSystem

**Description:** This service logs event messages issued by programs and the Windows operating system. Event Log reports contain information that can be useful in diagnosing problems. Reports are viewed in Event Viewer. The Event Log service writes events sent by applications, services, and the operating system to log files. The events contain diagnostic information in addition to errors specific to the source application, service, or component. The logs can be viewed programmatically through the Event Log APIs or through the Event Viewer in an MMC (Microsoft Management Console) snap-in.

By default, a computer running Windows 2000 Server, Windows XP and Windows Server 2003, records events in three kinds of logs:

**Application log**

- The application log contains events logged by applications or programs. For example, a database program might record a file error in the application log. Program developers decide which events to log.

**Security log**

- The security log records events such as valid and invalid logon attempts, as well as events related to resource use such as creating, opening, or deleting files or other objects. For example, if logon auditing is enabled, attempts to log on to the system are recorded in the security log.

**System log**

- The system log contains events logged by Windows system components. For example, the failure of a driver or other system component to load during startup is recorded in the system log. The event types logged by system components are predetermined by the server.

A computer running a Windows Server 2003 family operating system configured as a domain controller records events in two additional logs:

**Directory service log**

- The directory service log contains events logged by the Windows Active Directory service. For example, connection problems between the server and the global catalog are recorded in the directory service log.

**File Replication service log**

- The File Replication service log contains events logged by the Windows File Replication service. For example, file replication failures and events that occur while domain controllers are being updated with information about system volume changes are recorded in the file replication log.

A computer running Windows configured as a Domain Name System (DNS) server records events in an additional log:

**DNS server log**

- The DNS server log contains events logged by the Windows DNS service.

If the event log is disabled, you will be unable to track events, which will significantly reduce the ability to successfully diagnose system problems. In addition security events will not be audited and you will not be able to view previous event logs using the

MMC event viewer snap in.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

# Fast User Switching Compatibility

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** FastUserSwitchingCompatibility

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Provides management services for applications that require assistance in a multiple user environment. This service is responsible for activating the application compatibility shims for Fast User Switching. Fast User Switching allows multiple users to log on and run applications on a single machine. Some applications (usually non-Windows 2000 logo applications) are not able to run in this environment. We have created shims that allow these applications to run in a multiple user environment. This service only starts if there is more than one user logged on to the machine. It does not activate when there is only one user on the machine. Fast User Switching only works on Personal and Professional when joined to a workgroup. Thus, machines joined to a domain are not affected by this service.

If the service is stopped or disabled, the shims* used to make applications work in a multiple user environment will not occur. You will not have application compatibility for known Fast User Switching issues.

*Shims are application compatibility fixes which are used to address application compatibility issues reported to Microsoft.

**Available on:** Windows XP Home, Windows XP Professional.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

# Fax (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Fax

**Executable Name:** fxssvc.exe

**Log On As:** LocalSystem

**Description:** The Fax service, a TAPI-compliant service, provides fax capabilities from your computer. The Fax service allows users to send and receive faxes from their desktop applications using either a local fax device or a shared network fax device. The service offers the following features:

- Send and receive faxes
- Track and monitor fax activity
- Routing of inbound faxes
- Server and device configuration management
- Archiving of sent faxes

If stopped, the Fax service will automatically start when there are fax jobs pending in the queue and will stop when no longer needed to process fax requests. If the print spooler or telephony service is disabled, the Fax service will not start successfully.

*See also* **Print Spooler**, **Telephony**.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Installed by:** Add/Remove Windows Components

# File Replication (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NtFrs

**Executable Name:** ntfrs.exe

**Log On As:** LocalSystem

**Description:** Enables files to be automatically copied and maintained simultaneously on multiple servers. File Replication Service (FRS) is the automatic file replication service in Windows 2000 and the Windows Server 2003 family and its function is to replicate the volume (Sysvol) on all domain controllers. In addition, it can be configured to replicate files among alternate targets associated with the fault-tolerant Distributed File System (DFS).

This service that provides multimaster file replication for designated directory trees between designated servers running Windows 2000 or Windows Server 2003. The designated directory trees must be on disk partitions formatted with the version of NTFS used within the Windows Server 2003 family. FRS is used by the Distributed File System (DFS) to automatically synchronize content between assigned replicas and by Active Directory to automatically synchronize content of the system volume information across domain controllers.

If this service is stopped or disabled, file replication will not occur and server data will not be synchronized. Stopping the File Replication service on a domain controller may seriously impair a domain controllers ability to function.

For more information about FRS, see "File Replication Service" in the Windows Server Distributed Services Guide.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

# File Server for Macintosh (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MacFile

**Executable Name:** sfmsvc.exe

**Log On As:** LocalSystem

**Description:** This service enables Macintosh users to store and access files on a NTFS volume on a Windows Server. Encrypted files on an NTFS volume are not accessible from Macintosh clients.

If this service is stopped or disabled, Macintosh clients will not be able to view NTFS shares.

*See also* **Print Server for Macintosh**.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition.

**Installed through:** Add/Remove Windows Components

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Workstation

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 548

UDP: 548

# FTP Publishing Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MSFtpsvc

**Executable Name:** inetinfo.exe

**Log On As:** NetworkService

**Description:** Provides File Transfer Protocol (FTP) connectivity and administration through the Internet Information Service (IIS) snap-in. Features include bandwidth throttling, security accounts, and extensible logging. This includes the new FTP User Isolation feature, which allows users to access only their files on an FTP site. In addition, there is improved international support.

If the service is stopped or disabled, the computer cannot function as an FTP server.

**Available on:** Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components, Application Server, Internet Information Services (IIS).

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

IIS Admin Service

Remote Procedure Call

Security Accounts Manager

**The following system components depend on this service:** None

**IP Port Numbers used:**

# Help and Support (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Helpsvc

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Provides Help and Support application and framework functionality.

The help service supports the Help and Support Center application and enables communication between the client application and the help data it accesses. This includes access to stores and services such as the taxonomy database that contains metadata and information about the help topics, the support automation framework that enables data collection for registered support providers, user history and preference information, and the search engine manager. When a user is interacting with the Help and Support Center features like search, index, table of contents, and so on, the service allows for data transaction that supports all of these features.

If this service is set to manual, launching Help and Support in the user interface will start this service. Disabling this service renders the Help and Support Center essentially unusable and the user will receive a message Windows cannot open Help and Support because a system service is not running. The user can access some topics at a high level that might have been cached on the local system, but most of the help and support application features cannot function without the help service enabled. *.HLP and *.CHM files located in the Windows\Help directory can still be viewed, however.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed by:** Default operating system installation

**Startup type:** Automatic

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 80

# HTTP SSL

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** HTTPFilter

**Executable Name:** lsass.exe

**Log On As:** LocalSystem

**Description:** Enables Internet Information Services (IIS) to perform Secure Sockets Layer (SSL) functions. SSL is a proposed open standard for establishing a secure communications channel to prevent the interception of critical information, such as credit card numbers. Primarily, it enables secure electronic financial transactions on the World Wide Web, although it is designed to work on other Internet services as well. If IIS is not installed, the HTTP SSL service will depend on the HTTP driver to perform SSL functions.

If this service is stopped or disabled, If this service is stopped, the IIS service would stop . Any HTTP requests aimed for IIS would not be handled.. This service is called SSL for HTTP.SYS on Windows XP Professional.

For more information about SSL, see "Secure Web Communications", in the Windows Server 2003 Resource Kit Internet Information Services Resource Guide.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

IIS Admin Service

UDP: 443

# Human Interface Device Access (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Hidserv

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** This service provides generic access to specific functions contained within controls collections on HID (Human Interface Devices). It enables the use of predefined hot buttons on keyboards, remote controls and other multimedia devices.

If the service is stopped or disable, the buttons on USB keyboards will not function (i.e., back, forward, volume up, down, previous track, next track), nor will the volume buttons on USB speakers.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# IAS Jet Database Access (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** IASjet

**Executable Name:** svchost.exe –k iasjet

**Log On As:** LocalSystem

**Description:** The IAS Jet Database Access service uses the Remote Authentication Dial-in User Service (RADIUS) protocol to provide authentication, authorization, and accounting services. With IAS, you can centrally manage the authentication, authorization, and accounting of users. You can also use IAS to authenticate users in databases on your domain controller running Windows NT 4.0, Windows 2000, or Windows Server operating systems. IAS works equally well in homogeneous and heterogeneous networks running Windows Server operating systems.

Internet Authentication Service (IAS) can be used as a RADIUS proxy to provide the routing of RADIUS messages between RADIUS clients (access servers) and RADIUS servers that perform user authentication, authorization, and accounting for the connection attempt. When used as a RADIUS proxy, IAS is a central switching or routing point through which RADIUS access and accounting messages flow. IAS records information in an accounting log about the messages that are forwarded.

A RADIUS authentication, authorization, and accounting infrastructure consists of the following components:

**Access clients**

An access client is a device that requires some level of access to a larger network. Examples of access clients are dial-up or virtual private network (VPN) clients, wireless clients, or LAN clients connected to a switch.

**RADIUS clients (access servers)**

An access server is a device that provides some level of access to a larger network. An access server using a RADIUS infrastructure is also a RADIUS client, sending connection requests and accounting messages to a RADIUS server. Examples of access servers are:

- **Network access servers** (NASs) that provide remote access connectivity to an organization network or the Internet. An example is a Windows 2000 computer running the Routing and Remote Access service and providing either traditional dial-up or virtual private network (VPN) remote access services to an organization's intranet.

- **Wireless access points** that provide physical layer access to an organization's network, using wireless-based transmission and reception technologies.

- **Switches** that provide physical layer access to an organization's network, using traditional LAN technologies such as Ethernet.

**RADIUS proxies**

A RADIUS proxy is a device that forwards or routes RADIUS connection requests and accounting messages between RADIUS clients (and RADIUS proxies) and RADIUS servers (or RADIUS proxies). The RADIUS proxy uses information within the RADIUS message, such as the User-Name or Called-Station-ID RADIUS attributes, to route the RADIUS message to the appropriate RADIUS server.

A RADIUS proxy can be used as a forwarding point for RADIUS messages when the authentication, authorization, and accounting must occur at multiple RADIUS servers in different organizations.

**RADIUS servers**

A RADIUS server is a device that receives and processes connection requests or accounting messages sent by RADIUS clients or RADIUS proxies. In the case of connection requests, the RADIUS server processes the list of RADIUS attributes in the connection request. Based on a set of rules and the information in the user account database, the RADIUS server either authenticates and authorizes the connection and sends back an Access-Accept message or sends back an Access-Reject message. The Access-Accept message can contain connection restrictions that are implemented by the access server for the duration of the connection.

**User account database**

The user account database is the list of user accounts and their properties that can be checked by a RADIUS server to verify authentication credentials and user account properties containing authorization and connection parameter information.

The user account databases that IAS can use are the local Security Accounts Manager (SAM), a Microsoft Windows NT 4.0 domain, or the Active Directory service. For Active Directory, IAS can provide authentication and authorization for user or computer accounts in the domain in which the IAS server is a member, two-way trusted domains, and trusted forests with domain controllers running Windows Standard Server, Windows Enterprise Server, and Windows Datacenter Server.

If the user accounts for authentication reside in a different type of database, IAS can be configured as a RADIUS proxy to forward the authentication request to a RADIUS server that does have access to the user account database. Different databases for Active Directory include untrusted forests, untrusted domains, or one-way trusted domains.

If this service is disabled, both the Routing and Remote Access Service (RRAS) and Internet Authentication Service (IAS) will fail to start. You will also not be able to administer RRAS or IAS either locally or remotely. If this service is stopped or disabled, users will not be able to connect to the network in cases where network access requires user authentication (e.g., remote access [dial-up, VPN] or wireless LAN [802.1X], Ethernet 802.1X LAN access).

**Available on:** Windows Server 2003, Enterprise Edition (64-bit only) , Windows Server 2003, Datacenter) Edition (64-bit only).

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# IIS Admin Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** IISADMIN

**Executable Name:** inetinfo.exe

**Log On As:** LocalSystem

**Description:** IIS Admin service manages the IIS metabase and updates the Microsoft Windows operating system registry for the WWW service, FTP service, SMTP service, and NNTP service. The metabase is a data store that holds IIS configuration data. IIS Admin service exposes the metabase to other applications, including the core components of IIS, applications that are built on IIS, and third-party applications that are independent of IIS, such as management or monitoring tools.

IIS Admin service runs as Iisadmin.dll and is hosted by Inetinfo.exe.

This service allows administration of Microsoft Internet Information Server components such as FTP, Applications Pools, Web sites, Web service extensions and both NNTP and SMTP virtual servers.

If this service is stopped or disabled, you will not be able to run Web, FTP, Network News Transfer Protocol (NNTP), or Simple Mail Transfer Protocol (SMTP) sites, nor configure IIS and the MMC IIS snap-in will appear blank.

On Windows 2000, the IIS Admin service and related services were installed by default. On the Windows Server 2003 family, IIS must be installed using Add/Remove Windows Components or Configure Your Server, Manage Your Server.

*See also* **World Wide Web Publishing Service**, **FTP Publishing Service**, **HTTP SSL**, **Simple Mail Transfer Protocol (SMTP)**, **Network News Transfer Protocol (NNTP) services**.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default on Windows Server 2003, Web Edition. On Windows Server 2003, Standard Edition, Enterprise Edition and Datacenter Edition, the IIS Admin service must be added via Add\Remove Windows Components, Application Server, Internet Information Services (IIS), Configure Your Server or Manage Your Server.

# IMAPI CD-Burning COM Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ImapiService

**Executable Name:** imapi.exe

**Log On As:** LocalSystem

**Description:** This service manages burning CDs through the IMAPI (Image Mastering Applications Programming Interface) COM interface and performs CD-R writes when requested by the user through Windows explorer, WMP (Windows Media Player) or 3rd party applications which use this API.

The Image Mastering API (IMAPI) allows an application to stage and burn a simple audio or data image to CD-R and CD-RW devices. The API supports the following formats: Redbook audio and data discs with both Joliet and ISO 9660. The architecture allows for future expansion of the supported format set.

Stopping or disabling this service may prevent burning a CD-R. If a 3rd party CD-RW application is used, turning off this service may not impact recording to CD-R. If this service is started after log on, you must log off your computer in order to write data to CD-R media via your CD-R using Windows Explorer.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

# Indexing Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** cisvc

**Executable Name:** cisvc.exe

**Log On As:** LocalSystem

**Description:** Indexes contents and properties of files on local and remote computers and provides rapid access to files through a flexible querying language. It also enables quick searching of documents on local and remote computers and a search index for content shared on the Web. The Indexing Service builds indexes of all textual information in files and documents. Once the initial index build is complete, the Indexing Service maintains its indexes whenever a file is created, modified, or deleted.

Initial indexing can be resource-intensive. On Windows, the Indexing Service will index only when this service is started and the computer is idle. Using the MMC Indexing Service snap in, allows the configuration of resource allocation which are optimized for query or indexing usage patterns.

If this service is stopped or disabled, all search functionality is provided by traversing the folder hierarchy and scanning each file for the requested string and search responses will be slower. If the MMC Indexing Service snap in is used to create a new catalog, the catalog will remain offline until this service is started.

**Available on:** Windows XP Home, Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed by:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped, will start when using Configure Your Server/Manage Your Server to configure the File Server role.

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 80

# Infrared Monitor (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Irmon

**Executable Name:** svchost.exe –k netsvcs

**Log On As:** LocalSystem

**Description:** Supports infrared devices installed on the computer and detects other devices that are in range.

This service is installed by default only if an infrared device is detected during operating system installation. This service is not available on Windows Web, Enterprise or Datacenter Server.

**Available on:** Windows XP Home, Windows XP Professional, Windows Sever 2003 Standard Edition.

**Installed through:** Default operating system installation (only if an infrared port is detected during installation)

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

Terminal Services

IrDa Protocol

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# Internet Authentication Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** IAS

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Performs centralized authentication, authorization, auditing, and accounting of users who are connecting to a network (LAN or remote) using VPN (Virtual Private Network) equipment, RAS (Remote Access Service) equipment, or 802.1X Wireless and Ethernet/Switch Access Points. Internet Authentication Service implements the IETF standard RADIUS (Remote Authentication Dial-In User Service) protocol, which enables use of heterogeneous network access equipment.

If IAS is stopped or disabled, authentication requests will fail over to a backup IAS Server, if available. If there is no other backup IAS Servers are available, users will not be able to connect.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition.

**Installed through:** Add/Remove Programs, Add/Remove Windows Components, Networking Services

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: None

UDP: 1645, 1646, 1812, 1813

# Internet Connection Firewall (ICF) / Internet Connection Sharing (ICS) (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SharedAccess

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Provides NAT (network address translation), addressing and name resolution services for all computers on your home or small-office network through a dial-up or broadband connection. When Internet Connection Sharing is enabled, your computer becomes an "Internet gateway" on the network, enabling other client computers to share one connection to the Internet, share files, and use the same printers.

If this service is stopped or disabled, features such as Internet connection sharing, name resolution, and addressing will not be available to clients on the network. Therefore clients on the home or small office network may not be able to access the Internet and their IP addresses will expire, resulting in some clients using APIPA (Automatic Private IP Addressing) for peer-to-peer networking connectivity.

*This service was called Internet Connection Sharing on Windows 2000.

**Available on:** Windows XP Home, Windows XP Professional, Windows Server 2003, Standard Edition, Windows Server 2003, Enterprise Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Application Layer Gateway Service

Network Connections

Remote Access Connection Manager

Remote Access Auto Connection Manager

Remote Procedure Call

UDP: None

# Intersite Messaging (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** IsmServ

**Executable Name:** ismserv.exe

**Log On As:** LocalSystem

**Description:** Intersite Messaging enables messages to be exchanged between computers running Windows Server sites. This service is used for mail-based replication between sites. Active Directory includes support for replication between sites by using SMTP over IP transport. SMTP support is provided by the SMTP service, which is a component of IIS. The set of transports used for communication between sites must be extensible; therefore, each transport is defined in a separate add-in dynamic link library (DLL). These add-in DLLs are loaded into the ISM service, which runs on all domain controllers that are candidates for performing communication between sites. The ISM service directs send requests and receive requests to the appropriate transport add-in DLLs, which then route the messages to the ISM service on the destination computer.

If this service is stopped or disabled, Intersite messaging replication will not work nor will site routing information be calculated for other services.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Security Accounts Manager

Remote Procedure Call

**The following system components depend on this service:** None

**IP Port Numbers used:**

# IPv6 Helper Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** 6to4

**Executable Name:** svchost.exe –k netsvcs

**Log On As:** LocalSystem

**Description:** Offers IPv6 connectivity over an existing IPv4 network. 6to4 allows IPv6-enabled sites and hosts to communicate by using IPv6 over an IPv4 infrastructure (for example, the Internet). IPv6 sites and hosts can use their 6to4 address prefix and the Internet to communicate without obtaining an IPv6 global address prefix from an Internet service provider and connecting to the 6bone (the IPv6-enabled portion of the Internet).

6to4 is a tunneling technique that is described in RFC 3056. 6to4 hosts do not require any manual configuration and create 6to4 addresses by using standard auto configuration. 6to4 uses the global address prefix of 2002:WWXX:YYZZ::/48, where WWXX:YYZZ is the colon-hexadecimal representation of a public IPv4 address (w.x.y.z) that is assigned to a site or host. WWXX:YYZZ is the Next Level Aggregator (NLA) portion of a 6to4 address.

The IPv6 Helper service also supports 6over4, also known as IPv4 multicast tunneling, is a tunneling technique that is described in RFC 2529. 6over4 allows IPv6 and IPv4 nodes to communicate by using IPv6 over an IPv4 infrastructure. 6over4 uses the IPv4 infrastructure as a multicast-capable link. In order for 6over4 to work correctly, the IPv4 infrastructure must be IPv4 multicast-enabled.

If this service is stopped or disabled, the computer will only have IPv6 connectivity if connected to a native IPv6 network.

For more information about IPv6, see "Introduction to IPv6" and "Windows IPv6" in the Windows Server Resource Kit Networking Guide.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Network Connections, Protocol

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

Windows Management Instrumentation

Event Log

TCP/IP Protocol Driver

Microsoft IPv6 Protocol Driver

**The following system components depend on this service:** None

**IP Port Numbers used:** None

# IPSEC Services (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** PolicyAgent

**Executable Name:** lsass.exe

**Log On As:** LocalSystem

**Description:** Provides end-to-end security between clients and servers on TCP/IP networks. Manages IP security (IPSEC) policy, starts the Internet Key Exchange (IKE) and coordinates IPSEC policy settings with the IP security driver. The service is controlled using the net start or net stop policy agent command.

IPsec operates at the IP layer and is transparent to other operating system services and applications. It provides packet filtering, and can negotiate security between sending and receiving computers on IP networks. IPsec can be administratively configured to provide:

- Packet filtering - with actions permit, block, or negotiate security
- Negotiated trust and secure IP communication - The IKE protocol mutually authenticates the sender and receiver of IP data packets based on policy settings. Authentication can use the Kerberos authentication protocol, digital certificates, or a shared secret key (password). IKE automatically generates cryptographic keys, and IPsec security associations.
- Protect IP packets with IPsec secure formats: provides cryptographic integrity, authenticity, and optionally encryption of IP packets.
- Secure end-to-end connections: using IPsec transport mode.
- Secure IP tunnels: using IPsec tunnel mode.

IPsec also provides security for L2TP VPN connections. The IPsec security settings for L2TP are created automatically and require the IPsec service to be running in order to take effect.

*On Windows 2000 this service was called IPSEC Policy Agent.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

TCP/IP Protocol Driver

IPSEC

**The following system components depend on this service:** None

**IP Port Numbers used:**

TCP: 50 (ESP), 51 (AH)

UDP: 500 (ISAKMP)

# Kerberos Key Distribution Center (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Kdc

**Executable Name:** lsass.exe

**Log On As:** LocalSystem

**Description:** Enables users to log on to the network using the Kerberos v5 authentication protocol.

As in other implementations of the Kerberos protocol, the KDC is a single process that provides two services:

- **Authentication Service**

  This service issues ticket granting tickets (TGTs) for connection to the ticket-granting service in its own domain or in any trusted domain. Before a client can ask for a ticket to another computer, it must request a TGT from the authentication service in the clients account domain. The authentication service returns a TGT for the ticket granting service in the target computers domain. The TGT can be reused until it expires, but first access to any domains ticket-granting service always requires a trip to the authentication service in the clients account domain.

- **Ticket-Granting Service (TGS)**

  This service issues tickets for connection to computers in its own domain. When clients want access to a computer, it must request a TGT, and ask for a ticket to the computer. The ticket can be reused until it expires, but first access to any computer always requires a trip to the ticket-granting service in the target computers account domain.

If this service is stopped, users will be unable to log on to the domain and access services.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

# License Logging (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** LicenseService

**Executable Name:** llssrv.exe

**Log On As:** NetworkService

**Description:** Tracks Client Access License usage for server products, such as Internet Information Server (IIS), Terminal Services, File and Print services, as well as other products such as SQL Server and Microsoft Exchange Server.

The License Logging service for Windows Server 2003 operating systems collects site-licensing information on the site license server for a single site. This enables a geographical or organizational unit in an organization to purchase and manage their software licenses separately. However, because each site allocates licenses to users independently of other sites, a user connecting to a product in more than one site might be allocated more than one Client Access License for the same product.

If stopped or disabled, licensing logging for these programs will not be logged.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:** None

# Logical Disk Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Dmserver

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** Detects and monitors new hard disk drives and sends disk volume information to Logical Disk Manager Administrative Service for configuration. This service watches Plug and Play events for new drives detected and passes volume and/or disk information to the Logical Disk Manager Administrative Service to be configured. The Logical Disk Manager uses an administrator service and a watchdog service. The service should not be disabled if dynamic disks are in the system.

If this service is disabled or stopped, dynamic disk status and configuration information will become out of date and hard disk drives will not be detected. Also, any attempt to use the MMC Disk Management snap-in to configure disks will display the unable to connect to Logical Disk Manager service error message.

See also Logical Disk Manager Administrative Service.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Plug and Play

Remote Procedure Call

**The following system components depend on this service:**

Logical Disk Manager Administrative Service

**IP Port Numbers used:** None

# Logical Disk Manager Administrative Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Dmadmin

**Executable Name:** dmadmin.exe /com

**Log On As:** LocalSystem

**Description:** Performs administrative service for disk management requests. This service is started only when configuring a drive or partition or when a new drive is detected. This service is configured as manual by default, and is activated whenever dynamic disk configuration changes occur or when the Disk Management MMC snap-in is open. Such changes include converting a basic disk to dynamic, recovery of fault tolerant volumes, volume formatting, or changing a page file. The service starts, completes the configuration operation, and then exits.

This service only runs for disk configuration processes once invoked via the MMC Disk Management snap-in and then stops. If this service is disabled, attempts to use the MMC Disk Management snap-in to configure disks will display the unable to connect to Logical Disk Manager service error message.

*See also* **Logical Disk Manager**.

**Available on:** Windows XP Home, Windows XP Professional; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

# Message Queuing (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** msmq

**Executable Name:** mqsvc.exe

**Log On As:** LocalSystem

**Description:** The Message Queuing service is a messaging infrastructure and development tool for creating distributed messaging applications for Windows. Such applications can communicate across heterogeneous networks and can send messages between computers that might be temporarily unable to connect to each other. Message Queuing provides guaranteed message delivery, efficient routing, security, support for sending messages within transactions, and priority-based messaging. Message Queuing provides both Win32®and COM APIs for all programmatic functionality including administration and management.

If this service is stopped or disabled, distributed messages are unavailable.Disabling the Message Queuing service affects other services including COM+ Queued Component (QC) functionality, some functionality of Windows Management Instrumentation (WMI), and the Message Queuing Triggers service.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components, Application Server, and Message Queuing.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Message Queuing Access Control

NT LM Security Support Provider

Remote Procedure Call

RMCAST <Pgm> Protocol Driver

Security Accounts Manager

**The following system components depend on this service:** None

# Message Queuing Down Level Client Support (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** mqds

**Executable Name:** mqdssvc.exe

**Log On As:** LocalSystem

**Description:** The Message Queuing Down Level Clients Support service provides Active Directory access for Message Queuing clients (Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, Windows 2000, and Windows 2003) on domain controllers. The Message Queuing service optionally uses information published in Active Directory in order to obtain routing information for security-related objects (for example, destination public keys) and to learn about public queues.

If the Message Queuing service is installed in Workgroup mode, Active Directory is never accessed.

If this service is stopped or disabled on a domain controller, then previous versions of Message Queuing clients cannot obtain Active Directory services on the specified domain controller for public queue discoverability, message routing, and site recognition.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components, Application Server, Message Queuing, and Downlevel Client Support

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

IPSEC Driver

Message Queuing

Message Queuing Access Control

NTLM Security Support Provider

Remote Procedure Call (RPC)

RMCAST (Pgm) Protocol Driver

Security Accounts Manager

TCP/IP Protocol Driver

**The following system components depend on this service:** None

# Message Queuing Triggers (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MSMQTriggers

**Executable Name:** Mqtgsvc.exe

**Log On As:** LocalSystem

**Description:** The Message Queuing Triggers service provides rule-based monitoring of messages arriving in a Message Queuing queue and, when the conditions of a rule are satisfied, invokes a COM component or a stand-alone executable program to process the message.The Message Queuing Triggers service is installed as an integral part of Message Queuing.

If this service is stopped or disabled, you cannot apply rule-based monitoring nor invoke programs to process messages automatically.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components, Application Server, Message Queuing, and Triggers

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Distributed Transaction Coordinator

IPSEC Driver

Message Queuing

Message Queuing Access Control

NTLM Security Support Provider

Remote Procedure Call (RPC)

RMCAST (Pgm) Protocol Driver

Security Accounts Manager

TCP/IP Protocol Driver

**The following system components depend on this service:** None

# Messenger (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Messenger

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Messenger service transmits the net send command and Alerter service messages between clients and servers. For console messages to be received, the Messenger service must be enabled and started on the target computer.This service is not related to any Microsoft Windows or Microsoft® MSN® Messenger applications used for instant messaging.

If this service is stopped or disabled, Alerter service messages are not transmitted — for example, the command-line commands net send and net name cease to function.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Disabled

**This service depends on the following system components:**

NetBIOS Interface

Remote Procedure Call

Plug and Play

Workstation

**The following system components depend on this service:** None

# Microsoft POP3 Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** POP3SVC

**Executable Name:** Pop3svc.exe

**Log On As:** LocalService

**Description:** Microsoft POP3 Service provides e-mail transfer and retrieval services. Administrators can use Microsoft POP3 Service to store and manage e-mail accounts on the mail server. When you install Microsoft POP3 Service on the mail server, users can connect to the mail server and retrieve e-mail to their local computer by using an e-mail client that supports Post Office Protocol 3 (POP3) protocol (such as Microsoft® Outlook®). Microsoft POP3 Service is combined with the Simple Mail Transfer Protocol (SMTP) service — which allows users to send outgoing e-mail — for full e-mail services.Microsoft POP3 Service is the mechanism that allows users to retrieve their e-mail from the mail server. The sender's client computer is connected to the Internet through an Internet service provider (ISP). Using an e-mail client, the sender sends an e-mail, the e-mail is picked up according to the SMTP protocol and it is transferred to the sender's ISP, which then routes the e-mail out onto the Internet. The e-mail moves throughout the Internet and is relayed through a varying number of intermediate servers as it moves toward the recipient. When the e-mail reaches the recipient's ISP, it is dropped into the recipient's mailbox. When the recipient's computer connects to the recipient's ISP, the e-mail is then transferred from the ISP to the recipient's e-mail client on the local computer according to the POP3 protocol.

If this service is stopped or disabled, e-mail transfer and retrieval services do not function.

**Available on:**Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Configure Your Server Wizard or Manage Your Server, or go to Add/Remove Windows Components, E-mail Services, and POP3 Service.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

IIS Admin Service

Remote Procedure Call

Security Accounts Manager

**The following system components depend on this service:** None

# Microsoft Software Shadow Copy Provider (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:**SwPrv

**Executable Name:** svchost.exe -k swprv

**Log On As:** LocalSystem

**Description:** The Microsoft Software Shadow Copy Provider service manages software-based shadow copies taken by the Volume Shadow Copy service. A shadow copy enables you to create a copy (or apparent copy) of a disk volume that represents a consistent read-only point in time for that volume. This point in time then stays constant and allows an application (such as Backup) to copy data from the shadow copy to tape.

There are two general classes of shadow copies:

- **Hardware.** For hardware shadow copies, a mirror of two or more disks is split into separate volumes. One of the two volumes then remains the working set and the other one can be mounted separately.

- **Software.** A software volume uses a copy-on-write scheme to copy all sectors of a volume that change over time into a differential area. When the shadow copy is mounted, all unchanged sectors are read from the original volume and all sectors that have changed are read from the differential area.

Shadow copies can resolve three classic problems with Backup:

- The need to delete share flags in a filter driver in order to back up files that have been opened for exclusive access. The problem of backing up a file as it is changing. Without a shadow copy or a way to suspend the application, the result of doing this is typically a corrupt backup.

- Allowing a system to remain active while the shadow copy is being performed. Tax season is a good example of when organizations cannot afford to take the time to shut a system down long enough to back it up.

- Leveraging the snapshots approach and using the same communication channels to build information transfer between application and backup tools.

If this service is stopped or disabled, software-based volume shadow copies cannot be managed.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** None

# MSSQL$UDDI

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MSSQL$UDDI

**Executable Name:** sqlservr.exe –sUDDI

**Log On As:** LocalSystem

**Description:** The MSSQL$UDDI service is installed when you install the Universal Description, Discovery, and Integration (UDDI) feature of the Windows Server 2003 family, which provides UDDI capabilities within an enterprise. The SQL Server database engine is the core component of this feature.The MSSQL$UDDI service utilized by UDDI manages all of the files that comprise the databases owned by an instance of SQL Server. It is the component that processes all Transact-SQL statements sent from SQL Server client applications. The MSSQL$UDDI (SQLServer.exe) service allocates computer resources effectively among multiple concurrent users. It also enforces business rules defined in stored procedures and triggers, ensures the consistency of the data, and prevents logical problems such as allowing two people to try to update the same data at the same time.UDDI is an industry specification for the description and discovery of Web services. The UDDI specification builds on the Simple Object Access Protocol (SOAP), XML, and HTTP/S protocol standards developed by the World Wide Web Consortium (W3C) and Internet Engineering Task Force (IETF). UDDI services are standards-based XML Web Services designed for enterprise developers to efficiently publish, discover, share, and reuse Web Services directly through their development tools. Built on the Microsoft .NET Framework, UDDI services use proven SQL Server technology and tools to provide a scalable storage mechanism. IT managers can leverage UDDI services support for standard categorization schemes and Active Directory authentication, allowing for easy integration within an enterprise environment.

For more information about UDDI, see UDDI Services

If this service is stopped, the SQL Server database is unavailable on the computer and clients can no longer query against or access the data in its databases.

If this service is disabled, any services that explicitly depend on this service will fail to start.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

**The following system components depend on this service:** SQLAgent$UDDI

# MSSQLServerADHelper

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MSSQLServerADHelper

**Executable Name:** Sqladhlp.exe

**Log On As:** LocalSystem

**Description:** The MSSQLServerADHelper service enables SQL Server and Microsoft SQL Server Analysis Services to publish information in Active Directory when the services are not running under the LocalSystem account.

There is only one instance of MSSQLServerADHelper service on a computer. All instances of SQL Server and Microsoft SQL Server Analysis Services use it when needed.MSSQLServerADHelper is not a server service and does not service requests from the client. The service does not use a User Datagram Protocol (UDP) or TCP port.

This service cannot be stopped. This service is dynamically started by an instance of SQL Server or Analysis Manager when needed, and is stopped as soon as it has completed its work. This service should always be run from the LocalSystem account and should not be started manually from a console.

If this service is disabled, it might affect adding, updating, or deleting SQL Server–related Active Directory objects if MSSQLSERVER service is not running under LocalSystem.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components and UDDI Services.

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

None

**The following system components depend on this service:** None

# Net Logon (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Netlogon

**Executable Name:** lsass.exe

**Log On As:** LocalSystem

**Description:** The Net Logon service maintains a secure channel between your computer and the domain controller for authenticating users and services. It passes the user's credentials through a secure channel to a domain controller and returns the domain security identifiers and user rights for the user. This is commonly referred to as pass-through authentication.

| **Note** |
| --- |
| The secure channel is not directly used for Kerberos authentication, which is preferred authentication mechanism in Windows 2000 and Windows Server 2003. |

The Net Logon service is started automatically when the computer is a member of a domain. In Windows 2000 Server and Windows Server 2003 family, the Net Logon service publishes service resource records in the Domain Name System (DNS) and uses DNS to resolve names to the IP addresses of domain controllers. The Net Logon service registers DNS records on domain controllers only, not on member servers.

The Net Logon service also implements the replication protocol based on RPC for synchronizing Windows NT 4.0 backup domain controllers (BDCs) and the primary domain controller (PDC).

If this service is stopped or disabled, the computer might not authenticate users and services, and the domain controller cannot register DNS records.Specifically, it might deny NTLM authentication requests and, if this service is stopped or disabled on a domain controller, the domain controller is not discoverable by client computers.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Started (if joined to a domain)

**This service depends on the following system components:**

Workstation

**The following system components depend on this service:** None

# NetMeeting Remote Desktop Sharing (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** mnmsrvc

**Executable Name:** Mnmsrvc.exe

**Log On As:** LocalSystem

**Description:** The NetMeeting Remote Desktop Sharing service allows authorized users to remotely access your Windows desktop from another computer over a corporate intranet by using Microsoft® NetMeeting® conferencing software. The service must be explicitly enabled by NetMeeting, and can be disabled in NetMeeting or shut down by means of an icon in the notification area.

If this service is stopped or disabled, the NetMeeting display driver is unloaded and remote desktop sharing is unavailable.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

None

**The following system components depend on this service:** None

# Network Connections (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Netman

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Network Connections service manages objects in Network Connections, where you can view both network and remote connections. This service is responsible for network configuration of client computers. It displays network status in the notification area on the desktop (the area on the taskbar to the right of the taskbar buttons). Configuration parameters can also be accessed through this service.

This service starts automatically when the startup type is Manual and Network Connections is running.

If this service is stopped, client-side configuration for LAN and dial-up or VPN connections are unavailable.

If this service is disabled, the following might result:

- Connections do not appear in the Connections folder; thus, dial out access is prevented and LAN settings cannot be configured.
- Other services that use Network Connections to check for network-location-aware Group Policy settings do not function properly.
- Events pertaining to media connections and disconnections are not received.
- ICS does not function correctly.
- The ability to configure incoming connections, wireless settings, or your home network is unavailable.
- New connections are not created.
- Any services that explicitly depend on this service will fail to start.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call

**The following system components depend on this service:** Internet Connection Firewall (ICF)/Internet Connection Sharing (ICS)

# Network DDE (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NetDDE

**Executable Name:** Netdde.exe

**Log On As:** LocalSystem

**Description:** The Network DDE service provides network transport and security for Dynamic Data Exchange (DDE) for programs running on the same computer or on different computers. You can create Network DDE shared folders programmatically or by using Ddeshare.exe on your computer, and make them visible to other applications and computers. Traditionally, the user creating the shared folder will create and run a server process to handle incoming requests from client processes and/or applications (running on the same computer or remotely); after they are connected, these processes can exchange any kind of data over a secure network transport.

This service is disabled by default, and it is only started when invoked by an application using Network DDE, like Clipbrd.exe or Ddeshare.exe. In addition, applications running on remote computers can send messages to other computers that will invoke the Network DDE service.

If this service is stopped, DDE transport and security are unavailable.If this service is disabled, any services that explicitly depend on the service will fail to start.Any applications depending on Network DDE will time out while trying to start the service. If an application on a remote computer tries to start Network DDE on another computer, the remote computer will not be viewable on the network.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Network DDE DSDM

**The following system components depend on this service:** ClipBook

# Network DDE DSDM (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NetDDEdsdm

**Executable Name:** netdde.exe

**Log On As:** LocalSystem

**Description:** The Network DDE DSDM service manages Dynamic Data Exchange (DDE) shared folders. This service is used only by Network DDE to manage shared DDE conversations. You can create and trust DDE shares by using Ddeshare.exe to allow remote computers and applications to connect and share data. Network DDE DSDM maintains a database of DDE shared folders, including information on which ones are trusted. For each connection request from or to an application, the service queries the database and validates your security settings to determine if the request should be granted.

If this service is stopped, DDE shared folders are unavailable.If this service is disabled, any services that explicitly depend on the service will fail to start. Any applications depending on Network DDE will time out while trying to start the service. If an application on a remote computer tries to start Network DDE on another computer, the remote computer will not be viewable on the network.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

None

Network DDE

# Network Location Awareness (NLA) (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Nla

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Network Location Awareness (NLA) service collects and stores network configuration information such as changes to the names and locations of IP addresses and domain names, and notifies applications when this information changes. The NLA service component supports the Network Location Service. This component provides the infrastructure that informs applications and the operating system of the network connections on a specific computer. This component implements the NS_NLA Windows Sockets namespace.

This service will automatically start when the startup type is Manual.

If this service is disabled, NLA functionality is not available because the NLA service is a demand-start service and it is used by several critical system components, including Winlogon.exe.If this service is stopped, the change-requests of the services that are using NLA for network change notifications are cancelled. These services immediately try to reestablish the change requests, thereby demand-starting the service again almost instantaneously. NLA correctly reports to the Service Control Manager (SCM) thread, which requested the stop, that the service stopped successfully; however, Winlogon.exe or another service immediately restarts before you are able to verify the status in the Services snap-in.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Started

**This service depends on the following system components:**

AFD Networking Support Environment

IPSEC Driver

TCP/IP Protocol Driver

**The following system components depend on this service:**

Internet Connection Firewall (ICF)/Internet Connection Sharing (ICS)

IPSEC Driver

# Network News Transfer Protocol (NNTP) (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NntpSvc

**Executable Name:** Inetinfo.exe

**Log On As:** LocalSystem

**Description:** The Network News Transfer Protocol (NNTP) service provides NNTP, which is a member of the TCP/IP suite of protocols used to distribute network news messages to NNTP servers and clients (newsreaders) on the Internet. NNTP is designed so that news articles are stored on a server in a central database, thus enabling a user to select specific items to read.You can use a news client such as Microsoft Outlook Express to retrieve newsgroups from the server and read headers or bodies of the articles in each newsgroup. You can then post news back to the NNTP server.

| **Note** |
| --- |
| The version of Outlook Express included in Windows 2000 does not support feeds, where two news servers replicate their contents between each other. However, the version included in Exchange Server does include this functionality. |

If this service is stopped or disabled, client computers cannot connect, read, or retrieve posts. If IIS Admin Service is stopped, the NNTP service will stop as well.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components, Application Server, Internet Information Services (IIS), and NNTP Service.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Event Log

IIS Admin Service

Remote Procedure Call (RPC)

Security Accounts Manager

**The following system components depend on this service:** None

# NT LM Security Support Provider (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NtLmSsp

**Executable Name:** Lsass.exe

**Log On As:** LocalSystem

**Description:** The NT LM Security Support Provider service is the Local Security Authority (LSA) for the system. The NT LM Security Support Provider name used in the Services snap-in is a historical holdover.The LSA is responsible for two major tasks: authentication and management of local security policy objects.The LSA handles all authentication requests on the local system through the use of multiple security service providers. It provides interactive authentication for users in addition to noninteractive authentication for services. The LSA uses a variety of security service providers, which provide several different authentication protocols. Each of these providers is in a different DLL loaded by the LSA:

- Kerberos (Kerberos.dll)
- SChannel (Schannel.dll)
- Digest (Wdigest.dll)
- NTLM — LM, NTLM, and NTLMv2 (Msv1_0.dll)

The second major function of the LSA is to store and manage security objects. These objects include the access tokens for users, local security policy, and the trusted domains. For example, all access control list (ACL) checks use information from the LSA.

This is a critical system process. If it is stopped or disabled, all user and system authentication stops and all security policy checks fail — in short, the system no longer functions. For this reason, the administration tools do not allow an administrator to stop this process.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:** None

**The following system components depend on this service:**

Windows Internet Name Service (WINS)

# Performance Logs and Alerts (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SysmonLog

**Executable Name:** Smlogsvc.exe

**Log On As:** NetworkService

**Description:** The Performance Logs and Alerts service collects performance data from local or remote computers based on preconfigured schedule parameters, and then writes the data to a log or triggers an alert. The Performance Logs and Alerts service starts and stops each named performance data collection based on the information contained in the named log collection setting. This service runs only if at least one collection is scheduled.

If this service is stopped or disabled, performance information is not collected. Also, currently running data collections and future scheduled collections will not occur.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:** None

**The following system components depend on this service:** None

# Plug and Play (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** PlugPlay

**Executable Name:** services.exe

**Log On As:** LocalSystem

**Description:** The Plug and Play service enables a computer to recognize and adapt to hardware changes with little or no user input. Plug and Play enables you to add or remove devices without any intricate knowledge of computer hardware, and without being forced to manually configure hardware or the operating system. For example, you can plug in a USB keyboard, and Plug and Play will detect the new device, attempt to find a driver for it, and install it. Or you can dock a portable computer and use the docking station's Ethernet card to connect to the network without changing the configuration. Later, you can undock the same computer and use a modem to connect to the network without making any manual configuration changes.

This service cannot be stopped or disabled through the Services snap-in because of the impact on operating system stability. If this service is stopped using the System Configuration Utility (Msconfig.exe) troubleshooting tool, the Device Manager interface appears empty and no hardware devices are displayed.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:** None

**The following system components depend on this service:**

Fax

Internet Connection Firewall (ICF)/Internet Connection Sharing (ICS)

Logical Disk Manager

Logical Disk Manager Administrative Service

Messenger

Remote Access Auto Connection Manager

Remote Access Connection Manager

Smart Card

Telephony

Virtual Disk Service

Windows Audio

Windows Image Acquisition

# Portable Media Serial Number

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WmdmPmSN

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Portable Media Serial Number service retrieves the serial number of any portable music player connected to your computer. The service allows Windows Media Device Manager (WMDM) to acquire the serial number from devices so that media content can be copied securely to the device. Without the serial number, you cannot associate the content with the specific device. Thus, protected content might not be allowed to transfer to the device.

To uniquely identify portable media, many storage media manufacturers have implemented a unique serial number stored on a nonvolatile area of the storage. For example, the CompactFlash specification revision 1.3 from the CompactFlash Association (CFA) requires CompactFlash cards to have a unique serial number. Iomega Zip and Jaz disks also have unique serial numbers on them. Recently produced SmartMedia cards also have built in unique IDs. Emerging new portable media, such as MultiMediaCards (MMC), SD Memory Cards, and Sony MemoryStick, are all built with unique IDs by design.

For a portable media reader or adapter to be Windows Media–compliant, it must allow an application to retrieve media serial numbers.

In Windows 2000, this service was called WMDM PMSP Service.

If this service is stopped or disabled, protected content might not be allowed to be transferred to the device and the serial number might not be retrieved from portable media devices.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition (32-bit only)

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:** None

**The following system components depend on this service:** None

# Print Server for Macintosh (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MacPrint

**Executable Name:** Sfmprint.exe

**Log On As:** LocalSystem

**Description:** The Print Server for Macintosh service enables Macintosh clients to route printer files to a print spooler located on a computer running Windows 2000 or Windows Server 2003. This service also allows any Windows-based server to communicate with a print device by using the AppleTalk protocol.

If this service is stopped or disabled, printing is unavailable to Macintosh clients.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition.

**Installed through:** Add/Remove Windows Components, Other Network File and Print Services, and Print Server for Macintosh.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Apple Talk Protocol

Print Spooler

Remote Procedure Call (RPC)

**The following system components depend on this service:** None

# Print Spooler (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Spooler

**Executable Name:** spoolsv.exe

**Log On As:** LocalSystem

**Description:** The Print Spooler service manages all local and network print queues and controls all print jobs. The print spooler is the center of the Windows printing subsystem. It manages the print queues on the system and communicates with printer drivers and input/output (I/O) components (for example, the USB port and the TCP/IP protocol suite).

For more information about the Print Spooler service, see the *Server Management Guide* of the *Windows Server 2003 Resource Kit* (or see the *Server Management Guide* on the Web at http://www.microsoft.com/reskit).

If this service is stopped, both printing and faxing on the local computer are unavailable.

This service will not automatically start if it is stopped when it has either the Automatic or Manual startup types.

If this service is disabled, any services that explicitly depend on this service will fail to start.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

Fax

Print Server for Macintosh

TCP/IP Print Server

# Protected Storage (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ProtectedStorage

**Executable Name:** lsass.exe

**Log On As:** LocalSystem, to allow this service to interact with the desktop

**Description:** The Protected Storage service protects the storage of sensitive information, such as private keys, and prevents access by unauthorized services, processes, or users. Protected Storage is a set of software libraries that allows applications to retrieve security and other information from a personal storage location, hiding the implementation and details of the storage itself.

The storage location provided by this service is secure and protected from modification. Protected Storage uses the Hash-Based Message Authentication Code (HMAC) and the Secure Hash Algorithm (SHA1) cryptographic hash functions to encrypt the user's master key. This component requires no configuration.Protected Storage is an outdated service whose functions can now be performed by the Data Protection API (DPAPI), which is currently the preferred method for protected storage. Unlike DPAPI, the interface to Protected Storage is not publicly exposed. Protected Storage is needed to recover keys migrated from earlier versions of the Windows operating system. It is still needed for protecting keys in Internet Explorer and Outlook Express.

If this service is stopped or disabled, some migrations and earlier versions of applications might fail.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:** None

# Remote Access Auto Connection Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** RasAuto

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Remote Access Auto Connection Manager service creates a connection to a remote network whenever a program references a remote DNS or network BIOS (NetBIOS) name or address. This service (sometimes called the autodial service) detects an attempt to resolve the name of a remote computer or shared folder, or an unsuccessful attempt to send packets to a remote computer or shared folder. The service is activated only when there is no network access. In that case, the service brings up a dialog box that offers to make a dial-up or VPN connection to the remote computer.

To assist users, the service maintains a local database of connections that were used in the past to reach named computers or shared folders. When the service detects an unsuccessful attempt to reach a remote computer or shared folder, this service will offer to dial the connection that was last used to reach this remote device.

| **Note** |
| --- |
| Windows Product Activation will start both this service and the Telephony service when you do the product activation for any Windows XP or Windows Server operating system. |

If this service is stopped or disabled, you need to manually set up connections to remote computers.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Plug and Play

Remote Access Connection Manager

Remote Procedure Call (RPC)

Telephony

**The following system components depend on this service:** None

# Remote Access Connection Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** RasMan

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Remote Access Connection Manager service manages dial-up and VPN connections from your computer to the Internet or other remote networks. When you double-click a connection in Network Connections in Control Panel and then click Connect, the Remote Access Connection Manager service dials the connection (or sends a VPN connection request) and handles subsequent negotiations with the remote access server in order to set up the connection.

This service will stop when there are no further requests pending. Network Connections calls on this service to enumerate the set of connections and to display the status of each one. Therefore, except for the case in which there are no connections in Network Connections, the Remote Access Connection Manager service is always able to start.

If this service is stopped or disabled, the computer cannot make dial-up or VPN connections to a remote network, nor accept incoming connections. In addition, Network Connections will not display VPN or dial-up or connections. Any operating system components that depend on this service will fail to operate properly.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Plug and Play

Remote Procedure Call (RPC)

Telephony

**The following system components depend on this service:**

Internet Connection Firewall (ICF)/Internet Connection Sharing (ICS)

# Remote Administration Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SrvcSurg

**Executable Name:** srvcsurg.exe

**Log On As:** LocalSystem

**Description:** Remote Administration Service is responsible for performing the following remote administration tasks when Windows Server 2003 restarts:

- Increment the server boot count.
- Send an alert when the computer is running a backup of the operating system.
- Generate a self-signed certificate.
- Send an alert if the date and time has not been set on the computer.
- Send an alert if Alert E-mail functionality has not been configured.

Remote Administration Service starts performing the appropriate tasks when requested by the Remote Server Manager service through a COM interface. Remote Administration Service runs in the LocalSystem account and accepts requests through the COM interface only from clients running under the Administrators or LocalSystem accounts.

If the startup type is set to Manual, the service will start when it receives a request from the Remote Server Manager service; it can be subsequently stopped without affecting any server functionality.

If this service is stopped or disabled, some remote administration tools or features might not function properly, such as the Web interface for remote administration.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:** None

# Remote Desktop Help Session Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** RDSessMgr

**Executable Name:** Sessmgr.exe

**Log On As:** LocalSystem

**Description:** The Remote Desktop Help Session Manager service manages and controls the Remote Assistance feature within the Help and Support Center application (Helpctr.exe).

If this service is stopped or disabled, Remote Assistance is unavailable.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

Terminal Services

**The following system components depend on this service:**

None

# Remote Installation Services (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** BINLSVC

**Executable Name:** Tcpsvcs.exe

**Log On As:** LocalSystem

**Description:** Remote Installation Services (RIS) is a Windows deployment feature that is included in Windows Server 2003. With RIS, you can support on-demand, image-based, or script-based operating system installations over a network connection from a RIS server to a client computer. RIS is designed to simplify the deployment of operating systems and applications, and to improve failure recoverability.

You can use RIS in a variety of ways, including the following:

- Provide an operating system to users on demand.

You can use RIS to create automated installation images of Windows Server 2003, Windows XP, and Windows 2000. When a user starts a client computer, even if that computer contains no operating system, the RIS server can respond by installing an operating system over the network; no CD is required. To support this, client computers must use the Pre-boot eXecution Environment (PXE), a remote-boot technology that allows the client computer to begin a boot sequence from BIOS, using the network adapter. For more information about the process through which RIS installs an operating system, see PXE architecture and Technologies and components used by Remote Installation Services in see the *Server Management Guide* of the *Windows Server 2003 Resource Kit* (or see the *Server Management Guide* on the Web athttp://www.microsoft.com/reskit).

- Provide operating system images which include specific settings and applications.

For example, you can use RIS to create an image that complies with a corporate desktop standard and offer it to a particular group of users.

| **Note** |
| --- |
| In Windows 2000, this service was called the Boot Information Negotiation Layer Service. |

If this service is stopped or disabled, PXE-enabled client computers are unable to install Windows remotely or use other RIS-based tools.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition

**Installed through:** Add/Remove Windows Components and Remote Installation Services.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Server

TCP/IP Protocol Driver

**The following system components depend on this service:**

None

# Remote Procedure Call (RPC) (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** RpcSs

**Executable Name:** svchost -k rpcss

**Log On As:** LocalSystem

**Description:** The Remote Procedure Call (RPC) service is a secure interprocess communication (IPC) mechanism that enables data exchange and invocation of functionality that resides in a different process. That different process can be on the same computer, on the LAN, or across the Internet. The Remote Procedure Call service serves as the RPC endpoint mapper and Service Control Manager (SCM). Many services depend on the Remote Procedure Call service to start successfully.

For more information about RPC, see the *Internetworking Guide* of the *Windows Server 2003 Resource Kit* (or see the *Internetworking Guide* on the Web at http://www.microsoft.com/reskit).

This service should not be stopped or disabled. Disabling the Remote Procedure Call (RPC) service will result in the operating system not loading.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

# Remote Procedure Call (RPC) Locator (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** RpcLocator

**Executable Name:** Locator.exe

**Log On As:** NetworkService

**Description:** The Remote Procedure Call (RPC) Locator service enables RPC clients using the RpcNs family of APIs to locate RPC servers, and manages the RPC name service database.

The RPC Locator service (also known as RPC Named Service) can locate other services on the network. The instance of the RPC Locator service that runs on a domain controller acts as repository for information about other RPC services that are active on the network. If you run the RPC Locator service in Windows 2000 or Windows Server 2003, backup storage for information about other services on the network is Active Directory. The instances of the RPC Locator service that run on individual computers act as computer-wide caches for information about other services on the network. Those services that need to be located through the RPC Locator service register with the RPC Locator service. The RPC APIs that start with the prefix RpcNs are used to register services with the RPC Locator service and query the RPC Locator service about previously registered services.

For more information about the RpcNs family of APIs, see the Software Development Kit (SDK) information in the MSDN Library link on the Web Resources page (http://go.microsoft.com/fwlink/?linkid=291)

If this service is stopped or disabled, RPC clients that use RpcNs APIs might be unable to locate servers or fail to start. RPC clients that rely on RpcNs APIs from the same computer might not be able to find RPC servers that support a given interface. If this service is stopped or disabled on a domain controller, RPC clients that use the RpcNs APIs and the domain controller might experience interruption of service while trying to locate clients.

RpcNs APIs are not used internally in Windows; you need to start this service only if third-party applications require it.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual (Automatic on a domain controller)

**Service status:** Stopped (Started on a domain controller)

**This service depends on the following system components:**

Workstation

**The following system components depend on this service:**

None

# Remote Registry (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** RemoteRegistry

**Executable Name:** svchost.exe -k regsvc

**Log On As:** LocalService

**Description:** The Remote Registry service enables remote users to modify registry settings on the local computer, provided the remote users have the required administrative credentials. The service is primarily used by remote administrators and for performance counters.

If this service is stopped, the registry on the local computer can only be modified locally.

If this service is disabled, it will not affect registry operations on the local computer, but other computers or devices can no longer connect to the local computer's registry.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Remote Server Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** AppMgr

**Executable Name:** Appmgr.exe

**Log On As:** LocalSystem

**Description:** The Remote Server Manager service provides the following functionality:

- Holds the Remote Administration Service alert information.
- Provides an interface for raising, clearing, and enumerating Remote Administration Service alerts.
- Provides an interface for performing Remote Administration Service tasks.

The Remote Server Manager service acts as a Windows Management Instrumentation (WMI) instance provider for Remote Administration Service alert objects and a WMI method provider for Remote Administration Service tasks. The Remote Server Manager service runs in the LocalSystem account and accepts requests through the COM interface only from clients running under the Administrators or LocalSystem accounts.

If the startup type is set to Manual, the service will start when the next request for Remote Administration Service tasks or Remote Administration Service alerts is received.

When this service is stopped, the service is restarted if the Web interface for remote administration is accessed.

If this service is disabled, information about the current Remote Administration Service alerts on the system is lost.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Remote Storage Server (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Remote_Storage_Server

**Executable Name:** RsServ.exe

**Log On As:** LocalSystem

**Description:** The Remote Storage Server service stores infrequently used files in a secondary storage media. This service allows the Remote Storage application to notify the user when an offline file has been accessed.

Remote Storage is a hierarchical storage management application that migrates data from upper-level storage to lower-level storage. Upper-level storage is commonly known as local storage: data that is frequently accessed is stored locally on high-performance disks. Lower-level storage is also known as remote storage: data that is infrequently accessed is stored on less expensive media until it is needed again. Hierarchical storage management reduces the costs of storing large quantities of data, while ensuring that the data is still accessible.

File data is cached locally so that it can be accessed quickly as needed. When the amount of available space on a managed volume dips below the necessary level, Remote Storage automatically removes the content from the cached files, providing the disk space you need. When data is removed from a file, the disk space used by the file is reduced to zero. Data from cached files is not removed until more disk space is needed. When you need to open a file from which data has been removed, the data is automatically recalled from remote storage.

Because removable tapes or disks in a library are less expensive per megabyte (MB) than hard disks, Remote Storage can be an economical way to provide both maximum data storage and optimal local disk performance.

For more information about the Remote Storage Server service and the Remote Storage application, see the *Server Management Guide* of the *Windows Server 2003 Resource Kit* (or see the *Server Management Guide* on the Web at http://technet.microsoft.com/en-us/windowsserver/bb633748.aspx)

If this service is stopped or disabled, files cannot be moved to or retrieved from the secondary storage media.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components and Remote Storage

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Event Log

Remote Procedure Call (RPC)

Removable Storage

Task Scheduler

**The following system components depend on this service:**

None

# Removable Storage (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NtmsSvc

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Removable Storage service manages and catalogs removable media and operates automated removable media devices. This service maintains a catalog of identifying information for removable media used by your computer, including tapes and CDs. If the computer also has automated devices for maintaining removable media (such as a tape autoloader or CD jukebox), Removable Storage also automates mount, dismount, and eject media. Removable Storage is used by applications such as Backup and Remote Storage to handle media cataloging and automation.

Removable Storage labels, catalogs, and tracks media; controls library drives, slots, and doors; and provides drive-cleaning operations.

For more information about the Removable Storage service, see the Server Management Guide of the Windows Server 2003 Resource Kit (or see the Server Management Guide on the Web at http://technet.microsoft.com/en-us/windowsserver/bb633748.aspx)

If this service is stopped or disabled, applications that are dependent on the Removable Storage service, such as Backup and Remote Storage, operate more slowly.

The Removable Storage service stops when there is nothing to process. If there are no automated devices attached to the system, the Removable Storage service runs only while there are applications using it; therefore, it is not necessary to stop the service. When started under these circumstances, the Removable Storage service frequently needs to inventory the complete contents of attached autoloaders and jukeboxes, which includes mounting each media in a drive.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Resultant Set of Policy Provider (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** RSoPProv

**Executable Name:** RSoPProv.exe

**Log On As:** LocalSystem

**Description:** The Resultant Set of Policy Provider service enables you to connect to a Windows Server 2003 domain controller, access the Windows Management Instrumentation (WMI) database for that computer, and simulate Resultant Set of Policy (RSoP) for Group Policy settings. The policy settings are applied to a user or computer located in Active Directory on a Windows 2000 or later domain.

This service is used by the RsoP snap-in, and is also accessed by any client of the RSoP-Planning Mode Provider/WMI Provider. RSoP is an addition to Group Policy that makes policy implementation and troubleshooting easier. RSoP is a query engine that polls existing policy settings and planned policy settings, and then reports the results of those queries. It polls existing policy settings based on site, domain, domain controller, and organizational unit. RSoP gathers this information from the Common Information Management Object Model (CIMOM) database (otherwise known as CIM-compliant object repository) through WMI.

RSoP provides details about all policy settings that are configured by an administrator, including Administrative Templates, Folder Redirection, Internet Explorer Maintenance, Security Settings, Scripts, and Software Installation.

When policy settings are applied on multiple levels (for example, site, domain, domain controller, and organizational unit), the results can conflict. RSoP can help you determine a set of applied policy settings and their precedence (that is, the order in which policy settings are applied).

RSoP consists of two modes: planning mode and logging mode. By using planning mode, you can simulate the effect of policy settings that you want to apply to a computer and user. Logging mode reports the existing policy settings for a computer and the user that is currently logged on.

This service is used by the RsoP snap-in, and is also accessed by any client of the RsoP-Planning Mode Provider/WMI Provider.

For more information about RSoP, see the *Distributed Services Guide* of the *Windows Server 2003 Resource Kit* (or see the *Distributed Services Guide* on the Web at http://technet.microsoft.com/en-us/windowsserver/bb633748.aspx)

If this service is stopped or disabled, RSoP planning mode simulation is unavailable on the domain controller.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Routing and Remote Access (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NtmsSvc

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Routing and Remote Access service provides multiprotocol LAN-to-LAN, LAN-to-WAN, VPN, and network address translation (NAT) routing services. In addition, Routing and Remote Access also provides dial-up and VPN remote access services.

The Routing and Remote Access service (note capitalization) replaces the Routing and Remote Access Service (RRAS) and Remote Access Service (RAS) features from Windows NT 4.0. The Routing and Remote Access service is a single, integrated service that terminates connections from either dial-up or VPN clients or that provides routing (IP, IPX, and Services for Macintosh), or both. With the Routing and Remote Access service, your server can function as a remote access server, a VPN server, a gateway, or a branch-office router.

From a routing perspective, the Routing and Remote Access service supports the Open Shortest Path First (OSPF) and Routing Information Protocol (RIP) routing protocols, and controls the routing tables for the TCP/IP stack-forwarding engine.

If this service is stopped or disabled, the remote access server cannot accept incoming RAS, VPN, or demand-dial connections, and routing protocols are not received or transmitted.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

NetBIOS Group

NetBIOS Interface

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# SAP Agent (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** NwSapAgent

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The SAP Agent service advertises network services on an IPX network by using the Internetwork Packet Exchange Service Advertising Protocol (IPX SAP) protocol. It also forwards advertisements on a multihomed host. Some features, such as Client Services for NetWare, rely on the SAP Agent.

The SAP Agent service requires the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol to be installed.

If this service is stopped or disabled, IPX service discovery does not work; the server does not advertise itself, and clients are not able to reach it.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** In Network Connections, right-click a local area connection, click Properties, click Install, click Service, click Add, and then click Service Advertising Protocol.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

NWLink IPX/SPX/NetBIOS Compatible Transport Protocol

**The following system components depend on this service:**

None

# Secondary Logon (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** seclogon

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Secondary Logon service enables the starting of processes that run under alternate administrative credentials so that the user can create processes in the context of different security principals. A common use of this service is for administrators to log on as a restricted user and then use Secondary Logon to temporarily run an application as Administrator.

Another feature of this service is the Runas command. Using the Runas command, you can run programs (*.exe files), saved MMC consoles (*.msc files), shortcuts to programs, or Control Panel items as an Administrator while you are logged on to your computer as a member of another group, such as the Users or Power Users group. As long as you provide the appropriate user account and password information, the user account has the ability to log on to the computer, and the program, MMC console, or Control Panel item is available on the system and to the user account.

| **Note** |
| --- |
| In Windows 2000, this services was called the RunAs Service. |

If this service is stopped or disabled, the Run as snap-in generates the error message, “Windows cannot access the specified device, path or file. You may not have the appropriate permissions to access them.” Any calls to the CreateProcessWithLogonW API fail. Specifically, this causes the Run as snap-in and the run as command to function improperly.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

None

**The following system components depend on this service:**

None

# Security Accounts Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SamSs

**Executable Name:** Lsass.exe

**Log On As:** LocalSystem

**Description:** The Security Accounts Manager (SAM) service is a protected subsystem that manages user and group account information. In Windows 2000 and Windows Server 2003, workstation security accounts are stored by SAM in the registry of the local computer, and domain controller security accounts are stored in Active Directory. In Windows NT 4.0, both local and domain security accounts are stored in the registry.

The startup of this service signals other services that SAM is ready to accept requests.

This service cannot be stopped.

If you disable this service, other services in the system are not notified when SAM is ready, which might cause those services to fail to start correctly. This service should not be disabled.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

DHCP Server

Distributed File System

Distributed Transaction Coordinator

FTP Publishing Service

HTTP SSL

IIS Admin Service

Intersite Messenging

Message Queuing

Message Queuing Downlevel Client Support

Message Queuing Triggers

Microsoft POP3 Service

Network News Transfer Protocol (NNTP)

Simple Mail Transfer Protocol (SMTP)

Windows Internet name Services (WINS)

World Wide Web Publishing Service

# Server (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** lanmanserver

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Server service provides RPC support, file printing, and named pipe sharing over the network. It allows the sharing of local resources (such as disks and printers) so that other users on the network can access them. It also allows named pipe communication between applications running on other computers and your computer, which is used for RPC.

Named pipe communication is memory reserved for the output of one process to be used as input for another process. The input-accepting process does not need to be local to the computer.

If this service is stopped, you cannot share files and printers on this computer with other computers on the network, and the computer cannot satisfy RPC requests. You also cannot serve named pipes to other computers on the network.

If this service is disabled, any services that explicitly depend on this service will fail to start.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

None

**The following system components depend on this service:**

Computer Browser

Distributed File System

Net Logon

# Shell Hardware Detection (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ShellHWDetection

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Shell Hardware Detection service monitors and provides notification for AutoPlay hardware events. AutoPlay is a feature that detects content such as pictures, music, or video files on removable media and removable devices. AutoPlay then automatically starts applications to play or display that content. This simplifies the use of specialized peripheral devices such as Moving Picture Experts Group (MPEG) Audio Layer-3 (MP3) players and digital photo readers. It also makes it easier for users who are unfamiliar with the software needed to access various content types.

AutoPlay supports a variety of media content types and applications. Both independent hardware vendors (IHVs) and independent software vendors (ISVs) can extend this support to include their hardware devices and applications. A user can configure a different AutoPlay action for any combination of pictures, music files, and video.

Supported media and device types include the following:

- Removable storage media, such as Zip disks by Iomega
- Flash media, such as the CompactFlash specification from the CompactFlash Association, the SmartMedia specification from the SSFDC Forum, and the Memory Stick specification developed by Sony
- PC Cards
- External USB or IEEE 1394 fixed drives

Supported content types include the following:

- Pictures (.jpg, .bmp, .gif, .tif)
- Music files (.mp3, .wma)
- Video (.mpg, .asf)

If this service is stopped, you lose the hardware AutoPlay functionality, My Computer icons and labels are displayed in Classic View, and shell performance is also affected.

If this service is disabled, any services that explicitly depend on this service will fail to start.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

Windows Image Acquisition (WIA)

# Simple Mail Transfer Protocol (SMTP) (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SMTPSVC

**Executable Name:** Inetinfo.exe

**Log On As:** LocalSystem

**Description:** The Simple Mail Transfer Protocol (SMTP) service transports e-mail across the network. It is used as an e-mail submission and relay agent. It can accept and queue email for remote destinations and retry at specified intervals. Windows domain controllers use the SMTP service for intersite e-mail–based replication. The Collaboration Data Objects (CDO) for Windows Server 2003 COM component can use the SMTP service to submit and queue outbound e-mail.

Other applications — for example, Microsoft Exchange Server — might use the SMTP service as the basis for their SMTP support.

In Windows 2000, the SMTP service was installed by default. In Windows Server 2003, this service is now an optional component installed through Add/Remove Windows Components.

If this service is stopped or disabled, e-mail–based replication and forwarding do not function.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Event Log

IIS Admin Service

Remote Procedure Call (RPC)

Security Accounts Manager

**The following system components depend on this service:**

None

# Simple TCP/IP Services (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SimpTcp

**Executable Name:** Tcpsvcs.exe

**Log On As:** NetworkService

**Description:** Simple TCP/IP Services implements support for the Echo, Discard, Character Generator, Daytime, and Quote of the Day protocols.

- **Echo (port 7, RFC 862)** This protocol echoes back data from any messages it receives on this server port. Echo can be useful as a network debugging and monitoring tool.

- **Discard (port 9, RFC 863)** This protocol discards all messages received on this port without response or acknowledgment. It can serve as a null port for receiving and routing TCP/IP test messages during network setup and configuration or, in some cases, it can be used by programs as a message discard function.

- **Character Generator (CHARGEN) (port 19, RFC 864)** This protocol sends data made up of the set of 95 printable ASCII characters. It is useful as a debugging tool for testing or troubleshooting line printers.

- **Daytime (port 13, RFC 867)** This protocol returns messages containing the day of the week, month, day, year, current time (in hh:mm:ss format), and time-zone information. Some programs can use the output from this service for debugging or monitoring variations in system clock time or on a different host.

- **Quote of the Day (port 17, RFC 865)** This protocol returns a quotation as one or more lines of text in a message. Quotations are taken at random from the following file: *systemroot*\System32\Drivers\Etc\Quotes. A sample quote file is installed with Simple TCP/IP Services. If this file is missing, the quote service fails.

To find RFC standards, see the Request For Comments (RFC) link on the Web Resources page at http://technet.microsoft.com/windowsserver/bb633748.aspx.

After this service is installed and started, all five protocols are enabled on all network adapters. There is no provision for selectively enabling specific protocols or enabling this service on a per–network adapter basis.

Stopping or disabling this service has no effect on the rest of the operating system.

You should not install Simple TCP/IP Services unless you specifically need this service to support communication with other systems that use this protocol service.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

AFD Networking Support Environment

**The following system components depend on this service:**

None

# Single Instance Storage Groveler (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Groveler

**Executable Name:** grovel.exe

**Log On As:** LocalSystem

**Description:** The Single Instance Storage Groveler (SIS) service is an integral component of Remote Installation Services (RIS). SIS reduces the overall storage required on the RIS volume. The SIS drivers contain a feature called a "groveler agent" that scans the RIS volume for duplicate files. If the SIS groveler finds duplicate files, it copies the original file into the SIS and leaves a link file in its place. The link file contains information about the original file, such as its current location, size, and attributes. If an image contains duplicate files, those duplicates are copied into the store; as a result, less disk space is required on the RIS server.

SIS has two limitations:

- It cannot act upon any files that are referenced through junction points.
- It cannot be used with any file system except NTFS, which is the only file system supported on RIS servers.

If this service is stopped or disabled, files are no longer automatically linked in this manner, but the existing linked files are still accessible.

New RIS installation images will consume their full image size, and conserve little space.

If SIS is no longer needed on the system, use Add/Remove Windows Components to remove Remote Installation Services.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components and Remote Installation Services. (When you install Remote Installation Services, this service is automatically installed.)

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Single Instance Storage

**The following system components depend on this service:**

None

# Smart Card (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SCardSvr

**Executable Name:** SCardSvr.exe

**Log On As:** LocalService

**Description:** The Smart Card service manages and controls access to a smart card inserted into a smart card reader attached to your computer. The smart card subsystem is based on personal computer/smart card (PC/SC) consortium standards and consists of the following components:

**Resource manager.** This component manages access to readers and smart cards. To manage these resources, it performs the following functions:

- Identifies and tracks resources.
- Allocates readers and resources across multiple applications.
- Supports transaction primitives for accessing services available on a given card.

The resource manager also exposes a subset of the Win32 API to provide applications with access to these functions.

**Card/Reader Selection UI.** This component allows simple applications that work with smart cards to access a card and reader with minimum coding.

If this service is stopped or disabled, your computer cannot read smart cards.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Plug and Play

**The following system components depend on this service:**

None

# SNMP Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SNMP

**Executable Name:** Snmp.exe

**Log On As:** LocalSystem

**Description:** The SNMP service allows incoming Simple Network Management Protocol (SNMP) requests to be serviced by the local computer. SNMP includes agents that monitor activity in network devices and report to the network console workstation. SNMP provides a method of managing network hosts such as workstation or server computers, routers, bridges, and hubs from a centrally located computer running network management software. SNMP performs management services by using a distributed architecture of management systems and agents.

SNMP can be used to:

- Configure remote devices. Configuration information can be sent to each networked host from the management system.
- Monitor network performance. You can track the speed of processing and network throughput, and collect information about the success of data transmissions.
- Detect network faults or inappropriate access. You can configure trigger alarms on network devices when certain events occur. When an alarm is triggered, the device forwards an event message to the management system. Common types of events that need alarms include a device being shut down and restarted, a link failure being detected on a router, and inappropriate access.
- Audit network usage. You can monitor both overall network usage to identify user or group access, and types of usage for network devices and services.

The SNMP service also includes an SNMP agent that allows remote, centralized management of computers running the following:

- Microsoft® Windows® XP Home Edition
- Microsoft® Windows® XP Professional
- Microsoft® Windows® 2000 Professional
- Microsoft® Windows® 2000 Server
- Microsoft Windows Server 2003 family

The SNMP agent also allows management of the following services:

- Windows XP or the Windows Server 2003 family and Windows 2000–based WINS
- Windows XP or the Windows Server 2003 family and Windows 2000–based DHCP
- Windows XP or the Windows Server 2003 family and Windows 2000–based IIS
- LAN Manager

If this service is stopped or disabled, the computer cannot respond to SNMP requests. If the computer is being monitored by network management tools, those tools cannot collect data from the computer nor control its functionality through the SNMP

service.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components, Management and Monitoring Tools, and Simple Network Management Protocol.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Event Log

**The following system components depend on this service:**

None

# SNMP Trap Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SNMPTRAP

**Executable Name:** Snmptrap.exe

**Log On As:** LocalService

**Description:** SNMP Trap Service receives trap messages generated by local or remote Simple Network Management Protocol (SNMP) agents and forwards the messages to SNMP management programs running on your computer.

The SNMP service, when configured for an agent, generates trap messages if any specific events occur. These messages are sent to a trap destination. For example, an agent can be configured to initiate an authentication trap if a request for information is sent by an unrecognized management system.

Trap destinations consist of the computer name or the IP or IPX address of the management system. The trap destination must be a network-enabled host that is running SNMP management software. Trap destinations can be configured by a user, but the events (such as restarting a computer) that generate a trap message are internally defined by the SNMP agent.

If this service is stopped or disabled, SNMP-based programs on your computer cannot receive SNMP trap messages. If this computer is being used to monitor network devices or server applications by using SNMP traps, significant system events are lost.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Add/Remove Windows Components, Management and Monitoring Tools, and Simple Network Management Protocol. (When you install Simple Network Management Protocol, the SNMP Trap Service is automatically installed.)

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Event Log

**The following system components depend on this service:**

None

# Special Administration Console Helper (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Sacsvr

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** You can use the Special Administration Console (!SAC) Helper service to perform remote management tasks if Windows Server 2003 stops functioning because of a Stop error.

The main functions of !SAC are to:

- Redirect Stop error message explanatory text.
- Restart the system.
- Obtain computer identification information.

The Special Administration Console (!SAC) Helper service is an auxiliary Emergency Management Services command-line environment that is hosted by Windows Server 2003. It also accepts input and sends output through the out-of-band port. !SAC is a separate entity from both the Special Administration Console (SAC) and Windows Server 2003 command-line environments. After a specific failure point is reached, Emergency Management Services components determine when the shift should be made from SAC to !SAC. !SAC becomes available automatically if SAC fails to load or is not functioning.

If this service is stopped or disabled, !SAC services are not available.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

None

**The following system components depend on this service:**

None

# SQLAgent$UDDI

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SQLAgent$UDDI

**Executable Name:** SQLagent.exe –iUDDI

**Log On As:** Network Service or Domain Account

**Description:** The SQLAgent$ UDDI service is a job scheduler and monitoring service. It also moves information between computers running Microsoft SQL Server and is used heavily for backups and replication.

If this service is stopped or disabled, replication does not occur. Also, all scheduled jobs and alert/event monitoring, and auto restart of the SQL Server service, will be disrupted.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition (32-bit only)

**Installed through:** Add/Remove Windows Components and UDDI Services.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

MSSQL$UDDI

**The following system components depend on this service:**

None

# System Event Notification (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** SENS

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The System Event Notification service (SENS) tracks system events such as Windows logon network and power events, and notifies the COM+ Event System service subscribers of these events.

If this service is stopped or disabled, COM+ Event System service subscribers do not receive system event notifications. They also encounter the following problems:

- Win32 APIs IsNetworkAlive() and IsDestinationReachable() APIs do not work. These APIs are mostly used by mobile applications on portable computers.
- ISens* interfaces — specifically, SENS Logon/Logoff notifications — do not work.
- SyncMgr (mobsync.exe) does not work properly, because it depends on connectivity information and also on Network Connect/Disconnect and Logon/Logoff notifications from SENS.
- COM+ EventSystem tries to notify SENS of some events, but it does not succeed.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition.

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

COM+ Event System

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Task Scheduler (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Schedule

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Task Scheduler service allows you to perform automated tasks on a computer. By using Task Scheduler, you can schedule any script, program, or document to run at a time that is most convenient for you.

By using Task Scheduler, you can:

- Schedule a task to run daily, weekly, monthly, or at certain times (such as system startup).
- Change the schedule for a task.
- Stop a scheduled task.
- Customize how a task runs at a scheduled time.

Each scheduled task you create is stored as a .job file in the C:\Windows\Tasks folder. The .job file contains the properties and configuration information for the task. You can create a scheduled task on your computer and then drag the .job object to a remote computer. After you drag a task from one computer to another, you must update the account information for the task before it will run. Removing a scheduled task removes only the .job file from the schedule. The program file the task runs is not removed from the hard disk.

When you first install Windows Server 2003, the Task Scheduler service is started. By default, you must be a member of the Administrators, Backup Operators, or Server Operators group on the local computer to view, add, edit, or delete scheduled tasks, or to disable, pause, or restart the Task Scheduler service.

The Task Scheduler service can be started from the Services snap-in or set to automatically start. Task Scheduler can be accessed from the Task Scheduler graphical user interface by using the Task Scheduler API as described in the Microsoft Platform Software Development (SDK), or by using the Schtasks.exe tool.

For more information about Task Scheduler APIs, see the Microsoft Platform SDK link on the Web Resources page (http://go.microsoft.com/fwlink/?linkid=291).

If this service is stopped or disabled, tasks do not run at their scheduled times. For example, jobs that are scheduled to run do not run at their designated time or interval. If there are no jobs listed in the *systemroot*\Tasks\ folder, the effect of disabling this service is minimal; otherwise, jobs that are required to run might be severely impacted.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# TCP/IP NetBIOS Helper (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** LMHosts

**Executable Name:** svchost.exe -k LocalService

**Log On As:** LocalService

**Description:** The TCP/IP NetBIOS Helper service provides support for the NetBIOS over TCP/IP (NetBT) service and NetBIOS name resolution for clients on your network, enabling users to share files, print, and log on to the network. The TCP/IP NetBIOS Helper service provides support for the NetBT service by performing DNS name resolution and pinging a set of IP addresses that return a list of accessible IP addresses.

If this service is stopped or disabled, NetBT, RDR, SRV, Net Logon, and Messenger service clients might not be able to share files or printers, or log on to computers.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

AFD Networking Support Environment

NetBios over Tcpip

**The following system components depend on this service:**

None

# TCP/IP Print Server (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** LPDSVC

**Executable Name:** Tcpsvcs.exe

**Log On As:** LocalSystem

**Description:**The TCP/IP Print Server service enables TCP/IP-based printing by using the Line Printer Daemon protocol. The TCP/IP Print Server service on the print server receives documents from native Line Printer Remote (LPR) utilities running on UNIX computers.

If this service is stopped or disabled, TCP/IP-based printing is unavailable.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition

**Installed through:** Add/Remove Windows Components, Other Network File and Print Services, and Print Services for Unix. (The TCP/IP Print Server and LPRMON services are installed when you install Print Services for Unix.)

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

IPSEC Driver

Print Spooler

Remote Procedure Call (RPC)

TCP/IP Protocol Driver

**The following system components depend on this service:**

None

# Telephony (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** TapiSrv

**Executable Name:** svchost.exe -k tapisrv

**Log On As:** LocalSystem

**Description:** The Telephony service provides Telephony API (TAPI) support. Clients use the Telephony service to run programs that control telephony devices and IP-based voice connections on your computer and throughout the network. The Telephony service enables applications to act as clients to telephony equipment such as PBXs, telephones, and modems. Telephony supports the TAPI by which different wire protocols that communicate with telephony equipment can be supported. These protocols are implemented in Telephony service providers (TSPs).

If this service is stopped or disabled, any services that explicitly depend on this service, such as modem support, fail to start.

The Telephony service cannot be stopped if there is another dependent service, such as RAS, currently active. If there are no other dependent services running and you stop the Telephony service, it will be restarted when any application makes an initialization call to the TAPI interface.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Plug and Play

Remote Procedure Call (RPC)

**The following system components depend on this service:**

Fax

Internet Connection Firewall (ICF)/Internet Connection Sharing (ICS)

Remote Access Auto Connection Manager

Remote Access Connection Manager

# Telnet (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** TlntSvr

**Executable Name:** Tlntsvr.exe

**Log On As:** LocalService

**Description:** The Telnet service supports connections from various TCP/IP Telnet clients, including UNIX-based and Windows-based computers. Telnet Server for Windows provides ASCII terminal sessions to Telnet clients. Telnet Server supports two types of authentication and supports four types of terminals: ANSI, VT100, VT52, and VTNT.

Telnet also allows a remote user to log on to the system and run console programs by using the command line.

If this service is stopped, remote users cannot connect to the computer by using Telnet.

If this service is disabled, remote users are unable to connect to this computer through the Telnet protocol, and users cannot connect to the computer or run console-based applications.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

IPSEC Driver

NTLM Security Support Provider

Remote Procedure Call (RPC)

TCP/IP Protocol Driver

**The following system components depend on this service:**

None

# Terminal Server Licensing (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** TermServLicensing

**Executable Name:** Lserver.exe

**Log On As:** LocalSystem

**Description:** The Terminal Server Licensing service installs a license server and provides registered client licenses when a computer is connecting to a server that has Terminal Server enabled. The Terminal Server Licensing service is a low-impact service that stores the client licenses that have been issued for a terminal server and tracks the licenses that have been issued to client computers or terminals.

If this service is stopped or disabled, the computer running the Terminal Server Licensing service is unable to issue Terminal Server licenses to clients when they request them. If another Terminal Server License Server is installed on a domain controller in the forest, the requesting terminal server attempts to employ it.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Add/Remove Windows Components and Terminal Server Licensing.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Event Log

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Terminal Services (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** TermService

**Executable Name:** svchost.exe -k termsvcs

**Log On As:** LocalSystem

**Description:** Terminal Services provides a multisession environment that allows users to access a virtual Windows desktop session and Windows-based programs running on a remote computer. Terminal Services allows multiple users to be connected interactively to a terminal server (a server that has Terminal Server enabled), allows users to access desktops and applications on remote computers, and allows users to access another user's desktop for administration purposes.

If this service is stopped or disabled, the computer might become unreliable. To prevent remote use of your computer, clear the **Allow Remote Assistance** and **Allow Remote Desktop** check boxes on the **Remote** tab of the **System Properties** dialog box.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** By default, Remote Desktop for Administration is installed on computers running Windows Server 2003. To install Terminal Server, use the Configure Your Server Wizard or Add/Remove Windows Components.

**Startup type:** Manual

**Service status:** Started

**This service depends on the following system components:**

Infrared Monitor

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Terminal Services Session Directory (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Tssdis

**Executable Name:** Tssdis.exe

**Log On As:** LocalSystem

**Description:** The Terminal Services Session Directory service provides a multisession environment that allows client devices to access a virtual Windows desktop session and Windows-based programs running on a Windows Server 2003–based computer.

The Terminal Services Session Directory allows clusters of load-balanced terminal servers (servers that have Terminal Server enabled) to properly route a user's connection request to the server where the user already has a session running. Users are routed to the first-available terminal server, regardless of whether they have a running session elsewhere in the cluster. Load balancing pools the processing resources of several servers by using the TCP/IP networking protocol. You can use this service with a cluster of terminal servers to scale the performance of a single terminal server by distributing sessions across multiple servers. Session Directory keeps track of disconnected sessions on the cluster, and ensures that users are reconnected to those sessions.

If this service is stopped or disabled, load balancing for Terminal Services does not work.

Connection requests are routed to the first available server. Users are routed to the first-available terminal server, regardless of whether they have a running session elsewhere in the cluster.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Themes (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Themes

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Themes service provides user-experience theme-management services and rendering support for the new Windows Server 2003 graphical user interface (GUI). A desktop theme is a predefined set of icons, fonts, colors, sounds, and other window elements that give the computer desktop a unified and distinctive look. You can select from different themes, create your own theme by modifying a theme and then saving it with a new name, or restore the traditional Windows Classic look as your theme.

If this service is stopped or disabled, the new Windows Server 2003 visual style (windows, buttons, scrollbars, and other controls) reverts to the Windows Classic visual style.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

None

**The following system components depend on this service:**

None

# Trivial FTP Daemon (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** tftpd

**Executable Name:** tftpd.exe

**Log On As:** LocalSystem

**Description:** The Trivial FTP Daemon (TFTPD) service implements support for the Trivial File Transfer Protocol (TFTP) defined by the following RFCs:

- RFC 1350, "The TFTP Protocol (Revision 2)"
- RFC 2347, "TFTP Option Extension"
- RFC 2348, "TFTP Blocksize Option"
- RFC 2349, "TFTP Timeout Interval and Transfer Size Options"

To find RFC standards, see the Request For Comments (RFC) link on the Web Resources page (http://go.microsoft.com/fwlink/?linkid=291). TFTP does not require a user name or password and is an integral part of the Remote Installation Services (RIS).

A RIS server uses the TFTPD service to download the initial files required for the remote installation process to begin. The most common file downloaded to the client by using the TFTPD service is Startrom.com, which is responsible for bootstrapping the client computer. If the user then presses F12 when prompted, the Client Installation Wizard is downloaded to begin the remote installation process.

If this service is stopped, the server fails to reply to the client request.

If this service is disabled by using the Services snap-in, this server fails to send the initial files to the client computer.

The correct way to disable this service is to uninstall RIS.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Add/Remove Windows Components and Remote Installation Services. (When you install RIS, the Trivial FTP Daemon service is automatically installed.)

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

IPSEC Driver

TCP/IP Protocol Driver

**The following system components depend on this service:**

None

# Uninterruptible Power Supply (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** UPS

**Executable Name:** Ups.exe

**Log On As:** LocalService

**Description:** The Uninterruptible Power Supply service manages an uninterruptible power supply (UPS) connected to your computer by a serial port.

| **Note** |
| --- |
| If you have a USB UPS, you should not install this service. |

By default the startup type is Manual and the default status is Stopped, unless you install and configure a serial UPS. After you install and configure a serial UPS, the startup type changes to Automatic and the default status changes to Started.

If this service is stopped or disabled, communications with the UPS are lost. If power is lost on the AC line, the UPS is unable to pilot the computer to shut down as the UPS battery discharges towards a critically low state. This could potentially result in loss of data.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic, if you install and configure a serial UPS on the **UPS** tab of the **Power Options Properties** dialog box.

**Service status:** Started

**This service depends on the following system components:**

None

**The following system components depend on this service:**

None

# Upload Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** uploadmgr

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Upload Manager service manages synchronous and asynchronous file transfers between clients and servers on the network. Driver data is anonymously uploaded from customer computers to Microsoft and then used to help users find the drivers required for their systems. The Microsoft Driver Feedback Server asks the client's permission to upload the computer's hardware profile and then search the Internet for information about how to obtain the appropriate driver or get support from Microsoft or a third party.

Information uploaded from your computer for the purposes of finding driver information includes the hardware identification numbers for the device, the time at which the Windows Hardware Wizard was finished, and an ID for the Windows operating system you are running. The system information uploaded cannot be tracked to a user, computer, corporation, IP address, or any other source information.

The collected data is used to track which devices do not have easily obtainable drivers. If additional device driver information exists, it will be available after the device identification number is uploaded. If additional driver information is not available, Microsoft records the device's identification number to work with hardware vendors to increase the availability of drivers necessary to run devices on Windows, or provide information about driver availability and device support.

If this service is stopped or disabled, synchronous and asynchronous file transfers between clients and servers on the network do not occur.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Manual on Windows Server 2003, Standard Edition and Windows Server 2003, Enterprise Edition

Disabled on Windows Server 2003, Datacenter Edition and on Windows Server 2003, Web Edition

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Virtual Disk Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** VDS

**Executable Name:** Vds.exe

**Log On As:** LocalSystem

**Description:** Virtual Disk Service (VDS) provides a single interface for managing block storage virtualization, whether done in operating system software, redundant array of independent disks (RAID) storage hardware subsystems, or other virtualization engines.

VDS provides a vendor-neutral and technology-neutral interface for the management of logical volumes (in software) and logical units (in hardware). Management operations include binding, topology discovery and tracking, volume status and fault tracking, and performance monitoring.

Virtual disks should not be confused with snapshots. Unlike the Volume Shadow Copy service, VDS does not coordinate with applications or the file system. Thus, the data contained on a volume will not be synchronized prior to a volume or disk configuration operation. VDS might be used to configure a mirror plex, but a snapshot provider is necessary to perform the coordination when removing the plex and surfacing the snapshot. That use is outside the scope of this document with two exceptions:

- VDS coordinates with the file system prior to extending or shrinking volumes.
- Full-copy snapshots appear as plexes to VDS.

If this service is stopped or disabled, VDS is no longer available.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

Plug and Play

**The following system components depend on this service:**

None

# Volume Shadow Copy (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** VSS

**Executable Name:** Vssvc.exe

**Log On As:** LocalSystem

**Description:** The Volume Shadow Copy service manages volume shadow and is used by backup applications. When a backup application attempts to start a backup by using the new volume shadow infrastructure, the backup application calls methods to determine the number of writers that are running on the service. It queries each writer to gather the required metadata. After it has obtained the metadata, the backup application can collect the volumes that need to be shadow copied to ensure a successful backup session.

Volume Shadow Copy allows you to create shadow copy backups of volumes — exact copies of files, including all open files. For example, databases that are held open exclusively and files that are open due to operator or system activity are backed up during a volume shadow copy backup. In this way, files that have changed during the backup process are copied correctly.

Shadow copy backups ensure that:

- Applications can continue to write data to the volume during a backup.
- Files that are open are not omitted during a backup.
- Backups can be performed at any time, without locking out users.

Some applications manage storage consistency differently while files are open, which can affect the consistency of the files in the backup. For critical applications, consult the application vendor.

If this service is stopped or disabled, shadow copies are unavailable for backup and the backup process might not succeed.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Maunal

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# WebClient (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WebClient

**Executable Name:** svchost.exe -k LocalService

**Log On As:** LocalService

**Description:** The WebClient service allows Win32 applications to access documents on the Internet. It extends the networking capability of Windows by allowing standard Win32 applications to create, read, and write files on Internet file servers by using the Web Document Authoring & Versioning (WebDAV) protocol.

The WebDAV protocol is a file access protocol described in XML that travels over HTTP. By using standard HTTP, WebDAV runs over an existing Internet infrastructure (for example, firewalls and routers).

If this service is stopped or disabled, you cannot use the Web Publishing Wizard to publish data to the Internet for locations that use the WebDAV protocol.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

WebDav Client Redirector

**The following system components depend on this service:**

None

# Web Element Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** ELEMENTMGR

**Executable Name:** Elementmgr.exe

**Log On As:** LocalSystem

**Description:** The Web Element Manager service is responsible for serving Web user interface elements for the Administration Web site at port 8098. These elements are used to determine the following information:

- Tabs to display on the administration Web site
- Remote Administration tasks available to a member of the local Administrators group on the Server Appliance
- Table of Contents
- Help topics
- Remote Administration alerts that can be displayed

A member of the local Administrators group can remotely manage a server by connecting to the server at https://*servername*:8098. When a connection is received on this Web site, the default Active Server Pages (ASP) code queries the Web Element Manager service on the Microsoft® Windows® Powered Web server appliance for each type of information listed above. After all the information has been collected, the appropriate Web page is displayed to the administrator.

The Web Element Manager service loads up all the information at startup time; the client (in this case, the ASP code) requests the Web user interface elements through a COM interface. The service runs in the LocalSystem account and requests through the COM interface are accepted only from clients running under the Administrator or LocalSystem accounts. If the service is stopped or its startup type is Manual, this service will start when the next request for Web user interface elements is received.

If this service is stopped, the service is automatically restarted when the Web interface for remote administration is accessed.

If this service is disabled, the Remote Administration Tools Web user interface for server administration does not function properly.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Windows Audio (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** AudioSrv

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Windows Audio service provides support for sound and related Windows Audio event functions. This service manages Plug and Play events for audio devices such as sound cards and global audio effects (GFX) for Windows audio application program interfaces. Examples of GFXs are equalization (EQ), bass enhancement, and speaker correction. The service handles the loading, unloading, and state save/restore of the GFXs on a per-session basis.

Through the Multimedia item under Components in System Information, the user can do the following:

- Enable or disable a GFX.
- Select among several GFX filters if more than one GFX is available that is designed for the audio hardware in question. A GFX driver's INF file specifies the target hardware for the GFX.

This service cannot be stopped after it has started. If this service is disabled, audio functionality might be unable to provide sound or process GFXs.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic on Windows Server 2003, Standard Edition

Disabled on Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows Server 2003, Web Edition

**Service status:** Started

**This service depends on the following system components:**

Plug and Play

Remote Procedure Call (RPC)

**The following system components depend on this service:**

# Windows Image Acquisition (WIA) (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** StiSvc

**Executable Name:** svchost.exe -k imgsvc

**Log On As:** LocalService

**Description:** The Windows Image Acquisition (WIA) service provides image acquisition services for scanners and cameras.

Windows supports still-image devices through the WIA service, which uses the Windows Driver Model (WDM) architecture. The WIA service provides robust communication between applications and image-capture devices, allowing you to capture images efficiently and transfer them to your computer for editing and use. The service is needed to capture events generated by imaging devices.

The WIA service supports small computer system interface (SCSI), IEEE 1394, USB, and serial digital still-image devices. Support for infrared, parallel, and serial still-image devices — which are connected to standard COM ports — comes from the existing infrared, parallel, and serial interfaces. Image scanners and digital cameras are examples of still-image devices. The WIA service also supports Microsoft® DirectShow®–based Webcams and digital video (DV) camcorders to capture frames from video.

If this service is stopped or disabled, events from imaging devices are not captured and processed. If a WIA device is installed on the computer, the service will restart automatically when you restart the computer. Also, the service restarts any time a WIA-enabled application is started.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Disabled

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

Shell Hardware Detection

**The following system components depend on this service:**

# Windows Installer (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** MSIServer

**Executable Name:** msiexec.exe /V

**Log On As:** LocalSystem

**Description:** The Windows Installer service manages the installation and removal of applications by applying a set of centrally defined setup rules during the installation process. These setup rules define the installation and configuration of the installed application. In addition, this service can modify, repair, or remove an existing application. The Windows Installer technology consists of the Windows Installer service for the Windows operating systems and the package (.msi) file format used to hold information regarding the application setup and installations.

Windows Installer is not only an installation program; it is also an extensible software management system. Windows Installer manages the installation, addition, and deletion of software components, monitors file resiliency, and maintains basic disaster recovery by means of rollbacks. Additionally, Windows Installer supports installing and running software from multiple sources, and can be customized by developers who want to install custom applications.

If startup type is Manual, an application that uses the installer will start this service.

If this service is stopped or disabled, the installation, removal, repair, and modification of applications that use Windows Installer do not succeed. A number of applications make use of this service while they are running, and those applications might not work correctly.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Windows Internet Name Service (WINS) (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WINS

**Executable Name:** Wins.exe

**Log On As:** LocalSystem

**Description:** Windows Internet Name Service (WINS) enables NetBIOS name resolution. The presence of the WINS server(s) is crucial for locating the network resources identified by using NetBIOS names. WINS servers are required unless all domains have been migrated to Active Directory and all servers on the network are running Windows Server 2003.

| **Note** |
| --- |
| When performing a clean installation of any member of the Windows Server 2003 family, you have to explicitly select WINS in order to have it installed on the computer. By default, WINS is not installed. |

For more information about WINS, see the Networking Guide of the Windows Server 2003 Resource Kit (or see the Networking Guide on the Web at (http://technet.microsoft.com/en-us/windowsserver/bb633748.aspx)).

If this service is stopped or disabled, the following occurs:

- Locating Windows NT 4.0 domains and domain controllers does not succeed.
- Locating Windows 2000 or Windows Server 2003 Active Directory domains and domain controllers from Windows NT 4.0 clients does not succeed.
- NetBIOS name resolution fails, unless the device whose name must be resolved is on the same subnet as the device attempting name resolution. The device must be configured to attempt NetBIOS name resolution by using broadcasts.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Configure Your Server Wizard, or go to Add/Remove Windows Components, Networking Services, and Windows Internet Name Service (WINS)

**Startup type:** Automatic

**Service status:** Started

# Windows Management Instrumentation (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** winmgmt

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Windows Management Instrumentation (WMI) service provides a common interface and object model to access management information about operating system, devices, applications, and services. WMI is an infrastructure for building management applications and instrumentation shipped as part of the current generation of Microsoft operating systems.

The WMI infrastructure is a Windows operating system component that moves and stores information about managed objects. The WMI infrastructure is made of two components: the WMI service and the WMI repository. The WMI service acts as an intermediary between the providers, management applications, and the WMI repository, placing information from a provider into the WMI repository. The WMI service also accesses the WMI repository in response to queries and instructions from management applications. Finally, the WMI service can pass information directly between a provider and a management application. In contrast, the WMI repository acts as a storage area for information passed in by the various providers.

WMI provides accessible information about applications and services, including management events those applications and services might generate.

WMI provides access to the management data through a number of interfaces, including COM API, scripts, and command-line interfaces. WMI is compatible with previous management interfaces and protocols, such as SNMP.

If this service is stopped or disabled, most Windows-based software does not function properly and management data is unavailable.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

# Windows Management Instrumentation Driver Extensions (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** Wmi

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Windows Management Instrumentation Driver Extensions service monitors all drivers and event trace providers that are configured to publish WMI or event trace information.

| **Note** |
| --- |
| In Windows Server 2003, the Windows Management Instrumentation Driver Extensions service is primarily a stub service that was created to deal with Windows 2000 service compatibility issues. |

If this service is stopped or disabled, any services that explicitly depend on it will fail to start.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

**This service depends on the following system components:**

None

**The following system components depend on this service:**

None

# Windows Media Services (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WMServer

**Executable Name:** Wmserver.exe

**Log On As:** NetworkService

**Description:** Windows Media Services provides streaming media services over IP-based networks. It replaces the four separate services that comprised Windows Media Services versions 4.0 and 4.1:

- Windows Media Monitor Service
- Windows Media Program Service
- Windows Media Station Service
- Windows Media Unicast Service

Windows Media Services is now a single service that runs on the Windows Server 2003 family. Its core components were developed by using the Component Object Model (COM), creating a flexible architecture that is easily customized for specific applications. It supports a greater variety of control protocols, including Real Time Streaming Protocol (RTSP), Microsoft Media Server (MMS) protocol, and HTTP.

The Windows Media Service platform is compliant with the following industry standards:

- WMI for server event notification and messaging
- SNMP for networking components
- XML, Synchronized Multimedia Integration Language (SMIL) 2.0, and the Document Object Model (DOM) for playlist implementation
- MPEG 1 and 2 for audio and video formats

Most streaming scenarios can be accomplished by using the core components installed with Windows Media Services. However, more advanced scenarios might require that you incorporate some custom programming and integration work. For developers and systems integrators, the Windows Media Services Software Development Kit (SDK) provides access to all elements of the server through a combination of plug-ins, a fully documented object model, and a rich set of external event notifications, all designed to be easily customizable.

If this service is stopped or disabled, streaming media services might be unavailable.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Configure Your Server Wizard or Manage Your Server, or go to Add/Remove Windows Components and Windows Media Services.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Windows System Resource Manager (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WindowsSystemResourceManager

**Executable Name:** Wrm.exe

**Log On As:** LocalSystem

**Description:** The Windows System Resource Manager (WSRM) service is a tool to help deploy applications into consolidation scenarios. It provides policy-based management of CPU and memory consumption of processes running on a single operating system instance. Planned scenarios include multiple heterogeneous server applications, multiple Terminal Services users, multiple instances of SQL Server, multiple IIS 6.0 application pools, or Exchange Server and IIS 6.0 running together on the same computer.

The WSRM service enables a system administrator to do the following:

- Configure CPU and memory allocation policy settings on applications. This includes selecting processes to be managed and setting resource usage targets or limits.
- Manage CPU utilization (percent CPU in use).
- Limit the process working set size (physical resident pages in use).
- Manage committed memory (paging file usage).
- Apply policy settings to users or groups on a Terminal Services application server.
- Apply policy settings on a Date and Time schedule.
- Generate, store, view, and export resource utilization accounting records for management, service level agreement (SLA) tracking, and charge-back purposes.

The WSRM service maintains an updatable exclusion list of processes that should not be managed because of the negative system impact such management could create. The WSRM service also applies limits to process working set size and committed memory consumption. The WSRM service does not manage address windowing extensions (AWE) memory, large page memory, locked memory, or operating system pool memory.

The primary option for CPU management is bandwidth targets (expressed as a percent of system CPU). Targets are maintained by dynamically monitoring and adjusting process priorities. The WSRM service also provides affinity management, which is provided by using per-process APIs for hard affinity.

Memory management options include working set limits and committed memory maximum applied per process. Working set limits are set in policy and applied by the WSRM service by means of a kernel API. Subsequently, the kernel memory manager will apply and maintain the limits on working set size by paging the process as necessary. Committed memory is simply monitored against an upper limit. When the upper limit is exceeded, the process is stopped or an event is logged (at the user's discretion).

Additional features include full calendar features for scheduling desired policies, sophisticated pattern matching for identifying processes at runtime, WSRM service–specific counters, and a basic job accounting system.

The WSRM service must be installed on each managed computer. For administration of the service, an MMC snap-in and command-line programs are provided. These client components can be installed and run on any Windows 2000, Windows XP Professional, or Windows Server 2003 operating system. The service can be installed and run only on Windows Server 2003, Datacenter Edition and Windows Server 2003, Enterprise Edition.

If this service is stopped or disabled:

- You will not receive any management (WSRM provides runaway process protection by default).
- You will not receive any job accounting data.
- You will not be able to administer WSRM by means of the snap-in or CLI.

**Available on:** Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition

**Installed through:** Windows System Resource Management CD

**Startup type:** Automatic

**Service status:** Started or Stopped based on user check box in setup

**This service depends on the following system components:**

Remote Procedure Call (RPC)

**The following system components depend on this service:**

None

# Windows Time (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** W32Time

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Windows Time service maintains date and time synchronization on all computers running on a Windows-based network. It uses the Network Time Protocol (NTP) to synchronize computer clocks so that an accurate clock value, or time stamp, can be assigned to network validation and resource access requests. The implementation of NTP and the integration of time providers make the Windows Time service a reliable and scalable time service for enterprise administrators. For computers that are not joined to a domain, the Windows Time service can be configured to synchronize time with an external time source.

If this service is stopped or disabled, date and time synchronization is unavailable in the forest or an external NTP server.

There are two scenarios:

1. Stopping the Windows Time service on a workstation prevents the workstation from synchronizing its time with another source, but has no effect on any other external server.

2. Stopping the Windows Time service on a domain controller has the same effect as in item 1, but it also prevents any domain members from synchronizing time with it. This might adversely impact time synchronization in the enterprise.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

None

**The following system components depend on this service:**

Cluster Service

# WinHTTP Web Proxy Auto-Discovery Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WinHttpAutoSvc

**Executable Name:** svchost.exe –k LocalService

**Log On As:** LocalService

**Description:** WinHTTP Web Proxy Auto-Discovery Service (WinHttpAutoSvc) implements proxy configuration discovery for WinHTTP clients. It performs the lookup done by WinHttpGetProxyForUrl() as documented in Microsoft® MSDN®. Applications use the service to isolate the running of an autoproxy script in a sandbox from the client process.

The WinHttpGetProxyForUrl() function implements the Web Proxy Auto-Discovery (WPAD) protocol for automatically configuring the proxy settings for an HTTP request. The WPAD protocol downloads a Proxy Auto-Configuration (PAC) file, which is a script that identifies the proxy server to use for a given target URL. PAC files are typically deployed by the IT department within a corporate network environment.

To make configuring the proxy settings for WinHTTP-based applications easier, WinHTTP now implements the Web Proxy Auto-Discovery (WPAD) protocol, often referred to as autoproxy. This is the same protocol that Web browsers implement to automatically discover the proxy configuration without requiring an end user to specify a proxy server manually. This feature is available starting with WinHTTP version 5.1 in Windows 2000 Service Pack 3, Windows XP Service Pack 1, and Windows Server 2003.

Stopping or disabling this service might cause WinHTTP clients to be unable to automatically detect proxy settings, and might cause other WinHTTP clients to automatically detect proxy settings within their own process.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Started

**This service depends on the following system components:**

AFD Networking Support Environment

DHCP Client

IPSEC Driver

TCP/IP Protocol Driver

# Wireless Configuration (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WZCSVC

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Wireless Configuration service enables automatic configuration for IEEE 802.11 wireless adapters for wireless communications.

Microsoft partnered with 802.11 network adapter vendors to improve the wireless roaming experience on Windows by automating the process of configuring the network adapter to associate with an available network.

The wireless network adapter and its Network Driver Interface Specification (NDIS) driver need to do very little beyond supporting a few new NDIS Object Identifiers (OIDs) used for the querying and setting of device and driver behavior. The network adapter scans for available networks and passes those to a computer running Windows Server 2003. The wireless configuration service takes care of configuring the network adapter with an available network. In the case in which there are two networks covering the same area, the user can configure a preferred network order and the computer will try each network in order until it finds an active one. It is also possible to limit association to only the configured, preferred networks.

If this service is stopped or disabled, automatic wireless configuration is unavailable.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition.

Manual on Web Edition

**Service status:** Started

# WMI Performance Adapter (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** WmiApSrv

**Executable Name:** Wmiapsrv.exe

**Log On As:** LocalSystem

**Description:** The WMI Performance Adapter service provides performance library information from WMI HiPerf providers. Applications and services that need to provide performance counters today can do so in two ways: by writing a WMI High Performance provider, or by writing a performance library. Consumers of high performance data also have two ways to request performance data: through WMI, or through the Performance Data Helper (PDH) APIs. There are mechanisms in place so that the two models interact together, and clients accessing counters through each model can still see the counters provided by the other model. The Reverse Adapter is one of those mechanisms.

The WMI Performance Adapter service transforms performance counters supplied by WMI High Performance providers into counters that can be consumed by PDH through the Reverse Adapter Performance Library. This way, PDH clients (for example, System Monitor) can consume performance counters surfaced by any WMI High Performance providers on the computer.

The startup type is Manual and the service is not running by default. It runs on demand when a performance client (for example, System Monitor) uses PDH to query performance data. After the client disconnects, the service stops.

This service runs on demand when a performance client, (for example, System Monitor) uses PDH to query performance data. After the client disconnects, the service stops.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Manual

**Service status:** Stopped

# Workstation (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** lanmanworkstation

**Executable Name:** svchost.exe -k netsvcs

**Log On As:** LocalSystem

**Description:** The Workstation service creates and maintains client network connections to remote servers. The Workstation service is a user-mode layer for the Microsoft Networks redirector. It loads and performs configuration functions for the redirector, provides support for making network connections to remote servers, provides support for the WNet APIs, and furnishes redirector statistics.

If this service is stopped, you cannot establish connections to remote servers and access files through named-pipes. This prevents you from accessing files and printers located on other remote computers, but does not affect TCP/HTTP connectivity. Internet browsing and Web Client access will still work.

If this service is disabled, any services that explicitly depend on this service will fail to start.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** Default operating system installation

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

None

**The following system components depend on this service:**

Alerter

Computer Browser

Distributed File System

File Server for Macintosh

Messenger

Net Logon

Remote Procedure Call (RPC) Locator

# World Wide Web Publishing Service (System Services for the Windows Server 2003 Family and Windows XP Operating Systems)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service Name:** W3SVC

**Executable Name:** svchost.exe -k iissvcs

**Log On As:** LocalSystem

**Description:** World Wide Web Publishing Service provides Web connectivity and administration through IIS Manager.

World Wide Web Publishing Service provides HTTP services for applications on the Windows platform. The service contains a process manager and a configuration manager. The process manager controls the processes in which custom applications and simple Web sites reside. The configuration manager reads the stored system configuration and ensures that Windows is configured to route HTTP requests to the appropriate application pools or operating system processes.

This service can monitor the processes in which custom applications reside and provide recycling services for these applications. Recycling is a configuration property of an application pool and can be done on the basis of memory limits, request limits, processing time, or time of day. The service will queue HTTP requests if custom applications stop responding, and will also attempt to restart custom applications.

The service depends on IIS Admin Service and kernel TCP/IP support.

| **Note** |
| --- |
| In Windows 2000 Server, Windows 2000 Advanced Server, and Windows 2000 Datacenter Server, IIS was installed by default. This has changed on Windows Server 2003: IIS is installed by default only on Windows Server 2003, Web Edition. |

If this service is stopped or disabled, the Windows Server 2003 operating system will not be able to serve Web pages or any form of Web request.

**Available on:** Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition and Windows Server 2003, Web Edition

**Installed through:** By default on Windows Server 2003, Web Edition.

In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Server Edition, use the Configure Your Server Wizard, or go to Add/Remove Windows Components, Application Server, Internet Information Services (IIS), and World Wide Web Service.

**Startup type:** Automatic

**Service status:** Started

**This service depends on the following system components:**

HTTP SSL

IIS Admin Service

Remote Procedure Call (RPC)

Security Accounts Manager

**The following system components depend on this service:**

None

# Server and Domain Isolation

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Server and domain isolation enable you to implement network authentication based on policy rather than network topology, so that your Windows environment is dynamically segmented into more secure, isolated logical networks.

By using server and domain isolation, you can better:

- Reduce the scope of network security threats
- Safeguard sensitive data and intellectual property
- Extend the value of existing infrastructure

Server and domain isolation builds on Internet Protocol security (IPsec) and Active Directory® Domain Services (AD°DS), which are available in Windows Vista®, Windows Server® 2008, Windows Server® 2003, Windows XP, and Windows 2000. This removes the need to make potentially disruptive changes to your network topology, existing applications, or requiring costly hardware upgrades.

**Available documentation**
The following resources can help you to effectively design, deploy, and manage server and domain isolation scenarios in your network.

- Introduction to Server and Domain Isolation

  This paper introduces the basic concepts of server and domain isolation, and describes common scenarios in which each can be used to improve network security.

- Server Isolation with Microsoft Windows Explained

  This paper provides a detailed overview of server isolation in the Microsoft Windows operating systems. It explains how server isolation protects servers and describes the benefits of deploying server isolation in your IT environment. It also provides a brief overview of how to deploy server isolation.

- Domain Isolation with Microsoft Windows Explained

  This paper provides a detailed overview of domain isolation in the Microsoft Windows operating systems. It explains how domain isolation protects domain member computers and describes the benefits of deploying domain isolation in your IT environment. It also provides a brief overview of how to deploy domain isolation.

# Introduction to Server and Domain Isolation

Applies To: Windows Server 2008, Windows Vista

The proliferation of networking technologies that allow computers to freely communicate has ushered in a new age of productivity for businesses, governments, and individuals. People have around-the-clock access to e-mail, messages, files, databases, and Web pages. They can access this data through multiple types of connections, including wired (such as Ethernet), wireless, and remote access.

Unfortunately, the ease and ubiquity of connection poses new risks. The same ease of connectivity that allows users to access networked resources at any time from almost anywhere also allows malicious programs (such as viruses and worms) and malicious users to attack computers or their resources at any time and from anywhere. Although your company needs to allow access to resources, this access should be permitted to only authenticated and authorized users and computers. Protecting your network requires a layered defense-in-depth security model. Your network must be isolated, not only from the Internet, but also from unauthorized and unmanaged computers on your intranet.

To isolate the authorized and managed computers from the other computers on your network, you can create an isolated network; a set of network nodes whose grouping is independent of the physical network topology. You can create an isolated network based on the Physical layer of the Open Systems Interconnection (OSI) model, in which you run a separate cabling system for the isolated network. However, this type of isolated network is costly and difficult to maintain for large networks. You can also create an isolated network based on the Data Link layer of the OSI model, in which you use Layer 2 switches and virtual LAN (VLAN) technology to create logical network segments by grouping computers regardless of their physical connection to a set of switches. With VLAN technology, you can also create an isolated network based on the Network layer of the OSI model, in which you create logical subnets and define the routing between the subnets. However, for VLAN-based isolated networks, your switching fabric must support VLANs and the logical segments or subnets must be maintained over time as the topology of the network changes and computers move to different switch ports.

With the Microsoft® Windows® operating systems, you can logically isolate your domain and server resources to limit access to authenticated and authorized computers. For example, you can create a logical network consisting of computers that share a common Windows-based security framework and a set of requirements for secure communication. Each computer on the logically isolated network can provide authentication credentials to the other computers on the isolated network to prove its membership. Requests for communication that originate from computers that are not part of the isolated network are ignored.

Windows-based network isolation occurs at the Network layer of the OSI model. Therefore, the isolated network can span hubs, switches, and routers across the physical and geographical boundaries of your organization network.

By leveraging the authentication infrastructure of Windows-based computers, you can create an isolated network that does not depend on a separate cabling system or on the features of your switching or routing fabric. Additionally, Windows-based isolated networks do not require ongoing maintenance based on changes in network topology or computers moving to different switch ports. The result is an isolated network that leverages your existing Windows infrastructure with no additional costs associated with network reconfiguration or hardware upgrades.

Figure 1 shows an example of an isolated network.

In Figure 1, the entire organization network is isolated from the Internet by a firewall, a proxy server, or other types of security systems. A subset of the network's computers is located on the isolated network. The computers on the isolated network are protected from the other computers on the organization network.

For example, many types of viruses and worms cannot propagate into an isolated network. Malicious users and software from outside the isolated network cannot successfully attack isolated network computers because they lack the authentication credentials with which to establish communication.

The security requirements of the isolated network can optionally include data encryption. By requiring data encryption for the traffic exchanged between isolated network members, you can satisfy business partner and regulatory requirements to encrypt

data when it traverses a network.

**Server and Domain Isolation Solutions**

To create an isolated network, you need to separate the various types of computers on the organization network according to the type of access you want the computers to have. The communication requirements are the following:

- Computers on the isolated network can initiate communications with all of the computers on the organization network, including those that are not located on the isolated network.

- Computers that are not on the isolated network can initiate communications only with other computers that are not on the isolated network. They cannot initiate communications with computers on the isolated network.

Computers on the isolated network will ignore all requests to initiate communication from computers that are not on the isolated network. This helps provide protection against malicious programs and users outside the isolated network and decreases the exposure of computers on the isolated network to various types of network attacks (such as port scanning) and malicious software (such as viruses and worms). In addition, you can specify that traffic sent between the computers on the isolated network be encrypted.

To create an isolated network, you need the following elements:

- Credentials

  The computers on the isolated network use security credentials when initiating communications to prove their identity and authenticate themselves to the other computers on the isolated network.

- Network policy settings

  The computers on the isolated network use network policy settings to require authentication for incoming communication requests, to secure communications and, if needed, to provide encryption.

In an organization network, it is impractical to configure and administer credentials and network policy settings locally on individual computers. To create an isolated network that can be centrally configured and that scales as your organization grows, you need to manage the computers on your organization network. To centrally manage your network, you need an authentication and policy distribution infrastructure.

On a Windows-based network that is managed by a central IT department, computers use the authentication infrastructure and policy distribution mechanism to implement Server and Domain Isolation. A managed environment not only makes Server and Domain Isolation easier, it also provides the infrastructure that allows you to configure other security activities, such as distributing operating system updates and installing antivirus software.

In Windows, a computer can be a member of an Active Directory® directory service domain. During the process of joining an Active Directory domain, the computer is issued a set of credentials. On an ongoing basis after joining the domain, the computer receives centrally configured network policies through Group Policy. Network administrators use Group Policy to distribute computer and user settings to the member computers of an Active Directory domain. With the appropriate Group Policy settings to require authentication before communication, a domain member computer sends its credentials to authenticate a communication attempt, which can then be verified by any domain controller.

By leveraging Active Directory membership and Group Policy settings, everything that you need to create an isolated network is already available on computers running Windows Vista®, Windows Server® 2008 (currently in beta), Microsoft® Windows® XP, Microsoft® Windows Server® 2003, and Microsoft® Windows® 2000 Server operating systems. All that you need to do is to ensure that computers are members of your domain and to configure the appropriate Group Policy settings to require authentication for incoming communication attempts, to secure data traffic, and optionally, to encrypt data traffic. After you have configured and applied the appropriate Group Policy settings, you add a new computer to the isolated network by making it a member of the Active Directory domain. In contrast to cable or VLAN-based isolated networks, no new hardware or maintenance of the cabling system or switching fabric is required.

Figure 2 shows an example of an isolated network using an Active Directory domain.

In Figure 2, the computers on the isolated network are members of an Active Directory domain, which includes computers that are locally connected to the organization network—through Ethernet or Institute of Electrical and Electronic Engineering (IEEE) 802.11 wireless LAN connections, for example—or are remotely connected to the organization network, through a remote access dial-up connection or a virtual private network (VPN) connection across the Internet (not shown). The computers on the organization network that are not part of the isolated network include stand-alone computers running Windows—such as those that are members of workgroups or other untrusted domains—or other computers that do not support Active Directory, such as Apple Macintosh computers or UNIX-based computers.

If business operational requirements exist, options are available to enable non-Windows hosts to participate in the isolated network. For example, workstations and departmental servers running Linux, Mac OS X, and Solaris can be configured to communicate directly with an isolated domain. Alternatively, using ISA Server as an IPsec proxy, communication to isolated domains can also be configured for systems that do not natively support IPsec or for mainframes for which IPsec is not normally implemented.

Server and Domain Isolation provides an extra layer of security and access control that compliments other host- and network-based security technologies, such as antivirus, anti-spyware, firewall, 802.1X and intrusion detection, to enable greater resiliency in the presence of network security threats. This solution also further extends the value of Active Directory and the operational efficiency benefits of Group Policy. Logical isolation policies are created distributed and managed centrally using Active Directory Group Policy and existing Active Directory-based credentials (e.g. Kerberos or X.509 certificates). This results in a zero-touch deployment experience for IT administrators and an unchanged experience for end-users. No additional end-user training is required nor is there a need to install new software or visit each computer during deployment.

After you have deployed an Active Directory domain, you can configure Server and Domain Isolation.

**Domain Isolation**

To isolate a domain, you use an Active Directory domain and domain membership to enforce the following network policy: domain member computers accept only authenticated and secured communications from other domain member computers. This network policy isolates domain member computers from non-domain-member computers. With Domain Isolation, the isolated network consists, in the majority of cases, of the set of computers that belong to an Active Directory domain, as Figure 2 shows.

To configure Domain Isolation, use Group Policy settings to require that all incoming communication requests be authenticated using Active Directory and that domain member computers can initiate unprotected communications with non-domain-member computers. Optionally, you can require that all communication within the isolated domain be encrypted. You can also configure exemptions so that specific trusted computers that are not domain members can initiate unprotected communications with domain member computers.

Domain Isolation provides many benefits by:

- Restricting incoming communications to domain member computers.

  Domain member computers use their domain credentials to authenticate communication attempts and network policy settings to secure traffic with each other. This helps mitigate the risk of rogue or unmanaged devices from exploiting potentially unpatched vulnerabilities, propagating malicious software (malware) threats like viruses, worms or spyware, or disrupting business operations through denial-of-service (DoS) attacks. Non-domain-member computers do not have domain credentials and, therefore, cannot authenticate communication attempts with protected computers.

- Supplementing other security mechanisms designed to prevent unwanted communications.

  Domain Isolation provides end-to-end security that supplements the security mechanisms already deployed on your network, providing defense-in-depth. For example, if you deployed Domain Isolation and your firewall was compromised, malicious Internet users could not directly initiate communications with protected computers.

- Encouraging domain membership.

  By placing critical organization servers, such as database servers, on the isolated network, you prevent users on the organization network from connecting to them from a non-domain-member computer. To receive valid domain credentials for communicating with organization servers, computers must be joined to the domain. After a computer has been joined to the domain, you can manage it in other ways, such as by ensuring that it has the latest operating system and antivirus updates. These proactive measures also help increase system reliability and security, while reducing the risk of network-based attacks and lowering ongoing maintenance costs.

- Securing traffic between domain member computers.

  Traffic sent between domain member computers is secured so that the receiving computer can verify that an authenticated computer sent the packet and that the packet was not modified in transit. Optionally, the traffic between domain member computers can be encrypted, providing protection from malicious users on your organization network who attempt to capture and interpret network traffic.

For more information about Domain Isolation, see "Domain Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44642. For examples of how customers have deployed Domain Isolation, see the "Case Studies"section at http://go.microsoft.com/fwlink/?LinkId=79428.

**Server Isolation**

To isolate a specific server or servers, sensitive data, and associated clients, you use an Active Directory domain and domain membership to enforce the following network policy: specific server computers that are domain members accept authenticated and secured communications only from other domain member computers. This network policy isolates specific servers from non-domain-member computers. For example, to protect database traffic, you would configure and deploy Server Isolation Group Policy settings to require secured traffic between domain member client computers and their database servers. With Server Isolation, the isolated network consists of the server computers and domain member client computers, both of which belong to an Active Directory domain.

You can also create the following group-specific server isolation network policy: specific server computers that are domain members will accept authenticated and secured communications only from other domain member computers that are members of specific Active Directory security groups. Group-specific Server Isolation provides an additional layer of authorization and isolates specific servers from both non-domain-member computers and unauthorized domain member computers. Only an authorized domain member computer that has the business need can access the isolated server. With group-specific server isolation, the isolated network consists of the server computers and the group of authorized domain member client computers.

For example, you can configure group-specific Server Isolation settings so that a server that contains sensitive medical information allows secure communications only with computers that meet the following criteria:

- They are domain members.

- They are members of the ConfidentialMedical Active Directory security group.

After you have configured the appropriate Group Policy and server settings, you can allow a new computer to access this server by joining the computer to the domain and then adding the computer account of the new computer to the ConfidentialMedical Active Directory security group.

You can also use group-specific Server Isolation in conjunction with Domain Isolation to define and enforce tiered network access restrictions based on business objectives and policy versus network topology. For example, you can use Domain Isolation to better protect your entire Windows environment from rogue or unmanaged computers. Then, you can add another layer of protection through Server Isolation to further restrict access to specific networked resources to only the user requiring this access for business reasons.

Server Isolation provides many benefits by:

- Supplementing other security mechanisms designed to prevent unwanted communications.

- Encouraging domain membership.

  Non-domain-member computers cannot communicate with critical isolated servers unless they join the Active Directory

domain.

- Protecting traffic sent to and from isolated servers.

  The isolated server can verify that an authenticated computer sent the packet and that it was not modified in transit. Optionally, traffic to and from the isolated servers can be encrypted, providing protection from malicious users on your organization network who attempt to capture and interpret network traffic.

- Protecting applications that cannot protect themselves.

  Applications running on isolated servers that do not have facilities for enforcing access control or security can benefit from server isolation to enforce authentication, authorization, and communication security.

For more information about Server Isolation, see "Server Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44641.

**Overview of Server and Domain Isolation Documents**

This paper is the first in a series of papers that describes Server and Domain Isolation and provides guidelines for planning their deployment. The other papers include:

- "Domain Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44642

  This paper provides a detailed overview of Domain Isolation. It explains how Domain Isolation protects domain member computers and the benefits of deploying Domain Isolation. It also provides a brief overview of how to deploy Domain Isolation. This paper is intended for IT professionals in organizations that are investigating using the Microsoft implementation of Internet Protocol security (IPsec) in Windows to deploy Domain Isolation. It assumes that you are somewhat familiar with the Microsoft implementation of IPsec and would like more detailed information about using that technology to deploy Domain Isolation.

- "Server Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44641

  This paper provides a detailed overview of Server Isolation. It explains how Server Isolation protects isolated servers and the benefits of deploying Server Isolation. It also provides a brief overview of how to deploy Server Isolation. This paper is intended for IT professionals in organizations that are investigating using the Microsoft implementation of IPsec in Windows to deploy Server Isolation. It assumes that you are somewhat familiar with the Microsoft implementation of IPsec and would like more detailed information about using that technology to deploy Server Isolation.

- "Domain Isolation Planning Guide for IT Managers" at http://go.microsoft.com/fwlink/?LinkId=44645

  Designed for enterprise IT managers who are investigating using IPsec in Microsoft Windows to deploy Domain Isolation, this paper will help you and your IT staff to gather the information required to develop a Domain Isolation deployment plan and to design your IPsec policies. It includes an overview of the deployment process, a step-by-step guide to the planning process, and links to resources that you can use to plan and design your deployment. It does not explain how to deploy Domain Isolation.

- "A Guide to Domain Isolation for Security Architects" at http://go.microsoft.com/fwlink/?LinkId=44643

  Designed for security architects of enterprise organizations that are investigating the use of IPsec in Microsoft Windows to deploy Domain Isolation, this paper describes the implications of deploying Domain Isolation in an enterprise environment and explains how to assess the enterprise environment and plan Domain Isolation. Read this guide after you have developed a working knowledge of Domain Isolation.

- "Setting Up IPsec Server and Domain Isolation in a Test Lab" at http://go.microsoft.com/fwlink/?LinkId=44646

  This paper demonstrates how to set up IPsec Server and Domain Isolation in a limited test environment. It provides procedures for setting up a basic deployment, which you can use as the basis for your own deployment. This paper is designed for network architects who are investigating the use of IPsec in Microsoft Windows to deploy Server and Domain Isolation.

The size of your environment and IT staff will determine your planning and deployment requirements, which, in turn, will determine which of the server and domain deployment papers you will need to read.

**For Enterprises and Large Businesses**
For the purposes of these papers, an enterprise is a business or organization that has more than 100 servers and more than 500 desktop computers, comprises multiple organizational units, and has distributed branch offices. A large business is a business or organization that has more than 100 servers and more than 500 desktop computers and that might have multiple organizational units.

Typically, deployments in enterprises and large businesses require greater planning and more precisely defined processes. If you are planning Server and Domain Isolation deployment in an enterprise or large business, read the following papers in the order listed:

- "Domain Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44642
- "Server Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44641
- "Domain Isolation Planning Guide for IT Managers" http://go.microsoft.com/fwlink/?LinkId=44645
- "A Guide to Domain Isolation for Security Architects" at http://go.microsoft.com/fwlink/?LinkId=44643
- "Setting Up IPsec Server and Domain Isolation in a Test Lab" at http://go.microsoft.com/fwlink/?LinkId=44646

**For Medium and Small Businesses**
For the purposes of these papers, a medium business is a business or organization that has between 4 and 100 servers and 25 to 500 desktop computers, which might have only one organizational unit, and might have one or two distributed branch offices. A small business is a business or organization that has between 1 and 3 servers and 1 and 25 desktop computers, might not have a domain or has only one domain, and has no branch offices.

Typically, deployments in these organizations require less planning and less highly developed processes than larger deployments. If you are planning Server and Domain Isolation deployment in a medium or small business, read the following papers in the order listed:

- "Domain Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44642
- "Server Isolation with Microsoft Windows Explained" at http://go.microsoft.com/fwlink/?LinkId=44641
- "Domain Isolation Planning Guide for IT Managers" http://go.microsoft.com/fwlink/?LinkId=44645

Optionally, you might want to read the following papers:

- "A Guide to Domain Isolation for Security Architects" at http://go.microsoft.com/fwlink/?LinkId=44643
- "Setting Up IPsec Server and Domain Isolation in a Test Lab" http://go.microsoft.com/fwlink/?LinkId=44646

# Server Isolation with Microsoft Windows Explained

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As described in "Introduction to Server and Domain Isolation with Microsoft Windows," server isolation uses an Active Directory® directory service domain, domain membership, and Group Policy to enforce a network policy requiring specific server computers that are domain members to accept only authenticated and secured communications from other domain member computers. This network policy isolates specific servers from computers that are not domain members.

For example, sensitive data on servers is typically protected by access control security at the Application layer. Before accessing the files on a file server that contains sensitive data, a user must provide security credentials, such as a user name and a password. However, by specifying access control lists (ACLs) at the Application layer, you do not protect the server from attacks against other services running on the server or other types of network-level attacks—such as denial of service, viruses, or worms—launched from computers that are not domain members on your intranet.

To provide another layer of protection for servers that store sensitive data, you can isolate them from computers that are not domain members by implementing additional authentication and security at the Internet layer with Internet Protocol security (IPsec). By using IPsec-based server isolation, computers that are not domain members cannot initiate Internet Protocol (IP)-based communication with isolated servers. Organizations that send sensitive data over their networks and that must provide extra protection for sensitive data assets — such as those in the financial services, health care, or government sectors — require this additional level of protection.

Server isolation provides many benefits by:

- Restricting incoming communications to domain member computers.

  In the Microsoft® Windows® operating systems, you can manage a computer that is a member of an Active Directory domain by centrally configuring settings in Group Policy and applying those settings to all domain member computers. You can also apply other types of security updates, such as operating system updates and antivirus software signatures, to domain member computers. Domain member computers use their domain credentials to authenticate communication attempts with isolated servers. Computers that are not domain members — such as stand-alone, those that do not run Windows, unknown, and guest computers — do not have domain credentials and, therefore, cannot authenticate communication attempts with isolated servers.

- Supplementing security mechanisms designed to prevent unwanted communications.

  Server isolation supplements the security mechanisms already deployed on your network, such as ACLs, Institute of Electrical and Electronic Engineers (IEEE) 802.1X, Secure Sockets Layer (SSL), and firewalls. For example, if you isolated your servers and then your Internet firewall was compromised, malicious users from the Internet could not initiate direct communications with the isolated servers.

- Encouraging domain membership.

  By isolating critical organization servers, such as e-mail servers, you can prevent network users from accessing critical resources from a computer that is not a domain member. To receive valid domain credentials for authenticating with isolated servers, computers that are not domain members must join the domain. After being joined to the domain, these computers can be managed in other ways. For example, you can ensure that they have the latest operating system and antivirus updates.

- Protecting traffic sent to and from isolated servers.

  Traffic sent to and from isolated servers is cryptographically protected, so that the receiving computer can verify that an authenticated computer sent the packet and that the packet was not modified in transit. Optionally, the isolated server traffic can be encrypted, providing protection from malicious network users attempting to capture and interpret network traffic.

- Protecting applications that cannot protect themselves.

  Applications running on servers running Windows that cannot enforce access control or security at the Application layer can use server isolation to enforce authentication, authorization, and communication security at the Internet layer.

To isolate a server, you can configure Group Policy settings to require that all communication with isolated servers must be authenticated and protected by using IPsec. IPsec protects traffic from address spoofing, data injection, session hijacking, replay attacks, and other types of data tampering. Optionally, you can specify that packets are encrypted. You can also configure exceptions to specify that trusted computers, computers that are not domain members, or computers that are known as *exempted computers*, can initiate unprotected communications with isolated servers.

**How Server Isolation Works**

This section describes how Active Directory, Group Policy, and IPsec work together to implement server isolation.

**Components of Server Isolation**

To isolate a server, you need the following components:

- **An Active Directory domain.** A domain includes domain controllers and the appropriate trust relationships to establish trust with other domains or the directory trees of an organization network.
- **Member computers.** These are computers that have joined the Active Directory domain and received domain credentials.
- **Group Policy settings.** These computer and user settings are automatically downloaded to member computers.
- **Active IPsec policy settings.** These Group Policy settings determine the server isolation behavior of domain member computers.

In a simplified server isolation deployment, you configure and activate an IPsec policy with rules that define specific types of traffic and how the traffic should be handled. You then activate the IPsec policy for the appropriate Active Directory containers, such as sites, domains, and organizational units. The member computers in the Active Directory containers to which the Group Policy settings apply automatically download the Group Policy settings.

After the domain member computers have downloaded and applied the Group Policy settings, they have both the correct IPsec policy for server isolation and domain credentials that allow them to communicate securely with isolated servers. Computers that are not domain members, which do not have domain credentials or the correct IPsec settings, cannot initiate communications with isolated servers.

**Communication Processes**

When you implement server isolation by configuring domain member computers with the appropriate IPsec policy settings, communication between computers in your network differs depending on which type of computer (domain member or non-domain-member) initiates communication and which type of computer receives communication. This section describes how communication occurs:

- When a domain member computer initiates communication with an isolated server.
- When a computer that is not a domain member initiates communication with an isolated server.
- When an exempted computer initiates communication with an isolated server.

The following figure shows the types of communication that occur when you deploy server isolation.

**Legend**

**Communication with an isolated server initiated by a domain member computer**

When a domain member computer with both Active Directory credentials and server isolation IPsec policy settings (for example, COMPUTER1 in the figure) initiates communication with an isolated server (for example, SERVER1), the following occurs:

1. The initial communication packet sent by COMPUTER1—for example, a Transmission Control Protocol (TCP) Synchronize (SYN) segment destined for the IP address of an e-mail server that is isolated—matches the rule of the active IPsec policy that specifies that the initiating computer must secure the traffic with IPsec.

2. COMPUTER1 uses IPsec to perform mutual authentication with SERVER1 and to negotiate the use of IPsec protection.

3. Because both COMPUTER1 and SERVER1 have domain credentials, the IPsec authentication process succeeds. Because COMPUTER1 has IPsec policy settings that match SERVER1, negotiation of IPsec protection also succeeds.

4. COMPUTER1 sends the initial communication packet to SERVER1 with IPsec protection.

5. SERVER1 sends the response to the initial communication packet—for example, a TCP SYN-Acknowledgement (SYN-ACK) segment—to COMPUTER1 with IPsec protection.

6. Subsequent packets sent between COMPUTER1 and SERVER1 are protected by IPsec.

Domain member computers that have the appropriate IPsec policy settings authenticate and protect with IPsec communications to all isolated servers.

**Communication with an isolated server initiated by a non-domain-member computer**

When a non-domain-member computer (for example, COMPUTER2 in the figure) initiates communication with an isolated server (for example, SERVER1), the following occurs:

1. Because COMPUTER2 does not have IPsec policy settings, it sends its initial communication packet—for example, a TCP SYN segment—without IPsec protection to SERVER1.

2. On SERVER1, the initial communication packet sent by COMPUTER2 matches the IPsec policy rule for the server that requires IPsec protection for all incoming packets.

3. Because SERVER1 does not accept unprotected packets, it silently discards the TCP SYN segment sent by COMPUTER2.

4. SERVER1 also discards subsequent communication initiation packets sent by COMPUTER2.

5. Eventually, COMPUTER2 ends its attempt to communicate with SERVER1.

The IPsec policy on SERVER1 causes unprotected communications to be dropped. Non-domain-member computers that attempt to communicate with an isolated server never receive a response and, therefore, cannot connect to the server. Even if a user on a non-domain-member computer was able to duplicate the IPsec policy settings of a domain member computer, communications with SERVER1 would fail because the non-domain-member computer does not have valid domain

credentials.

**Communication with an isolated server initiated by an exempted computer**
When an exempted computer (for example, COMPUTER3 in the figure) initiates communication with an isolated server (for example, SERVER1), the following occurs:

1. Because COMPUTER3 does not have IPsec policy settings, it sends its initial communication packet—for example, a TCP SYN segment—without IPsec protection to SERVER1.

2. On SERVER1, the initial communications packet sent by COMPUTER3 matches the IPsec policy rule for the server that permits unsecured communication to its own IP address from the IP addresses of specific exempted computers.

3. SERVER1 sends a response—for example, a TCP SYN-ACK segment—to COMPUTER3 without IPsec protection.

4. Subsequent packets sent between COMPUTER3 and SERVER1 are sent without IPsec protection.

The specified IPsec policy allows exempted computers to communicate with isolated servers without requiring IPsec protection.

**Group-Specific Server Isolation**
The server isolation configuration described thus far allows all domain member and exempted computers to communicate with an isolated server. However, servers differ in the level of sensitivity of their data and whether they permit universal access or access only from specific computers. For example, e-mail servers typically must be available to all domain member computers in order to allow a user on any domain member computer to access e-mail. However, finance or legal department servers should only be available to a specific subset of computers.

To further isolate servers that store sensitive data and prevent unauthorized domain member computers from communicating with them, you can separate these servers and authorized computers by providing them with an IP address on a separate subnet, or by using a different authentication method, such as digital certificates. However, both solutions require additional administrative overhead.

For servers running Windows, you can use another method to enforce authorization. By applying the **Access this computer from the network** user right (a local Group Policy setting), you can specify the computer accounts or Active Directory security groups that you want to allow to access a server over the network. When IPsec processes the credentials of the computer requesting communications, Windows checks the **Access this computer from the network** user right.

Therefore, to further isolate servers that store sensitive data based on Active Directory group membership, you can do the following:

1. Ensure that the servers have been added to the existing IPsec rule for isolated servers.

2. Create an Active Directory security group and add the computer accounts of the authorized computers to the group.

3. Configure the local Group Policy settings of each server that stores sensitive data and change the **Access this computer from the network** user right as follows:

    a. Click **Computer Configuration**, click **Windows Settings**, and then click **Security Settings**.

    b. Click **Local Policies**, and then click **User Rights Assignment** so that it contains only the Active Directory security group created in step 2.

For a file server that contains sensitive financial data, add the financial server to the IPsec rule of the isolated servers, create a ConfidentialFinancial security group, and then add the authorized computer accounts. Finally, change the **Access this computer from the network** user right on the financial file server to contain only the ConfidentialFinancial security group.

**Overview of Server Isolation Deployment**
To deploy server isolation, do the following:

1. Determine the state of your network infrastructure.

    Before you can begin planning for server isolation, you must assess your organization's network. In your assessment, identify and document your network's physical topology (such as client and server computer configurations), logical

topology (such as your Active Directory infrastructure including trust relationships and system container structure), and current use of Group Policy settings. You must also determine which computers to exempt.

2. Design and test server isolation IPsec policy in a lab network.

   Create a scaled-down version of your network in a physically isolated lab that is not connected to your production network. Your test lab network should include domain member client computers, client computers that are not a member of the domain, and exempted computers. Then, configure the IPsec rules required to implement server isolation for your network. Use the test lab to ensure that the policies work as expected. Fine-tune your policy settings, as needed.

3. Perform a pilot using a subset of computers.

   After verifying the IPsec policy settings in the test lab, configure and activate the server isolation IPsec policy on a subset of computers on your production network to test their behavior. For example, you might want to activate the IPsec policy for the computers in a specific Active Directory organizational unit.

4. Roll out the IPsec policy in phases.

   After the pilot program is complete, begin activating the IPsec policy for other parts of your domain infrastructure in a phased roll out.

For more information about deploying server isolation, see "Server and Domain Isolation Using IPsec and Group Policy."

# Domain Isolation with Microsoft Windows Explained

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As described in "Introduction to Server and Domain Isolation with Microsoft Windows," domain isolation uses an Active Directory® directory service domain, domain membership, and Group Policy settings to enforce a network policy that requires domain member computers to accept incoming communication requests only from computers that can authenticate themselves with domain credentials. This network policy isolates domain member computers from non-domain-member computers.

By isolating your domain, you provide an additional layer of protection for your network traffic. Security technologies, such as Institute of Electrical and Electronic Engineers (IEEE) standard 802.1X, require a computer to authenticate itself before sending frames on a network. However, 802.1X does not protect the traffic sent by an 802.1X-authenticated computer after it is on the network. Secure Sockets Layer (SSL) provides computer authentication and data confidentiality (encryption) for SSL-enabled client and server applications. However, SSL works only if the client and server application support SSL. Whereas 802.1X works at the Data Link layer (of the Open Systems Interconnections [OSI] model) and SSL works at the Application layer, domain isolation works at the Network layer, providing additional protection for IP-based traffic. Organizations that routinely send sensitive data on their networks and, therefore, must provide extra protection for data assets—such as those in the financial services or health care industries or government institutions—need this additional level of protection at the Network layer.

Domain isolation provides many benefits by:

- Restricting incoming connections to domain member computers.

  In Microsoft® Windows®, you can manage a computer that is a member of an Active Directory domain by centrally configuring settings in Group Policy and by applying those settings to all domain member computers. You can also apply other types of security updates, such as operating system updates and antivirus software signatures, to domain member computers. Domain member computers use their domain credentials to authenticate communication attempts with each other. Computers that are not domain members — stand-alone, unknown, and guest computers — do not have domain credentials and, therefore, cannot authenticate communication attempts with domain member computers.

- Supplementing other security mechanisms designed to prevent unwanted communications.

  Domain isolation supplements the security provided by security mechanisms already deployed on your network. For example, if you isolated your domain and then your firewall was compromised, malicious users from the Internet could not initiate direct communications with the isolated hosts.

- Encouraging domain membership.

  By placing critical organization servers, such as e-mail servers, on the isolated domain, you prevent network users from connecting to any of those servers from a computer that is not a domain member. To receive valid domain credentials for authenticating with isolated organization servers, computers that are not domain members must be joined to the domain. After they have been joined to the domain, you can manage these computers in other ways, such as ensuring that they have the latest operating system and antivirus updates.

- Protecting traffic between domain member computers.

  Traffic sent between domain member computers is cryptographically protected so that the receiving computer can verify that an authenticated computer sent the packet and that the packet was not modified in transit. Optionally, the traffic between domain member computers can be encrypted, providing protection from malicious network users who attempt to capture and interpret network traffic.

To deploy domain isolation, you configure Group Policy settings to require that all incoming connection requests and subsequent data be authenticated and protected by using Internet Protocol security (IPsec). IPsec protects traffic from address spoofing, data injection, session hijacking, replay attacks, and other types of data tampering. Optionally, you can specify that packets be encrypted. You also can configure exemptions so that specific computers that are not domain members can initiate communications with isolated hosts.

**How Domain Isolation Works**

This section describes how Active Directory, Group Policy, and IPsec work together to implement domain isolation.

**Components of Domain Isolation**

To isolate a domain, you need the following components:

- **An Active Directory domain.** The domain includes domain controllers and the appropriate trust relationships to establish trust with other domains or the directory trees of an organization network.
- **Member computers.** These are computers that have joined the Active Directory domain and received domain credentials.
- **Group Policy settings.** These computer and user settings are automatically downloaded to domain member computers.
- **Active IPsec policy settings.** These Group Policy settings determine the domain isolation behavior of domain member computers.

In a simplified domain isolation deployment, you configure and activate an IPsec policy with rules that define specific types of traffic and how the traffic will be handled. You then activate the IPsec policy for the appropriate Active Directory containers, such as sites, domains, and organizational units. The member computers in the Active Directory containers to which the Group Policy settings apply automatically download the Group Policy settings.

After the domain member computers have downloaded and applied the Group Policy settings, they have both the correct IPsec policy for domain isolation and the domain credentials that will allow them to communicate securely with each other and to communicate without security with non-domain-member computers. Computers that are not domain members, which do not have the correct IPsec policy settings for domain isolation or domain credentials, cannot initiate communication with isolated hosts.

**Communication Processes**

When you implement domain isolation, communication between hosts in your network differs depending on which type of host (isolated or non-isolated) initiates communication and which type of host the initiating host attempts to communicate with. This section describes how communication occurs:

- When an isolated host initiates communication with another isolated host.
- When a non-isolated host initiates communication with an isolated host.
- When an isolated host initiates communication with a non-isolated host.

The following figure shows the types of communication that occur when you deploy domain isolation.

**Legend**

**Communication with an isolated host initiated by another isolated host**

When an isolated host with both Active Directory credentials and domain isolation IPsec policy settings (for example, COMPUTER1 in the figure) initiates communication with another isolated host (for example, COMPUTER2), the following occurs:

1. The initial communication packet sent by COMPUTER1—for example, a Transmission Control Protocol (TCP) Synchronize

(SYN) segment—matches the rule of the active IPsec policy that specifies that the initiating host must attempt to secure the traffic with IPsec.

2. COMPUTER1 uses IPsec to perform mutual authentication with COMPUTER2 and to negotiate the use of IPsec protection.

3. Because COMPUTER2 has domain credentials, the IPsec authentication process succeeds. Because COMPUTER2 has IPsec policy settings that match those on COMPUTER1, negotiation of IPsec protection also succeeds.

4. COMPUTER1 sends the initial communication packet to COMPUTER2 with IPsec protection.

5. COMPUTER2 sends the response to the initial communication packet—for example, a TCP SYN-Acknowledgement (SYN-ACK) segment—to COMPUTER1 with IPsec protection.

6. Subsequent packets sent between COMPUTER1 and COMPUTER2 are also protected by IPsec.

Because they are domain members and have IPsec policy settings, isolated hosts authenticate and protect with IPsec communications initiated with other isolated hosts.

**Communication with a non-isolated host initiated by an isolated host**
When an isolated host with both Active Directory credentials and domain isolation IPsec policy settings (for example, COMPUTER1 in the figure) initiates communication with a non-isolated host (for example, COMPUTER3), the following occurs:

1. The initial communication packet being sent by COMPUTER1—for example, a TCP SYN segment—matches the rule of the IPsec policy that specifies that the initiating host must attempt to secure the traffic with IPsec.

2. COMPUTER1 attempts to use IPsec to authenticate COMPUTER3 and to negotiate the use of IPsec protection.

3. Because COMPUTER3 does not have domain credentials, the IPsec authentication attempt fails.

4. Because the rule matched in Step 1 allows unsecured communication with computers that fail the IPsec authentication, COMPUTER1 sends the initial communication packet without IPsec protection.

5. COMPUTER3 sends the response to the initial communication packet sent by COMPUTER1 without IPsec protection.

6. COMPUTER1 and COMPUTER3 send subsequent packets without IPsec protection.

An isolated host tries to authenticate non-isolated hosts. If it cannot authenticate a host, an isolated host sends packets without IPsec protection, allowing isolated hosts to initiate communications with non-isolated hosts.

**Communication with an isolated host initiated by a non-isolated host**
When a non-isolated host (for example, COMPUTER3 in the figure) initiates communication with an isolated host (for example, COMPUTER2), the following occurs:

1. Because COMPUTER3 does not have IPsec policy settings, it sends its initial communication packet—for example, a TCP SYN segment—without IPsec protection to COMPUTER2.

2. On COMPUTER2, the initial communications packet sent by COMPUTER3 matches the rule of the IPsec policy that requires incoming communication attempts to be protected by IPsec.

3. Because the rule does not allow COMPUTER2 to accept incoming communication attempts that are not protected by IPsec, COMPUTER2 discards the initial communications packet sent by COMPUTER3.

4. COMPUTER2 also discards subsequent incoming communication attempts from COMPUTER3.

5. COMPUTER3 fails in its attempt to communicate with COMPUTER2.

Isolated hosts discard all initial communication packets sent by non-isolated hosts.

**Overview of Domain Isolation Deployment**

To deploy domain isolation, use the following basic procedure:

1. Determine the state of your network infrastructure.

   Before you can begin planning for domain isolation, you must assess your organization's network. In your assessment, identify and document your network's physical topology (such as client and server computer configurations), logical topology (such as your Active Directory infrastructure including trust relationships and system container structure), and current use of Group Policy settings. You must also determine which computers to exempt.

2. Design and test domain isolation IPsec policy in a lab network.

   Create a scaled-down version of your network in a physically isolated lab that is not connected to your production network. Then, configure the IPsec rules required to implement domain isolation for your network. Be sure to include isolated and non-isolated client computers in your test lab network. Use the test lab to ensure that the IPsec policies work as expected. Fine-tune your policy settings, as needed.

3. Perform a pilot with a subset of computers.

   After verifying IPsec policy settings in the test lab, configure and activate the domain isolation IPsec policy on a subset of computers on your production network to test their behavior. For example, you might want to activate the IPsec policy settings for the computers in a specific Active Directory organizational unit.

4. Roll out the IPsec policy in phases.

   After the pilot program is complete, begin activating the IPsec policy for other parts of your domain infrastructure in a phased rollout.

For more information about deploying domain isolation, see "Server and Domain Isolation Using IPsec and Group Policy." For an example of how Microsoft deployed domain isolation, see "Improving Security with Domain Isolation."

# What's New in Windows Server 2003 R2

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Microsoft® Windows Server™ 2003 R2, a software update to the Windows Server 2003 operating system, makes it easier and more cost effective to extend connectivity and control to identities, locations, data, and applications throughout and beyond your organization.

Built on Windows Server 2003, Windows Server 2003 R2 takes advantage of the stability and security of the code base while extending connectivity and control into new areas. With Windows Server 2003 R2, you get the following improvements:

- Identity and access management
- Branch office server management
- Storage setup and management
- Application development inside and outside your organization's traditional boundaries

For more information about Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45560).

This topic describes the following new components that you can install with Windows Server 2003 R2:

**Server Manageability**

- Administration Tools Packs
- Hardware Management
- MMC 3.0

**Features for Active Directory**

- Active Directory Application Mode (ADAM)
- Active Directory Federation Services

**Disk and File Management Features**

- Branch Office
    - Distributed File System (DFS)
- Common Log File System (CLFS)
- File Server Management
- Microsoft Services for Network File System
- Storage Management for SANs
- File Server Resource Manager

**Printer and Protocol Support**

- Print Management

**Microsoft .NET Framework**

- Microsoft .NET Framework 2.0

**Internet and E-Mail Services and Features**

- Windows Sharepoint Services

**UNIX Interoperability**

- Identity Management for UNIX
- Subsystem for UNIX-based Applications

**Server Manageability**
To help you manage your server, Windows Server 2003 R2 provides Administration Tools Packs and the following improvements to hardware management and Microsoft Management Console (MMC) 3.0.

**Administration Tools Packs**
To make the remote management of your servers easier, you can install the Administration Tools Packs for Windows Server 2003 R2 located on Disc 2 in the \mgmttls directory. Each of the following components has an Administration Tools Pack:

- Microsoft Management Console (MMC) 3.0
- Print Management
- File Server Resource Manager
- DFS Replication
- Identity Management for UNIX
- File Server Management

In order to administer components, you must first install the MMC 3.0 Administration Tools Pack. The Administration Tools Packs can be installed on computers running Windows® XP Professional with Service Pack 2 (SP2). For specific installation instructions, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=54293).

**Hardware Management**
You can use Windows Remote Management (WinRM) to manage server hardware remotely across firewalls and monitor conditions on servers that are offline.

This new feature in Windows Server 2003 R2 is implemented using WS-Management, an industry-standard, Web services-based remoting protocol. WS-Management uses HTTPS as the secure transport that enables firewall traversal.

WinRM provides a command-line interface for common management tasks and a scripting application programming interface (API) for writing Windows Script Host-based system administration scripts.

Using WinRM, you can write scripts to monitor and control the state of server hardware by communicating with a Baseboard Management Controller (BMC). A BMC is a separate micro-controller with its own network adapter that is connected to the processor board of a server and can monitor conditions even when the server is off or malfunctioning. A new Windows Management Interface (WMI) provider for Intelligent Platform Management Interface (IPMI) exposes six new WMI classes for accessing BMC information with scripts.

WinRM is not installed by default with Windows Server 2003 R2. To install it, open Add or Remove Programs from Control Panel, and click **Add/Remove Windows Components**.

For more information about hardware management, see "Hardware Management in Microsoft Windows Server 2003 R2" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45204).

Back to Top

**MMC 3.0**

Microsoft Management Console (MMC) 3.0 supports richer functionality in snap-ins designed for the MMC 3.0 infrastructure. In addition, the following improvements apply to all MMC 3.0 consoles:

- **Action pane.** The Action pane appears on the right side of the snap-in console. It lists the actions that are currently available to you, based on the currently selected items in the tree or the results pane.

  To show or hide the action pane, click the **Show/Hide Action Pane** button on the toolbar, which is similar to the **Show/Hide Console Tree** button.

- **New Add or Remove Snap-in dialog box.** The new **Add or Remove Snap-in** dialog box makes it easy to add, organize, and remove snap-ins. You can control which extensions are available, and whether to automatically enable snap-ins that may be installed later. You can nest snap-ins and rearrange the snap-ins in the tree.

- **Improved error handling.** MMC 3.0 notifies you of errors in snap-ins that could cause MMC to fail and provides several options for responding to those errors.

MMC 3.0 is automatically installed when you install Windows Server 2003 R2.

Back to Top

**Features for Active Directory**

The following Active Directory components are included in Windows Server 2003 R2.

**Active Directory Application Mode (ADAM)**

Active Directory Application Mode (ADAM) is an independent mode of the Active Directory® directory service, without infrastructure features, that provides directory services for applications. It provides a data store and services for accessing the data store. It uses standard application programming interfaces (APIs) for accessing the application data. ADAM operates either as a standalone data store, or it operates with replication. Its independence enables local control and autonomy of directory services for specific applications. It also facilitates independent, flexible schemas and naming contexts.

Back to Top

**Active Directory Federation Services**

The fundamental purpose of Active Directory Federation Services (ADFS) is to leverage single user sign-on to authenticate the user to multiple related Web applications over the life of a single online session. ADFS does this by securely sharing digital identity and entitlement rights across security and enterprise boundaries.

Back to Top

**Disk and File Management Features**

Windows Server 2003 R2 includes the following disk and file management features.

**Branch Office**

Branch offices are the remote locations of an organization that connect to a headquarters or hub over a wide-area network (WAN). The technologies included in Windows Server 2003 R2 can simplify how you manage a variety of activities and tasks in branch offices. These activities and tasks include:

- Publishing files from centralized hubs to branch offices.

- Replicating files from branch locations for backup, fault-tolerance, or cross-publishing.

- Collaborating on documents that are shared among branches or between hubs and branches.

- Efficiently managing printers, printer drivers, and print queues in branch offices.

These improvements are supported by the enhanced print-management tools in Windows Server 2003 R2. They are also supported by Distributed File System (DFS) in Windows Server 2003 R2.

For more information about these technologies in Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=51679).

Back to Top

**Distributed File System (DFS)**
The Distributed File System (DFS) solution in Windows Server 2003 R2 provides simplified, fault-tolerant access to files and WAN-friendly replication. Distributed File System consists of two technologies:

- **DFS Namespaces.** Formerly known as Distributed File System, DFS Namespaces allows administrators to group shared folders located on different servers and present them to users as a virtual tree of folders known as a namespace. A namespace provides numerous benefits, including increased availability of data, load sharing, and simplified data migration.

- **DFS Replication.** The successor to File Replication service (FRS), DFS Replication is a new state-based, multimaster replication engine that supports scheduling and bandwidth throttling. DFS Replication uses a new compression algorithm known as Remote Differential Compression (RDC). RDC is a "diff over the wire" protocol that can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, re-arrangements of data in files, enabling DFS Replication to replicate only the deltas (changes) when files are updated.

For more information about Distributed File System in Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=51679).

Back to Top

**Common Log File System (CLFS)**
Common Log File System (CLFS) is a loadable driver that provides kernel- or user-mode applications with a robust logging subsystem. CLFS is a unique Windows technology that can be used to develop applications and middleware that depend on durably writing and reading sequential data. Examples include replication agents, auditing agents, databases, and other transactional resource managers.

Features include the ability to create log files with a single stream of data or with multiple streams of data for shared use by one or more clients; both circular and linear logging; guaranteed ability to flush buffered data by pre-reserving space in the log; policy-based log size and space management; sharing of a single log by both kernel and user clients; a notification mechanism to allow different users within the same log to coordinate their log use; flexible buffering of log data; archiving APIs do not interfere with normal operations; atomic multi-sector writes; and torn-write detection.

CLFS is optimized for performance. All writes to the log file are buffered until an explicit flush, an opportunity to share a write with another client, or the buffer is filled. Log data is written directly to the hard disk from the log buffers without copying. Multiple streams of data can be written during the same I/O operation, resulting in only one disk seek for what normally takes multiple seeks and writes. Reads are cached to save disk accesses during normal operation or bursts of read activity.

For more information, see the "Platform SDK" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=44489).

Back to Top

**File Server Management**
You can use File Server Management to perform many tasks, such as formatting volumes, creating shares, defragmenting volumes, creating and managing shares, setting quota limits, creating storage utilization reports, replicating data to and from the file server, managing Storage Area Networks (SANs), and sharing files with UNIX and Macintosh systems.

Back to Top

**File Server Resource Manager**
With the increasing demand on storage resources, as organizations rely more heavily on data than ever before, IT administrators face the challenge of overseeing a larger and more complex storage infrastructure, while at the same time, tracking the kind of information available in it.

File Server Resource Manager is a new Microsoft Management Console (MMC) snap-in that provides a suite of tools for administrators to understand, control, and manage the quantity and type of data stored on their servers. By using File Server Resource Manager, administrators can place quotas on folders and volumes, actively screen files, and generate comprehensive storage reports.

**File Server Resource Manager quotas vs. NTFS disk quotas**
The Windows 2000 and Windows Server 2003 operating systems support disk quotas, which are used to track and control disk

usage per user on NTFS volumes. The following table outlines the advantages of using the quota management tools in File Server Resource Manager.

| Quota features | File Server Resource Manager | NTFS disk quotas |
|---|---|---|
| Quota tracking | By folder or by volume | Per user on a volume |
| Disk usage calculation | Actual disk space | Logical file size |
| Notification mechanisms | E-mail, custom reports, command execution, event logs | Event logs only |

Back to Top

**Microsoft Services for Network File System**

Microsoft Services for Network File System (NFS) is a component of Windows Server 2003 R2 that provides a file-sharing solution for enterprises that have a mixed Windows and UNIX environment. Microsoft Services for NFS allows users to transfer files between Windows Server 2003 R2 and UNIX computers using the Network File System (NFS) protocol.

Microsoft Services for NFS is an update to the NFS components that were previously available in Services for UNIX 3.5. Microsoft Services for NFS includes the following new features:

- Support for 64-bit

  Microsoft Services for NFS components can be installed on all editions of Windows Server 2003 R2, including 64-bit versions.

- Updated Microsoft Management Console (MMC) Microsoft Services for NFS Administration snap-in

- Enhanced reliability

- Support for UNIX special devices (mknod)

Microsoft Services for NFS allows you to support a mixed environment of Windows- and UNIX-based operating systems. It also allows you to update your organization's computers while supporting older technology during the transition phase. The following scenarios are examples of how enterprises can benefit from deploying Microsoft Services for NFS.

- Allows UNIX clients to access resources on computers running Windows Server 2003 R2. Your company may have UNIX clients accessing resources, such as files, on UNIX file servers. To take advantage of new Windows Server 2003 features, such as Shadow Copies for Shared Folders, you can move resources from your UNIX servers to computers running Windows Server 2003 R2, and then set up Microsoft Services for NFS to enable access by UNIX clients that are running NFS software. All of your UNIX clients will be able to access the resources using the NFS protocol with no changes required.

- Allows computers running Windows Server 2003 R2 to access resources on UNIX file servers. Your company may have a mixed Windows and UNIX environment with resources, such as files, stored on UNIX file servers. You can use Microsoft Services for NFS to enable computers running Windows Server 2003 R2 to access these resources when the file servers are running NFS software.

Back to Top

**Storage Management for SANs**

Storage Manager for SANs is a new Microsoft Management Console (MMC) snap-in that helps you create and manage logical unit numbers (LUNs) on fibre channel and iSCSI disk drive subsystems in your storage area network (SAN). Storage Manager for SANs can be used on storage subsystems that support Virtual Disk Server (VDS).

Use Storage Manager for SANs to create and assign LUNs, manage connections between LUNs and the servers in your SAN, and set the security properties for iSCSI storage subsystems.

Back to Top

**Printer and Protocol Support**

Windows Server 2003 R2 provides an updated MMC snap-in for Print Management.

**Print Management**
Print Management is an updated Microsoft Management Console (MMC) snap-in that you can use to view and manage printers and print servers in your organization. You can use Print Management from any computer running Windows Server 2003 R2, and you can manage all network printers on print servers running Windows 2000 Server, Windows Server 2003, or Windows Server 2003 R2.

Print Management provides up-to-the-minute details such as the queue status, printer name, driver name, and server name. You can also set custom views by using the Print Management filtering capability. For example, you can create a view that only displays printers in a particular error state. You can also configure Print Management to send e-mail notifications or run scripts when a printer or print server needs attention. The filtering capability also allows you to bulk edit print jobs, such as canceling all print jobs at once. You can also delete multiple printers at the same time.

Administrators can install printers remotely by using the automatic detect feature, which finds and installs printers on the local subnet to the local print server. Administrators can log on to a local server at a branch location by using Remote Desktop and then easily install printers remotely.

When a printer model has a Web page feature, Print Management can display troubleshooting details, such as the location of the paper jam or printer toner level. Some printer models have Web pages that provide options for remote control functions that can help resolve problems at branch locations.

For more information, see the "Print Management Step-by-Step Guide" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=50141).

Back to Top

**Microsoft .NET Framework**
New features for .NET Framework 2.0 are available in Windows Server 2003 R2.

**Microsoft .NET Framework 2.0**
The .NET Framework version 2.0 is the latest version of the .NET Framework, a Windows component for building, deploying and running applications. The .NET Framework 2.0 is focused on delivering developer productivity, operational excellence, and the ability to preserve and enhance existing software investments. Core enhancements include support for 64-bit processors for increased performance and scalability, transactional enhancements and optimizations, productivity improvements in ASP.NET, and support for WS-I BP 1.1 and SOAP 1.2 with Web Services.

For a comprehensive list of the new .NET Framework 2.0 features, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=50322).

Back to Top

**Internet and E-Mail Services and Features**
Windows SharePoint® Services is included in Windows Server 2003 R2.

**Windows SharePoint Services**
Microsoft Windows SharePoint Services is an integrated portfolio of collaboration and communication services designed to connect people, information, processes, and systems both within and beyond the organizational firewall. Windows SharePoint Services Service Pack 2 is included in this release of Windows Server 2003. Now you can install Windows SharePoint Services directly from the Configure Your Server wizard or Manage Your Server. When you install Windows SharePoint Services, you get the following features:

**SharePoint sites – file storage plus collaboration**
Web sites based on Microsoft Windows SharePoint Services 2.0 provide a place where teams can communicate, share documents, and work together on a project. SharePoint sites include:

- Team collaboration features, such as event calendars, contacts, Web links, discussions, issues lists, announcements, and much more.
- Document libraries, which are places where users can store and retrieve documents while taking advantage of rich features such as check-in and check-out, version history, custom metadata, and flexible, customizable views.
- Web Parts, which can provide data access, Web services, and many other applications and content to SharePoint sites.

Site users can contribute to the site by using nothing more than a Web browser. However, if users have Windows SharePoint Services-compatible client programs, such as Microsoft Office 2003, installed on their computers they can work seamlessly with the site, saving files to libraries, editing documents in the client program, and moving or linking that information to the

site.

**SharePoint Central Administration – Web browser interface for managing your server**
You can manage a single server or an entire server farm running Windows SharePoint Services from a Web browser interface called SharePoint Central Administration. Use SharePoint Central Administration to extend a virtual server, create sites or turn on Self-Service Site Creation so users can create their own sites, manage security settings, manage the list of servers in your server farm, and so on. If you prefer, you can also use the Stsadm.exe command-line utility to manage your servers running Windows SharePoint Services.

**Applications for Windows SharePoint Services – download and install ready-to-use applications to get working quickly**
Boost worker productivity by downloading and installing an application for Windows SharePoint Services. These applications are tailored to address specific processes or tasks. There are many to choose from, including recruiting, project management, help desk issue tracking, timesheet and scheduling, event planning, and more. Use the applications as soon as you install them or customize them further to meet your organization's specific needs and requirements.

For more information, see "Applications for Windows SharePoint Services" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47987).

**Support for advanced extranet configurations**
A URL zone mapping feature (new in Windows SharePoint Services, Service Pack 2) allows for easier interactions with a proxy server or firewall. Windows SharePoint Services uses absolute URLs to generate some hyperlinks in its Web pages and e-mail messages. This prevented Windows SharePoint Services from supporting certain advanced extranet configurations (such as SSL termination, host header modification, and port translation) where a reverse proxy server is deployed in front of the Windows SharePoint Services server. Now you can set up URL zones, such as Internet, intranet, and extranet, and map incoming and outgoing URLs to those zones, so that these configurations can work correctly.

For more information about Windows SharePoint Services in Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45560).

Back to Top

**UNIX Interoperability**
For improved interoperability with UNIX, the following features are available in Windows Server 2003 R2.

**Identity Management for UNIX**
Windows Services for UNIX delivers Windows and UNIX integration with updated identity management solutions. The following solutions help provide uninterrupted user access and efficient management of network resources across operating systems:

- **Server for NIS.** Helps integrate Windows and UNIX-based Network Information Service (NIS) servers by enabling an Active Directory domain controller to act as a master NIS server for one or more NIS domains.

- **Password Synchronization.** Helps integrate Windows and UNIX servers by simplifying the process of maintaining secure passwords. With Password Synchronization, users do not need to maintain separate passwords for their Windows and UNIX accounts or remember to change the password in multiple locations.

Back to Top

**Subsystem for UNIX-based Applications**
Subsystem for UNIX-based Applications (SUA) is a source-compatibility subsystem for compiling and running custom UNIX-based applications on a computer running a Windows server-class operating system. You can make your UNIX applications fully interoperable with Windows in SUA with little or no change to your original source code.

Subsystem for UNIX-based Applications provides an operating system for Portable Operating System Interface (POSIX) processes. SUA, along with its package of support utilities (such as shells and a telnet client), provides a complete UNIX environment. The package of support utilities includes a comprehensive set of scripting utilities and a software development kit (SDK) designed to fully support the development capabilities of SUA.

SUA also supports case-sensitive file names, job control, compilation tools, and the use of over 300 UNIX commands, utilities, and shell scripts. Because the subsystem installs separately from the Windows kernel, it offers true UNIX functionality without any emulation.

New features in this release include the following:

- **Database (OCI/ODBC) library connectivity.** SUA supports connectivity to Oracle and SQL Server from database

applications by using the Oracle Call Interface (OCI) and the Open Database Connectivity (ODBC) standard.

- **Microsoft® Visual Studio® Debugger Extension for debugging POSIX applications.** SUA includes support for debugging your POSIX processes using Visual Studio IDE.

- **Utilities based on SVR-5 and BSD UNIX environments.** The SUA download package supports two different UNIX environments: SVR-5 and BSD.

- **Support for 64-bit applications.** Using a process called thunking, SUA provides support not only for 64-bit applications running on a 64-bit operating system, but also default support for 32-bit binaries running on a 64-bit operating system.

To download the support utilities, see "Installing and Using Utilities and SDK for UNIX-based Applications" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=38959).

# Overview of ADFS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Introduction to ADFS**
Active Directory® Federation Services (ADFS) is a component in Windows Server® 2003 R2 that provides Web single-sign-on (SSO) technologies to authenticate a user to multiple Web applications over the life of a single online session. ADFS accomplishes this by securely sharing digital identity and entitlement rights, or "claims," across security and enterprise boundaries.

ADFS is not:

- A database or repository for employee or customer identity data.
- An extension of the Active Directory schema.
- A type of Windows domain or forest trust.

ADFS in Windows Server 2003 R2 supports the WS-Federation Passive Requestor Profile (WS-F PRP).

**Key features of ADFS**
The following are some of the key features of ADFS in Windows Server 2003 R2:

- Federation and Web SSO

  When an organization uses the Active Directory™ directory service, it currently experiences the benefit of SSO functionality through Windows-integrated authentication within the organization's security or enterprise boundaries. ADFS extends this functionality to Internet-facing applications, which enables customers, partners, and suppliers to have a similar, streamlined, Web SSO user experience when they access the organization's Web-based applications. Furthermore, federation servers can be deployed in multiple organizations to facilitate business-to-business (B2B) federated transactions between partner organizations.

- Web Services (WS)-* interoperability

  ADFS provides a federated identity management solution that interoperates with other security products that support the WS-* Web Services Architecture. ADFS does this by employing the federation specification of WS-*, called WS-Federation. The WS-Federation specification makes it possible for environments that do not use the Windows identity model to federate with Windows environments.

- Extensible architecture

  ADFS provides an extensible architecture that supports the Security Assertion Markup Language (SAML) token type and Kerberos authentication (in the Federated Web SSO with Forest Trust scenario). ADFS can also perform claim mapping, for example, modifying claims using custom business logic as a variable in an access request. Organizations can use this extensibility to modify ADFS to coexist with their current security infrastructure and business policies.

**Extending Active Directory to the Internet**
Active Directory serves as a primary identity and authentication service in many organizations. With Windows Server 2003 Active Directory, forest trusts can be created between two or more Windows Server 2003 forests to provide access to resources that are located in different business units or organizations. For more information about forest trusts, see How Domain and Forest Trusts Work on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

However, there are scenarios in which forest trusts are not a viable option. For example, access across organizations may need to be limited to only a small subset of individuals, not every member of a forest.

By employing ADFS, organizations can extend their existing Active Directory infrastructures to provide access to resources that are offered by trusted partners across the Internet. These trusted partners can include external third parties or other

departments or subsidiaries in the same organization.

ADFS is tightly integrated with Active Directory. ADFS retrieves user attributes from Active Directory, and it authenticates users against Active Directory. ADFS also uses Windows Integrated Authentication.

ADFS works with both Active Directory and Active Directory Application Mode (ADAM). Specifically, ADFS works with both enterprise-wide deployments of Active Directory or instances of ADAM. When it works with Active Directory, ADFS can take advantage of the strong authentication technologies in Active Directory, including Kerberos, X.509 digital certificates, and smart cards. When it works with ADAM, ADFS uses Lightweight Directory Access Protocol (LDAP) Bind as a means to authenticate users.

ADFS supports distributed authentication and authorization over the Internet. ADFS can be integrated into an organization's or department's existing access management solution to translate the terms that are used in the organization into claims that are agreed on as part of a federation. ADFS can create, secure, and verify the claims that move between organizations. It can also audit and monitor the activity between organizations and departments to help ensure secure transactions.

**Federation scenarios**

ADFS supports federated identity scenarios that use Web Services Federation (WS-Federation), WS-F PRP, and WS-Federation Passive Requestor Interoperability Profile specifications. The ADFS solution helps administrators deal with federated identity management challenges by making it possible for organizations to securely share a user's identity information over federation trusts. The following three descriptions of deployment scenarios illustrate how you can use ADFS server roles to federate identities, depending on the needs of your organization.

**Federated Web SSO**

The ADFS Federated Web SSO scenario involves secure communication that often spans multiple firewalls, perimeter networks, and name resolution servers, in addition to the entire Internet routing infrastructure. Communication over a federated Web SSO environment can help foster more efficient and secure online transactions between organizations that are joined by federation trust relationships.

As shown in the following illustration, a federation trust relationship can be established between two businesses. In this scenario, federation servers route authentication requests from user accounts in Tailspin Toys to Web-based applications that are located in the network of Online Retailer.

Federation servers authenticate requests from trusted partners based on the credentials of the partners. Representations of the credentials are exchanged in the form of security tokens.

For enhanced security, federation server proxies can be used to relay requests to federation servers that are not directly accessible from the Internet.

**Federated Web SSO with Forest Trust**

The ADFS Federated Web SSO with Forest Trust scenario involves two Active Directory forests in a single organization, as shown in the following illustration. One of the forests is located in the organization's perimeter network (also known as a demilitarized zone (DMZ) or a screened subnet). The other forest is located in the internal network. A one-way, forest trust is established so that the forest in the perimeter network trusts the forest in the internal network. Federation servers are deployed in both networks. A federation trust is established so that accounts in the internal forest can be used to access a Web-based application in the perimeter network, whether the accounts access the site from the intranet forest or from the Internet.

**A. Datum Corp.**

In this scenario, external users, such as customers, can access the Web application by authenticating to the external account federation server, which is located in the perimeter network. External users have user accounts in the perimeter-network Active Directory forest. Internal users, such as employees, can also access the Web application by authenticating to the internal account federation server, which is located in the internal network. Internal users have accounts in the internal Active Directory forest.

If the Web-based application is a Windows NT token-based application, the ADFS Web Agent that is running on the Web application server intercepts requests and creates Windows NT security tokens, which are required by the Web application to make authorization decisions. For external users, this is possible because the Web server that hosts the Windows NT® token-based application is joined to the domain in the external forest. For internal users, this is enabled through the forest trust relationship that exists between the perimeter forest and the internal forest.

If the Web-based application is a claims-aware application, the ADFS Web Agent that is running on the Web application server does not have to create Windows NT security tokens for the user. The ADFS Web agent can expose the claims that come across, which allows the application to make authorization decisions based on the contents of the security token that is provided by the account federation server. As a result when it deploys claims-aware applications, the Web server does not have to be joined to the domain, and the external-forest-to-internal-forest trust is not required.

**Web SSO**

In the ADFS Web SSO scenario, users must authenticate only once to access multiple Web-based applications. In this scenario all users are external, and no federation trust exists. Because the Web servers must be Internet accessible and also joined to the Active Directory domain, they are connected to two networks; that is, they are multihomed. The first network is Internet facing (the perimeter network) to provide the needed connectivity. The second network contains the Active Directory forest (the protected network), which is not directly Internet accessible. The federation server proxy is also multihomed to provide the necessary connectivity to the federation server and the Internet. In this scenario, placing the federation server on a network that is not directly accessible from the Internet greatly reduces the risk to the federation server.

**Partner organizations**
When you plan for cross-organizational (federation-based) collaboration using ADFS, you first determine whether your organization will host a Web resource to be accessed by other organizations across the Internet — or the reverse. This determination affects how you deploy ADFS, and it is fundamental in the planning of your ADFS infrastructure.

For federation scenarios such as Federated Web SSO and Federated Web SSO with Forest Trust (but not the Web SSO scenario), ADFS uses terms such as "account partner" and "resource partner" to help differentiate the organization that hosts the accounts (the account partner) from the organization that hosts the Web-based resources (the resource partner). The term "federation trust" is used in ADFS to characterize the one-way, nontransitive relationship that is established between the account partner and the resource partner.

The following sections explain some of the concepts that are related to account partners and resource partners.

**Account partner**
An account partner represents the organization in the federation trust relationship that physically stores user accounts in either an Active Directory store or an ADAM store. The account partner is responsible for collecting and authenticating a user's credentials, building up claims for that user, and packaging the claims into security tokens. These tokens can then be presented across a federation trust to access Web-based resources that are located in the resource partner organization.

In other words, an account partner represents the organization for whose users the account-side Federation Service issues security tokens. The Federation Service in the account partner organization authenticates local users and creates security tokens that are used by the resource partner in making authorization decisions.

In relation to Active Directory, the account partner in ADFS is conceptually equivalent to a single Active Directory forest whose accounts need access to resources that are physically located in another forest. Accounts in this example forest can access resources in the resource forest only when an external trust or forest trust relationship exists between the two forests and the resources to which the users are trying to gain access have been set with the proper authorization permissions.

| **Note** |
| --- |
| This analogy is meant strictly to emphasize how the relationship between account and partner organizations in ADFS is similar, in concept, to the relationship between an account forest and a resource forest in Active Directory. External trusts and forest trusts are not required for ADFS to function. |

**Resource partner**
A resource partner is the second organizational partner in the federation trust relationship. A resource partner is where the Web servers that host one or more Web-based applications (the resources) reside. The resource partner trusts the account partner to authenticate users. Therefore, to make authorization decisions, the resource partner consumes the claims that are packaged in security tokens coming from users in the account partner.

In other words, a resource partner represents the organization whose Web servers are protected by the resource-side Federation Service. The Federation Service at the resource partner uses the security tokens that are produced by the account partner to make authorization decisions for Web servers that are located in the resource partner.

To function as an ADFS resource, Web servers in the resource partner organization must have the ADFS Web Agent component of ADFS installed. Web servers that function as an ADFS resource can host either claims-aware applications or Windows NT token-based applications.

| Note |
| --- |
| If the application that is hosted on the Web server is a Windows NT token–based application, a resource account may be required for the Active Directory forest in the resource partner organization. |

In relation to Active Directory, the resource partner is conceptually equivalent to a single forest whose resources are made available over an external trust or forest trust relationship to accounts that are physically stored in another forest.

| Note |
| --- |
| This analogy is meant strictly to emphasize how the relationship between account and partner organizations in ADFS is similar, in concept, to the relationship between an account forest and a resource forest in Active Directory. External trusts and forest trusts are not required for ADFS to function. |

#### Enhanced identity privacy

**Enhanced identity privacy** is an optional setting that can be configured on a resource partner in the trust policy. If the **Enhanced identity privacy** option is enabled, this setting hashes the user-name portion of outgoing UPN claims and e-mail claims. It substitutes the common name with a random value.

The purpose of this feature is to prevent:

- The resource partner from correlating identity claims to personally identifiable user information.
- Collusion between partners in correlating identity claims to personally identifiable user information. This setting creates a unique hash per partner so that identity claim values are different across different trusting realm partners but consistent across sessions for a single partner.
- Simple dictionary attacks against the hash by salting the user value with data that is in the trust policy — data that is not known by the resource partners.

#### How enhanced identity privacy works

If the **Enable enhanced identity privacy** setting is enabled, the user's identity is transformed by the account Federation Service before it is sent to the resource realm. The account Federation Service does this by hashing a combination of the privacy key (for salting), the resource partner Uniform Resource Identifier (URI), and the identity claim itself. Therefore, the resulting transformed identity will be the same when the following values are the same:

- Privacy key
- Resource partner URI
- Identity claim (user principal name (UPN) or e-mail)

The hashing algorithm is case sensitive. Therefore, the hashed results are different if the case of the URI or the user-name portion of the UPN claim or e-mail claim is different.

#### ADFS server roles

ADFS can operate only when the servers running Windows Server 2003 R2 are configured appropriately. Depending on the environment in your organization, specific ADFS server roles must be deployed. The following sections describe the server roles that can be used to provide an ADFS federated identity management solution.

#### Federation server

Federation servers host the Federation Service component of ADFS. They are used to route authentication requests that are made from user accounts in other organizations (in Federated Web SSO scenarios) or from clients that can be located anywhere on the Internet (in the Web SSO scenario).

Federation servers also host a security token service that issues tokens that are based on the credentials (for example, user name and password) that are presented to it. After the credentials are verified (by the user logging on), claims for the user are collected through examination of the attributes for the user that are stored in Active Directory or ADAM.

In Federated Web SSO scenarios, claims can then be modified by claim mappings for a specific resource partner. The claims are built into a token that is sent to a federation server in the resource partner. After a federation server in the resource partner

receives the claims as incoming claims, it maps them into their organization claims. The organization claims are then built into a new token that is sent to the ADFS Web Agent.

The role that a federation server plays in either of the Federated Web SSO scenarios (Federated Web SSO or Federated Web SSO with Forest Trust) can depend on whether your organization is designated as the account partner or the resource partner:

- Federation servers in the account partner are used to log on local user accounts in either an Active Directory store or an ADAM store. Federation servers also issue initial security tokens that the local user accounts can use to access Web-based applications that are hosted in the resource partner. In addition, federation servers in the account partner issue cookies to users to maintain login status. These cookies include claims for those users. These cookies enable SSO capabilities so that users do not have to enter credentials each time that they visit different Web-based applications in the resource partner.

- Federation servers at the resource partner validate the security tokens that are issued by the federation servers at the account partner. Federation servers at the resource partner also issue security tokens that are meant for the Web-based applications in the resource partner. In addition, federation servers in the resource partner issue cookies to the user accounts, which come from the account partner. These cookies enable SSO capabilities so that users do not have to log in again at their federation servers in the account partner when users attempt to access different Web-based applications at the resource partner.

**Federation server proxy**

Federation server proxies host the Federation Service Proxy component of ADFS. Federation server proxies can be deployed in an organization's perimeter network (also known as a DMZ or a screened subnet) to forward requests to federation servers that are not accessible from the Internet.

| **Note** |
| --- |
| Although you can deploy separate servers to host the Federation Service Proxy component, it is not necessary to deploy a separate server to act as a federation server proxy in the intranet forest of either the account partner or the resource partner. A federation server performs this role automatically. |

The role that a federation server proxy plays in your organization can depend on whether your organization is the account partner or the resource partner:

- Federation server proxies at the account partner act as proxies for user logons to federation servers that are located in the intranet. Federation server proxies also act as proxies for security tokens that are issued by the account partner federation server for both its own tokens and those tokens that are destined for resource partners.

- Federation service proxies in the resource partner act as proxies for user security tokens, which are issued from federation servers in both the account partner and the resource partner, to Web-based applications in the resource partner.

**Web server**

In ADFS, Web servers in the resource forest host the ADFS Web Agent component to provide secure access to the Web applications that are hosted on those Web servers. The ADFS Web Agent manages security tokens and authentication cookies that are sent to a Web server. The Web server requires a relationship with a Federation Service so that all authentication tokens come from that Federation Service.

The ADFS Web Agent supports two types of applications: claims-aware applications and Windows NT token–based applications.

**Federation trusts**

You can use ADFS to enable efficient and secure online transactions between partner organizations that are joined by federation trust relationships. In other words, a federation trust is the embodiment of a business-level agreement or partnership between two organizations.

As shown in the following illustration, you can establish federation trust relationships between two partner organizations when both of the organizations deploy at least one ADFS federation server and they configure their Federation Service settings appropriately. The one-way arrow signifies the direction of the trust, which — like the direction of Windows trusts — always points to the account side of the forest. This means that authentication flows from the account partner organization to the resource partner organization.

| Note |
| --- |
| No communication occurs over the network between the account Federation Service and the resource Federation Service. |

After you create the federation trust, users who are located in the account partner organization can send authentication requests successfully through the federation trust to the Web server in the resource partner organization. A federation trust is created when the account partner organization and the resource partner organization both install the Federation Service component of ADFS and they both use the Active Directory Federation Services snap-in to configure the account partner and resource partner appropriately.

If one side of a federation trust (either the account partner or the resource partner) is not configured or if it is configured incorrectly by the administrator for either organization, the federation trust will not be created successfully. For detailed guidance about how to create federation trusts, look for ADFS step-by-step or deployment content on the ADFS home page (http://go.microsoft.com/fwlink/?LinkId=79542).

| Note |
| --- |
| Federation trusts are not used in the Web SSO scenario. |

**Federation Service**

The Federation Service is a component of ADFS that can be installed independently from other ADFS components. The Federation Service functions as a security token service. The act of installing the Federation Service component on a computer makes that computer a federation server. It also makes the Active Directory Federation Services snap-in available in the **Administrative Tools** menu on that computer.

The Federation Service is designed to use Active Directory to provide tokens in response to requests for security tokens. This enables Active Directory domains and forests to function as:

- Identity providers that can federate with compliant account partners and resource partners. As an identity provider, the Federation Service can project Active Directory identities across the Internet to interact with applications at compliant service providers.

- Service providers that can federate with compliant account partners and resource partners. As a service provider, the Federation Service can allow identities from other organizations to access a partner's Windows-based and Microsoft ASP.NET-based applications.

- Security token providers for applications that are compliant with the WS-F PRP specification.

As an account partner, the Federation Service allows Active Directory users to access resources at partner organizations. In response to a request from a resource partner, the Federation Service collects and verifies user credentials against Active Directory or ADAM. The Federation Service can then populate a set of organization claims based on the LDAP attributes of the user account. The organization claims are then mapped to appropriate claims for the resource partner and packaged into a security token that is signed by the Federation Service's token-signing certificate. The resultant security token is posted as the response to the resource partner's original request. The resource partner then uses the token to allow access for the user.

As a resource partner, the Federation Service plays the opposite role. When a user attempts to access an ADFS-protected application, the Federation Service determines which account partner should authenticate the user. It then sends an authentication request to that partner. When the user returns with a security token, the Federation Service verifies that the token has been correctly signed by the partner. It then extracts the claims from the token. The claims are mapped to organization claims, and the filtering policy for the specific application is applied. The filtered organization claims are packaged

into a security token that is either signed by the Federation Service's token-signing certificate or protected by a Kerberos session key for the Web application. The resultant security token is posted back to the original application Uniform Resource Locator (URL). The application then uses the token to allow access for the user.

ADFS uses the WS-F PRP protocol to carry claims in security tokens that are issued by the Federation Service to the Web application.

These claims are populated initially from account stores, either Active Directory or ADAM account stores. The Federation Service issues tokens based on the credentials that are presented. After the credentials are verified using the account store, the claims for the user are generated according to the rules of the trust policy. The obtained inbound claims are mapped into outbound claims that are appropriate for a resource partner. The resulting claim mappings are added to a security token that is issued to the resource partner.

After the token is verified, an authentication cookie is issued and written to the client browser. Each time that the client needs to be authenticated, this cookie is used by the Federation Service so that the client does not have to enter credentials again, thereby enabling SSO.

**Federation Service Web pages**
The Federation Service provides a Web page that prompts the user to select an appropriate account partner to which the user can authenticate. The Federation Service also provides a Web page that prompts for the user's credentials, such as a user name and password for forms-based authentication. A Web page is also provided that supports Windows Integrated Authentication.

Behind the Web pages, the Federation Service provides an ASP.NET Web service that processes requests from the client or the federation server proxy. The federation server proxy is located in the perimeter network. It acts as an intermediary between an Internet client and a Federation Service in the intranet. There are two basic types of requests to which the Federation Service responds:

- Requests to issue security tokens
- Requests to retrieve trust policy data

**Account partner discovery**
Account partner discovery is the process by which a client can identify what account partner it prefers for authentication in the event that more than a single account partner is configured. The Federation Server presents this choice to the client browser as a drop box containing the account partner names as they are configured in the trust policy.

One mechanism that you can use to avoid account partner discovery is to include the **`whr`** parameter in the query string for the resource being accessed, for example,

`https://webserver/testapp/testpage.aspx?whr=urn:federation:<` *accountpartner*`>`, where `<`*accountpartner*`>` indicates the account partner realm of the client.

When the **`whr`** parameter is used, the Web server removes the parameter and writes a cookie to the client browser to remember this setting for future requests. Then, the request proceeds in the same way as if it had not been provided.

**Federation Service Proxy**
The Federation Service Proxy is a component of ADFS in Windows Server 2003 R2 that can be installed independently from other ADFS components. The Federation Service Proxy functions as a proxy in a perimeter network (also known as a DMZ or a screened subnet) for the Federation Service. The act of installing the Federation Service Proxy component on a computer makes that computer a federation server proxy. It also makes the Active Directory Federation Services snap-in available on that computer in the **Administrative Tools** menu.

A federation server proxy participates in the WS-F PRP protocol by communicating with a protected Federation Service on the client's behalf. When the federation server proxy is protecting an account partner, it collects user credential information from browser clients. When the federation server proxy is protecting a resource partner, it relays requests by and for Web applications to the Federation Service.

The federation server proxy also stores Hypertext Transfer Protocol (HTTP) cookies on clients when necessary to facilitate SSO. The federation server proxy writes all three types of cookies: authentication cookies, account partner cookies, and sign-out cookies.

**ADFS Web Agent**
The ADFS Web Agent is a component of ADFS. It is used to consume security tokens and either allow or deny a user access to a Web application. To accomplish this, the Web server requires a relationship with a resource Federation Service so that it can direct the user to the Federation Service as needed.

The ADFS Web Agent can be used for two different types of applications:

- Claims-aware applications: An ASP.NET application that is written to published ADFS objects that allow the querying of ADFS security token claims. The application makes authorization decisions based on these claims. Security token failures for this type of application result in the client seeing an "Access Denied" message and events in the Federation Service event log.

- Windows NT token–based applications: An application that uses Windows-based authorization mechanisms. The ADFS Web Agent supports conversion from an ADFS security token to an impersonation-level Windows NT access token.

The Web server also stores HTTP cookies on clients where necessary to facilitate SSO.

**Terminology used in ADFS**

ADFS uses terminology from several different technologies, including certificate services, Internet Information Services (IIS), Active Directory, ADAM, and Web Services (WS-*). The following table describes these terms.

| Term | Description |
|---|---|
| account partner | A federation partner that is trusted by the Federation Service to provide security tokens. The account partner issues these tokens to its users (that is, users in the account partner realm) so that they can access Web-based applications in the resource partner. |
| Active Directory Federation Services (ADFS) | A Windows Server 2003 R2 component that provides Web SSO technologies to authenticate a user to multiple Web applications over the life of a single online session. ADFS accomplishes this by securely sharing digital identity and entitlement rights across security and enterprise boundaries. ADFS in Windows Server 2003 R2 supports the WS-F PRP. |
| claim | A statement that an issuer makes (for example, name, identity, key, group, privilege, or capability) about a client. |
| claim mapping | The act of mapping, removing or filtering, or passing claims between various claim sets. |
| claims-aware application | An ASP.NET application that performs authorization based on the claims that are present in an ADFS security token. |
| client account partner discovery Web page | The Web page that is used to interact with the user to determine which account partner the user belongs to when ADFS cannot automatically determine which of the account partners should authenticate the user. |
| client logoff Web page | When ADFS performs a logoff operation, a Web page that is executed to provide visual feedback to the user that the logoff has occurred. |
| client logon Web page | When ADFS collects client credentials, a Web page that is executed to perform the user interaction. The client logon Web page may use any necessary business logic to determine the type of credentials to collect. |
| federation | A pair of realms or domains that have established a federation trust. |
| Federation Service | A security token service that is built into Windows Server 2003 R2. The Federation Service provides tokens in response to requests for security tokens. |
| Federation Service Proxy | A proxy to the Federation Service in the perimeter network (also known as a DMZ or a screened subnet). The Federation Service Proxy uses WS-F PRP protocols to collect user credential information from browser clients and Web applications and send the information to the Federation Service on their behalf. |
| organization claims | Claims in intermediate or normalized form within an organization's namespace. |

| | |
|---|---|
| passive client | An HTTP browser, capable of broadly supported HTTP, that can make use of cookies. ADFS in Windows Server 2003 R2 supports only passive clients, and it adheres to the WS-F PRP specification. |
| resource partner | A federation partner that trusts the Federation Service to issue claims-based security tokens. The resource partner contains published Web-based applications that users in the account partner can access. |
| security token | A cryptographically signed data unit that expresses one or more claims. |
| security token service (STS) | A Web service that issues security tokens. An STS makes assertions based on evidence that it trusts, to whoever trusts it (or to specific recipients). To communicate trust, a service requires proof, such as a signature, to prove knowledge of a security token or set of security tokens. A service itself can generate tokens or it can rely on a separate STS to issue a security token with its own trust statement. This forms the basis of trust brokering. In ADFS, the Federation Service is an STS. |
| server farm | In ADFS, a collection of load-balanced federation servers, federation server proxies, or Web servers hosting the ADFS Web Agent. |
| single sign-on (SSO) | An optimization of the authentication sequence to remove the burden of repeated logon actions by an end user. |
| token-signing certificate | An X509 certificate whose associated public/private key pair is used to provide integrity for security tokens. |
| Uniform Resource Identifier (URI) | A compact string of characters that identifies an abstract resource or physical resource. URIs are explained in RFC 2396 (http://go.microsoft.com/fwlink/?LinkId=48289). In ADFS, URIs are used to uniquely identify partners and account stores. |
| Web Services (WS-*) | The specifications for a Web Services Architecture that is based on industry standards such as Simple Object Access Protocol (SOAP); XML; Web Service Description Language (WSDL); and Universal Description, Discovery, and Integration (UDDI). WS-* provides a foundation for delivering complete, interoperable business solutions for the extended enterprise, including the ability to manage federated identity and security.<br><br>The Web services model is based on the idea that enterprise systems are written in different languages, with different programming models, which run on and are accessed from many different types of devices. Web services are a means of building distributed systems that can connect and interact with one another easily and efficiently across the Internet, regardless of what language they are written in or what platform they run on. |
| Web Services Security (WS-Security) | A series of specifications that describes how to attach signature and encryption headers to SOAP messages. In addition, WS-Security describes how to attach security tokens, including binary security tokens such as X.509 certificates and Kerberos tickets, to messages. In ADFS, WS-Security is used when Kerberos signs security tokens. |
| Windows NT token–based application | A Windows application that relies on a Windows NT token to perform authorization of users. |
| WS-Federation | A specification that defines a model and set of messages for brokering trust and the federation of identity and authentication information across different trust realms.<br><br>The WS-Federation specification identifies two sources of identity and authentication requests across trust realms: active requestors, such as SOAP-enabled applications, and passive requestors, which are defined as HTTP browsers capable of supporting broadly supported HTTP, for example, HTTP 1.1. |
| WS-Federation Passive Requestor Profile (WS-F PRP) | An implementation of the WS-Federation specification that proposes a standard protocol for how passive clients (such as Web browsers) apply the federation framework. Within this protocol, Web service requestors are expected to understand the new security mechanisms and be capable of interacting with Web service providers. |

**ADFS resources**

You can find detailed documentation about Active Directory Federation Services (ADFS) on the ADFS home page (http://go.microsoft.com/fwlink/?LinkId=79542).

For more information about ADFS or for other ADFS-related information, see the following Web resources:

- Web Services and Other Distributed Technologies Developer Center on the MSDN Web site (http://go.microsoft.com/fwlink/?LinkId=44189)
- Web Services Protocol Workshops on the MSDN Web site (http://go.microsoft.com/fwlink/?LinkId=44190)
- Web Services Specifications on the MSDN Web site (http://go.microsoft.com/fwlink/?LinkId=44191)
- Web Services Interoperability Organization (WS-I) (http://go.microsoft.com/fwlink/?LinkId=34328)

# Overview of the Distributed File System Solution in Microsoft Windows Server 2003 R2

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

| Tip |
| --- |
| Distributed File System is enhanced in Windows Server 2012. Explore the Evaluation Guide and download the Windows Server 2012 Trial. |

One of the goals of information technology (IT) groups in medium and large organizations is to manage file servers and their resources efficiently while keeping them available and secure for users. As organizations expand to include more users and servers—whether they are located in one site or in geographically distributed sites—administrators find it increasingly difficult to keep users connected to the files they need. On one hand, storing files on distributed servers makes files available to more users and decreases latency and bandwidth use when the servers are located near users. On the other hand, as the number of distributed servers increases, users have difficulty locating files they need, and operational costs increase.

Administrators who manage these distributed, remote servers need a solution that helps them limit network traffic over slow WAN connections, ensure the availability of files during WAN outages or server failures, and ensure that branch servers are backed up correctly. The Distributed File System solution in the Microsoft® Windows Server™ 2003 R2 operating system helps administrators address these challenges by providing two technologies, DFS Namespaces and DFS Replication, which, when used together, offer simplified, fault-tolerant access to files, load sharing, and WAN-friendly replication.

- DFS Replication is a new state-based, multimaster replication engine that supports replication scheduling and bandwidth throttling. DFS Replication uses a new compression protocol called Remote Differential Compression (RDC), which can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, and re-arrangements of data in files, thereby enabling DFS Replication to replicate only the changes when files are updated. Additionally, a function of RDC called *cross-file RDC* can help reduce the amount of bandwidth required to replicate new files.

- DFS Namespaces, formerly known as Distributed File System, allows administrators to group shared folders located on different servers and present them to users as a virtual tree of folders known as a *namespace*. A namespace provides numerous benefits, including increased availability of data, load sharing, and simplified data migration.

For the latest information about DFS Namespaces and DFS Replication, see DFS Namespaces and DFS Replication overview.

The following figure illustrates how DFS Namespaces and DFS Replication work together. The processes marked 1 and 2 are described in more detail following the figure.

As the figure shows, when a user attempts to access a folder in the namespace (1), the client computer contacts a namespace server. The namespace server sends the client computer a referral that contains a list of servers that host the shared folders (called folder targets) associated with the folder. The client computer caches the referral and then contacts the first server in the referral (2), typically a server in the client's own site unless no same-site servers exist or the administrator configures target priority.

The highlighted folder in the figure shows that it is hosted by shared folders on two servers, one in New York and one in London, to provide users in those sites with fast, reliable access to files. The shared folders are kept synchronized by DFS Replication. The fact that multiple servers host the folder is transparent to users, who see only a single folder in the namespace. If one of the servers becomes unavailable, the client computer fails over to the remaining server.

**Key Scenarios**
Although DFS Namespaces and DFS Replication are two separate technologies, when used together they provide solutions for a number of key scenarios in medium and large organizations.

**Data collection**
The data collection scenario helps address the need to eliminate the use of tape backup in branch offices and significantly reduce operational costs for branch offices. To accomplish this, data is replicated from a server in a branch office to a server in a hub office or data center. Administrators at the hub office can use backup software to back up the branch server's data from a hub server, eliminating the often error-prone process of having non-IT administrators performing the backups at branch offices that are not staffed by trained IT personnel. Centralizing backups at the hub office also allows organizations to consolidate backup hardware and related management tasks.

Thanks to RDC, DFS Replication replicates only the differences (or changes) between the two servers; as a result, bandwidth used during replication is minimized, an important consideration for branch offices that use low-bandwidth WAN connections to the hub office. In addition, replication schedules and bandwidth throttling can be used to set up replication windows during off-hours and regulate the amount of bandwidth used during replication, providing administrators more control over WAN traffic.

When DFS Replication is used in conjunction with DFS Namespaces, administrators can configure a namespace so that branch clients always connect to the branch server. If the branch server becomes unavailable, branch clients fail over to the hub server. And, using a DFS Namespaces enhancement known as *client failback*, branch clients running a client failback hotfix will fail back to the branch server after it is restored.

**Data distribution**
DFS Namespaces and DFS Replication can be used to publish documents, software, and line-of-business data to users throughout an organization. Although DFS Replication alone is sufficient to distribute data, using DFS Namespaces allows administrators to configure the namespace so that a folder in the namespace is hosted by multiple servers, which increases data availability and distributes the client load across servers. When browsing the namespace, users see a single folder and are not aware the folder is hosted by multiple servers. When a user opens the folder, the client computer is automatically referred to a server in its own site; if no same-site servers are available, administrators can configure the namespace to refer the client to a server that has the lowest connection cost as defined in the Active Directory® directory service. And, using a DFS Namespaces enhancement known as *target priority*, administrators can specify the priority of servers so that a specific server is always placed first or last in the list of servers (known as a referral) the client receives when accessing a folder in the namespace.

**Sharing files across branch offices**
In large organizations that have branch offices located around the world, users in one branch office often need access to shared folders and files stored at another branch or at the hub office or data center. Although in some cases the need is collaborative, in other cases users simply need access to those files. If low latency and data availability during WAN outages is worth the tradeoff of network traffic and disk space used in the branch office, administrators can use DFS Replication to replicate files between branch servers, providing users fast access to files in their respective branch offices. Having files in multiple branch offices also benefits users who travel from one branch office to another. The users can make changes to their files in one branch office, and those changes are replicated back to the user's branch office.

When the shared folders in a branch office are defined as folders in a namespace, users access them by browsing what appears to be a single server, giving the users a consistent place to begin browsing for files. For example, a user who travels from one branch office to another will access what appears to be the same folder in the namespace, but the user is actually referred to the closest server that contains the data. If that data is replicated using DFS Replication, the user's changes are replicated back to the user's branch office.

Collaboration scenarios using DFS Replication are recommended only if users can tolerate some inconsistency of the files as the changes are replicated to other branch servers. In addition, because DFS Replication uses a heuristic of last writer wins for changes made to the same file on multiple servers, this scenario works best when a file is updated from a single server or by a single user. Setting shared folder permissions can help ensure that conflicting changes don't occur. For collaboration scenarios that require file locking, we recommend using Microsoft® Windows® SharePoint® Services.

| **Note** |
| --- |
| Because DFS Replication only replicates a file after it is closed, DFS Replication is not recommended for replicating database files or any files that are held open for long periods of time. |

**DFS Replication Benefits in Windows Server 2003 R2**
DFS Replication is a new replication engine that provides substantial improvements over the File Replication service (FRS). The benefits of using DFS Replication are described below.

**Simplified process for replicating discrete folders to the same set of servers**
The process of setting up replicated folders is simplified in Windows Server 2003 R2 by the introduction of *replication groups* and *replicated folders*, which are illustrated in the following figure.

As this figure shows, a *replication group* is a set of servers, known as *members*, that participates in the replication of one or more replicated folders. A *replicated folder* is a folder that is kept synchronized on each member. In the previous figure, there are two replicated folders, Projects and Proposals. As data changes in each replicated folder, the changes are replicated across *connections* between the members. The connections between all members form the replication *topology*.

Creating multiple replicated folders in a single replication group simplifies the process of deploying replicated folders because the topology, schedule, and bandwidth throttling for the replication group are applied to each replicated folder. Each replicated folder also has its own settings, such as file and subfolder filters, so that administrators can filter out different files and subfolders for each replicated folder. To deploy additional replicated folders, administrators use a brief wizard to define the local path and permissions for each new replicated folder.

The replicated folders stored on each member can be located on different volumes in the member, and the replicated folders do not need to be shared folders or part of a namespace, though the DFS Management snap-in makes it easy to share replicated folders and optionally publish them in an existing namespace.

**Differential replication of changes to files**

DFS Replication uses RDC to replicate only the differences (or changes) between the members. This allows branch offices with slow WAN connections to participate in replication using minimal bandwidth.

RDC is especially efficient when small changes are made to large files. For example, a change that is made to a 2-megabyte (MB) PowerPoint® presentation can result in only 60 kilobytes (KB) being sent across the network, a 97 percent savings in bytes transferred. A test was run on a mix of 780 Office files (.doc, .ppt, and .xls) replicating from a source server to a target server using DFS Replication with RDC. The goal was to determine how effective RDC is for Office files on which typical edits are made. The target server had version *x* of the files and the source server had version *x+*, and the two versions differed with significant edits. The percent savings in bytes transferred was on average 50 percent and significantly better for large files.

Also, by using RDC and compression, DFS Replication provides bandwidth savings for distributing software files. For example, the IT department at Microsoft uses DFS Replication to replicate software files to Microsoft offices in several countries/regions. Although bandwidth used varies over time, in one typical case, a 63.14 percent reduction in bandwidth was measured in network traffic, specifically, 16.22 gigabytes (GB) replicated instead of 44.0 GB.

| **Note** |
| --- |
| RDC is not used on files smaller than 64 KB and might not be beneficial on high-speed LANs where network bandwidth is not contended. RDC can be disabled on a per-connection basis using the DFS Management snap-in. |

**Reduction of bandwidth used for replicating new files**

Another function of RDC, known as cross-file RDC, uses a heuristic to identify files that are similar to the file that needs to be replicated. This is useful when a new file is created on one server and needs to be replicated to another server. Instead of replicating the entire file, DFS Replication can use portions from files that are similar to the replicating file to minimize the amount of data transferred over the WAN.

Cross-file RDC is available only if one of the servers (in a replicating pair of servers) is running Windows Server 2003 R2, Enterprise Edition; Windows Server 2003 R2, Datacenter Edition; or Windows® Storage Server R2, Enterprise Edition. For example, if a branch office server is running Windows Server 2003 R2, Standard Edition, and the hub server is running Windows Server 2003 R2, Enterprise Edition, cross-file RDC will be used.

**Efficient and scalable replication**

When two members of a replication group begin to synchronize with each other, they use an efficient algorithm for determining which files need to be replicated. The amount of metadata exchanged is minimal, and the possibility of sending changes unnecessarily (due to the order the changes occur) is eliminated because the synchronization is state-based instead of event-based, as in File Replication service (FRS).

The introduction of state-based synchronization, along with RDC, allows DFS Replication to support replicating more files to more members than FRS. The tested scalability figures are as follows:

- Each server can be a member of up to 256 replication groups.
- Each replication group can contain up to 256 replicated folders.
- Each server can have up to 256 connections (for example, 128 incoming connections and 128 outgoing connections).
- On each server, the number of replication groups multiplied by the number of replicated folders multiplied by the number of simultaneously replicating connections must be kept to 1024 or fewer. If the replication schedule is staggered, you do not need to count the connections that are not replicating due to a closed schedule.
- A replication group can contain up to 256 members.
- A volume can contain up to 8 million replicated files, and a server can contain up to 1 terabyte of replicated files. These are tested numbers and recommended guidelines for performance and scalability reasons.

**Flexible scheduling and bandwidth throttling**
DFS Replication supports replication scheduling and bandwidth throttling in 15-minute increments during a 7-day period. When specifying a replication interval, administrators choose the start and stop times as well as the bandwidth to use during that interval. The settings for bandwidth usage range from 16 kilobits per second (Kbps) to 256 megabits per second (Mbps) as well as full (unlimited) bandwidth. Administrators can configure a default schedule and bandwidth that applies to all connections between members and, optionally, create a custom schedule and bandwidth for individual connections.

To help administrators configure replication windows for servers in different time zones, administrators can set the schedule so that the server that initiates replication interprets the schedule as being in either Coordinated Universal Time (UTC) or in the server's local time.

**Supported in stand-alone and domain-based namespaces and on individual folders**
DFS Replication can be used in both stand-alone and domain-based namespaces as well as for folders that are not part of any namespace. The folders to be replicated can be shared or unshared.

**Self-healing after USN journal wraps and database corruption**
DFS Replication provides "self-healing" for update sequence number (USN) journal wraps and Jet database corruption. Although replication temporarily stops during this healing process, the service recovers without any administrator intervention. To repair itself, DFS Replication scans the file system and re-creates the DFS Replication database that contains metadata associated with the files in the replicated folder. The database must then be synchronized with a database on another member. During the synchronization process, the amount of metadata sent across the network is dictated by the number of files under the replicated folder's local path (that is, the number of ID records in the database) and the size of the metadata to be sent per file. The metadata size for a file is two times the length of the file name plus approximately 144 bytes. Additional RPC and TCP overhead results in a roughly 5 percent overhead; therefore, in the worst case, for 1 million files in the database with an average file name size of 50 bytes, approximately 194 megabytes (MB) of metadata is sent across the network.

**Ease of member recovery**
DFS Replication stores its global configuration settings, such as the topology and replication schedule, in Active Directory. These settings are also cached in a local .xml file on each member; DFS Replication can rebuild this file (using the settings stored in Active Directory) if the file becomes corrupted or if the member is restored after a failure. This type of self-healing allows for greater server uptime and reliability and makes it easier to rebuild a member of a replication group during disaster recovery.
DFS Replication also uses the .xml file to store member-specific settings, such as debug log settings or RPC port settings that are configured using Windows Management Instrumentation (WMI).

**Simple and flexible prestaging of new servers**
Before adding a new server to a replication group, administrators can prestage the replicated folders on the target servers by copying the data to the servers, restoring a backup, or copying files from a tape, DVD, or removable hard disk. As described earlier, the synchronization process is very efficient in terms of bandwidth usage and metadata exchanged, resulting in minimal WAN traffic during the initial synchronization for files that are the same on the source server (known as the *primary member*) and target servers. If the files on the target server are out-of-date, DFS Replication will use RDC to replicate only the changes that occurred since the data was prestaged. Any prestaged files that existed on the target servers, but not on the source server, are moved to the PreExisting folder under the target server's replicated folder path.

**New management tools**
Administrators can use the DFS Management snap-in to configure both DFS Namespaces and DFS Replication. The snap-in provides integration between the two Distributed File System components so that administrators can:

- Select an existing folder in a namespace and configure DFS Replication on the folder targets (shared folders) associated with

the folder.

- Add a replicated folder to an existing namespace.

Administrators can also perform administrative tasks at the command line using Dfsradmin.exe or Dfsrdiag.exe. Both tools are part of Windows Server 2003 R2. Additional configurations can be made programmatically using WMI.

**Delegation of management tasks**
Administrators who are not part of the Domain Admins group can be delegated the ability to create new replication groups in a domain, manage an existing replication group, or both. Members of the Domain Admins group can use either the DFS Management snap-in or the Dfsradmin.exe command-line tool to perform this delegation.

**Built-in health metrics and diagnostic events**
DFS Replication provides built-in WMI providers for monitoring the health of DFS Replication. For example, the WMI providers can report USN journal wraps, database loss, insufficient disk space, network connectivity issues, sharing violations, excessive replication, and clock skew between members. These events are also reported in the DFS Replication event log, which is used exclusively for storing events related to replication.

There are two ways of monitoring DFS Replication: a built-in diagnostic report and the Windows DFS Replication Management Pack for Microsoft Operations Manager (MOM). The diagnostic report is an .html file generated using either the DFS Management snap-in or the Dfsradmin.exe command-line tool. The report contains a wealth of DFS Replication information, including error and warning events; service state and uptime; replication efficiency based on RDC and stream compression; backlogged sending and receiving transactions; free disk space, and more. An example health report is shown in the following figure:

# DFS Replication Health Report

**INFORMATIONAL**

- Service state: Running
- DFS Replication service uptime: 4 days 9 hr.
- Summary of replicated folder status

  The following table provides a high-level overview of replicated folder status on this server.

| Replicated Folder | Status | Backlogged Sending Transactions | Backlogged Receiving Transactions | # of Files Received | DFS Replication Efficiency Savings |
|---|---|---|---|---|---|
| Software\Applications\Server\ISA Server 2004 | Normal | 120 | 289 | 568 | 93.13% |
| Software\Applications\Server\SQL Server | Normal | 84 | 416 | 632 | 65.54% |

The Windows DFS Replication Management Pack is a real-time monitoring tool that monitors the health state and replication progress of DFS Replication on a per-member basis. Administrators can use this management pack to monitor the state of the DFS Replication service, replication groups, replicated folders, and the volumes where replicated folders are stored. Conditions that cause full or partial replication failures will temporarily change the state of objects; these objects will change back to a healthy state when the problem is resolved, either automatically by the service (as in the case of intermittent connection failures) or by the administrator.

The management pack is supported on Microsoft Operations Manager 2005 and will be available for download on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=55220).

**DFS Namespaces Enhancements in Windows Server 2003 R2**

As described earlier, the Distributed File System technology in Windows Server™ 2003 has been renamed to DFS Namespaces. Although the underlying service and basic functionality are unchanged, there are a number of DFS Namespaces enhancements exposed in Windows Server 2003 R2. These enhancements, introduced as updated APIs in Windows Server 2003 Service Pack 1 (SP1), provide easier management and more flexibility for namespaces used in branch offices.

### New and updated management tools

The new DFS Management snap-in in Windows Server 2003 R2 provides an improved graphical user interface for managing namespaces and DFS Replication. The snap-in allows administrators to configure DFS Namespaces enhancements, such as target priority, delegation, and client failback, as well as existing features that in Windows Server 2003 were configurable only by using Dfsutil.exe. For example, administrators can use the DFS Management snap-in to configure how servers are ordered in a referral, such as by lowest cost or restricted to the same site as the client. Administrators can also enable root scalability mode, which reduces the load on the primary domain controller (PDC) emulator in large namespaces.

The command-line tool Dfsutil.exe, which is part of the Windows Support Tools in Windows Server 2003 SP1, is updated to include the DFS Namespaces enhancements. The operating system tool Dfscmd.exe is also updated to allow administrators to move or rename folders in the namespace.

### Client failback

Client failover in DFS Namespaces is the process in which clients attempt to access another server in a referral after one of the servers fails or is removed from the namespace. Unless client failback is configured, clients will continue using the server they failed over to unless the client is restarted or the client's referral cache is cleared. When client failback is configured, and clients have the appropriate client failback hotfix installed, clients will fail back to a preferred, local server when it is restored.

### Target priority

When a client accesses a namespace, the client receives a referral that contains a list of targets associated with the namespace root or folder. These targets are listed according to the current ordering method for the namespace or folder. To fine-tune how particular targets are ordered, administrators can specify whether a server appears first or last in a referral. Assigning target priority is useful in many scenarios, such as “hot-standby” scenarios where one server is considered the server of last resort. In this scenario, the administrator can specify that the standby server always appears last in referrals, and clients will fail over to this server only if all the other servers fail or become unavailable due to network outages.

### Better delegation

Administrators can easily delegate the ability to create domain-based namespaces and manage individual stand-alone and domain-based namespaces. The DFS Management snap-in sets the appropriate permissions on either the DFS Namespace configuration objects in Active Directory or in the namespace server’s registry (depending on the namespace type).

### Ability to restructure the namespace

Renaming or moving folders in the namespace is easy using the DFS Management snap-in. Administrators can restructure the namespace to correct mistakes or to adjust the hierarchy as business needs change or as new folders are added to the namespace. Administrators can also move namespace folders by using the updated version of the command-line tool, Dfscmd.exe.

#### Configuration Requirements

The following sections describe how servers must be configured to support DFS Replication and DFS Namespaces in Windows Server 2003 R2.

### DFS Replication requirements

Before DFS Replication can be deployed, administrators must configure servers and storage as follows:

- The Active Directory schema must be updated to include the new DFS Replication objects. These schema changes are provided on disc 2 of the Windows Server 2003 R2 operating system installation discs. This schema can be applied to domain controllers running Microsoft® Windows® 2000 Server, Windows Server 2003, and Windows Server 2003 R2.

- The servers that will participate in DFS Replication must run Windows Server 2003 R2. After you install Windows Server 2003 R2, you must install the DFS Replication Service on each server that will take part in replication, and you must install the DFS Management snap-in to manage replication. For information about installing the DFS Management snap-in on a client computer running Windows XP with Service Pack 2 (SP2), see "Administering Distributed File System from a computer running Windows XP" later in this document.

- Antivirus software must be compatible with DFS Replication; contact your antivirus software vendor to check for compatibility.

- Servers in a replication group must be in the same forest. You cannot enable replication across servers in different forests.

- Replicated folders must be stored on NTFS volumes.

- On server clusters, replicated folders should be located in the local storage of a node because the Distributed File System Replication service is not cluster aware and the service will not fail over to another node.

| **Important** |
| --- |
| DFS Replication is not supported for SYSVOL replication in Windows Server 2003 R2. Do not attempt to configure DFS Replication on SYSVOL by disabling FRS and setting up a replication group for SYSVOL. Continue to use FRS for SYSVOL replication on domain controllers running Windows Server 2003 R2. FRS and DFS Replication can co-exist on the same member server or domain controller. |

**DFS Namespaces requirements**

To enable all features in DFS Namespaces, you must configure lab servers and clients as follows:

- Servers where the DFS Management snap-in will be used must run Windows Server 2003 R2 or Windows XP SP2. For information about installing the DFS Management snap-in on a client computer running Windows XP with SP2, see "Administering Distributed File System from a computer running Windows XP" later in this document.
- To support new namespace features, all servers that host namespaces must run Windows Server 2003 SP1 or Windows Server 2003 R2.
- To support new namespace features, all domain controllers must run Windows Server 2003 with SP1 or Windows Server 2003 R2.
- Namespaces must be created on NTFS volumes.
- Clients that access namespaces can run any of the supported client operating systems, but only clients running the following operating systems, service packs, and the appropriate client failback hotfix can be configured for client failback:
    - Windows XP SP2 and the Client Failback hotfix.
    - Windows Server 2003 SP1 and the Client Failback hotfix.

For more information about the Client Failback hotfix, see article 898900 in the Microsoft Knowledge Base on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=53202.

For more information about supported operating systems for DFS Namespaces clients, see "Evaluating Client and Server Compatibility" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=37455.

It is possible to use DFS Namespaces when domain controllers and namespace servers run a mix of Windows 2000 Server, Windows Server 2003 with SP1, and Windows Server 2003 without SP1, but some functionality is disabled or available inconsistently, depending on the operating systems on the servers. Some examples of mixed-mode behavior are as follows:

- If domain controllers or namespace servers are running Windows Server 2003 without SP1, they cannot provide referrals that support target priority or client failback.
- If domain controllers or namespace servers are running Windows 2000 Server, they cannot provide referrals that support target server priority or client failback, nor can they order targets by lowest cost in referrals. Additional configuration is required to enable these namespace servers and domain controllers to detect the site of each target server in the namespace. For details, see the answer to the question "What are the issues to consider when I use multiple servers running Windows 2000 Server and Windows Server 2003 to host a domain-based DFS root?" in the DFS FAQ on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=39465.
- If the DFS Management snap-in connects to a namespace server that is not running Windows Server 2003 SP1 or Windows Server 2003 R2, none of the new configuration settings (such as client failback and target priority) can be enabled. Renaming or moving folders will not work, and delegation will not be effective.

**Administering Distributed File System from a computer running Windows XP**

You can also manage DFS Namespaces and DFS Replication from a computer running Windows XP with SP2 by installing the Administration Tools Packs for Windows Server 2003 R2. When this pack is installed, the DFS Management snap-in is available as

part of the File Server Management snap-in. For more information about installing this pack, see the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=55225.

# DFS Replication: Frequently Asked Questions (FAQ)

Published: October 16, 2006

Updated: October 9, 2013

Applies To: Windows Server 2003 R2, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2

This FAQ answers questions about Distributed File System (DFS) Replication (also known as DFS-R or DFSR) for the Windows Server 2012 R2, Windows Server 2012, Windows Server® 2008 R2, Windows Server 2008, and Windows Server 2003 R2 operating systems.

For information about DFS Namespaces, see DFS Namespaces: Frequently Asked Questions.

For information about what's new in DFS Replication, see the following topics:

- DFS Namespaces and DFS Replication Overview (in Windows Server 2012)
- What's New in Distributed File System topic in Changes in Functionality from Windows Server 2008 to Windows Server 2008 R2
- Distributed File System topic in Changes in Functionality from Windows Server 2003 with SP1 to Windows Server 2008

For a list of recent changes to this topic, see the Change History section of this topic.

**Interoperability**

- Can DFS Replication communicate with FRS?
- Can DFS Replication replace FRS for SYSVOL replication
- Can I upgrade from FRS to DFS Replication without losing configuration settings?
- Can I use DFS Replication in a mixed Windows/UNIX environment?
- Can I use the Volume Shadow Copy Service with DFS Replication?
- Can I use Windows Backup (Ntbackup.exe) to remotely back up a replicated folder?
- Do file system policies impact DFS Replication?
- Does DFS Replication replicate mailboxes hosted on Microsoft Exchange Server?
- Does DFS Replication support file screens created by File Server Resource Manager?
- Is DFS Replication cluster aware?
- Is DFS Replication compatible with Data Deduplication?
- Is DFS Replication compatible with RIS and WDS?
- Is it possible to use DFS Replication with Offline Files?
- What antivirus applications are compatible with DFS Replication?
- What are the benefits of using DFS Replication instead of Windows SharePoint Services?

**Limitations and requirements**

- Can DFS Replication replicate between branch offices without a VPN connection?
- Can DFS Replication replicate files encrypted with the Encrypting File System?
- Can DFS Replication replicate Outlook .pst or Microsoft Office Access database files?
- Can I use DFS Replication in a workgroup?
- Can more than one folder be replicated on a single server?
- Does DFS Replication require DFS Namespaces?
- Does DFS Replication require time synchronization between servers?
- Does DFS Replication support replicating an entire volume?
- Does DFS Replication support RPC over HTTP?
- Does DFS Replication work across wireless networks?
- Does DFS Replication work on ReFS or FAT volumes?
- Does DFS Replication work with sparse files?
- Do I need to log in as administrator to replicate files?
- How can I upgrade or replace a DFS Replication member?
- Is DFS Replication suitable for replicating roaming profiles?
- Is there a file character limit or limit to the folder depth?
- Must members of a replication group reside in the same domain?
- What are the supported limits of DFS Replication?
- When should I not use DFS Replication?
- Why is a schema update required for DFS Replication?

**Monitoring and management tools**

- Can I automate the health report to receive warnings?
- Can I use Microsoft System Center Operations Manager to monitor DFS Replication?
- Does DFS Replication support remote management?
- Do Ultrasound and Sonar work with DFS Replication?
- How can files be recovered from the ConflictAndDeleted or PreExisting folders?
- Is there a way to know the state of replication?

**Performance**

- Does DFS Replication support dial-up connections?
- Does DFS Replication perform bandwidth sensing?
- Does DFS Replication throttle bandwidth per schedule, per server, or per connection?
- Does DFS Replication use Active Directory Domain Services to calculate site links and connection costs?
- How can I improve replication performance?
- How does DFS Replication avoid saturating a connection?
- How does DFS Replication performance compare with FRS?
- How frequently does DFS Replication replicate data?
- How much of my server's system resources will DFS Replication consume?
- What happens if a WAN link fails during replication?

**Remote Differential Compression details**

- Are changes compressed before being replicated?
- Can an administrator turn off RDC or change the threshold?
- Does RDC work on all file types?
- How does RDC work on a compressed file?
- Is cross-file RDC enabled when upgrading to Windows Server Enterprise Edition or Datacenter Edition?
- Is RDC true block-level replication?
- What happens if I rename a file?
- What is cross-file RDC?
- What is RDC?
- When is RDC used for replication?
- Which editions of the Windows operating system support cross-file RDC?

**Replication details**

- Can I change the path for a replicated folder after it is created?
- Can I configure which file attributes are replicated?
- Can I control which member is replicated?
- Can I seed a replication group member with data prior to the initial replication?

- Does DFS Replication overcome common File Replication Service issues?
- Does DFS Replication replicate files in chronological order?
- Does DFS Replication replicate files that are being used by another application?
- Does DFS Replication replicate NTFS file permissions, alternate data streams, hard links, and reparse points?
- Does DFS Replication replicate timestamp changes if no other changes are made to the file?
- Does DFS Replication replicate updated permissions on a file or folder?
- Does DFS Replication support merging text files in the event of a conflict?
- Does DFS Replication use encryption when transmitting data?
- Is it possible to disable the use of encrypted RPC?
- How are simultaneous replications handled?
- How do I force replication or polling?
- Is it possible to configure a quiet time between replications for files that change frequently?
- Is it possible to configure one-way replication with DFS Replication?
- Is there a way to force a complete replication of all files including unchanged files?
- What happens if the primary member suffers a database loss during initial replication?
- What happens if the replication schedule closes while a file is being replicated?
- What happens when two users simultaneously update the same file on different servers?

**Staging**

- Does DFS Replication continue staging files when replication is disabled by a schedule or bandwidth throttling quota, or when a connection is manually disabled?
- Does DFS Replication prevent other applications from accessing a file during staging?
- Is it possible to change the location of the staging folder with the DFS Management Tool?
- When are files staged?
- What happens if a file is changed after it is staged but before it is completely transmitted to the remote site?

**Interoperability**

**Can DFS Replication communicate with FRS?**

No. DFS Replication does not communicate with File Replication Service (FRS). DFS Replication and FRS can run on the same server at the same time, but they must never be configured to replicate the same folders or subfolders because doing so can cause data loss.

**Can DFS Replication replace FRS for SYSVOL replication**

Yes, DFS Replication can replace FRS for SYSVOL replication on servers running Windows Server 2012 R2, Windows Server 2012, Windows Server 2008 R2, or Windows Server 2008. Servers running Windows Server 2003 R2 do not support using

DFS Replication to replicate the SYSVOL folder.

For more information about replicating SYSVOL by using DFS Replication, see the SYSVOL Replication Migration Guide: FRS to DFS Replication.

**Can I upgrade from FRS to DFS Replication without losing configuration settings?**
Yes. To migrate replication from FRS to DFS Replication, see the following documents:

- To migrate replication of folders other than the SYSVOL folder, see DFS Operations Guide: Migrating from FRS to DFS Replication and FRS2DFSR – An FRS to DFSR Migration Utility (http://go.microsoft.com/fwlink/?LinkID=195437).

- To migrate replication of the SYSVOL folder to DFS Replication, see SYSVOL Replication Migration Guide: FRS to DFS Replication.

**Can I use DFS Replication in a mixed Windows/UNIX environment?**
Yes. Although DFS Replication only supports replicating content between servers running Windows Server, UNIX clients can access file shares on the Windows servers. To do so, install Services for Network File Systems (NFS) on the DFS Replication server.

You can also use the SMB/CIFS client functionality included in many UNIX clients to directly access the Windows file shares, although this functionality is often limited or requires modifications to the Windows environment (such as disabling SMB Signing by using Group Policy).

DFS Replication interoperates with NFS on a server running a Windows Server operating system, but you cannot replicate an NFS mount point.

**Can I use the Volume Shadow Copy Service with DFS Replication?**
Yes. DFS Replication is supported on Volume Shadow Copy Service (VSS) volumes and previous snapshots can be restored successfully with the Previous Versions Client.

**Can I use Windows Backup (Ntbackup.exe) to remotely back up a replicated folder?**
No, using Windows Backup (Ntbackup.exe) on a computer running Windows Server 2003 or earlier to back up the contents of a replicated folder on a computer running Windows Server 2012, Windows Server 2008 R2, or Windows Server 2008 is not supported.

To back up files that are stored in a replicated folder, use Windows Server Backup or Microsoft® System Center Data Protection Manager. For information about Backup and Recovery functionality in Windows Server 2008 R2 and Windows Server 2008, see Backup and Recovery. For more information, see System Center Data Protection Manager (http://go.microsoft.com/fwlink/?LinkId=182261).

**Do file system policies impact DFS Replication?**
Yes. Do not configure file system policies on replicated folders. The file system policy reapplies NTFS permissions at every Group Policy refresh interval. This can result in sharing violations because an open file is not replicated until the file is closed.

**Does DFS Replication replicate mailboxes hosted on Microsoft Exchange Server?**
No. DFS Replication cannot be used to replicate mailboxes hosted on Microsoft Exchange Server.

**Does DFS Replication support file screens created by File Server Resource Manager?**
Yes. However, the File Server Resource Manager (FSRM) file screening settings must match on both ends of the replication. In addition, DFS Replication has its own filter mechanism for files and folders that you can use to exclude certain files and file types from replication.

The following are best practices for implementing file screens or quotas:

- The hidden DfsrPrivate folder must not be subject to quotas or file screens.

- Screened files must not exist in any replicated folder before screening is enabled.

- No folders may exceed the quota before the quota is enabled.

- You must use hard quotas with caution. It is possible for individual members of a replication group to stay within a quota before replication, but exceed it when files are replicated. For example, if a user copies a 10 megabyte (MB) file onto server A (which is then at the hard limit) and another user copies a 5 MB file onto server B, when the next replication occurs, both servers will exceed the quota by 5 megabytes. This can cause DFS Replication to continually retry replicating

the files, causing holes in the version vector and possible performance problems.

**Is DFS Replication cluster aware?**
Yes, DFS Replication in Windows Server 2012 R2, Windows Server 2012 and Windows Server 2008 R2 includes the ability to add a failover cluster as a member of a replication group. For more information, see Add a Failover Cluster to a Replication Group (http://go.microsoft.com/fwlink/?LinkId=155085).The DFS Replication service on versions of Windows prior to Windows Server 2008 R2 is not designed to coordinate with a failover cluster, and the service will not fail over to another node.

| **Note** |
| --- |
| DFS Replication does not support replicating files on Cluster Shared Volumes. |

**Is DFS Replication compatible with Data Deduplication?**
Yes, DFS Replication can replicate folders on volumes that use Data Deduplication in Windows Server.

**Is DFS Replication compatible with RIS and WDS?**
Yes. DFS Replication replicates volumes on which Single Instance Storage (SIS) is enabled. SIS is used by Remote Installation Services (RIS), Windows Deployment Services (WDS), and Windows Storage Server.

**Is it possible to use DFS Replication with Offline Files?**
You can safely use DFS Replication and Offline Files together in scenarios when there is only one user at a time who writes to the files. This is useful for users who travel between two branch offices and want to be able to access their files at either branch or while offline. Offline Files caches the files locally for offline use and DFS Replication replicates the data between each branch office.

Do not use DFS Replication with Offline Files in a multi-user environment because DFS Replication does not provide any distributed locking mechanism or file checkout capability. If two users modify the same file at the same time on different servers, DFS Replication moves the older file to the DfsrPrivate\ConflictandDeleted folder (located under the local path of the replicated folder) during the next replication.

**What antivirus applications are compatible with DFS Replication?**
Antivirus applications can cause excessive replication if their scanning activities alter the files in a replicated folder. For more information, Testing Antivirus Application Interoperability with DFS Replication (http://go.microsoft.com/fwlink/?LinkId=73990).

**What are the benefits of using DFS Replication instead of Windows SharePoint Services?**
Windows® SharePoint® Services provides tight coherency in the form of file check-out functionality that DFS Replication does not. If you are concerned about multiple people editing the same file, we recommend using Windows SharePoint Services. Windows SharePoint Services 2.0 with Service Pack 2 is available as part of Windows Server 2003 R2. Windows SharePoint Services can be downloaded from the Microsoft Web site; it is not included in newer versions of Windows Server. However, if you are replicating data across multiple sites and users will not edit the same files at the same time, DFS Replication provides greater bandwidth and simpler management.

**Limitations and requirements**
**Can DFS Replication replicate between branch offices without a VPN connection?**
Yes—assuming that there is a private Wide Area Network (WAN) link (not the Internet) connecting the branch offices. However, you must open the proper ports in external firewalls. DFS Replication uses the RPC Endpoint Mapper (port 135) and a randomly assigned ephemeral port above 1024. You can use the **Dfsrdiag** command line tool to specify a static port instead of the ephemeral port. For more information about how to specify the RPC Endpoint Mapper, see article 154596 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=73991).

**Can DFS Replication replicate files encrypted with the Encrypting File System?**
No. DFS Replication will not replicate files or folders that are encrypted using the Encrypting File System (EFS). If a user encrypts a file that was previously replicated, DFS Replication deletes the file from all other members of the replication group. This ensures that the only available copy of the file is the encrypted version on the server.

**Can DFS Replication replicate Outlook .pst or Microsoft Office Access database files?**
DFS Replication can safely replicate Microsoft Outlook personal folder files (.pst) and Microsoft Access files only if they are stored for archival purposes and are not accessed across the network by using a client such as Outlook or Access (to open .pst or Access files, first copy the files to a local storage device). The reasons for this are as follows:

- Opening .pst files over network connections could lead to data corruption in the .pst files. For more information about why .pst files cannot be safely accessed from across a network, see article 297019 in the Microsoft Knowledge Base

(http://go.microsoft.com/fwlink/?LinkId=125363).

- .pst and Access files tend to stay open for long periods of time while being accessed by a client such as Outlook or Office Access. This prevents DFS Replication from replicating these files until they are closed.

**Can I use DFS Replication in a workgroup?**
No. DFS Replication relies on Active Directory® Domain Services for configuration. It will only work in a domain.

**Can more than one folder be replicated on a single server?**
Yes. DFS Replication can replicate numerous folders between servers. Ensure that each of the replicated folders has a unique root path and that they do not overlap. For example, D:\Sales and D:\Accounting can be the root paths for two replicated folders, but D:\Sales and D:\Sales\Reports cannot be the root paths for two replicated folders.

**Does DFS Replication require DFS Namespaces?**
No. DFS Replication and DFS Namespaces can be used separately or together. In addition, DFS Replication can be used to replicate standalone DFS namespaces, which was not possible with FRS.

**Does DFS Replication require time synchronization between servers?**
No. DFS Replication does not explicitly require time synchronization between servers. However, DFS Replication does require that the server clocks match closely. The server clocks must be set within five minutes of each other (by default) for Kerberos authentication to function properly. For example, DFS Replication uses time stamps to determine which file takes precedence in the event of a conflict. Accurate times are also important for garbage collection, schedules, and other features.

**Does DFS Replication support replicating an entire volume?**
Yes. However, you must first install Windows Server 2003 Service Pack 2 or the hotfix. For more information, see article 920335 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=76776). Additionally, replicating an entire volume can cause the following problems:

- If the volume contains a Windows paging file, replication fails and logs DFSR event 4312 in the system event log.

- DFS Replication sets the System and Hidden attributes on the replicated folder on the destination server(s). This occurs because Windows applies the System and Hidden attributes to the volume root folder by default. If the local path of the replicated folder on the destination server(s) is also a volume root, no further changes are made to the folder attributes.

- When replicating a volume that contains the Windows system folder, DFS Replication recognizes the %WINDIR% folder and does not replicate it. However, DFS Replication does replicate folders used by non-Microsoft applications, which might cause the applications to fail on the destination server(s) if the applications have interoperability issues with DFS Replication.

**Does DFS Replication support RPC over HTTP?**
No.

**Does DFS Replication work across wireless networks?**
Yes. DFS Replication is independent of the connection type.

**Does DFS Replication work on ReFS or FAT volumes?**
No. DFS Replication supports volumes formatted with the NTFS file system only; the Resilient File System (ReFS) and the FAT file system are not supported. DFS Replication requires NTFS because it uses the NTFS change journal and other features of the NTFS file system.

**Does DFS Replication work with sparse files?**
Yes. You can replicate sparse files. The **Sparse** attribute is preserved on the receiving member.

**Do I need to log in as administrator to replicate files?**
No. DFS Replication is a service that runs under the local system account, so you do not need to log in as administrator to replicate. However, you must be a domain administrator or local administrator of the affected file servers to make changes to the DFS Replication configuration.

For more information, see "DFS Replication security requirements and delegation" in the Delegate the Ability to Manage DFS Replication (http://go.microsoft.com/fwlink/?LinkId= 182294).

**How can I upgrade or replace a DFS Replication member?**
To upgrade or replace a DFS Replication member, see this blog post on the Ask the Directory Services Team blog: Replacing

DFSR Member Hardware or OS.

**Is DFS Replication suitable for replicating roaming profiles?**
Yes. Certain scenarios are supported when replicating roaming user profiles. For information about the supported scenarios, see Microsoft's Support Statement Around Replicated User Profile Data (http://go.microsoft.com/fwlink/?LinkId=201282).

**Is there a file character limit or limit to the folder depth?**
Windows and DFS Replication support folder paths with up to 32 thousand characters. DFS Replication is not limited to folder paths of 260 characters.

**Must members of a replication group reside in the same domain?**
No. Replication groups can span across domains within a single forest but not across different forests.

**What are the supported limits of DFS Replication?**
The following list provides a set of scalability guidelines that have been tested by Microsoft on Windows Server 2012 R2:

- Size of all replicated files on a server: 100 terabytes.
- Number of replicated files on a volume: 70 million.
- Maximum file size: 250 gigabytes.

| **Important** |
| --- |
| When creating replication groups with a large number or size of files we recommend exporting a database clone and using pre-seeding techniques to minimize the duration of initial replication. For more information, see DFS Replication Initial Sync in Windows Server 2012 R2: Attack of the Clones. |

The following list provides a set of scalability guidelines that have been tested by Microsoft on Windows Server 2012, Windows Server 2008 R2, and Windows Server 2008:

- Size of all replicated files on a server: 10 terabytes.
- Number of replicated files on a volume: 11 million.
- Maximum file size: 64 gigabytes.

| **Note** |
| --- |
| There is no longer a limit to the number of replication groups, replicated folders, connections, or replication group members. |

For a list of scalability guidelines that have been tested by Microsoft for Windows Server 2003 R2, see DFS Replication scalability guidelines (http://go.microsoft.com/fwlink/?LinkId=75043).

**When should I not use DFS Replication?**
Do not use DFS Replication in an environment where multiple users update or modify the same files simultaneously on different servers. Doing so can cause DFS Replication to move conflicting copies of the files to the hidden DfsrPrivate\ConflictandDeleted folder.

When multiple users need to modify the same files at the same time on different servers, use the file check-out feature of Windows SharePoint Services to ensure that only one user is working on a file. Windows SharePoint Services 2.0 with Service Pack 2 is available as part of Windows Server 2003 R2. Windows SharePoint Services can be downloaded from the Microsoft Web site; it is not included in newer versions of Windows Server.

**Why is a schema update required for DFS Replication?**
DFS Replication uses new objects in the domain-naming context of Active Directory Domain Services to store configuration information. These objects are created when you update the Active Directory Domain Services schema. For more information, see Review Requirements for DFS Replication (http://go.microsoft.com/fwlink/?LinkId=182264).

**Monitoring and management tools**
**Can I automate the health report to receive warnings?**
Yes. There are three ways to automate health reports:

- Use the DFSR Windows PowerShell module included in Windows Server 2012 R2 or DfsrAdmin.exe in conjunction with Scheduled Tasks to regularly generate health reports. For more information, see Automating DFS Replication Health Reports (http://go.microsoft.com/fwlink/?LinkId=74010).

- Use the DFS Replication Management Pack for System Center Operations Manager to create alerts that are based on specified conditions.

- Use the DFS Replication WMI provider to script alerts.

**Can I use Microsoft System Center Operations Manager to monitor DFS Replication?**
Yes. For more information, see the DFS Replication Management Pack for System Center Operations Manager 2007 in the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=182265).

**Does DFS Replication support remote management?**
Yes. DFS Replication supports remote management using the DFS Management console and the **Add Replication Group** command. For example, on server A, you can connect to a replication group defined in the forest with servers A and B as members.

DFS Management is included with Windows Server 2012 R2, Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, and Windows Server 2003 R2. To manage DFS Replication from other versions of Windows, use Remote Desktop or the Remote Server Administration Tools for Windows 7.

| **Important** |
| --- |
| To view or manage replication groups that contain read-only replicated folders or members that are failover clusters, you must use the version of DFS Management that is included with Windows Server 2012 R2, Windows Server 2012, Windows Server 2008 R2, the Remote Server Administration Tools for Windows 8, or the Remote Server Administration Tools for Windows 7. |

**Do Ultrasound and Sonar work with DFS Replication?**
No. DFS Replication has its own set of monitoring and diagnostics tools. Ultrasound and Sonar are only capable of monitoring FRS.

**How can files be recovered from the ConflictAndDeleted or PreExisting folders?**
To recover lost files, restore the files from the file system folder or shared folder using File History, the **Restore previous versions** command in File Explorer, or by restoring the files from backup. To recover files directly from the ConflictAndDeleted or PreExisting folder, use the `Get-DfsrPreservedFiles` and `Restore-DfsrPreservedFiles` Windows PowerShell cmdlets (included with the DFSR module in Windows Server 2012 R2), or the RestoreDFSR sample script from the MSDN Code Gallery. This script is intended only for disaster recovery and is provided AS-IS, without warranty.

**Is there a way to know the state of replication?**
Yes. There are a number of ways to monitor replication:

- DFS Replication has a management pack for System Center Operations Manager that provides proactive monitoring.

- DFS Management has an in-box diagnostic report for the replication backlog, replication efficiency, and the number of files and folders in a given replication group.

- The DFSR Windows PowerShell module in Windows Server 2012 R2 contains cmdlets for starting propagation tests and writing propagation and health reports. For more information, see Distributed File System Replication Cmdlets in Windows PowerShell.

- Dfsrdiag.exe is a command-line tool that can generate a backlog count or trigger a propagation test. Both show the state of replication. Propagation shows you if files are being replicated to all nodes. Backlog shows you how many files still need to replicate before two computers are in sync. The backlog count is the number of updates that a replication group member has not processed. On computers running Windows Server 2012 R2, Windows Server 2012 or Windows Server 2008 R2, Dfsrdiag.exe can also display the updates that DFS Replication is currently replicating.

- Scripts can use WMI to collect backlog information—manually or through MOM.

**Performance**

**Does DFS Replication support dial-up connections?**

Although DFS Replication will work at dial-up speeds, it can get backlogged if there are large numbers of changes to replicate. If small changes are made to existing files, DFS Replication with Remote Differential Compression (RDC) will provide a much higher performance than copying the file directly.

**Does DFS Replication perform bandwidth sensing?**

No. DFS Replication does not perform bandwidth sensing. You can configure DFS Replication to use a limited amount of bandwidth on a per-connection basis (bandwidth throttling). However, DFS Replication does not further reduce bandwidth utilization if the network interface becomes saturated, and DFS Replication can saturate the link for short periods. Bandwidth throttling with DFS Replication is not completely accurate because DFS Replication throttles bandwidth by throttling RPC calls. As a result, various buffers in lower levels of the network stack (including RPC) may interfere, causing bursts of network traffic.

**Does DFS Replication throttle bandwidth per schedule, per server, or per connection?**

If you configure bandwidth throttling when specifying the schedule, all connections for that replication group will use that setting for bandwidth throttling. Bandwidth throttling can be also set as a connection-level setting using DFS Management.

**Does DFS Replication use Active Directory Domain Services to calculate site links and connection costs?**

No. DFS Replication uses the topology defined by the administrator, which is independent of Active Directory Domain Services site costing.

**How can I improve replication performance?**

To learn about different methods of tuning replication performance, see Tuning Replication Performance in DFSR on the Ask the Directory Services Team blog.

**How does DFS Replication avoid saturating a connection?**

In DFS Replication you set the maximum bandwidth you want to use on a connection, and the service maintains that level of network usage. This is different from the Background Intelligent Transfer Service (BITS), and DFS Replication does not saturate the connection if you set it appropriately.

Nonetheless, the bandwidth throttling is not 100% accurate and DFS Replication can saturate the link for short periods of time. This is because DFS Replication throttles bandwidth by throttling RPC calls. Because this process relies on various buffers in lower levels of the network stack, including RPC, the replication traffic tends to travel in bursts which may at times saturate the network links.

DFS Replication in Windows Server 2008 includes several performance enhancements, as discussed in the Distributed File System topic in Changes in Functionality from Windows Server 2003 with SP1 to Windows Server 2008.

**How does DFS Replication performance compare with FRS?**

DFS Replication is much faster than FRS, particularly when small changes are made to large files and RDC is enabled. For example, with RDC, a small change to a 2 MB PowerPoint® presentation can result in only 60 kilobytes (KB) being sent across the network—a 97 percent savings in bytes transferred.

RDC is not used on files smaller than 64 KB and might not be beneficial on high-speed LANs where network bandwidth is not contended. RDC can be disabled on a per-connection basis using DFS Management.

**How frequently does DFS Replication replicate data?**

Data replicates according to the schedule you set. For example, you can set the schedule to 15-minute intervals, seven days a week. During these intervals, replication is enabled. Replication starts soon after a file change is detected (generally within seconds).

The replication group schedule may be set to Universal Time Coordinate (UTC) while the connection schedule is set to the local time of the receiving member. Take this into account when the replication group spans multiple time zones. Local time means the time of the member hosting the inbound connection. The displayed schedule of the inbound connection and the corresponding outbound connection reflect time zone differences when the schedule is set to local time.

**How much of my server's system resources will DFS Replication consume?**

The disk, memory, and CPU resources used by DFS Replication depend on a number of factors, including the number and size of the files, rate of change, number of replication group members, and number of replicated folders. In addition, some resources are harder to estimate. For example, the Extensible Storage Engine (ESE) technology used for the DFS Replication database can consume a large percentage of available memory, which it releases on demand. Applications other than DFS Replication can be hosted on the same server depending on the server configuration. However, when hosting multiple applications or server roles on a single server, it is important that you test this configuration before implementing it in a production environment.

**What happens if a WAN link fails during replication?**

If the connection goes down, DFS Replication will keep trying to replicate while the schedule is open. There will also be

connectivity errors noted in the DFS Replication event log that can be harvested using MOM (proactively through alerts) and the DFS Replication Health Report (reactively, such as when an administrator runs it).

**Remote Differential Compression details**

**Are changes compressed before being replicated?**

Yes. Changed portions of files are compressed before being sent for all file types except the following (which are already compressed): .wma, .wmv, .zip, .jpg, .mpg, .mpeg, .m1v, .mp2, .mp3, .mpa, .cab, .wav, .snd, .au, .asf, .wm, .avi, .z, .gz, .tgz, and .frx. Compression settings for these file types are not configurable in Windows Server 2003 R2.

**Can an administrator turn off RDC or change the threshold?**

Yes. You can turn off RDC through the property page of a given connection. Disabling RDC can reduce CPU utilization and replication latency on fast local area network (LAN) links that have no bandwidth constraints or for replication groups that consist primarily of files smaller than 64 KB. If you choose to disable RDC on a connection, test the replication efficiency before and after the change to verify that you have improved replication performance.

You can change the RDC size threshold by using the **Dfsradmin Connection Set** command, the DFS Replication WMI Provider, or by manually editing the configuration XML file.

**Does RDC work on all file types?**

Yes. RDC computes differences at the block level irrespective of file data type. However, RDC works more efficiently on certain file types such as Word docs, PST files, and VHD images.

**How does RDC work on a compressed file?**

DFS Replication uses RDC, which computes the blocks in the file that have changed and sends only those blocks over the network. DFS Replication does not need to know anything about the contents of the file—only which blocks have changed.

**Is cross-file RDC enabled when upgrading to Windows Server Enterprise Edition or Datacenter Edition?**

The Standard Editions of Windows Server do not support cross-file RDC. However, it is automatically enabled when you upgrade to an edition that supports cross-file RDC, or if a member of the replication connection is running a supported edition. For a list of editions that support cross-file RDC, see Which editions of the Windows operating system support cross-file RDC?

**Is RDC true block-level replication?**

No. RDC is a general purpose protocol for compressing file transfer. DFS Replication uses RDC on blocks at the file level, not at the disk block level. RDC divides a file into blocks. For each block in a file, it calculates a signature, which is a small number of bytes that can represent the larger block. The set of signatures is transferred from server to client. The client compares the server signatures to its own. The client then requests the server send only the data for signatures that are not already on the client.

**What happens if I rename a file?**

DFS Replication renames the file on all other members of the replication group during the next replication. Files are tracked using a unique ID, so renaming a file and moving the file within the replica has no effect on the ability of DFS Replication to replicate a file.

**What is cross-file RDC?**

Cross-file RDC allows DFS Replication to use RDC even when a file with the same name does not exist at the client end. Cross-file RDC uses a heuristic to determine files that are similar to the file that needs to be replicated, and uses blocks of the similar files that are identical to the replicating file to minimize the amount of data transferred over the WAN. Cross-file RDC can use blocks of up to five similar files in this process.

To use cross-file RDC, one member of the replication connection must be running an edition of Windows that supports cross-file RDC. For a list of editions that support cross-file RDC, see Which editions of the Windows operating system support cross-file RDC?

**What is RDC?**

Remote differential compression (RDC) is a client-server protocol that can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, and rearrangements of data in files, enabling DFS Replication to replicate only the changes when files are updated. RDC is used only for files that are 64 KB or larger by default. RDC can use an older version of a file with the same name in the replicated folder or in the DfsrPrivate\ConflictandDeleted folder (located under the local path of the replicated folder).

**When is RDC used for replication?**

RDC is used when the file exceeds a minimum size threshold. This size threshold is 64 KB by default. After a file exceeding that threshold has been replicated, updated versions of the file always use RDC, unless a large portion of the file is changed or RDC is disabled.

**Which editions of the Windows operating system support cross-file RDC?**

To use cross-file RDC, one member of the replication connection must be running an edition of the Windows operating system

that supports cross-file RDC. The following table shows which editions of the Windows operating system support cross-file RDC.

**Cross-file RDC availability in editions of the Windows operating system**

| Operating System Version | Standard Edition | Enterprise Edition | Datacenter Edition |
|---|---|---|---|
| Windows Server 2012 R2 | Yes* | Not available | Yes* |
| Windows Server 2012 | Yes | Not available | Yes |
| Windows Server 2008 R2 | No | Yes | Yes |
| Windows Server 2008 | No | Yes | No |
| Windows Server 2003 R2 | No | Yes | No |

* You can optionally disable cross-file RDC on Windows Server 2012 R2.

**Replication details**

**Can I change the path for a replicated folder after it is created?**

No. If you need to change the path of a replicated folder, you must delete it in DFS Management and add it back as a new replicated folder. DFS Replication then uses Remote Differential Compression (RDC) to perform a synchronization that determines whether the data is the same on the sending and receiving members. It does not replicate all the data in the folder again.

**Can I configure which file attributes are replicated?**

No, you cannot configure which file attributes that DFS Replication replicates.

For a list of attribute values and their descriptions, see File Attributes on MSDN (http://go.microsoft.com/fwlink/?LinkId=182268).

The following attribute values are set by using the `SetFileAttributes dwFileAttributes` function, and they are replicated by DFS Replication. Changes to these attribute values trigger replication of the attributes. The contents of the file are not replicated unless the contents change as well. For more information, see SetFileAttributes Function in the MSDN library (http://go.microsoft.com/fwlink/?LinkId=182269).

- FILE_ATTRIBUTE_HIDDEN
- FILE_ATTRIBUTE_READONLY
- FILE_ATTRIBUTE_SYSTEM
- FILE_ATTRIBUTE_NOT_CONTENT_INDEXED
- FILE_ATTRIBUTE_OFFLINE

The following attribute values are replicated by DFS Replication, but they do not trigger replication.

- FILE_ATTRIBUTE_ARCHIVE
- FILE_ATTRIBUTE_NORMAL

The following file attribute values also trigger replication, although they cannot be set by using the `SetFileAttributes` function (use the `GetFileAttributes` function to view the attribute values).

- FILE_ATTRIBUTE_REPARSE_POINT

> **Note**
>
> DFS Replication does not replicate reparse point attribute values unless the reparse tag is IO_REPARSE_TAG_SYMLINK. Files with the IO_REPARSE_TAG_DEDUP, IO_REPARSE_TAG_SIS or IO_REPARSE_TAG_HSM reparse tags are replicated as normal files. However, the reparse tag and reparse data buffers are not replicated to other servers because the reparse point only works on the local system.

- FILE_ATTRIBUTE_COMPRESSED
- FILE_ATTRIBUTE_ENCRYPTED

| **Note** |
| --- |
| DFS Replication does not replicate files that are encrypted by using the Encrypting File System (EFS). DFS Replication does replicate files that are encrypted by using non-Microsoft software, but only if it does not set the FILE_ATTRIBUTE_ENCRYPTED attribute value on the file. |

- FILE_ATTRIBUTE_SPARSE_FILE
- FILE_ATTRIBUTE_DIRECTORY

DFS Replication does not replicate the FILE_ATTRIBUTE_TEMPORARY value.

**Can I control which member is replicated?**
Yes. You can choose a topology when you create a replication group. Or you can select **No topology** and manually configure connections after the replication group has been created.

**Can I seed a replication group member with data prior to the initial replication?**
Yes. DFS Replication supports copying files to a replication group member before the initial replication. This "prestaging" can dramatically reduce the amount of data replicated during the initial replication.

The initial replication does not need to replicate contents when files differ only by real attributes or time stamps. A real attribute is an attribute that can be set by the Win32 function `SetFileAttributes`. For more information, see SetFileAttributes Function in the MSDN library (http://go.microsoft.com/fwlink/?LinkId=182269). If two files differ by other attributes, such as compression, then the contents of the file are replicated.

To prestage a replication group member, copy the files to the appropriate folder on the destination server(s), create the replication group, and then choose a primary member. Choose the member that has the most up-to-date files that you want to replicate because the primary member's content is considered "authoritative." This means that during initial replication, the primary member's files will always overwrite other versions of the files on other members of the replication group.

For information about pre-seeding and cloning the DFSR database, see DFS Replication Initial Sync in Windows Server 2012 R2: Attack of the Clones.

For more information about the initial replication, see Create a Replication Group.

**Does DFS Replication overcome common File Replication Service issues?**
Yes. DFS Replication overcomes three common FRS issues:

- Journal wraps: DFS Replication recovers from journal wraps on the fly. Each existing file or folder will be marked as journalWrap and verified against the file system before replication is enabled again. During the recovery, this volume is not available for replication in either direction.
- Excessive replication: To prevent excessive replication, DFS Replication uses a system of credits.
- Morphed folders: To prevent morphed folder names, DFS Replication stores conflicting data in a hidden DfsrPrivate\ConflictandDeleted folder (located under the local path of the replicated folder). For example, creating multiple folders simultaneously with identical names on different servers replicated using FRS causes FRS to rename the older folder(s). DFS Replication instead moves the older folder(s) to the local Conflict and Deleted folder.

**Does DFS Replication replicate files in chronological order?**
No. Files may be replicated out of order.

**Does DFS Replication replicate files that are being used by another application?**
If an application opens a file and creates a file lock on it (preventing it from being used by other applications while it is open), DFS Replication will not replicate the file until it is closed. If the application opens the file with read-share access, the file can still be replicated.

**Does DFS Replication replicate NTFS file permissions, alternate data streams, hard links, and reparse points?**

- DFS Replication replicates NTFS file permissions and alternate data streams.
- Microsoft does not support creating NTFS hard links to or from files in a replicated folder – doing so can cause replication issues with the affected files. Hard link files are ignored by DFS Replication and are not replicated. Junction points also are not replicated, and DFS Replication logs event 4406 for each junction point it encounters.
- The only reparse points replicated by DFS Replication are those that use the IO_REPARSE_TAG_SYMLINK tag; however, DFS Replication does not guarantee that the target of a symlink is also replicated. For more information, see the Ask the Directory Services Team blog.
- Files with the IO_REPARSE_TAG_DEDUP, IO_REPARSE_TAG_SIS, or IO_REPARSE_TAG_HSM reparse tags are replicated as normal files. The reparse tag and reparse data buffers are not replicated to other servers because the reparse point only works on the local system. As such, DFS Replication can replicate folders on volumes that use Data Deduplication in Windows Server 2012, or Single Instance Storage (SIS), however, data deduplication information is maintained separately by each server on which the role service is enabled.

**Does DFS Replication replicate timestamp changes if no other changes are made to the file?**
No, DFS Replication does not replicate files for which the only change is a change to the timestamp. Additionally, the changed timestamp is not replicated to other members of the replication group unless other changes are made to the file.

**Does DFS Replication replicate updated permissions on a file or folder?**
Yes. DFS Replication replicates permission changes for files and folders. Only the part of the file associated with the Access Control List (ACL) is replicated, although DFS Replication must still read the entire file into the staging area.

| **Note** |
| --- |
| Changing ACLs on a large number of files can have an impact on replication performance. However, when using RDC, the amount of data transferred is proportionate to the size of the ACLs, not the size of the entire file. The amount of disk traffic is still proportional to the size of the files because the files must be read to and from the staging folder. |

**Does DFS Replication support merging text files in the event of a conflict?**
DFS Replication does not merge files when there is a conflict. However, it does attempt to preserve the older version of the file in the hidden DfsrPrivate\ConflictandDeleted folder on the computer where the conflict was detected.

**Does DFS Replication use encryption when transmitting data?**
Yes. DFS Replication uses Remote Procedure Call (RPC) connections with encryption.

**Is it possible to disable the use of encrypted RPC?**
No. The DFS Replication service uses remote procedure calls (RPC) over TCP to replicate data. To secure data transfers across the Internet, the DFS Replication service is designed to always use the authentication-level constant, `RPC_C_AUTHN_LEVEL_PKT_PRIVACY`. This ensures that the RPC communication across the Internet is always encrypted. Therefore, it is not possible to disable the use of encrypted RPC by the DFS Replication service.

For more information, see the following Microsoft Web sites:

- RPC Technical Reference
- About Remote Differential Compression
- Authentication-Level Constants

**How are simultaneous replications handled?**
There is one update manager per replicated folder. Update managers work independently of one another.

By default, a maximum of 16 (four in Windows Server 2003 R2) concurrent downloads are shared among all connections and replication groups. Because connections and replication group updates are not serialized, there is no specific order in which updates are received. If two schedules are opened, updates are generally received and installed from both connections at the same time.

**How do I force replication or polling?**
You can force replication immediately by using DFS Management, as described in Edit Replication Schedules. You can also force replication by using the `Sync-DfsReplicationGroup` cmdlet, included in the DFSR PowerShell module introduced with Windows Server 2012 R2, or the **Dfsrdiag SyncNow** command. You can force polling by using the `Update-DfsrConfigurationFromAD` cmdlet, or the **Dfsrdiag PollAD** command.

**Is it possible to configure a quiet time between replications for files that change frequently?**
No. If the schedule is open, DFS Replication will replicate changes as it notices them. There is no way to configure a quiet time for files.

**Is it possible to configure one-way replication with DFS Replication?**
Yes. If you are using Windows Server 2012 or Windows Server 2008 R2, you can create a read-only replicated folder that replicates content through a one-way connection. For more information, see Make a Replicated Folder Read-Only on a Particular Member (http://go.microsoft.com/fwlink/?LinkId=156740).

We do not support creating a one-way replication connection with DFS Replication in Windows Server 2008 or Windows Server 2003 R2. Doing so can cause numerous problems including health-check topology errors, staging issues, and problems with the DFS Replication database.

If you are using Windows Server 2008 or Windows Server 2003 R2, you can simulate a one-way connection by performing the following actions:

- Train administrators to make changes only on the server(s) that you want to designate as primary servers. Then let the changes replicate to the destination servers.

- Configure the share permissions on the destination servers so that end users do not have Write permissions. If no changes are allowed on the branch servers, then there is nothing to replicate back, simulating a one-way connection and keeping WAN utilization low.

**Is there a way to force a complete replication of all files including unchanged files?**
No. If DFS Replication considers the files identical, it will not replicate them. If changed files have not been replicated, DFS Replication will automatically replicate them when configured to do so. To overwrite the configured schedule, use the WMI method **ForceReplicate()**. However, this is only a schedule override, and it does not force replication of unchanged or identical files.

**What happens if the primary member suffers a database loss during initial replication?**
During initial replication, the primary member's files will always take precedence in the conflict resolution that occurs if the receiving members have different versions of files on the primary member. The primary member designation is stored in Active Directory Domain Services, and the designation is cleared after the primary member is ready to replicate, but before all members of the replication group replicate.

If the initial replication fails or the DFS Replication service restarts during the replication, the primary member sees the primary member designation in the local DFS Replication database and retries the initial replication. If the primary member's DFS Replication database is lost after clearing the primary designation in Active Directory Domain Services, but before all members of the replication group complete the initial replication, all members of the replication group fail to replicate the folder because no server is designated as the primary member. If this happens, use the **Dfsradmin membership /set /isprimary:true** command on the primary member server to restore the primary member designation manually.

For more information about initial replication, see Create a Replication Group.

| ⚠**Caution** |
| --- |
| The primary member designation is used only during the initial replication process. If you use the **Dfsradmin** command to specify a primary member for a replicated folder after replication is complete, DFS Replication does not designate the server as a primary member in Active Directory Domain Services. However, if the DFS Replication database on the server subsequently suffers irreversible corruption or data loss, the server attempts to perform an initial replication as the primary member instead of recovering its data from another member of the replication group. Essentially, the server becomes a rogue primary server, which can cause conflicts. For this reason, specify the primary member manually only if you are certain that the initial replication has irretrievably failed. |

**What happens if the replication schedule closes while a file is being replicated?**
If remote differential compression (RDC) is enabled on the connection, inbound replication of a file larger than 64 KB that began replicating immediately prior to the schedule closing (or changing to **No bandwidth**) continues when the schedule

opens (or changes to something other than **No bandwidth**). The replication continues from the state it was in when replication stopped.

If RDC is turned off, DFS Replication completely restarts the file transfer. This can delay when the file is available on the receiving member.

**What happens when two users simultaneously update the same file on different servers?**
When DFS Replication detects a conflict, it uses the version of the file that was saved last. It moves the other file into the DfsrPrivate\ConflictandDeleted folder (under the local path of the replicated folder on the computer that resolved the conflict). It remains there until Conflict and Deleted folder cleanup, which occurs when the Conflict and Deleted folder exceeds the configured size or DFS Replication encounters an Out of disk space error. The Conflict and Deleted folder is not replicated, and this method of conflict resolution avoids the problem of morphed directories that was possible in FRS.

When a conflict occurs, DFS Replication logs an informational event to the DFS Replication event log. This event does not require user action for the following reasons:

- It is not visible to users (it is visible only to server administrators).
- DFS Replication treats the Conflict and Deleted folder as a cache. When a quota threshold is reached, it cleans out some of those files. There is no guarantee that conflicting files will be saved.
- The conflict could reside on a server different from the origin of the conflict.

**Staging**
**Does DFS Replication continue staging files when replication is disabled by a schedule or bandwidth throttling quota, or when a connection is manually disabled?**
No. DFS Replication does not continue to stage files outside of scheduled replication times, if the bandwidth throttling quota has been exceeded, or when connections are disabled.

**Does DFS Replication prevent other applications from accessing a file during staging?**
No. DFS Replication opens files in a way that does not block users or applications from opening files in the replication folder. This method is known as "opportunistic locking."

**Is it possible to change the location of the staging folder with the DFS Management Tool?**
Yes. The staging folder location is configured on the **Advanced** tab of the **Properties** dialog box for each member of a replication group.

**When are files staged?**
Files are staged on the sending member when the receiving member requests the file (unless the file is 64 KB or smaller) as shown in the following table. If Remote Differential Compression (RDC) is disabled on the connection, the file is staged unless it is 256 KB or smaller. Files are also staged on the receiving member as they are transferred if they are less than 64 KB in size, although you can configure this setting between 16 KB and 1 MB. If the schedule is closed, files are not staged.

**The minimum file sizes for staging files**

| | RDC enabled | RDC disabled |
|---|---|---|
| Sending member | 64 KB | 256 KB |
| Receiving member | 64 KB by default | 64 KB by default |

**What happens if a file is changed after it is staged but before it is completely transmitted to the remote site?**
If any part of the file is already being transmitted, DFS Replication continues the transmission. If the file is changed before DFS Replication begins transmitting the file, then the newer version of the file is sent.

**Change History**

| Date | Description | Reason |
|---|---|---|
| October 9th, 2013 | Updated the What are the supported limits of DFS Replication? section with results from tests on Windows Server 2012 R2. | Updates for the latest version of Windows Server |
| January 30th, 2013 | Added the Does DFS Replication continue staging files when replication is disabled by a schedule or bandwidth throttling quota, or when a connection is manually disabled? entry. | Customer questions |

| | | |
|---|---|---|
| October 31st, 2012 | Edited the What are the supported limits of DFS Replication? entry to increase the tested number of replicated files on a volume. | Customer feedback |
| August 15, 2012 | Edited the Does DFS Replication replicate NTFS file permissions, alternate data streams, hard links, and reparse points? entry to further clarify how DFS Replication handles hard links and reparse points. | Feedback from Customer Support Services |
| June 13, 2012 | Edited the Does DFS Replication work on ReFS or FAT volumes? entry to add discussion of ReFS. | Customer feedback |
| April 25, 2012 | Edited the Does DFS Replication replicate NTFS file permissions, alternate data streams, hard links, and reparse points? entry to clarify how DFS Replication handles hard links. | Reduce potential confusion |
| March 30, 2011 | Edited the Can DFS Replication replicate Outlook .pst or Microsoft Office Access database files? entry to correct the potential impact of using DFS Replication with .pst and Access files.<br><br>Added How can I improve replication performance? | Customer questions about the previous entry, which incorrectly indicated that replicating .pst or Access files could corrupt the DFS Replication database. |
| January 26, 2011 | Added How can files be recovered from the ConflictAndDeleted or PreExisting folders? | Customer feedback |
| October 20, 2010 | Added How can I upgrade or replace a DFS Replication member? | Customer feedback |

# Security Configuration Wizard Quick Start Guide

Updated: March 2, 2005

Applies To: Windows Server 2003

This guide is designed to get you up and running quickly with Security Configuration Wizard (SCW), a tool for reducing the attack surface of computers running Windows Server® 2003 with Service Pack 1 (SP1). It provides system requirements, installation instructions, steps for getting started with SCW, and instructions for troubleshooting simple problems.

SCW determines the minimum functionality required for a server's role or roles, and disables functionality that is not required. Specifically, SCW:

- Disables unneeded services.
- Blocks unused ports.
- Allows further address or security restrictions for ports that are left open.
- Prohibits unnecessary Internet Information Services (IIS) Web extensions, if applicable.
- Reduces protocol exposure to server message block (SMB), LanMan, and Lightweight Directory Access Protocol (LDAP).
- Defines a high signal-to-noise audit policy.

SCW guides you through the process of creating, editing, applying, or rolling back a security policy based on the selected roles of the server. The security policies that are created with SCW are XML files that, when applied, configure services, network security, specific registry values, audit policy, and if applicable, Internet Information Services (IIS).

**Requirements for Installing and Running SCW**
SCW is an optional component included with Windows Server 2003 SP1. You can install and run SCW only on computers running Windows Server 2003 with SP1. The computers you target with SCW (for prototyping to create security policy or for application of SCW-created security policy) must also run Windows Server 2003 with SP1.

Several security-related IIS settings can be configured by using SCW. You need a server running IIS if you want to do this.

SCW is not used with Windows XP or other client operating systems or Microsoft Windows Small Business Server 2003.

**Securing Windows Small Business Server 2003**
Instead of SCW, Windows Small Business Server 2003 uses the default settings in Setup and in the Configure E-mail and Internet Connection Wizard to help secure your server.

If you have not already run the Configure E-mail and Internet Connection Wizard, you should run it to help secure your server.

### To start the Configure E-mail and Internet Connection Wizard on the computer running Windows Small Business Server 2003

1. Click **Start**, and then click **Server Management**.
2. In the console tree, click **Internet and E-mail**.
3. In the details pane, click **Connect to the Internet**.

**Getting Help**
SCW Help is installed with Windows Server 2003 SP1, and it contains information beyond what is in this Quick Start Guide, including help for every page of SCW. After you install Windows Server 2003 SP1, you can access SCW Help through Help and Support Center, or at the command line.

**Viewing SCW Help topics**
The SCW Help is available even though SCW itself is not installed by default.

### To access SCW help through Help and Support Center

1. Click **Start**, and then click **Help and Support**.
2. In **Search**, type **SCW** or type **Security Configuration Wizard**, and then press ENTER.
3. Click one of the listed SCW Help topics.

**To access SCW help at the command line**

1. Click **Start**, and then click **Run**.
2. Type **hh scwhelp.chm**, and then press ENTER.

| **Note** |
| --- |
| In some cases, you must be connected to the Internet to use the links in SCW Help. If your computer is not connected to the Internet, you can find the same topic in Help and Support Center by searching for the link text. |

# Getting Started with SCW

Updated: December 16, 2008

Applies To: Windows Server 2003

This topic provides information about getting started with SCW. For procedures to install and use SCW, see SCW Procedures.

**SCW Components**
There are three main components that you need to know about in order to get started using SCW:

- SCW User Interface
- Scwcmd command-line tool
- Security Configuration Database

**SCW User Interface**
SCW guides you through the process of creating a security policy, based on the roles performed by a given server. Once a policy is created, it can be edited or applied to one or more similarly configured servers. Applied policies can be rolled back in order to undo changes that have caused problems. To edit, apply, or roll back a security policy, you must have created the policy with SCW.

You can use the SCW user interface for the following tasks:

- Create a new security policy.
- Edit an existing SCW-generated security policy.
- Apply an existing SCW-generated security policy.
- Roll back the last applied SCW policy.

**Scwcmd Command-Line Tool**
SCW includes the Scwcmd.exe command-line tool. You can use Scwcmd for the following tasks:

- Configure one or many servers with an SCW-generated policy.
- Analyze one or many servers with an SCW-generated policy.
- View analysis results in HTML format.
- Roll back SCW policies.
- Transform an SCW-generated policy into native files that are supported by Group Policy.
- Register a Security Configuration Database extension with SCW.

When you use Scwcmd to configure, analyze, or roll back a policy on a remote server, SCW must be installed on the remote server.

**To get basic help about the Scwcmd tool**

1. Install SCW, as described in SCW Procedures.
2. Open a command prompt, and type:

   **Scwcmd**

**Security Configuration Database**

The Security Configuration Database consists of a set of XML documents that list services and ports that are required for each server role that is supported by SCW. These files are installed in %Systemroot%\Security\Msscw\KBs. After you select a server, on the **Processing Security Configuration Database** page, the server is scanned to determine the following:

- Roles that are installed on the server.
- Roles that are likely being performed by the server.
- Services that are installed but not part of the Security Configuration Database.
- IP addresses and subnets that are configured for the server.

SCW combines this server-specific information into a single XML file named Main.xml. The Security Configuration Wizard displays Main.xml if you click **View Security Configuration Database** on the **Processing Security Configuration Database** page.

The directory %Systemroot%\Security\Msscw\transformfiles contains .xsl transform files. These are applied to the .xml policy file for the rendering process when you view analysis results through the **scwcmd /view** command.

# Best Practices for SCW

Updated: March 2, 2005

Applies To: Windows Server 2003

This topic tells how to get the most out of SCW by using Best Practices.

This topic tells how to get the most out of SCW by using Best Practices.

**Identify and target similar servers**
SCW helps to reduce the attack surface of servers by creating a security policy that is specifically designed for their specific roles. Administrators can simplify policy authoring and distribution by identifying groups of servers that perform the same or similar tasks. Here are ways you can do this:

- **Author one policy for a group of servers**. SCW authors a security policy based on the roles, tasks, and functions performed by a server. Others servers that perform the same, or very similar, functions can be configured with the same security policy. Administrators can use SCW once to author a security policy, save it, and apply it to all servers that perform the job function.

- **Group similar servers in one organizational unit (OU) in Active Directory**. The SCW transform operation can apply a security policy to a domain or OU by using Group Policy. To simplify policy distribution, an administrator could group servers that perform similar job functions, and use the same security policy, into a single OU. A new security policy can be distributed quickly and easily to the server OU by using the SCW transform operation.

- **Create policies for similar platforms**. For services or ports specific to 64-bit computers, create the policies on a 64-bit computer. Then deploy these policies only to other 64-bit computers (not 32-bit computers) to ensure that the services are properly identified and configured.

- **Model your prototype server after the target servers to be configured at the service level**. It is highly recommended that the prototype server from which the security policy will be created matches the target servers to be configured at the service level. The security policy disables any service on the server that is contained in the Security Configuration Database but was not present on the prototype server when the policy was created.

  For example, if the DCOM Server Process Launcher service is listed in the Security Configuration Database, but is not present on the prototype server, the security policy created based on the prototype server will set the DCOM Server Process Launcher state to disabled. When you apply the security policy to other servers, the DCOM Server Process Launcher service will be disabled on those servers. You can configure unnecessary services in SCW (you can disable the service or leave the startup mode of the service unchanged), but only services that are not in the Security Configuration Database, and therefore are not defined in the security policy that you create with SCW.

**Test new security policies offline before deployment**
The settings configured in the new security policies may cause compatibility issues with applications or services. Therefore, thoroughly test new security policies in a test environment before applying the policies to production servers.

**Create one complete security policy**
SCW should be used to author a single security policy that contains all desired security settings for a server or a group of servers. This will simplify configuration, rollback, and analysis. For simple configuration and rollback, a single security policy for a computer, or group of computers, is much easier to understand and update than a series of policies. If a security policy defines all the desired settings for a server, a compliance report can be generated by running one scan, which facilitates analysis when using the **scwcmd /analyze** command. For more information about Scwcmd, see Getting Started with SCW.

# Deploying SCW

Updated: March 2, 2005

Applies To: Windows Server 2003

This topic discusses deploying SCW.

In addition to using Add or Remove Programs, there are two additional principal mechanisms for deploying SCW:

- **Microsoft Systems Management Server**. Systems Management Server can be used to deploy SCW to multiple servers.
- **Unattended installation of SCW**. Unattended installation of SCW is possible. See SCW Help for more information about unattended installation.

For detailed information about SCW deployment options, see SCW Deployment V2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=45183).

In addition to using SCW, you can use Group Policy to apply the security policies SCW creates to either a single server or multiple servers. To do this, you first create the policy by using SCW user interface, and then use the command-line tool to create a Group Policy-compatible version.

# SCW Procedures

Updated: March 2, 2005

Applies To: Windows Server 2003

This topic walks you through five basic SCW tasks.

This topic walks you through five basic SCW tasks.

**Basic SCW Tasks**
These five tasks are presented in the order in which they would typically be carried out.

1. Install SCW
2. Create a security policy based on a prototype server
3. Apply a security policy to a server
4. Analyze and view security policy for a server
5. Save an SCW security policy in native Group Policy format

The SCW user interface is used for the second and third tasks, and the Scwcmd command-line tool for the last two tasks, but the third and fourth tasks could be done by using either the command-line tool or the user interface.

**Install SCW**
After you have installed Windows Server 2003 SP1, you are ready to install SCW.

**To install SCW**

1. In Control Panel, double-click **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**, select the check box for **Security Configuration Wizard**, and then click **Next**.

| **Note** |
| --- |
| You can also install SCW on individual computers by using an unattended installation. Consult the SCW Help for information about unattended installation of SCW. You can deploy SCW to multiple computers by using Microsoft Systems Management Server. |

**Create a security policy based on a prototype server**
Prototype, or model, servers are always used as a basis for creating SCW security policies for groups of similarly configured servers. Use the following procedure to create a security policy that you can test on a prototype server before applying it to production servers.

**To create a security policy based on a prototype server**

1. Click **Start**, click **Administrative Tools**, and then click **Security Configuration Wizard**.
2. Read the **Welcome** page, and click **Next**.
3. Select **Create a new security policy**, and then click **Next**.
4. Type the name of the prototype server, and then click **Next**.
5. When processing is complete, click **Next**.
6. For each of the next five wizard pages, just click **Next**:
    - **Role-Based Service Configuration** page.

- **Select Server roles** page.
- **Select Client Features** page.
- **Select Administration and Other Options** page.
- **Select Additional Services** page.

7. On the **Handling Unspecified Services** page, select either **Do not change the startup mode of the service** (default) or **Disable the service**, and then click **Next**.

| **Note** |
| --- |
| The settings on the **Handling Unspecified Services** page control how SCW treats services that it finds on the prototype server, but that are not defined in the Security Configuration Database, and thus are not known to SCW. For information about extending the database, see Extending the Security Configuration Wizard on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=45183). |

8. For each of the next 20 wizard pages, just click **Next**:
   - **Confirm Service Changes** page.
   - **Network Security** page.
   - **Open Ports and Confirm Applications** page.
   - **Confirm Service Changes** page.
   - **Confirm Port Configuration** page.
   - **Registry Settings** page.
   - **Require SMB Security Signatures** page.
   - **Require LDAP Signing** page.
   - **Outbound Authentication Methods** page.
   - **Outbound Authentication Methods using Domain Accounts** page.
   - **Registry Settings Summary** page.
   - **Audit Policy** page.
   - **System Audit Policy** page.
   - **Audit Policy Summary** page.
   - **Internet Information Services** page.
   - **Select Web Service Extensions for Dynamic Content** page.
   - **Select the Virtual Directories to Retain** page.
   - **Prevent Anonymous Users from Accessing Content Files** page.

- **IIS Settings Summary** page.
- **Save Security Policy** page.

9. On the **Security Policy File Name** page, type a name for the prototype policy, and then click **Next**.

| **Caution** |
| --- |
| Do not use the name of the prototype computer because scwcmd.exe uses *computername.xml* to save analysis results, and you do not want the policy to be created to have the same name. |

| **Note** |
| --- |
| The security policy settings that you can configure within SCW are a subset of those that can be set by using security templates (.inf files). On the Security Policy File Name page, you can include a security template if you want to add settings that cannot be configured directly from SCW. If you attach a security template, and it contains settings that conflict with some SCW-configured settings, the SCW-configured settings have precedence. |

10. On the **Completing the Security Configuration Wizard** page, click **Finish**.

#### Apply a security policy to a server

The following procedure can apply a security policy to either a single server or multiple servers.

**To apply a security policy to a server**

1. Click **Start**, click **Administrative Tools**, and then click **Security Configuration Wizard**.
2. Read the **Welcome** page, and then click **Next**.
3. On the **Configuration Action** page, select **Apply an existing security policy**, type the full path and file name of the policy, and then click **Next**.
4. On the **Select Server** page, type the name of the server to which the policy will be applied, and then click **Next**.

| **Note** |
| --- |
| To configure multiple servers with a policy, you can use **scwcmd configure /p:***PolicyFile* **/i:***MachineList* at the command prompt, rather than this SCW UI procedure. Type **scwcmd configure** at the command prompt to learn about the parameters. |

5. On the **Apply Security Policy** page, click **Next**.
6. On the **Applying Security Policy** page, wait for processing to finish, and then click **Next**.
7. On the **Completing the Security Configuration Wizard** page, click **Finish**.

#### Analyze and view security policy for a server

Use the following procedure to analyze and view security policy for a computer from the command line.

**To analyze and view security policy for a server**

1. At the command prompt, type

   **scwcmd analyze /m:** *MachineName* **/p:** *PathAndPolicyFileName* **/o:** *OutputDirectory*

| **Note** |
| --- |
| You should first replace the italic parameters with your specific ones. When **scwcmd analyze** is finished processing, you will find that it has saved *MachineName.xml*. This is the analysis result for that server, saved as XML. |

2. When **scwcmd analyze** processing is complete, type:

   **scwcmd view /x:** *MachineName.xml* **/s:scwanalysis.xsl**

Scwanalysys.xsl is one of the files installed with SCW. It formats the analysis results for display.

**Save an SCW security policy in native Group Policy format**

The following procedure makes the security policy available for used in Group Policy.

| **Note** |
| --- |
| You might not always decide to save SCW security policy in Group Policy format, because Security policy applied through Group Policy cannot be rolled back. |

**To save an SCW security policy in native Group Policy format**

- At the command prompt, type:

  **scwcmd transform /p:** *PathAndPolicyFileName* **/g:** *GPODisplayName*

  where *PathAndPolicyFileName* is the policy you created earlier with SCW, including its .xml file name extension and *GPODisplayName* is the name that the Group Policy object (GPO) will show when you view it in Group Policy Object Editor or in Group Policy Management Console (GPMC).

When the **scwcmd transform** command has completed, the GPO will have been created in Active Directory, but the policy it contains will not be applied until the GPO is linked to a site, domain, or organizational unit. For instructions about linking GPOs, see the GPMC Help.

# Troubleshooting SCW

Updated: March 2, 2005

Applies To: Windows Server 2003

This topic discusses troubleshooting SCW.

This topic lists some problems and error messages and provides suggestions for handling them. For more detailed information about troubleshooting SCW, see SCW Troubleshooting Guide on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=45183).

**Common SCW Problems**
This section lists circumstances under which SCW might not work as you expect.

**SCW does not run on a specific computer**
SCW is supported only on Windows Server 2003 with SP1. For details about SCW requirements, see "Requirements for Installing and Running SCW" in Security Configuration Wizard Quick Start Guide.

**SCW security policies do not apply to some computers**
The security policies that are created with SCW should only be applied to servers and groups of servers running Windows Server 2003 with SP1. The security policies should not be applied to operating systems such as Windows XP or Windows Small Business Server.

**IIS role is not detected by SCW**
If an SCW security policy is applied to a server before Internet Information Services (IIS) is installed, the server will be configured with the Hypertext Transport Protocol (HTTP) Secure Sockets Layer (SSL) service disabled, as HTTP SSL is not required on a computer that is not a Web server. If IIS is then installed on the server and SCW is run, the Administrator must first ensure that IIS is started, in order for IIS to be detected by SCW. IIS cannot run without the HTTP SSL service.

**Error messages**
Here are some errors you might encounter with SCW.

**Cannot Process XML Data**
The Microsoft XML core services are corrupted or not installed.

**Cannot Process Security Configuration Database**
There is a problem with Main.XML. Check the Application log, which might have more information.

**The Security Configuration Wizard cannot continue because the security configuration database processing failed**
There is a problem with Main.XML. Check the Application log, which might have more information.

**You do not have administrator privileges on the selected server. Click Specify User Account to provide an administrator account on the selected server**
You must be an administrator on the local server to run SCW, or you must specify Administrative credentials on a remote server. If you are trying to apply a policy to a server, the policy must be available on the server running SCW. You must also be authenticated as an administrator on the computer that is receiving the policy.

**Cannot rollback last applied security policy**
Check the Application log, which might have more information.

**The selected security policy file has a format that is not valid. Select another security policy file and try again**
You can receive this message if you browse to, or type in, an XML file that is not a security policy file. If this is a security policy file that you created, try running SCW again to recreate it.

**Not Found!**
In the Network Security section of SCW, this message appears if SCW cannot verify that an approved application exists at the specified path. This is not necessarily a problem, as you might be configuring a policy for a remote server. If the application will exist at the specified path at the time the policy is applied, the Not Found! message can be ignored.

**Cannot determine the IP address from the computer name. The lookup service is not available**
In the Network Security section of SCW, the IP address of the computer name you entered must be resolvable, or you cannot continue. If the computer has a static IP address (not assigned by DHCP), then you can enter the IP address instead of the name.

# Quick Start Guide for Server Clusters

Applies To: Windows Server 2003 R2

This guide provides system requirements, installation instructions, and other, step-by-step instructions that you can use to deploy server clusters if you are using Microsoft® Windows Server™ 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, operating systems.

The server cluster technology in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, helps ensure that you have access to important server-based resources. You can use server cluster technology to create several cluster nodes that appear to users as one server. If one of the nodes in the cluster fails, another node begins to provide service. This is a process known as "failover." In this way, server clusters can increase the availability of critical applications and resources.

The names of actual companies and products mentioned herein may be the trademarks of their respective owners.

**Requirements and Guidelines for Configuring Server Clusters**
The section lists requirements and guidelines that will help you set up a server cluster effectively.

**Software requirements and guidelines**

- You must have either Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, installed on all computers in the cluster. We strongly recommend that you also install the latest service pack for Windows Server 2003. If you install a service pack, the same service pack must be installed on all computers in the cluster.

- All nodes in the cluster must be of the same architecture. You cannot mix x86-based, Itanium-based, and x64-based computers within the same cluster.

- Your system must be using a name-resolution service, such as Domain Name System (DNS), DNS dynamic update protocol, Windows Internet Name Service (WINS), or Hosts file. Hosts file is supported as a local, static file method of mapping DNS domain names for host computers to their Internet Protocol (IP) addresses. The Hosts file is provided in the systemroot\System32\Drivers\Etc folder.

- All nodes in the cluster must be in the same domain. As a best practice, all nodes should have the same domain role (either member server or domain controller), and the recommended role is member server. Exceptions that can be made to these domain role guidelines are described later in this document.

- When you first create a cluster or add nodes to it, you must be logged on to the domain with an account that has administrator rights and permissions on all nodes in that cluster. The account does not need to be a Domain Admin level account, but can be a Domain User account with Local Admin rights on each node.

**Hardware requirements and guidelines**

- For Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, Microsoft supports only complete server cluster systems chosen from the Windows Catalog. To determine whether your system and hardware components are compatible, including your cluster disks, see the Microsoft Windows Catalog at the Microsoft Web site. For a geographically dispersed cluster, both the hardware and software configuration must be certified and listed in the Windows Catalog. For more information, see article 309395, "The Microsoft support policy for server clusters, the Hardware Compatibility List, and the Windows Server Catalog," in the Microsoft Knowledge Base.

- If you are installing a server cluster on a storage area network (SAN), and you plan to have multiple devices and clusters sharing the SAN with a cluster, your hardware components must be compatible. For more information, see article 304415, "Support for Multiple Clusters Attached to the Same SAN Device," in the Microsoft Knowledge Base.

- You must have two mass-storage device controllers in each node in the cluster: one for the local disk, one for the cluster storage. You can choose between SCSI, iSCSI, or Fibre Channel for cluster storage on server clusters that are running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. You must have two controllers because one controller has the local system disk for the operating system installed, and the other controller has the shared storage installed.

- You must have two Peripheral Component Interconnect (PCI) network adapters in each node in the cluster.

- You must have storage cables to attach the cluster storage device to all computers. Refer to the manufacturer's instructions for configuring storage devices.

- Ensure that all hardware is identical in all cluster nodes. This means that each hardware component must be the same make, model, and firmware version. This makes configuration easier and eliminates compatibility problems.

**Network requirements and guidelines**

- Your network must have a unique NetBIOS name.

- A WINS server must be available on your network.

- You must use static IP addresses for each network adapter on each node.

| **Important** |
| --- |
| Server clusters do not support the use of IP addresses assigned from Dynamic Host Configuration Protocol (DHCP) servers. |

- The nodes in the cluster must be able to access a domain controller. The Cluster service requires that the nodes be able to contact the domain controller to function correctly. The domain controller must be highly available. In addition, it should be on the same local area network (LAN) as the nodes in the cluster. To avoid a single point of failure, the domain must have at least two domain controllers.

- Each node must have at least two network adapters. One adapter will be used exclusively for internal node-to-node communication (the private network). The other adapter will connect the node to the client public network. It should also connect the cluster nodes to provide support in case the private network fails. (A network that carries both public and private communication is called a mixed network.)

- If you are using fault-tolerant network cards or teaming network adapters, you must ensure that you are using the most recent firmware and drivers. Check with your network adapter manufacturer to verify compatibility with the cluster technology in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition.

| **Note** |
| --- |

Using teaming network adapters on all cluster networks concurrently is not supported. At least one of the cluster private networks must not be teamed. However, you can use teaming network adapters on other cluster networks, such as public networks.

**Storage requirements and guidelines**

- An external disk storage unit must be connected to all nodes in the cluster. This will be used as the cluster storage. You should also use some type of hardware redundant array of independent disks (RAID).

- All cluster storage disks, including the quorum disk, must be physically attached to a shared bus.

**Note**

This requirement does not apply to Majority Node Set (MNS) clusters when they are used with some type of software replication method.

- Cluster disks must not be on the same controller as the one that is used by the system drive, except when you are using boot from SAN technology. For more information about using boot from SAN technology, see "Boot from SAN in Windows Server 2003 and Windows 2000 Server" at the Microsoft Web site.

- You should create multiple logical unit numbers (LUNs) at the hardware level in the RAID configuration instead of using a single logical disk that is then divided into multiple partitions at the operating system level. We recommend a minimum of two logical clustered drives. This enables you to have multiple disk resources and also allows you to perform manual load balancing across the nodes in the cluster.

- You should set aside a dedicated LUN on your cluster storage for holding important cluster configuration information. This information makes up the cluster quorum resource. The recommended minimum size for the volume is 500 MB. You should not store user data on any volume on the quorum LUN.

- If you are using SCSI, ensure that each device on the shared bus (both SCSI controllers and hard disks) has a unique SCSI identifier. If the SCSI controllers all have the same default identifier (the default is typically SCSI ID 7), change one controller to a different SCSI ID, such as SCSI ID 6. If more than one disk will be on the shared SCSI bus, each disk must also have a unique SCSI identifier.

- Software fault tolerance is not natively supported for disks in the cluster storage. For cluster disks, you must use the NTFS file system and configure the disks as basic disks with all partitions formatted as NTFS. They can be either compressed or uncompressed. Cluster disks cannot be configured as dynamic disks. In addition, features of dynamic disks, such as spanned volumes (volume sets), cannot be used without additional non-Microsoft software.

- All disks on the cluster storage device must be partitioned as master boot record (MBR) disks, not as GUID partition table (GPT) disks.

**Deploying SANs with server clusters**

This section lists the requirements for deploying SANs with server clusters.

- Nodes from different clusters must not be able to access the same storage devices. Each cluster used with a SAN must be deployed in a way that isolates it from all other devices. This is because the mechanism the cluster uses to protect access to the disks can have adverse effects if other clusters are in the same zone. Using zoning to separate the cluster traffic from other cluster or non-cluster traffic prevents this type of interference. For more information, see "Zoning vs. LUN masking" later in this guide.

- All host bus adapters in a single cluster must be the same type and have the same firmware version. Host bus adapters are the interface cards that connect a cluster node to a SAN. This is similar to the way that a network adapter connects a server to a typical Ethernet network. Many storage vendors require that all host bus adapters on the same zone—and, in some cases, the same fabric—share these characteristics.

- In a cluster, all device drivers for storage and host bus adapters must have the same software version. We strongly recommend that you use a Storport mini-port driver with clustering. Storport (Storport.sys) is a storage port driver that is provided in Windows Server 2003. It is especially suitable for use with high-performance buses, such as Fibre Channel buses, and RAID adapters.

- Tape devices should never be used in the same zone as cluster disk storage devices. A tape device could misinterpret a bus reset and rewind at inappropriate times, such as when backing up a large amount of data.

- In a highly available storage fabric, you should deploy server clusters with multiple host bus adapters using multipath I/O software. This provides the highest level of redundancy and availability.

| **Note** |
| --- |
| Failover software for host bus adapters can be version sensitive. If you are implementing a multipath solution for your cluster, you should work closely with your hardware vendor to become fully aware of how the adapter interacts with Windows Server 2003. |

**Creating a Cluster**

It is important to plan the details of your hardware and network before you create a cluster.

If you are using a shared storage device, ensure that when you turn on the computer and start the operating system, only one

node has access to the cluster storage. Otherwise, the cluster disks can become corrupted.

In Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, logical disks that are not on the same shared bus as the boot partition are not automatically mounted and assigned a drive letter. This helps prevent a server in a complex SAN environment from mounting drives that might belong to another server. (This is different from how new disks are mounted in Microsoft Windows® 2000 Server operating systems.) Although the drives are not mounted by default, we still recommend that you follow the procedures provided in the table later in this section to ensure that the cluster disks will not become corrupted.

The table in this section can help you determine which nodes and storage devices should be turned on during each installation step. The steps in the table pertain to a two-node cluster. However, if you are installing a cluster with more than two nodes, the Node 2 column lists the required state of all other nodes.

| Step | Node 1 | Node 2 | Storage | Notes |
|---|---|---|---|---|
| Set up networks | On | On | Off | Verify that all storage devices on the shared bus are turned off. Turn on all nodes. |
| Set up cluster disks | On | Off | On | Shut down all nodes. Turn on the cluster storage, and then turn on the first node. |
| Verify disk configuration | Off | On | On | Turn off the first node, turn on second node. Repeat for nodes three and four if necessary. |
| Configure the first node | On | Off | On | Turn off all nodes; and then turn on the first node. |
| Configure the second node | On | On | On | After the first node is successfully configured, turn on the second node. Repeat for nodes three and four as necessary. |
| Post-installation | On | On | On | All nodes should be turned on. |

**Preparing to create a cluster**

Complete the following three steps on each cluster node before you install a cluster on the first node.

- Install Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, on each node of the cluster. We strongly recommend that you also install the latest service pack for Windows Server 2003. If you install a service pack, the same service pack must be installed on all computers in the cluster.
- Set up networks.
- Set up cluster disks.

All nodes must be members of the same domain. When you create a cluster or join nodes to a cluster, you specify the domain user account under which the Cluster service runs. This account is called the Cluster service account (CSA).

**Installing the Windows Server 2003 operating system**

Install Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, on each node of the cluster. For information about how to perform this installation, see the documentation you received with the operating system.

Before configuring the Cluster service, you must be logged on locally with a domain account that is a member of the local administrators group.

| **Important** |
|---|
| If you attempt to join a node to a cluster that has a blank password for the local administrator account, the installation will fail. For security reasons, Windows Server 2003 operating systems prohibit blank administrator passwords. |

**Setting up networks**

Each cluster node requires at least two network adapters and must be connected by two or more independent networks. At least two LAN networks (or virtual LANs) are required to prevent a single point of failure. A server cluster whose nodes are connected by only one network is not a supported configuration. The adapters, cables, hubs, and switches for each network must fail independently. This usually means that the components of any two networks must be physically independent.

Two networks must be configured to handle either **All communications (mixed network)** or **Internal cluster communications only (private network)**. The recommended configuration for two adapters is to use one adapter for the private (node-to-node only) communication and the other adapter for mixed communication (node-to-node plus client-to-cluster communication).

You must have two PCI network adapters in each node. They must be certified in the Microsoft Windows Catalog and supported by Microsoft Product Support Services. Assign one network adapter on each node a static IP address, and assign the other network adapter a static IP address on a separate network on a different subnet for private network communication.

Because communication between cluster nodes is essential for smooth cluster operations, the networks that you use for cluster communication must be configured optimally and follow all hardware compatibility-list requirements. For additional information about recommended configuration settings, see article 258750, "Recommended private heartbeat configuration on a cluster server," in the Microsoft Knowledge Base.

You should keep all private networks physically separate from other networks. Specifically, do not use a router, switch, or bridge to join a private cluster network to any other network. Do not include other network infrastructure or application servers on the private network subnet. To separate a private network from other networks, use a cross-over cable in a two-node cluster configuration or a dedicated hub in a cluster configuration of more than two nodes.

**Additional network considerations**

- All cluster nodes must be on the same logical subnet.
- If you are using a virtual LAN (VLAN), the one-way communication latency between any pair of cluster nodes on the VLAN must be less than 500 milliseconds.
- In Windows Server 2003 operating systems, cluster nodes exchange multicast heartbeats rather than unicast heartbeats. A heartbeat is a message that is sent regularly between cluster network drivers on each node. Heartbeat messages are used to detect communication failure between cluster nodes. Using multicast technology enables better node communication because it allows several unicast messages to be replaced with a single multicast message. Clusters that consist of fewer than three nodes will not send multicast heartbeats. For additional information about using multicast technology, see article 307962, "Multicast Support Enabled for the Cluster Heartbeat," in the Microsoft Knowledge Base.

Determine an appropriate name for each network connection. For example, you might want to name the private network "Private" and the public network "Public." This will help you uniquely identify a network and correctly assign its role.

The following figure shows the elements of a four-node cluster that uses a private network.

**Setting the order of the network adapter binding**

One of the recommended steps for setting up networks is to ensure the network adapter binding is set in the correct order. To do this, use the following procedure.

**To set the order of the network adapter binding**

1. To open **Network Connections**, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
2. On the **Advanced** menu, click **Advanced Settings**.
3. In **Connections**, click the connection that you want to modify.

4. Set the order of the network adapter binding as follows:
    - External public network
    - Internal private network (Heartbeat)
    - [Remote Access Connections]
5. Repeat this procedure for all nodes in the cluster.

**Configuring the private network adapter**
As stated earlier, the recommended configuration for two adapters is to use one adapter for private communication, and the other adapter for mixed communication. To configure the private network adapter, use the following procedure.

**To configure the private network adapter**

1. To open **Network Connections**, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
2. Right-click the connection for the adapter you want to configure, and then click **Properties**. **Local Area Properties** opens and looks similar to the following figure:

3. On the **General** tab, verify that the **Internet Protocol (TCP/IP)** check box is selected, and that all other check boxes in the list are clear.
4. If you have network adapters that can transmit at multiple speeds and that allow you to specify the speed and duplex mode, manually configure the Duplex Mode, Link Speed, and Flow Control settings for the adapters to the same values and settings on all nodes. If the network adapters you are using do not support manual settings, contact your adapter manufacturer for specific information about appropriate speed and duplex settings for your network adapters. The amount of information that is traveling across the heartbeat network is small, but latency is critical for communication. Therefore, if you have the same speed and duplex settings, this helps ensure that you have reliable communication. If the adapters are connected to a switch, ensure that the port settings of the switch match those of the adapters. If you do not know the supported speed of your card and connecting devices, or if you run into compatibility problems, you should set all devices on that path to 10 megabytes per second (Mbps) and Half Duplex.

    Teaming network adapters on all cluster networks concurrently is not supported because of delays that can occur when heartbeat packets are transmitted and received between cluster nodes. For best results, when you want redundancy for the private interconnect, you should disable teaming and use the available ports to form a second private interconnect. This achieves the same end result and provides the nodes with dual, robust communication paths.

    You can use Device Manager to change the network adapter settings. To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.

Right-click the network adapter you want to change, and then click **Properties**. Click **Advanced** to manually change the speed and duplex mode for the adapter. The page that opens looks similar to the following figure:

5. On the **General** tab in **Network Connections**, select **Internet Protocol (TCP/IP)**, and click **Properties**.

   Internet Protocol (TCP/IP) Properties opens and looks similar to the following figure:

6. On the **General** tab, verify you have selected a static IP address that is not on the same subnet or network as any other public network adapter. You should put the private network adapter in one of the following private network ranges:

   - 10.0.0.0 through 10.255.255.255 (Class A)
   - 172.16.0.0 through 172.31.255.255 (Class B)
   - 192.168.0.0 through 192.168.255.255 (Class C)

7. On the **General** tab, verify that no values are defined in **Default Gateway** under **Use the following IP address**, and no values are defined under **Use the Following DNS server addresses**. After you have done so, click **Advanced**.

8. On the **DNS** tab, verify that no values are defined on the page and that the check boxes for **Register this connection's addresses in DNS** and **Use this connection's DNS suffix in DNS registration** are clear.

9. On the **WINS** tab, verify that no values are defined on the page, and then click **Disable NetBIOS over TCP/IP.**

   **Advanced TCP/IP Settings opens and looks similar to the following figure:**

10. After you have verified the information, click **OK**. You might receive the message "This connection has an empty primary WINS address. Do you want to continue?" To continue, click **Yes**.

11. Repeat this procedure for all additional nodes in the cluster. For each private network adapter, use a different static IP address.

**Configuring the public network adapter**

If DHCP is used to obtain IP addresses, it might not be possible to access cluster nodes if the DHCP server is inaccessible. For increased availability, static, valid IP addresses are required for all interfaces on a server cluster. If you plan to put multiple network adapters in each logical subnet, keep in mind that the Cluster service will recognize only one network interface per subnet.

- **Verifying connectivity and name resolution**. To verify that the private and public networks are communicating properly, "ping" all IP addresses from each node. To "ping" an IP address means that you search for and verify it. You should be able to ping all IP addresses, both locally and on the remote nodes. To verify the name resolution, ping each node from a client using the node's computer name instead of its IP address. It should only return the IP address for the public network. You might also want to try using the `PING -a` command to perform a reverse name resolution on the IP addresses.

- **Verifying domain membership**. All nodes in the cluster must be members of the same domain, and they must be able to access a domain controller and a DNS server. They can be configured as member servers or domain controllers. You should have at least one domain controller on the same network segment as the cluster. To avoid having a single point of failure, another domain controller should also be available. In this guide, all nodes are configured as member servers, which is the recommended role.

  In a two-node server cluster, if one node is a domain controller, the other node must also be a domain controller. In a four-node cluster, it is not necessary to configure all four nodes as domain controllers. However, when following a "best practices" model of having at least one backup domain controller, at least one of the remaining three nodes should also be configured as a domain controller. A cluster node must be promoted to a domain controller before the Cluster service is configured.

  The dependence in Windows Server 2003 on DNS requires that every node that is a domain controller must also be a

DNS server if another DNS server that supports dynamic updates is not available.

You should consider the following issues if you are planning to deploy cluster nodes as domain controllers:

- If one cluster node in a two-node cluster is a domain controller, the other node must also be a domain controller.
- There are performance implications associated with the overhead of running a computer as a domain controller. There is increased memory usage and additional network traffic from replication because these domain controllers must replicate with other domain controllers in the domain and across domains.
- If the cluster nodes are the only domain controllers, they each must be DNS servers as well. They should point to themselves for primary DNS resolution and to each other for secondary DNS resolution.
- The first domain controller in the forest or domain will assume all Operations Master Roles. You can redistribute these roles to any node. However, if a node fails, the Operations Master Roles assumed by that node will be unavailable. Because of this, you should not run Operations Master Roles on any cluster node. This includes Schema Master, Domain Naming Master, Relative ID Master, PDC Emulator, and Infrastructure Master. These functions cannot be clustered for high availability with failover.
- Because of resource constraints, it might not be optimal to cluster other applications such as Microsoft SQL Server™ in a scenario where the nodes are also domain controllers. This configuration should be thoroughly tested in a lab environment before deployment.

Because of the complexity and overhead involved when cluster nodes are domain controllers, all nodes should be member servers.

- **Setting up a Cluster service user account**. The Cluster service requires a domain user account that is a member of the Local Administrators group on each node. This is the account under which the Cluster service can run. Because Setup requires a user name and password, you must create this user account before you configure the Cluster service. This user account should be dedicated to running only the Cluster service and should not belong to an individual.

| **Note** |
| --- |
| It is not necessary for the Cluster service account (CSA) to be a member of the Domain Administrators group. For security reasons, domain administrator rights should not be granted to the Cluster service account. |

The Cluster service account requires the following rights to function properly on all nodes in the cluster. The Cluster Configuration Wizard grants the following rights automatically:

- Act as part of the operating system
- Adjust memory quotas for a process
- Back up files and directories
- Restore files and directories
- Increase scheduling priority
- Log on as a service

You should ensure that the Local Administrator Group has access to the following user rights:

- Debug programs
- Impersonate a client after authentication

- Manage auditing and security log

You can use the following procedure to set up a Cluster service user account.

**To set up a Cluster service user account**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the folder to which you want to add a user account.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder*

3. Point to **New**, and then click **User.**
4. **New Object - User** opens and looks similar to the following figure:

5. Type a first name and last name (these should make sense but are usually not important for this account)
6. In **User logon name**, type a name that is easy to remember, such as ClusterService1, click the UPN suffix in the drop-down list, and then click **Next**.
7. **In Password** and **Confirm password**, type a password that follows your organization's guidelines for passwords, and then select **User Cannot Change Password** and **Password Never Expires**. Click **Finish** to create the account.

   If your administrative security policy does not allow the use of passwords that never expire, you must renew the password and update the Cluster service configuration on each node before the passwords expire.

8. In the console tree of the Active Directory Users and Computers snap-in, right-click **Cluster**, and then click **Properties**.
9. Click **Add Members to a Group**.
10. Click **Administrators**, and then click **OK**. This gives the new user account administrative permissions on the computer.

**Setting up disks**

This section includes information and step-by-step procedures you can use to set up disks.

| **Important** |
| --- |
| To avoid possible corruption of cluster disks, ensure that both the Windows Server 2003 operating system and the Cluster service are installed, configured, and running on at least one node before you start the operating system on another node in the cluster. |

**Quorum resource**

The quorum resource maintains the configuration data necessary for recovery of the cluster. The quorum resource is generally accessible to other cluster resources so that any cluster node has access to the most recent database changes. There can only be one quorum disk resource per cluster.

The requirements and guidelines for the quorum disk are as follows:

- The quorum disk should be at least 500 MB in size.
- You should use a separate LUN as the dedicated quorum resource.
- A disk failure could cause the entire cluster to fail. Because of this, we strongly recommend that you implement a hardware RAID solution for your quorum disk to help guard against disk failure. Do not use the quorum disk for anything other than cluster management.

When you configure a cluster disk, it is best to manually assign drive letters to the disks on the shared bus. The drive letters should not start with the next available letter. Instead, leave several free drive letters between the local disks and the shared disks. For example, start with drive Q as the quorum disk and then use drives R and S for the shared disks. Another method is to start with drive Z as the quorum disk and then work backward through the alphabet with drives X and Y as data disks. You might also want to consider labeling the drives in case the drive letters are lost. Using labels makes it easier to determine what the drive letter was. For example, a drive label of "DriveR" makes it easy to determine that this drive was drive letter R. We recommend that you follow these best practices when assigning driver letters because of the following issues:

- Adding disks to the local nodes can cause the drive letters of the cluster disks to be revised up by one letter.
- Adding disks to the local nodes can cause a discontinuous flow in the drive lettering and result in confusion.
- Mapping a network drive can conflict with the drive letters on the cluster disks.

The letter Q is commonly used as a standard for the quorum disk. Q is used in the next procedure.

The first step in setting up disks for a cluster is to configure the cluster disks you plan to use. To do this, use the following procedure.

**To configure cluster disks**

1. Make sure that only one node in the cluster is turned on.
2. Open Computer Management (Local).
3. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
4. When you first start Disk Management after installing a new disk, a wizard appears that provides a list of the new disks detected by the operating system. If a new disk is detected, the Write Signature and Upgrade Wizard starts. Follow the instructions in the wizard.
5. Because the wizard automatically configures the disk as dynamic storage, you must reconfigure the disk to basic storage. To do this, right-click the disk, and then click **Convert To Basic Disk**.
6. Right-click an unallocated region of a basic disk, and then click **New Partition**.
7. In the New Partition Wizard, click **Next**, click **Primary partition**, and then click **Next**.
8. By default, the maximum size for the partition is selected. Using multiple logical drives is better than using multiple partitions on one disk because cluster disks are managed at the LUN level, and logical drives are the smallest unit of failover.
9. Change the default drive letter to one that is deeper into the alphabet. For example, start with drive Q as the quorum disk, and then use drives R and S for the data disks.
10. Format the partition with the NTFS file system.
11. In **Volume Label**, enter a name for the disk; for example, "Drive Q." Assigning a drive label for cluster disks reduces the time it takes to troubleshoot a disk recovery scenario.

After you have finished entering values for the new partition, it should look similar to the following figure:

**Important**

Ensure that all disks are formatted as MBR; GPT disks are not supported as cluster disks.

After you have configured the cluster disks, you should verify that the disks are accessible. To do this, use the following procedure.

**To verify that the cluster disks are accessible**

1. Open Windows Explorer.
2. Right-click one of the cluster disks, such as "Drive Q," click **New**, and then click **Text Document**.
3. Verify that the text document was created and written to the specified disk, and then delete the document from the cluster disk.
4. Repeat steps 1 through 3 for all cluster disks to verify that they are all accessible from the first node.
5. Turn off the first node, and then turn on the second node.
6. Repeat steps 1 through 3 to verify that the disks are all accessible from the second node.
7. Repeat again for any additional nodes in the cluster.
8. When finished, turn off the nodes and then turn on the first node again.

**Creating a new server cluster**

In the first phase of creating a new server cluster, you must provide all initial cluster configuration information. To do this, use the New Server Cluster Wizard.

**Important**

Before configuring the first node of the cluster, make sure that all other nodes are turned off. Also make sure that all cluster storage devices are turned on.

The following procedure explains how to use the New Server Cluster Wizard to configure the first cluster node.

**To configure the first node**

1. Open Cluster Administrator. To do this, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Cluster Administrator**.
2. In the **Open Connection to Cluster dialog box**, in **Action**, select **Create new cluster, and then click OK**.

3. The New Server Cluster Wizard appears. Verify that you have the necessary information to continue with the configuration, and then click **Next** to continue.

4. In **Domain**, select the name of the domain in which the cluster will be created. In **Cluster name**, enter a unique NetBIOS name. It is best to follow the DNS namespace rules when entering the cluster name. For more information, see article 254680, "DNS Namespace Planning," in the Microsoft Knowledge Base.

5. On the **Domain Access Denied** page, if you are logged on locally with an account that is not a domain account with local administrative permissions, the wizard will prompt you to specify an account. This is not the account the Cluster service will use to start the cluster.

| **Note** |
| --- |
| If you have the appropriate credentials, the **Domain Access Denied** screen will not appear. |

6. Since it is possible to configure clusters remotely, you must verify or type the name of the computer you are using as the first node. On the **Select Computer** page, verify or type the name of the computer you plan to use.

| **Note** |
| --- |
| The wizard verifies that all nodes can see the cluster disks. In some complicated SANs, the target IDs for the disks might not match on all the cluster nodes. If this occurs, the Setup program might incorrectly determine that the disk configuration is not valid. To address this issue, click **Advanced**, and then click **Advanced (minimum) configuration**. |

7. On the **Analyzing Configuration** page, Setup analyzes the node for possible hardware or software issues that can cause installation problems. Review any warnings or error messages that appear. Click **Details** to obtain more information about each warning or error message.

8. On the **IP Address** page, type the unique, valid, cluster IP address, and then click **Next**. The wizard automatically associates the cluster IP address with one of the public networks by using the subnet mask to select the correct network. The cluster IP address should be used for administrative purposes only, and not for client connections.

9. On the **Cluster Service Account** page, type the user name and password of the Cluster service account that was created during pre-installation. In **Domain**, select the domain name, and then click **Next**. The wizard verifies the user account and password.

10. On the **Proposed Cluster Configuration** page, review the information for accuracy. You can use the summary information to reconfigure the cluster if a system recovery occurs. You should keep a hard copy of this summary information with the change management log at the server. To continue, click **Next**.

| **Note** |
| --- |
| If you want, you can click **Quorum** to change the quorum disk designation from the default disk resource. To make this change, in the **Quorum resource** box, click a different disk resource. If the disk has more than one partition, click the partition where you want the cluster-specific data to be kept, and then click **OK**. |

11. On the **Creating the Cluster** page, review any warnings or error messages that appear while the cluster is being created. Click to expand each warning or error message for more information. To continue, click **Next**.

12. Click **Finish** to complete the cluster configuration.

| **Note** |
| --- |
| To view a detailed summary, click **View Log**, or view the text file stored at the following location: |

%SystemRoot%\System32\LogFiles\Cluster\ClCfgSrv.Log

**Validating the cluster installation**

You should validate the cluster configuration of the first node before configuring the second node. To do this, use the following procedure.

### To validate the cluster configuration

1. Open Cluster Administrator. To do this, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Cluster Administrator**.

2. Verify that all cluster resources are successfully up and running. Under **State**, all resources should be "Online."

**Configuring subsequent nodes**

After you install the Cluster service on the first node, it takes less time to install it on subsequent nodes. This is because the Setup program uses the network configuration settings configured on the first node as a basis for configuring the network settings on subsequent nodes. You can also install the Cluster service on multiple nodes at the same time and choose to install it from a remote location.

| Note |
| --- |
| The first node and all cluster disks must be turned on. You can then turn on all other nodes. At this stage, the Cluster service controls access to the cluster disks, which helps prevent disk corruption. You should also verify that all cluster disks have had resources automatically created for them. If they have not, manually create them before adding any more nodes to the cluster. |

After you have configured the first node, you can use the following procedure to configure subsequent nodes.

**To configure the second node**

1. Open Cluster Administrator. To do this, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Cluster Administrator**.
2. In the **Open Connection to Cluster** dialog box, in **Action**, select **Add nodes to cluster**. Then, in **Cluster or server name**, type the name of an existing cluster, select a name from the drop-down list box, or click **Browse** to search for an available cluster, and then click **OK** to continue.
3. When the Add Nodes Wizard appears, click **Next** to continue.
4. If you are not logged on with the required credentials, you will be asked to specify a domain account that has administrator rights and permissions on all nodes in the cluster.
5. In the **Domain** list, click the domain where the server cluster is located, make sure that the server cluster name appears in the **Cluster name** box, and then click **Next**.
6. In the **Computer name** box, type the name of the node that you want to add to the cluster. For example, to add Node2, you would type Node2.

7. Click **Add**, and then click **Next**.
8. When the Add Nodes Wizard has analyzed the cluster configuration successfully, click **Next**.
9. On the **Cluster Service Account** page, in **Password**, type the password for the Cluster service account. Ensure that the correct domain for this account appears in the **Domain** list, and then click **Next**.
10. On the **Proposed Cluster Configuration** page, view the configuration details to verify that the server cluster IP address, the networking information, and the managed disk information are correct, and then click **Next**.
11. When the cluster is configured successfully, click **Next**, and then click **Finish**.

**Configuring the server cluster after installation**
**Heartbeat configuration**
After the network and the Cluster service have been configured on each node, you should determine the network's function within the cluster. Using Cluster Administrator, select the **Enable this network for cluster use** check box and select from among the following options.

| Option | Description |
| --- | --- |
| Client access only (public network) | Select this option if you want the Cluster service to use this network adapter only for external communication with other clients. No node-to-node communication will take place on this network adapter. |
| Internal cluster communications only (private network) | Select this option if you want the Cluster service to use this network only for node-to-node communication. |
| All communications (mixed network) | Select this option if you want the Cluster service to use the network adapter for node-to-node communication and for communication with external clients. This option is selected by default for all networks. |

This guide assumes that only two networks are in use. It explains how to configure these networks as one mixed network and one private network. This is the most common configuration.

Use the following procedure to configure the heartbeat.

**To configure the heartbeat**

1. Open Cluster Administrator. To do this, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Cluster Administrator**.
2. In the console tree, double-click **Cluster Configuration**, and then click **Networks**.
3. In the details pane, right-click the private network you want to enable, and then click **Properties**. **Private Properties** opens and looks similar to the following figure:

4. Select the **Enable this network for cluster use** check box.
5. Click **Internal cluster communications only (private network)**, and then click **OK**.
6. In the details pane, right-click the public network you want to enable, and then click **Properties**. **Public Properties** opens and looks similar to the following figure:

7. Select the **Enable this network for cluster use** check box.

8. Click **All communications (mixed network)**, and then click **OK**.

**Prioritize the order of the heartbeat adapter**

After you have decided the roles in which the Cluster service will use the network adapters, you must prioritize the order in which the adapters will be used for internal cluster communication. To do this, use the following procedure.

**To configure network priority**

1. Open Cluster Administrator. To do this, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Cluster Administrator**.

2. In the console tree, click the cluster you want.

3. On the **File** menu, click **Properties**.

4. Click the **Network Priority** tab.

5. In **Networks used for internal cluster communications**, click a network.

6. To increase the network priority, click **Move Up**; to lower the network priority click **Move Down.**

7. When you are finished, click **OK.**

| **Note** |
| --- |
| If multiple networks are configured as private or mixed, you can specify which one to use for internal node communication. It is usually best for private networks to have higher priority than mixed networks. |

**Quorum disk configuration**

The New Server Cluster Wizard and the Add Nodes Wizard automatically select the drive used for the quorum device. The wizard automatically uses the smallest partition it finds that is larger then 50 MB. If you want to, you can change the automatically selected drive to a dedicated one that you have designated for use as the quorum. The following procedure explains what to do if you want to use a different disk for the quorum resource.

**To use a different disk for the quorum resource**

1. Open Cluster Administrator. To do this, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Cluster Administrator**.

2. If one does not already exist, create a physical disk or other storage-class resource for the new disk.

3. In the console tree, click the cluster name.

4. On the **File** menu, click **Properties, and then click the Quorum tab**. The quorum property page opens and looks similar to the following figure:

5. On the **Quorum** tab, click **Quorum resource**, and then select the new disk or storage-class resource that you want to use as the quorum resource for the cluster.

6. In **Partition**, if the disk has more than one partition, click the partition where you want the cluster specific data kept.

7. In **Root path**, type the path to the folder on the partition; for example:

   **\MSCS**

**Testing the Server Cluster**

After Setup, there are several methods you can use to verify a cluster installation.

- **Use Cluster Administrator**. After Setup is run on the first node, open Cluster Administrator, and then try to connect to the cluster. If Setup was run on a second node, start Cluster Administrator on either the first or second node, attempt to connect to the cluster, and then verify that the second node is listed.

- **Services snap-in**. Use the Services snap-in to verify that the Cluster service is listed and started.

- **Event log**. Use Event Viewer to check for **ClusSvc** entries in the system log. You should see entries that confirm the Cluster service successfully formed or joined a cluster.

#### Testing whether group resources can fail over

You might want to ensure that a new group is functioning correctly. To do this, use the following procedure.

**To test whether group resources can fail over**

1. Open Cluster Administrator. To do this, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Cluster Administrator**.

2. In the console tree, double-click the **Groups** folder.

3. In the console tree, click a group.

4. On the **File** menu, click **Move Group**. On a multi-node cluster server, when using **Move Group**, select the node to move the group to. Make sure the **Owner** column in the details pane reflects a change of owner for all of the group's dependencies.

5. If the group resources successfully fail over, the group will be brought online on the second node after a short period of time.

#### SCSI Drive Installations

This section of the guide provides a generic set of instructions for parallel SCSI drive installations.

| **Important** |
| --- |
| If the SCSI hard disk vendor’s instructions differ from the instructions provided here, follow the instructions supplied by the vendor. |

The SCSI bus listed in the hardware requirements must be configured before you install the Cluster service. This configuration applies to the following:

- The SCSI devices.

- The SCSI controllers and the hard disks. This is to ensure that they work properly on a shared SCSI bus.

- The termination of the shared bus. If a shared bus must be terminated, it must be done properly. The shared SCSI bus must have a terminator at each end of the bus. It is possible to have multiple shared SCSI buses between the nodes of a cluster.

In addition to the following information, refer to documentation from the manufacturer of your SCSI device.

#### Configuring SCSI devices

Each device on the shared SCSI bus must have a unique SCSI identification number. Because most SCSI controllers default to SCSI ID 7, configuring the shared SCSI bus includes changing the SCSI ID number on one controller to a different number, such as SCSI ID 6. If there is more than one disk that will be on the shared SCSI bus, each disk must have a unique SCSI ID number.

#### Storage Area Network Considerations

Fibre Channel systems are required for all server clusters running 64-bit versions of Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. It is also best to use Fibre Channel systems for clusters of three or more nodes. Two methods of Fibre Channel-based storage are supported in a cluster that is running Windows Server 2003: arbitrated loops and switched fabric.

| **Note** |
| --- |
| To determine which type of Fibre Channel hardware to use, read the Fibre Channel vendor's documentation. |

**Fibre Channel arbitrated loops (FC-AL)**
A Fibre Channel arbitrated loop (FC-AL) is a set of nodes and devices connected into a single loop. FC-AL provides a cost-effective way to connect up to 126 devices into a single network.

Fibre Channel arbitrated loops provide a solution for a small number of devices in a relatively fixed configuration. All devices on the loop share the media, and any packet traveling from one device to another must pass through all intermediate devices. FC-AL is a good choice if a low number of cluster nodes is sufficient to meet your high-availability requirements.

FC-AL offers the following advantages:

- The cost is relatively low.
- Loops can be expanded to add storage; however, nodes cannot be added.
- Loops are easy for Fibre Channel vendors to develop.

The disadvantage of FC-ALs is that they can be difficult to deploy successfully. This is because every device on the loop shares the media, which causes the overall bandwidth of the cluster to be lower. Some organizations might also not want to be restricted by the 126-device limit. Having more than one cluster on the same arbitrated loop is not supported.

**Fiber Channel switched fabric (FC-SW)**
With Fibre Channel switched fabric, switching hardware can link multiple nodes together into a matrix of Fibre Channel nodes. A switched fabric is responsible for device interconnection and switching. When a node is connected to a Fibre Channel switching fabric, it is responsible for managing only the single point-to-point connection between itself and the fabric. The fabric handles physical interconnections to other nodes, transporting messages, flow control, and error detection and correction. Switched fabrics also offer very fast switching latency.

The switching fabric can be configured to allow multiple paths between the same two ports. It provides efficient sharing (at the cost of higher contention) of the available bandwidth. It also makes effective use of the burst nature of communications with high-speed peripheral devices.

Other advantages to using switched fabric include the following:

- It is easy to deploy.
- It can support millions of devices.
- The switches provide fault isolation and rerouting.
- There is no shared media, which allows faster communication in the cluster.

**Zoning vs. LUN masking**
Zoning and LUN masking are important to SAN deployments, especially if you are deploying a SAN with a server cluster that is running Windows Server 2003.

**Zoning**
Many devices and nodes can be attached to a SAN. With data stored in a single storage entity (known as a "cloud") it is important to control which hosts have access to specific devices. Zoning allows administrators to partition devices in logical volumes, thereby reserving the devices in a volume for a server cluster. This means that all interactions between cluster nodes and devices in the logical storage volumes are isolated within the boundaries of the zone; other non-cluster members of the SAN are not affected by cluster activity. The elements used in zoning are shown in the following figure:

You must implement zoning at the hardware level with the controller or switch, not through software. This is because zoning is a security mechanism for a SAN-based cluster. Unauthorized servers cannot access devices inside the zone. Access control is implemented by the switches in the fabric, so a host adapter cannot gain access to a device for which it has not been configured. With software zoning, the cluster would not be secure if the software component failed.

In addition to providing cluster security, zoning also limits the traffic flow within a given SAN environment. Traffic between ports is routed only to segments of the fabric that are in the same zone.

**LUN masking**

A logical unit number (LUN) is a logical disk defined within a SAN. Server clusters see LUNs and act as though the LUNs are physical disks. With LUN masking, which is performed at the controller level, you can define relationships between LUNs and cluster nodes. Storage controllers usually provide the means for creating LUN-level access controls that allow one or more hosts to access a given LUN. With access control at the storage controller, the controller itself can enforce access policies to the devices.

LUN masking provides security at a more detailed level than zoning. This is because LUNs allow for zoning at the port level. For example, many SAN switches allow overlapping zones, which enable a storage controller to reside in multiple zones. Multiple clusters in multiple zones can share the data on those controllers. The elements used in LUN masking are shown in the following figure:

**Other Resources**

# What's New in Windows Server 2003 R2

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Microsoft® Windows Server™ 2003 R2, a software update to the Windows Server 2003 operating system, makes it easier and more cost effective to extend connectivity and control to identities, locations, data, and applications throughout and beyond your organization.

Built on Windows Server 2003, Windows Server 2003 R2 takes advantage of the stability and security of the code base while extending connectivity and control into new areas. With Windows Server 2003 R2, you get the following improvements:

- Identity and access management
- Branch office server management
- Storage setup and management
- Application development inside and outside your organization's traditional boundaries

For more information about Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45560).

This topic describes the following new components that you can install with Windows Server 2003 R2:

**Server Manageability**

- Administration Tools Packs
- Hardware Management
- MMC 3.0

**Features for Active Directory**

- Active Directory Application Mode (ADAM)
- Active Directory Federation Services

**Disk and File Management Features**

- Branch Office
    - Distributed File System (DFS)
- Common Log File System (CLFS)
- File Server Management
- Microsoft Services for Network File System
- Storage Management for SANs
- File Server Resource Manager

**Printer and Protocol Support**

- Print Management

**Microsoft .NET Framework**

- Microsoft .NET Framework 2.0

**Internet and E-Mail Services and Features**

- Windows Sharepoint Services

**UNIX Interoperability**

- Identity Management for UNIX
- Subsystem for UNIX-based Applications

**Server Manageability**
To help you manage your server, Windows Server 2003 R2 provides Administration Tools Packs and the following improvements to hardware management and Microsoft Management Console (MMC) 3.0.

**Administration Tools Packs**
To make the remote management of your servers easier, you can install the Administration Tools Packs for Windows Server 2003 R2 located on Disc 2 in the \mgmttls directory. Each of the following components has an Administration Tools Pack:

- Microsoft Management Console (MMC) 3.0
- Print Management
- File Server Resource Manager
- DFS Replication
- Identity Management for UNIX
- File Server Management

In order to administer components, you must first install the MMC 3.0 Administration Tools Pack. The Administration Tools Packs can be installed on computers running Windows® XP Professional with Service Pack 2 (SP2). For specific installation instructions, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=54293).

**Hardware Management**
You can use Windows Remote Management (WinRM) to manage server hardware remotely across firewalls and monitor conditions on servers that are offline.

This new feature in Windows Server 2003 R2 is implemented using WS-Management, an industry-standard, Web services-based remoting protocol. WS-Management uses HTTPS as the secure transport that enables firewall traversal.

WinRM provides a command-line interface for common management tasks and a scripting application programming interface (API) for writing Windows Script Host-based system administration scripts.

Using WinRM, you can write scripts to monitor and control the state of server hardware by communicating with a Baseboard Management Controller (BMC). A BMC is a separate micro-controller with its own network adapter that is connected to the processor board of a server and can monitor conditions even when the server is off or malfunctioning. A new Windows Management Interface (WMI) provider for Intelligent Platform Management Interface (IPMI) exposes six new WMI classes for accessing BMC information with scripts.

WinRM is not installed by default with Windows Server 2003 R2. To install it, open Add or Remove Programs from Control Panel, and click **Add/Remove Windows Components**.

For more information about hardware management, see "Hardware Management in Microsoft Windows Server 2003 R2" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45204).

Back to Top

**MMC 3.0**

Microsoft Management Console (MMC) 3.0 supports richer functionality in snap-ins designed for the MMC 3.0 infrastructure. In addition, the following improvements apply to all MMC 3.0 consoles:

- **Action pane.** The Action pane appears on the right side of the snap-in console. It lists the actions that are currently available to you, based on the currently selected items in the tree or the results pane.

  To show or hide the action pane, click the **Show/Hide Action Pane** button on the toolbar, which is similar to the **Show/Hide Console Tree** button.

- **New Add or Remove Snap-in dialog box.** The new **Add or Remove Snap-in** dialog box makes it easy to add, organize, and remove snap-ins. You can control which extensions are available, and whether to automatically enable snap-ins that may be installed later. You can nest snap-ins and rearrange the snap-ins in the tree.

- **Improved error handling.** MMC 3.0 notifies you of errors in snap-ins that could cause MMC to fail and provides several options for responding to those errors.

MMC 3.0 is automatically installed when you install Windows Server 2003 R2.

Back to Top

**Features for Active Directory**

The following Active Directory components are included in Windows Server 2003 R2.

**Active Directory Application Mode (ADAM)**

Active Directory Application Mode (ADAM) is an independent mode of the Active Directory® directory service, without infrastructure features, that provides directory services for applications. It provides a data store and services for accessing the data store. It uses standard application programming interfaces (APIs) for accessing the application data. ADAM operates either as a standalone data store, or it operates with replication. Its independence enables local control and autonomy of directory services for specific applications. It also facilitates independent, flexible schemas and naming contexts.

Back to Top

**Active Directory Federation Services**

The fundamental purpose of Active Directory Federation Services (ADFS) is to leverage single user sign-on to authenticate the user to multiple related Web applications over the life of a single online session. ADFS does this by securely sharing digital identity and entitlement rights across security and enterprise boundaries.

Back to Top

**Disk and File Management Features**

Windows Server 2003 R2 includes the following disk and file management features.

**Branch Office**

Branch offices are the remote locations of an organization that connect to a headquarters or hub over a wide-area network (WAN). The technologies included in Windows Server 2003 R2 can simplify how you manage a variety of activities and tasks in branch offices. These activities and tasks include:

- Publishing files from centralized hubs to branch offices.

- Replicating files from branch locations for backup, fault-tolerance, or cross-publishing.

- Collaborating on documents that are shared among branches or between hubs and branches.

- Efficiently managing printers, printer drivers, and print queues in branch offices.

These improvements are supported by the enhanced print-management tools in Windows Server 2003 R2. They are also supported by Distributed File System (DFS) in Windows Server 2003 R2.

For more information about these technologies in Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=51679).

Back to Top

**Distributed File System (DFS)**
The Distributed File System (DFS) solution in Windows Server 2003 R2 provides simplified, fault-tolerant access to files and WAN-friendly replication. Distributed File System consists of two technologies:

- **DFS Namespaces.** Formerly known as Distributed File System, DFS Namespaces allows administrators to group shared folders located on different servers and present them to users as a virtual tree of folders known as a namespace. A namespace provides numerous benefits, including increased availability of data, load sharing, and simplified data migration.

- **DFS Replication.** The successor to File Replication service (FRS), DFS Replication is a new state-based, multimaster replication engine that supports scheduling and bandwidth throttling. DFS Replication uses a new compression algorithm known as Remote Differential Compression (RDC). RDC is a "diff over the wire" protocol that can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, re-arrangements of data in files, enabling DFS Replication to replicate only the deltas (changes) when files are updated.

For more information about Distributed File System in Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=51679).

Back to Top

**Common Log File System (CLFS)**
Common Log File System (CLFS) is a loadable driver that provides kernel- or user-mode applications with a robust logging subsystem. CLFS is a unique Windows technology that can be used to develop applications and middleware that depend on durably writing and reading sequential data. Examples include replication agents, auditing agents, databases, and other transactional resource managers.

Features include the ability to create log files with a single stream of data or with multiple streams of data for shared use by one or more clients; both circular and linear logging; guaranteed ability to flush buffered data by pre-reserving space in the log; policy-based log size and space management; sharing of a single log by both kernel and user clients; a notification mechanism to allow different users within the same log to coordinate their log use; flexible buffering of log data; archiving APIs do not interfere with normal operations; atomic multi-sector writes; and torn-write detection.

CLFS is optimized for performance. All writes to the log file are buffered until an explicit flush, an opportunity to share a write with another client, or the buffer is filled. Log data is written directly to the hard disk from the log buffers without copying. Multiple streams of data can be written during the same I/O operation, resulting in only one disk seek for what normally takes multiple seeks and writes. Reads are cached to save disk accesses during normal operation or bursts of read activity.

For more information, see the "Platform SDK" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=44489).

Back to Top

**File Server Management**
You can use File Server Management to perform many tasks, such as formatting volumes, creating shares, defragmenting volumes, creating and managing shares, setting quota limits, creating storage utilization reports, replicating data to and from the file server, managing Storage Area Networks (SANs), and sharing files with UNIX and Macintosh systems.

Back to Top

**File Server Resource Manager**
With the increasing demand on storage resources, as organizations rely more heavily on data than ever before, IT administrators face the challenge of overseeing a larger and more complex storage infrastructure, while at the same time, tracking the kind of information available in it.

File Server Resource Manager is a new Microsoft Management Console (MMC) snap-in that provides a suite of tools for administrators to understand, control, and manage the quantity and type of data stored on their servers. By using File Server Resource Manager, administrators can place quotas on folders and volumes, actively screen files, and generate comprehensive storage reports.

**File Server Resource Manager quotas vs. NTFS disk quotas**
The Windows 2000 and Windows Server 2003 operating systems support disk quotas, which are used to track and control disk

usage per user on NTFS volumes. The following table outlines the advantages of using the quota management tools in File Server Resource Manager.

| Quota features | File Server Resource Manager | NTFS disk quotas |
|---|---|---|
| Quota tracking | By folder or by volume | Per user on a volume |
| Disk usage calculation | Actual disk space | Logical file size |
| Notification mechanisms | E-mail, custom reports, command execution, event logs | Event logs only |

Back to Top

**Microsoft Services for Network File System**

Microsoft Services for Network File System (NFS) is a component of Windows Server 2003 R2 that provides a file-sharing solution for enterprises that have a mixed Windows and UNIX environment. Microsoft Services for NFS allows users to transfer files between Windows Server 2003 R2 and UNIX computers using the Network File System (NFS) protocol.

Microsoft Services for NFS is an update to the NFS components that were previously available in Services for UNIX 3.5. Microsoft Services for NFS includes the following new features:

- Support for 64-bit

  Microsoft Services for NFS components can be installed on all editions of Windows Server 2003 R2, including 64-bit versions.

- Updated Microsoft Management Console (MMC) Microsoft Services for NFS Administration snap-in

- Enhanced reliability

- Support for UNIX special devices (mknod)

Microsoft Services for NFS allows you to support a mixed environment of Windows- and UNIX-based operating systems. It also allows you to update your organization's computers while supporting older technology during the transition phase. The following scenarios are examples of how enterprises can benefit from deploying Microsoft Services for NFS.

- Allows UNIX clients to access resources on computers running Windows Server 2003 R2. Your company may have UNIX clients accessing resources, such as files, on UNIX file servers. To take advantage of new Windows Server 2003 features, such as Shadow Copies for Shared Folders, you can move resources from your UNIX servers to computers running Windows Server 2003 R2, and then set up Microsoft Services for NFS to enable access by UNIX clients that are running NFS software. All of your UNIX clients will be able to access the resources using the NFS protocol with no changes required.

- Allows computers running Windows Server 2003 R2 to access resources on UNIX file servers. Your company may have a mixed Windows and UNIX environment with resources, such as files, stored on UNIX file servers. You can use Microsoft Services for NFS to enable computers running Windows Server 2003 R2 to access these resources when the file servers are running NFS software.

Back to Top

**Storage Management for SANs**

Storage Manager for SANs is a new Microsoft Management Console (MMC) snap-in that helps you create and manage logical unit numbers (LUNs) on fibre channel and iSCSI disk drive subsystems in your storage area network (SAN). Storage Manager for SANs can be used on storage subsystems that support Virtual Disk Server (VDS).

Use Storage Manager for SANs to create and assign LUNs, manage connections between LUNs and the servers in your SAN, and set the security properties for iSCSI storage subsystems.

Back to Top

**Printer and Protocol Support**

Windows Server 2003 R2 provides an updated MMC snap-in for Print Management.

**Print Management**
Print Management is an updated Microsoft Management Console (MMC) snap-in that you can use to view and manage printers and print servers in your organization. You can use Print Management from any computer running Windows Server 2003 R2, and you can manage all network printers on print servers running Windows 2000 Server, Windows Server 2003, or Windows Server 2003 R2.

Print Management provides up-to-the-minute details such as the queue status, printer name, driver name, and server name. You can also set custom views by using the Print Management filtering capability. For example, you can create a view that only displays printers in a particular error state. You can also configure Print Management to send e-mail notifications or run scripts when a printer or print server needs attention. The filtering capability also allows you to bulk edit print jobs, such as canceling all print jobs at once. You can also delete multiple printers at the same time.

Administrators can install printers remotely by using the automatic detect feature, which finds and installs printers on the local subnet to the local print server. Administrators can log on to a local server at a branch location by using Remote Desktop and then easily install printers remotely.

When a printer model has a Web page feature, Print Management can display troubleshooting details, such as the location of the paper jam or printer toner level. Some printer models have Web pages that provide options for remote control functions that can help resolve problems at branch locations.

For more information, see the "Print Management Step-by-Step Guide" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=50141).

Back to Top

**Microsoft .NET Framework**
New features for .NET Framework 2.0 are available in Windows Server 2003 R2.

**Microsoft .NET Framework 2.0**
The .NET Framework version 2.0 is the latest version of the .NET Framework, a Windows component for building, deploying and running applications. The .NET Framework 2.0 is focused on delivering developer productivity, operational excellence, and the ability to preserve and enhance existing software investments. Core enhancements include support for 64-bit processors for increased performance and scalability, transactional enhancements and optimizations, productivity improvements in ASP.NET, and support for WS-I BP 1.1 and SOAP 1.2 with Web Services.

For a comprehensive list of the new .NET Framework 2.0 features, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=50322).

Back to Top

**Internet and E-Mail Services and Features**
Windows SharePoint® Services is included in Windows Server 2003 R2.

**Windows SharePoint Services**
Microsoft Windows SharePoint Services is an integrated portfolio of collaboration and communication services designed to connect people, information, processes, and systems both within and beyond the organizational firewall. Windows SharePoint Services Service Pack 2 is included in this release of Windows Server 2003. Now you can install Windows SharePoint Services directly from the Configure Your Server wizard or Manage Your Server. When you install Windows SharePoint Services, you get the following features:

**SharePoint sites – file storage plus collaboration**
Web sites based on Microsoft Windows SharePoint Services 2.0 provide a place where teams can communicate, share documents, and work together on a project. SharePoint sites include:

- Team collaboration features, such as event calendars, contacts, Web links, discussions, issues lists, announcements, and much more.
- Document libraries, which are places where users can store and retrieve documents while taking advantage of rich features such as check-in and check-out, version history, custom metadata, and flexible, customizable views.
- Web Parts, which can provide data access, Web services, and many other applications and content to SharePoint sites.

Site users can contribute to the site by using nothing more than a Web browser. However, if users have Windows SharePoint Services-compatible client programs, such as Microsoft Office 2003, installed on their computers they can work seamlessly with the site, saving files to libraries, editing documents in the client program, and moving or linking that information to the

site.

**SharePoint Central Administration – Web browser interface for managing your server**
You can manage a single server or an entire server farm running Windows SharePoint Services from a Web browser interface called SharePoint Central Administration. Use SharePoint Central Administration to extend a virtual server, create sites or turn on Self-Service Site Creation so users can create their own sites, manage security settings, manage the list of servers in your server farm, and so on. If you prefer, you can also use the Stsadm.exe command-line utility to manage your servers running Windows SharePoint Services.

**Applications for Windows SharePoint Services – download and install ready-to-use applications to get working quickly**
Boost worker productivity by downloading and installing an application for Windows SharePoint Services. These applications are tailored to address specific processes or tasks. There are many to choose from, including recruiting, project management, help desk issue tracking, timesheet and scheduling, event planning, and more. Use the applications as soon as you install them or customize them further to meet your organization's specific needs and requirements.

For more information, see "Applications for Windows SharePoint Services" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47987).

**Support for advanced extranet configurations**
A URL zone mapping feature (new in Windows SharePoint Services, Service Pack 2) allows for easier interactions with a proxy server or firewall. Windows SharePoint Services uses absolute URLs to generate some hyperlinks in its Web pages and e-mail messages. This prevented Windows SharePoint Services from supporting certain advanced extranet configurations (such as SSL termination, host header modification, and port translation) where a reverse proxy server is deployed in front of the Windows SharePoint Services server. Now you can set up URL zones, such as Internet, intranet, and extranet, and map incoming and outgoing URLs to those zones, so that these configurations can work correctly.

For more information about Windows SharePoint Services in Windows Server 2003 R2, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45560).

Back to Top

**UNIX Interoperability**
For improved interoperability with UNIX, the following features are available in Windows Server 2003 R2.

**Identity Management for UNIX**
Windows Services for UNIX delivers Windows and UNIX integration with updated identity management solutions. The following solutions help provide uninterrupted user access and efficient management of network resources across operating systems:

- **Server for NIS.** Helps integrate Windows and UNIX-based Network Information Service (NIS) servers by enabling an Active Directory domain controller to act as a master NIS server for one or more NIS domains.

- **Password Synchronization.** Helps integrate Windows and UNIX servers by simplifying the process of maintaining secure passwords. With Password Synchronization, users do not need to maintain separate passwords for their Windows and UNIX accounts or remember to change the password in multiple locations.

Back to Top

**Subsystem for UNIX-based Applications**
Subsystem for UNIX-based Applications (SUA) is a source-compatibility subsystem for compiling and running custom UNIX-based applications on a computer running a Windows server-class operating system. You can make your UNIX applications fully interoperable with Windows in SUA with little or no change to your original source code.

Subsystem for UNIX-based Applications provides an operating system for Portable Operating System Interface (POSIX) processes. SUA, along with its package of support utilities (such as shells and a telnet client), provides a complete UNIX environment. The package of support utilities includes a comprehensive set of scripting utilities and a software development kit (SDK) designed to fully support the development capabilities of SUA.

SUA also supports case-sensitive file names, job control, compilation tools, and the use of over 300 UNIX commands, utilities, and shell scripts. Because the subsystem installs separately from the Windows kernel, it offers true UNIX functionality without any emulation.

New features in this release include the following:

- **Database (OCI/ODBC) library connectivity.** SUA supports connectivity to Oracle and SQL Server from database

applications by using the Oracle Call Interface (OCI) and the Open Database Connectivity (ODBC) standard.

- **Microsoft® Visual Studio® Debugger Extension for debugging POSIX applications.** SUA includes support for debugging your POSIX processes using Visual Studio IDE.

- **Utilities based on SVR-5 and BSD UNIX environments.** The SUA download package supports two different UNIX environments: SVR-5 and BSD.

- **Support for 64-bit applications.** Using a process called thunking, SUA provides support not only for 64-bit applications running on a 64-bit operating system, but also default support for 32-bit binaries running on a 64-bit operating system.

To download the support utilities, see "Installing and Using Utilities and SDK for UNIX-based Applications" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=38959).

# Step-by-Step Guide for the Distributed File System Solution in Windows Server 2003 R2

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**About This Guide**
Welcome to the Step-by-Step Guide for the Distributed File System (DFS) solution in Microsoft® Windows Server™ 2003 R2. This guide provides system requirements, installation instructions, and step-by-step walkthroughs for deploying the DFS Namespaces and DFS Replication features in the Distributed File System solution in Windows Server 2003 R2 in a lab environment.

If you are not familiar with DFS Namespaces and DFS Replication in Windows Server 2003 R2, we recommend that you read the document titled "Overview of the Distributed File System Solution in Windows Server 2003 R2" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=46801). The overview describes the benefits of DFS Replication and the improvements it offers over File Replication service (FRS). It also describes the DFS Namespaces enhancements exposed in Windows Server 2003 R2. These enhancements, introduced as updated application programming interfaces (APIs) in Windows Server 2003 with Service Pack 1 (SP1), provide easier management and more flexibility for namespaces used in branch offices.

**Lab Requirements**
Two step-by-step sections are provided in this guide. The requirements for completing each of the step-by-step sections are as follows:

**Lab Requirements for Completing the Step-by-Step Guide to Deploying a Namespace**
To complete all tasks in this section, you need a minimum of two servers configured in the test lab as follows:

- One server must run Windows Server 2003 R2. This is the server on which you will install the DFS Management snap-in to perform the tasks in this guide.
- The second server must run Windows Server 2003 SP1 or Windows Server 2003 R2.
- To create domain-based namespaces in these tasks, you must have Active Directory® deployed in the test lab. You must also be a member of the Domain Admins group or have been delegated the ability to create domain-based namespaces. For more information about delegation, see "Security requirements for creating and managing namespaces" in the DFS Management snap-in Help.
- To deploy DFS Replication in the namespace, you must have extended the schema to include the new DFS Replication objects in Active Directory. Refer to the section "Installing Windows Server 2003 R2 and Distributed File System" later in this guide for specific configuration requirements.

You can complete a subset of tasks if you have a single server or if you do not have Active Directory deployed in the test lab.

**Lab Requirements for Completing the Step-by-Step Guide to Deploying DFS Replication**
To complete all tasks in this section, you need to configure the test lab as follows:

- You need a minimum of three file servers. All three servers must have Windows Server 2003 R2 and the DFS Replication service installed. One of the servers must have the DFS Management snap-in installed. Follow the procedures in "Installing Windows Server 2003 R2 and Distributed File System" later in this guide to install the service and snap-in.
- The test lab must have Active Directory installed, and you must extend the schema using the instructions described in "Installing Windows Server 2003 R2 and Distributed File System" later in this guide.

Before beginning either step-by-step section, it is important to review the following requirements and limitations of DFS Replication.

- Servers in a replication group must be in the same forest. You cannot enable replication across servers in different forests.
- Replicated folders must be stored on NTFS volumes.
- On server clusters, replicated folders should be located in the local storage of a node, because the DFS Replication service is not cluster aware and the service will not fail over to another node.
- Antivirus software must be compatible with DFS Replication. Contact your antivirus software vendor to check for compatibility.
- DFS Replication might not work across firewalls because it uses the RPC dynamic endpoint mapper. Additionally, configuring DFS Replication using the DFS Management snap-in does not work when a firewall is enabled. To allow DFS Replication to work through a firewall, you can define a static port using the Dfsrdiag.exe command-line tool.

**Getting Started**

The following sections provide instructions on installing Windows Server 2003 R2 and the DFS Management snap-in.

**Installing Windows Server 2003 R2 and Distributed File System**

During Setup, follow the on-screen prompts to install Windows Server 2003 R2. Refer to the section "Lab Requirements" earlier in this guide for details about which servers must run Windows Server 2003 R2 and which servers can run Windows Server 2003 SP1.

If you plan to use DFS Replication, you must first update the Active Directory schema to install the Active Directory components of DFS Replication. To upgrade the schema, on the schema operations master, run **adprep.exe /forestprep**. The adprep.exe command-line tool is available in the Cmpnents\R2\Adprep folder on the second Windows Server 2003 R2 installation CD.

After Windows Server 2003 R2 is installed and the schema is updated as necessary, you can install the Distributed File System (DFS) components and open the DFS Management snap-in by using the following procedures.

| **Note** |
| --- |
| Two methods for installing Distributed File System are provided. The method using the **Manage Your Server** file server tool allows you to install Distributed File System as a part of the file server role. This method also installs other file server tools, such as File Server Resource Manager and File Server Management. The method using **Add or Remove Programs** allows you to install either the DFS Management snap-in, the DFS Replication Service, or both. |

Use the following procedure if the file server role has not been added.

**To install Distributed File System using Manage Your Server**

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Manage Your Server**.
2. Click **Add or remove a role**.
3. In the **Configure Your Server Wizard**, click **Next**. On the **Server Role** page, click **File Server**, and then click **Next.** Click **Next** again.
4. In the **Add File Server Role Wizard**, click **Next**, and then click **Replicate data to and from this server**. Follow the steps in the wizard to complete the installation. You will be asked to restart the server when the installation is complete.

Use the following procedure if the file server role has already been installed and you see an option called **Update this role** in **Manage Your Server**.

**To update the file server role using Manage Your Server**

1. In **Manage Your Server**, click **Update this role**.
2. In the **File Server Role Wizard**, click **Next**.
3. On the **File Server Environment** page, click **Replicate data to and from this server**.
4. Follow the steps in the wizard to complete the installation. You will be asked to restart the server when the installation is complete.

**To install Distributed File System using Add or Remove Programs**

1. In **Control Panel**, double-click **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**, highlight **Distributed File System**, and then click **Details**.
3. Click all three options, and then click **OK**.

| **Note** |
| --- |
| Installing DFS Management also installs Microsoft .NET Framework 2.0, which is required to run the DFS Management snap-in. |

**To open the DFS Management snap-in**

- Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **DFS Management**.

**Overview of the DFS Management Snap-in**

The DFS Management snap-in is the graphical user interface tool for managing DFS Namespaces and DFS Replication. This snap-in is new and differs from the Distributed File System snap-in in Windows Server 2003. Therefore, before you begin using DFS Namespaces and DFS Replication, you might want to review the components of this snap-in, which are shown in the following figure and described in the sections that follow.

**Console Tree**

The console tree has two nodes, Namespaces and Replication, from which you can manage namespaces and DFS Replication.

**Namespaces node**

The following figure shows the elements under the Namespaces node in the console tree.

As the figure shows, the Namespaces node contains the namespaces you create as well as any existing namespaces you add to the console display. In the previous figure, one namespace is shown, **\\Contoso.com\Public**. Under each namespace is a hierarchical view of folders. Folders that have targets use a special icon to differentiate them from folders that do not have targets.

| **Note** |
| --- |
| If you are not familiar with namespace terminology, see the section "Introduction to Namespaces" later in this guide. |

**Replication node**

The following figure shows the elements under the Replication node in the console tree.

As the figure shows, the Replication node contains the replication groups you create as well as any existing replication groups that you add to the console display. A replication group represents a group of servers that participates in the replication of data. For more information about replication groups, see "Introduction to DFS Replication" later in this guide.

**Details Pane**

The contents of the details pane change according to what you have selected in the console tree. For example, if you select a namespace in the console tree, you see tabs named **Namespace**, **Namespace Servers**, and **Delegation** in the details pane. If you select a replication group, you see tabs named **Memberships**, **Connections**, **Replicated Folders**, and **Delegation**. You can double-click objects in the details pane to view their properties.

**Action Pane**

The Action pane shows two types of tasks: common tasks and tasks that apply to the selected object. If the Action pane is not visible, you can open it using the following steps: click the **View** menu, click **Customize**, and then click the **Action pane** option in the **Customize View** dialog box.

**Step-by-Step Guide to Deploying a Namespace**

The following sections introduce namespaces and walk you step-by-step through the process of deploying a namespace in a test lab. The tasks in these sections are designed for administrators who are new to DFS Namespaces as well as administrators who have experience using DFS in Windows Server 2003 and Windows® 2000 Server. These tasks walk you through deployment steps and point out aspects of the DFS Management snap-in that are new or significantly different from previous DFS management tools.

If you have not used DFS in Windows Server 2003 or Windows 2000 Server, we recommend that you read the introduction section that follows to

learn more about namespaces before you begin the tasks.

**Introduction to Namespaces**

DFS Namespaces allows you to group shared folders located on different servers by transparently connecting them to one or more namespaces. A *namespace* is a virtual view of shared folders in an organization. When you create a namespace, you select which shared folders to add to the namespace, design the hierarchy in which those folders appear, and determine the names that the shared folders show in the namespace. When a user views the namespace, the folders appear to reside on a single, high-capacity hard disk. Users can navigate the namespace without needing to know the server names or shared folders hosting the data.

The path to a namespace is similar to a Universal Naming Convention (UNC) path of a shared folder, such as \\Server1\Public\Software\Tools. If you are familiar with UNC paths, you know that in this example the shared folder, Public, and its subfolders, Software and Tools, are all hosted on Server1. Now, assume you want to give users a single place to locate data, but you want to host data on different servers for availability and performance purposes. To do this, you can deploy a namespace similar to the one shown in the following figure. The elements of this namespace are described after the figure.

- **Namespace server**. A namespace server hosts a namespace. The namespace server can be a member server or a domain controller.

- **Namespace root**. The root is the starting point of the namespace. In the previous figure, the name of the root is Public, and the namespace path is \\Contoso\Public. This type of namespace is known as a domain-based namespace, because it begins with a domain name (for example, Contoso) and its metadata is stored in Active Directory. Although a single namespace server is shown in the previous figure, a domain-based namespace can be hosted on multiple namespace servers.

- **Folder**. Folders help build the namespace hierarchy. Folders can optionally have folder targets. When users browse a folder with targets in the namespace, the client computer receives a referral that directs the client computer to one of the folder targets.

- **Folder targets**. A folder target is a UNC path of a shared folder or another namespace that is associated with a folder in a namespace. In the previous figure, the folder named **Tools** has two folder targets, one in London and one in New York, and the folder named **Training Guides** has a single folder target in New York. A user who browses to \\Contoso\Public\Software\Tools is transparently redirected to the shared folder \\LDN-SVR-01\Tools or \\NYC-SVR-01\Tools, depending on which site the user is in.

To view an online demo that describes the purpose and benefits of Distributed File System in Windows Server 2003, click the link "Distributed File System: Simplifying Complexity" on the Distributed File System and File Replication services page on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=39468).

**Deploying a Namespace**

The tasks in this section walk you through the process of deploying a namespace that looks similar to the namespace shown in the figure that appears in "Introduction to Namespaces" earlier in this guide.

**Task 1: Create a Namespace**

In this task, you create a new namespace using the DFS Management snap-in.

**To create a namespace**

1. In the console tree of the DFS Management snap-in, right-click the **Namespaces** node, and then click **New Namespace**.

2. Follow the steps in the **New Namespace Wizard** and supply the information described in the following table.

| New Namespace Wizard Page | What to Enter |
|---|---|
| **Namespace Server** | Enter the name of the server to host the namespace. The server can be a domain controller or a member server. |
| **Namespace Name and Settings** | In **Name**, type **Public**. |
| **Namespace Type** | If Active Directory is deployed in your test lab and you are a member of the Domain Admins group or have been delegated permission to create domain-based namespaces, choose **Domain-based namespace**. Otherwise, choose **Stand-alone namespace**.<br><br>To learn how a member of the Domain Admins group can delegate permission to create domain-based namespaces, see "Security requirements for creating and managing namespaces" in DFS Management Help. |

| | |
|---|---|
| **Review Settings and Create Namespace** | Click **Create** to create the namespace. |
| **Confirmation** | Click **Close** to close the wizard. |

When the wizard finishes, your new namespace will be added to the console tree. Double-click the **Namespaces** node, if necessary, to view your namespace, which should be similar to the following figure.

To browse the new namespace, type the following command in the Run dialog box, substituting either the server name (if you created a stand-alone namespace) or the domain name (if you created a domain-based namespace) as appropriate:

**** *server_or_domain* **\Public**

**Task 2: Add a Namespace Server**

If you created a domain-based namespace, perform this task to specify an additional server to host the namespace. Doing so increases the availability of the namespace and allows you to place namespace servers in the same sites as users. If you created a stand-alone namespace, you must skip this task because stand-alone namespaces only support a single namespace server.

**To add a namespace server**

1. In the console tree of the DFS Management snap-in, right-click *****domain***\Public**, and then click **Add Namespace Server**.
2. In **Namespace server**, type the name of another server to host the namespace, and then click **OK**.

After you finish this procedure, click the *****domain***\Public** namespace in the console tree and review the contents of the **Namespace Servers** tab in the details pane, which should look similar to the following figure. Notice that two UNC paths are listed. The site of each namespace server is also displayed.

**Task 3: Delegate Management Permissions**

You can delegate management permissions so that users who are not members of the Domain Admins group can create domain-based namespaces, and you can delegate management permissions so that users or groups can manage existing namespaces. In this section, you will delegate permissions to manage the namespace you created in the previous task.

**To delegate permission to manage an existing namespace**

1. In the console tree of the DFS Management snap-in, right-click *****server_or_domain***\Public**, and then click **Delegate Management Permissions**.
2. Type the name of a user or group that you want to manage the namespace, and then click **OK**.

After you finish this procedure, review the contents of the **Delegation** tab in the details pane. It should look similar to the following figure.

Notice that the user or group you added shows "Explicit" in the **How Permission Is Granted** column. "Explicit" means that you can remove the user or group from the delegation list by right-clicking the user or group, and then clicking **Remove**. Any users or groups that show "Inherited" have inherited management permissions from Active Directory, and you cannot remove them from the delegation list using the DFS Management snap-in.

| **Note** |
|---|
| To delegate the ability to create domain-based namespaces, see "Security requirements for creating and managing namespaces" in DFS Management Help. |

**Task 4: Add Folders to the Namespace**

In this task, you add three folders to the namespace. Two of the folders will have folder targets. The hierarchy of the folders you will add is shown in the "Elements of a Namespace" figure earlier in this guide.

**To create a folder named Software in the namespace**

1. In the console tree of the DFS Management snap-in, right-click *****server_or_domain***\Public**, and then click **New Folder**.

2. In **Name**, type **Software**, and then click **OK**.

Note that the previous procedure creates a new folder in the namespace to build depth in the namespace hierarchy. You are not specifying the name of an existing folder, nor will you store data in this folder. This folder will not have folder targets that direct clients to other servers.

After you finish this procedure, the Software folder is added to the console tree as shown in the following figure. (You might need to double-click the *****server_or_domain***\Public** root to display the Software folder.

Next, you add two folders with targets to the namespace. You create one folder named Tools within the Software folder, and you create another folder named Training Guides directly under the root named Public.

**To create a folder named Tools in the namespace**

1. In the console tree of the DFS Management snap-in, right-click the **Software** folder, and then click **New Folder**.

2. In **Name**, type **Tools**.

3. Click **Add** to add a folder target.

4. Click **Browse** to open the **Browse for Shared Folders** dialog box.

5. In **Server**, enter the name of the server that will host the Tools shared folder.

6. Click **New Shared Folder**.

7. In the **Create Share** dialog box, in the **Share name** box, type **Tools**, and then enter the local path where you want the shared folder to be created. If the folder does not exist, you are prompted to create it. Click **OK** to close all dialog boxes.

After you finish this procedure, the Tools folder is added to the console tree as shown in the following figure. (You might need to double-click the Software folder to display the Tools folder.) Notice the icon next to the Tools folder and how it differs from the Software folder's icon. This icon appears next to all folders that have targets to differentiate them from folders that do not have targets.

Now, select the Tools folder and review the contents of the **Folder Targets** tab in the details pane. Notice there is a single path shown. This means that only one server hosts the folder target that corresponds to the Tools folder. If that server becomes unavailable, the shared folder is also unavailable.

To increase the availability of the Tools folder, you can add a second folder target.

**To add a second folder target to the Tools folder**

1. In the console tree of the DFS Management snap-in, right-click the **Tools** folder, and then click **Add Folder Target**.

2. Click **Browse** to open the Browse for Shared Folders dialog box.

3. In **Server**, enter the name of another server that will host the Tools shared folder. Be sure to enter a different server from the one you specified in the previous procedure.

4. Click **New Shared Folder**.

5. In the **Create Share** dialog box, in the **Share name** box, type **Tools**, and then enter the local path where you want the shared folder to be created. If the folder does not exist, you are prompted to create it. Click **OK** to close all dialog boxes.

6. You are prompted to choose whether to create a replication group for these folder targets. For now, click **No**. You will enable DFS Replication on this folder in a later task.

**To create a folder named Training Guides in the namespace**

1. In the console tree of the DFS Management snap-in, right-click *****server_or_domain***\Public**, and then click **New Folder**.

2. In **Name**, type **Training Guides**.

3. Click **Add** to add a folder target.

4. Click **Browse** to open the Browse for Shared Folders dialog box.

5. In **Server**, enter the name of the server that will host the Training Guides shared folder.

6. Click **New Shared Folder**.

7. In the **Create Share** dialog box, in the **Share name** box, type **Training Guides**, and then enter the local path where you want the shared folder to be created. If the folder does not exist, you are prompted to create it. Click **OK** to close all dialog boxes.

When you finish these procedures, your namespace will look like the following figure.

**Task 5: Change How Targets Are Ordered in Referrals**

In this task, you change settings that optimize how targets are ordered in referrals. If you are not familiar with referrals, a *referral* is a list of targets that a client computer receives from a domain controller or namespace server when the user accesses a namespace root or folder with targets in the namespace. The referral tells the client which servers host the associated root target or folder target. So, for example, when a client navigates to *server_or_domain*\Public, the client receives a root referral that contains a list of root targets on the namespace servers. When the client then navigates to the Tools folder, which has folder targets, the client receives a folder referral that contains a list of folder targets that correspond to the Tools folder.

When a client requests a referral, the Distributed File System service takes into account the site of the client and the site of the target and provides a referral with targets that are ordered according to the current referral ordering method. By default, targets in a client's site are listed first in a referral in random order, followed by a list of targets outside of the client's site, sorted by lowest cost.

To fine-tune how targets outside of a client's site are ordered, you can change the ordering method for an entire namespace or for individual folders with targets. Changing the ordering method is an important consideration in namespaces whose targets span sites. For example, there might be situations in which you want to prevent the client from accessing targets outside of its own site. If so, you can configure the namespace root or folder with targets so that clients receive referrals only for targets within their own site.

To further optimize how targets are listed in referrals, you can set target priority, which overrides the ordering method. For example, you can specify that a target is always first or last in a referral, regardless of the client's site, or you can specify that a target is always first or last among the targets that have the same connection cost. One common scenario for using target priority is when you have a "hot standby" server that is considered the server of last resort. In this scenario, you can specify that the standby server always appears last in referrals, and clients will fail over to this server only if all the other servers fail or become unavailable due to network outages.

In the following procedures, you verify the referral ordering method for the namespace and choose target priority of a folder target.

**To verify the referral ordering method for a namespace**

1. In the console tree of the DFS Management snap-in, right-click *****server_or_domain***\Public**, and then click **Properties**.

2. On the **Referrals** tab, in **Ordering method**, verify that **Lowest cost** is selected.

In the lowest cost ordering method, also called least expensive target selection or site costing in previous documentation, targets in a referral are ordered as follows:

1. Targets in the same site as the client are listed in random order at the top of the referral.

2. Targets outside of the client's site are listed in order of lowest cost to highest cost. Referrals with the same cost are grouped together and within each group the targets are listed in random order.

This method ensures that clients do not traverse expensive wide area network (WAN) links to access targets when lower-cost targets are available. This ordering method works in both stand-alone and domain-based namespaces, as long as all namespace servers and all domain controllers are running Windows Server 2003.

| **Note** |
| --- |
| If you do not want clients to access folder targets outside of their site, you can override the ordering method for individual folders. To do this, right-click a folder with targets in the console tree, click **Properties**, click the **Referrals** tab, and then click **Exclude targets outside of the client's site**. Note that if no same-site targets are available, the client fails to access the folder because no folder targets are returned in the referral. |

In the next procedure, you change the priority of one of the folder targets of the Tools folder.

**To change the priority of a folder target**

1. In the console tree of the DFS Management snap-in, click the **Tools** folder.

2. In the details pane, on the **Folder Targets** tab, right-click one of the folder targets, and then click **Properties**.

3. On the **Advanced** tab, click **Override referral ordering**, and then click **Last among all targets**.

**Task 6: Rename and Move a Folder**

You can use the DFS Management snap-in to rename folders or move folders to another location in the namespace. This is useful if you need to change a folder name or restructure the namespace.

In this task, you rename the Training Guides folder to Training Demos and move it to the Software folder. Currently, your namespace should look similar to the following figure.

**To rename the Training Guides folder**

1. In the console tree of the DFS Management snap-in, right-click the **Training Guides** folder, and then click **Rename Folder**.
2. In the **Rename Folder** dialog box, in **New name**, type **Training Demos**.

**To move the Training Demos folder**

- In the console tree of the DFS Management snap-in, click the **Training Demos** folder, and then drag it to the **Software** folder.

After you finish these procedures, your namespace should look like this:

**Task 7: Replicate a Folder in the Namespace Using DFS Replication**

In this task, you enable DFS Replication on the Tools folder. If you recall from "Task 4: Add Folders to the Namespace," you created two folder targets for the Tools folder. Because users can be directed to either one of the folder targets, you need to ensure that the contents of the folders are kept synchronized.

If you are familiar with File Replication service (FRS) in Windows Server 2003, you know that FRS is only supported in domain-based namespaces. In Windows Server 2003 R2, you can use DFS Replication in both stand-alone and domain-based namespaces. Therefore, you can complete this task regardless of the type of namespace you created in "Task 1: Create a Namespace."

| **Important** |
|---|
| To perform this task, you need to have Active Directory deployed in your test lab environment, and you must be a member of the Domain Admins group or have been delegated the ability to create replication groups to perform this task. |

| **Important** |
|---|
| After you complete this task, replication does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member. |

**To enable DFS Replication on the Tools folder**

1. In the console tree of the DFS Management snap-in, right-click the **Tools** folder, and then click **Replicate Folder**.
2. Follow the steps in the Replicate Folder Wizard and supply the information in the following table.

| Replicate Folder Wizard Page | What to Enter |
|---|---|
| **Replication Group and Replicated Folder Name** | Accept the defaults. |
| **Replication Eligibility** | Accept the defaults. |
| **Primary Member** | If the folder targets are empty, choose either member. If both folder targets contain content, choose the member that has the most up-to-date content. |
| **Topology Selection** | Select **Full mesh.** |
| **Replication Group Schedule and Bandwidth** | Select **Replicate continuously using the specified bandwidth**. |
| **Review Settings and Create Replication Group** | Click **Create** to create the replication group. |
| **Confirmation** | Click **Close** to close the wizard. |
| **Replication Delay** | Click **OK** to close the dialog box that warns you about the delay in initial replication. |

After you finish the previous procedure, navigate to the **Replication** node in the console tree. Notice that a new replication group has been

created, as shown in the following figure.

If you are not familiar with DFS Replication terminology, a *replication group* is a set of servers, known as members, that participates in the replication of one or more replicated folders. A *replicated folder* is a folder that is kept synchronized on each member. When you enable DFS Replication on a folder with targets, the servers that host the folder targets become members of the replication group, and the folder targets are associated with the replicated folder. The name of the replication group matches the namespace path (Contoso.com\Public\Software\Tools), and the name of the replicated folder matches the folder name (Tools).

From the **Replication** node, you can manage aspects of DFS Replication, such as the schedule and bandwidth usage, file and subfolder filters, and the topology (a framework of replication paths between members). On the **Replicated Folders** tab in the details pane, you can also view the namespace path that corresponds to the replicated folder, as shown in the following figure.

If you navigate back to the **Tools** folder in the **Namespaces** node, notice that the **Replication** tab in the details pane shows that the Tools folder is being replicated using DFS Replication.

If one of the folders targets contained data when you enabled DFS Replication, you can verify that replication has completed by clicking the **Folder Targets** tab, right-clicking the folder target that initially held no data, and then clicking **Open in Explorer**. After the initial replication delay, the files in this folder target should match the files in the target that initially held the data.

Another way to view the status of replication is to create a diagnostic report. You will do this in the following task.

**Task 8: Create a Diagnostic Report**

In this task, you create a diagnostic report to check the status of replication. The diagnostic report is an .html file that includes error and warning events, replication statistics, backlogged files, and other information for each member of the replication group.

**To create a diagnostic report**

1. In the console tree of the DFS Management snap-in, under the **Replication** node, right-click the *domain*\Public\Software\Tools replication group, and then click **Create Diagnostic Report**.

2. Follow the steps in the Diagnostic Report Wizard and supply the information in the following table.

| Diagnostic Report Wizard Page | What to Enter |
|---|---|
| **Path and Name** | Accept the defaults. |
| **Members to Include** | Accept the defaults. |
| **Options** | Ensure that **Yes, count backlogged files in this report** is selected, and also click the **Count the replicated files and their sizes on each member** check box. |
| **Review Settings and Create Report** | Click **Create** to create the diagnostic report. |
| **Confirmation** | The wizard closes automatically, and the diagnostic report appears. |

Review the diagnostic report created for the Tools replication group. In particular, take a look at the following sections:

- Note the DFS Replication efficiency savings. This savings will change over time as files are added and changed.

- Review any errors or warnings, if any, for the members. These are typically event log errors that appear in the member's respective DFS Replication event log.

- In the informational section for each member, review the replicated folder status (the status will be "Normal" after initial replication is

complete) and other information. Notice that the primary member will show different statistics from the non-primary member; this is because data originated from the primary member and replicated to the non-primary member during initial replication.

**Task 9: Browse the Namespace**

In this task, you browse the namespace you created and view the referrals in the client's referral cache as you browse portions of the namespace. Viewing referrals cached on the client is useful in troubleshooting scenarios. The following procedures assume you are performing these tasks from a client computer running Windows XP or Windows Server 2003.

**To browse to the namespace root and view the root referral**

1. Click **Start**, click **Run**, type *****server_or_domain***\Public**, and then click **OK**.

   Windows Explorer opens and your view of the namespace looks similar to the following figure:

2. In Windows Explorer, click the **Folders** button to display the Public root in the folder tree.
3. In the folder tree, right-click **Public**, and then click **Properties** to open the **Properties** dialog box.
4. On the **DFS** tab, review the paths listed under **Referral list**. These are the root targets in the root referral that the client received when it accessed *****server_or_domain***\Public**. These should match the root targets you created earlier in this guide. The target marked Active is the target currently connected to your client computer.
5. Click **OK** to close the dialog box.

**To browse to the Tools and Training Demos folders and view their folder referrals**

1. In Windows Explorer, double-click the **Software** folder. You should see two folders, **Tools** and **Training Demos**.
2. Double-click the **Tools** folder to open it.
3. In the folder tree, right-click the **Tools** folder, and then click **Properties**.
4. On the **DFS** tab, review the paths listed under **Referral list**. These are the folder targets in the folder referral that the client received when it accessed *****server_or_domain***\Public\Software\Tools**. These should match the folder targets you created earlier in this guide, and the target you marked as **Last among all targets,** when you set the target priority, should be listed last. The target marked Active is the target currently connected to your client computer.
5. Click **OK** to close the dialog box.
6. Click the **Training Demos** folder in the folder tree to open it.
7. Right-click the **Training Demos** folder in the folder tree, click **Properties**, and then click the **DFS** tab. Notice that only one folder target is listed in the referral list. Your client computer is currently connected to this folder target.

**Task 10: Test Failover**

In this task, disable the network card or turn off the server that hosts one of the root targets for the *****domain***\Public** namespace. Do the same for a server that hosts one of the folder targets for the Tools folder. After the network cards are disabled or the servers are turned off, repeat the procedures in "Task 9: Browse the Namespace." The procedures should work because another server continues to host the *****domain***\Public** namespace and the Tools folder.

**Step-by-Step Guide to Deploying DFS Replication**

This section walks you through the process of deploying DFS Replication in a test lab. Although it is not necessary to have completed the tasks in "Step-by-Step Guide to Deploying a Namespace," it is helpful to complete the previous section first so that you have an existing namespace in which to publish a replicated folder.

**Introduction to DFS Replication**

DFS Replication is the new state-based, multimaster replication engine in Windows Server 2003 R2. Although some DFS Replication concepts and processes are similar to the concepts and processes in File Replication service (FRS), there are several important differences that you should be aware of before you deploy DFS Replication.

**DFS Replication Concepts**

First, let's review the basic concepts of DFS Replication. These concepts—replication groups, connections, members, and replicated folders—are illustrated in the following figure.

As this figure shows, a *replication group* is a set of servers, known as *members*, that participates in the replication of one or more replicated folders. A *replicated folder* is a folder that is kept synchronized on each member. In the previous figure, there are two replicated folders, Projects and Proposals. As data changes in each replicated folder, the changes are replicated across *connections* between the members. The connections between all members form the replication *topology*.

Creating multiple replicated folders in a single replication group simplifies the process of deploying replicated folders, because the topology, schedule, and bandwidth throttling for the replication group are applied to each replicated folder. To deploy additional replicated folders, you can use a short wizard to define the local path and permissions for the new replicated folder. Each replicated folder also has its own settings, such as file and subfolder filters, so that you can filter out different files and subfolders for each replicated folder.

The replicated folders stored on each member can be located on different volumes in the member, and the replicated folders do not need to be shared folders or part of a namespace, though the DFS Management snap-in makes it easy to share replicated folders and optionally publish them in an existing namespace. You will do both in one of the tasks later in this guide.

**What to Expect During Initial Replication**

When you first set up replication, you must choose a primary member. Choose the member that has the most up-to-date files that you want replicated to all other members of the replication group, because the primary member's content is considered "authoritative." This means that during initial replication, the primary member's files will always win the conflict resolution that occurs when the receiving members have files that are older or newer than the same files on the primary member.

The following explanations will help you better understand the initial replication process:

- Initial replication does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

- Initial replication always occurs between the primary member and the receiving replication partners of the primary member. After a member has received all files from the primary member, then that member will replicate files to its receiving partners as well. In this way, replication for a new replicated folder starts from the primary member and then progresses out to the other members of the replication group.

- When receiving files from the primary member during initial replication, the receiving members that contain files that are not present on the primary member move those files to their respective DfsrPrivate\PreExisting folder. If a file is identical to a file on the primary member, the file is not replicated. If the version of a file on the receiving member is different from the primary member's version, the receiving member's version is moved to the Conflict and Deleted folder and remote differential compression (RDC) can be used to download only the changed blocks.

- To determine whether files are identical on the primary member and receiving member, DFS Replication compares the files using a hash algorithm. If the files are identical, only minimal metadata is transferred.

- After the initialization of the replicated folder, the "primary member" designation is removed. Initialization takes place after all files that exist before DFS Replication picks up the configuration are added to the DFS Replication database. The member that was previously the primary member is then treated like any other member and its files are no longer considered authoritative over those of other members that have completed initial replication. Any member that has completed initial replication is considered authoritative over members that have not completed initial replication.

**Deploying DFS Replication**

The tasks in this section walk you through the process of deploying DFS Replication, adding a member to a replication group, publishing a replicated folder in a namespace, and creating a diagnostic report.

**Task 1: Create a Multipurpose Replication Group and Two Replicated Folders**

To enable DFS Replication, you use the **New Replication Group Wizard** to specify the members, topology, and default schedule and bandwidth for the replication group. In this task, you create a replication group named Data Distribution and two replicated folders named Antivirus Signatures and LOB Data.

| **Important** |
| --- |
| When you create a new replication group, replication does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and each member's long polling interval (60 minutes). |

Before you enable replication, you will create two folders on one of the servers to be added to the replication group. You will then add files to the folders.

**Create folders named Antivirus Signatures and LOB Data**

1. On one server, create two separate (non-overlapping) folders named Antivirus Signatures and LOB Data. Add some files to each folder but do not exceed the recommended limits described in "DFS Replication limits" in DFS Management Help.

2. Optionally, you can create the same folders on the second server. You can add the same files or different files from the primary member. If you add the same files, the files will be used for prestaging and will not be re-replicated. If you add files that don't exist on the primary member, those files will be moved to the PreExisting folder on the second member. (This folder is in the DfsrPrivate folder under the replicated folder's local path.) If you want to observe how the primary member's content becomes authoritative during initial replication, use updated versions of the files you added to the primary member. These updated files will be moved to the Conflict and Deleted folder on the non-primary members.

Next, create a replication group to replicate files between the two servers.

**To create a replication group and two replicated folders**

1. In the console tree of the DFS Management snap-in, right-click the **Replication** node, and then click **New Replication Group**.

2. Follow the steps in the New Replication Group Wizard and supply the information in the following table.

| New Replication Group Wizard Page | What to Enter |
|---|---|
| **Replication Group Type** | Select **Multipurpose replication group**. |
| **Name and Domain** | In **Name of replication group**, type **Data Distribution**. |
| **Replication Group Members** | Click **Add** to select at least two servers that will participate in replication. The servers must have the DFS Replication Service installed. |
| **Topology Selection** | Select **Full mesh**. |
| **Replication Group Schedule and Bandwidth** | Select **Replicate continuously using the specified bandwidth**. |
| **Primary Member** | Select the member that has the most up-to-date content that you want to replicate to the other member. |
| **Folders to Replicate** | Click **Add** to enter the local path of the LOB Data folder you created earlier on the first server. Use the name **LOB Data** for the replicated folder name. Repeat this procedure and enter the local path of the **Antivirus Signatures** folder. |
| **Local Path of LOB Data on Other Members** | On this page, you specify the location of the LOB Data folder on the other members of the replication group. To specify the path, click **Edit**, and then on the **Edit Local Path** dialog box, click **Enabled**, and then type the local path of the LOB Data folder. |
| **Local Path of Antivirus Signatures on Other Members** | On this page, you specify the location of the Antivirus Signatures folder on the other members of the replication group. To specify the path, click **Edit**, and then on the **Edit Local Path** dialog box, click **Enabled**, and then type the local path of the Antivirus Signatures folder. |
| **Review Settings and Create Replication Group** | Click **Create** to create the replication group. |
| **Confirmation** | Click **Close** to close the wizard. |
| **Replication Delay** | Click **OK** to close the dialog box that warns you about the delay in initial replication. |

After you finish the New Replication Group Wizard, click the new replication group named **Data Distribution** located under the **Replication** node in the console tree as shown in the following figure:

Notice the four tabs in the details pane: **Memberships**, **Connections**, **Replicated Folders**, and **Delegation**. Each of these tabs displays different details about the selected replication group, its members, and its replicated folders. Review the following details about each tab.

- On the **Memberships** tab, notice that entries on the tab are sorted by replicated folder and that there are two replicated folders listed. For example, the rows under the **Replicated Folder: Antivirus Signatures** heading are the members that host the Antivirus Signatures replicated folder. Double-click a member to view per-member, per-replicated folder properties on the **General**, **Replicated Folder**, and **Advanced** tabs. For example, on the **Advanced** tab, you can view the location and size of the staging folder and Conflict and Deleted folder on the selected member.

- On the **Connections** tab, two connections are listed. Each connection is a one-way replication path, so replication between two members requires two connections that replicate data in the opposite direction. Each connection has a schedule and other settings, such as a check box for enabling or disabling remote differential compression (RDC). Double-click a connection to view its settings.

- On the **Replicated Folders** tab, notice that two replicated folders are listed and that they are not published in a namespace. Double-click a replicated folder to view its properties, such as file and subfolder filters.

- On the **Delegation** tab, review the default users and groups granted permissions to manage the replication group. Any users or groups shown as "Inherited" have inherited management permissions from Active Directory, and you cannot remove them from the delegation list using the DFS Management snap-in.

**Task 2: Add a New Member to a Replication Group**

In this task, you add a third server to the Data Distribution replication group and specify where one of the two replicated folders, Antivirus Signatures, will be stored on the new member. You'll use a new feature in DFS Replication to specify that the LOB Data replicated folder is not replicated to the new member. You also will create a custom schedule that applies only to the connections to and from the new member.

| **Important** |
|---|
| Replication does not begin immediately on the new member. The DFS Replication settings for the new member must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency, the short polling interval (5 minutes) on the new member, and the long polling interval (60 minutes) on existing members. |

**To add a new member to the Data Distribution replication group**

1. In the console tree of the DFS Management snap-in, right-click the **Data Distribution** replication group, and then click **New Member**.

2. Follow the steps in the **New Member Wizard** and supply the information in the following table.

| New Member Wizard Page | What to Enter |
|---|---|
| **New Member** | Enter the name of the server to add to the replication group. The server must have the DFS Replication Service installed. |
| **Local Path of Replicated Folders** | Select the **Antivirus Signatures** replicated folder, click **Edit**, click **Enabled**, and then enter the local path of the replicated folder to be created on the new member. When you close the **Edit Local Path** dialog box, notice that the LOB Data replicated folder shows **<Disabled>**, which means that this replicated folder will not be replicated to the new member. Because you only want the Antivirus Signatures folder to be replicated to the new member, you can ignore the warning message that appears. |
| **Connections** | Under **Available members**, click a member, and then click **Add**. Repeat this step to add the second member. The new member will replicate directly with both existing members. |
| **Replication Schedule** | Select **Custom connection schedule**, and then click **Edit Schedule**. In the Edit Schedule dialog box, click **Details** to expand the schedule, and then select the entry that begins **Sunday 12:00 AM** and then click **Edit**. In the Edit Schedule dialog box, under **Bandwidth usage**, click **128 Mbps**. |

| | |
|---|---|
| **Review Settings and Create Member** | Click **Create** to add the new member to the Data Distribution replication group. |
| **Confirmation** | Click **Close** to close the wizard. |
| **Replication Delay** | Click **OK** to close the dialog box that warns you about the delay in initial replication. |

After you finish the wizard, click **Data Distribution** in the console tree, and then review the contents of the **Connections** tab. It should look similar to the following figure:

Notice that in the **Schedule Type** column, connections to and from the new member show **Custom Connection Schedule** instead of **Replication Group Schedule**. These show **Custom Connection Schedule** because you chose a custom schedule when you added the new member. Creating custom schedules for individual connections allows you to fine-tune the replication interval and bandwidth used when replicating to specific members. Although it isn't obvious in the user interface, each connection marked **Custom Connection Schedule** is a separate schedule. You can modify one schedule marked **Custom Connection Schedule**, but the other custom schedules are not affected.

| **Note** |
|---|
| To change how the items are grouped, click a column heading. For example, to group the items by schedule type, click the **Schedule Type** heading. |

Entries marked **Replication Group Schedule** use the default replication schedule; this schedule is applied to all connections in the replication group that do not have a custom schedule. To modify the default replication schedule, right-click the **Data Distribution** replication group in the console tree, click **Properties**, and then click **Edit Schedule**. To change a connection schedule from a custom connection schedule to the replication group schedule or vice versa, on the **Connections** tab in the details pane, double-click the connection, click the **Schedule** tab, and then click **Replication group schedule** or **Custom connection schedule**.

#### Task 3: Share and Publish Replicated Folders in a Namespace

When you created replicated folders in the previous tasks, you specified the local path of a folder on each member of the replication group. Unless the local path on each server was previously shared, users cannot access the replicated folders after they are created. To make replicated folders available to users, you must share them and, optionally, publish them in an existing namespace.

In this task, you publish the LOB Data replicated folder in the *****server_or_domain***\Public** namespace that you created in the DFS Namespaces step-by-step section. If you did not complete the previous step-by-step section or do not have a namespace in your test lab, skip this procedure.

**To share the LOB Data replicated folder and publish it in a namespace**

1. In the console tree of the DFS Management snap-in, under the **Replication** node, click the **Data Distribution** replication group.
2. In the details pane, click the **Replicated Folders** tab, right-click the **LOB Data** replicated folder, and then click **Share and Publish in Namespace**.
3. Follow the steps in the **Share and Publish Replicated Folder Wizard** and supply the information in the following table.

| **Share or Publish Replicated Folder Wizard Page** | **What to Enter** |
|---|---|
| **Publishing Method** | Select **Share and publish the replicated folder in a namespace**. |

| | |
|---|---|
| **Share Replicated Folders** | For each member that shows **[Shared Folder Needed]** in the **Action** column, select the member, and then click **Edit** to create the new shared folder and adjust shared folder permissions if necessary. If the **Action** column shows **Create shared folder: LOB Data** or **Existing Shared Folder**, you can click **Next**. |
| **Namespace Path** | In **Parent folder in namespace**, type *****server_or_domain***\Public\Software**. |
| **Review Settings and Share Replicated Folder** | Click **Share** to share the replicated folders and publish the LOB Data replicated folder in the namespace. |
| **Confirmation** | Click **Close** to close the wizard. |

After you finish the wizard, review the console tree and the **Replicated Folders** tab in the details pane. First, notice in the console tree that an LOB Data folder was added to the namespace and the folder icon indicates that the folder is replicated, as shown in the following figure.

Next, review the namespace path listed in the **Replicated Folders** tab, which should look similar to the following figure.

You can see that the LOB Data replicated folder is published in a namespace but the Antivirus Signatures replicated folder is not. To access the LOB Data folder in the namespace, in the Run dialog box, type *****server_or_domain***\Public\Software\LOB Data**.

| **Note** |
|---|
| If you want to stop publishing the LOB Data replicated folder in the namespace, you can right-click the replicated folder and then click **Remove from Namespace**. |

#### Task 4: Create a Replication Group for Collection Purposes

In this task, assume that you have a hub server in a central hub or data center location and a branch server in a remote office. The branch server contains folders named Projects and Proposals that are very important to the branch office, but there is a concern that the backups performed at the branch office are performed incorrectly. You want to back up the Projects and Proposals folders from the data center to ensure that the backups are successful.

To accomplish this goal, you will set up a replication group for data collection purposes. This type of replication group consists of two members and one replicated folder for each folder that you want to back up from the hub server at the data center. The permissions that are set on the replicated folders on the branch server will be applied to the replicated folders on the hub server. You specify a single folder on the hub server under which subfolders for the replicated folders will be created. This allows you to back up multiple replicated folders from a single location on the hub server.

| **Important** |
|---|
| When you create a new replication group, replication does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and each member's long polling interval (60 minutes). |

**To create a replication group to replicate the Projects and Proposals folders from a branch server to a hub server**

1. In Windows Explorer or from the command prompt, create a folder named **Projects** and a folder named **Proposals** on a server that will act as the branch server. The folders should be separate folders (that is, not nested in one another).
2. Add some data to the **Projects** and **Proposals** folders on the branch server.
3. In Windows Explorer or from the command prompt, create a folder named **Branch_Backups** on a server that will act as the hub server. Do not put data in this folder.
4. In the console tree of the DFS Management snap-in, right-click the **Replication** node, and then click **New Replication Group**.
5. Follow the steps in the **New Replication Group Wizard** and supply the information in following table.

| New Replication Group Wizard Page | What to Enter |
|---|---|

| | |
|---|---|
| **Replication Group Type** | Select **Replication group for data collection**. |
| **Name and Domain** | In **Name of replication group**, type **Branch Backups**. |
| **Branch Server** | Type the name of a server that will act as the branch server. |
| **Replicated Folders** | Click **Add**. In the **Add Folder to Replicate** dialog box, type the local path of the Projects folder you created in Step 1. Repeat this step for the local path of the Proposals folder. |
| **Hub Server** | Type the name of a server that will act as the hub server. This is the server where you can back up the Projects and Proposals folders using backup software. |
| **Target Folder on Hub Server** | In **Target folder**, type the path of the folder you created in Step 3. |
| **Replication Group Schedule and Bandwidth** | Select **Replicate continuously using the specified bandwidth**. |
| **Review Settings and Create Replication Group.** | Click **Create** to create the replication group. |
| **Confirmation** | Click **Close** to close the wizard. |
| **Replication Delay** | Click **OK** to close the dialog box that warns you about the delay in initial replication. |

After you finish the wizard, click the **Branch Backups** replication group in the console tree and view the **Memberships** tab in the details pane. Notice that two replicated folders were created, **Projects** and **Proposals**, as shown in the following figure:

In the previous figure, notice that the path of the Projects and Proposals replicated folders on server BO-08 (the hub server) are both within the C:\Branch_Backups folder. This allows you to back up both replicated folders from a single location on the hub.

#### Task 5: Create a Diagnostic Report

In this task, you create a diagnostic report to check the status of replication. The diagnostic report is an .html file that includes error and warning events, replication statistics, backlogged files, and so forth for each member of the replication group.

**To create a diagnostic report**

1. In the console tree of the DFS Management snap-in, under the **Replication** node, right-click the **Branch Backups** replication group, and then click **Create Diagnostic Report**.
2. Follow the steps in the Diagnostic Report Wizard and supply the information in the following table.

| Diagnostic Report Wizard Page | What to Enter |
|---|---|
| **Path and Name** | Accept the defaults. |
| **Members to Include** | Accept the defaults. |
| **Options** | Ensure that **Yes, count backlogged files in this report** is selected, and also click the **Count the replicated files and their sizes on each member** check box. |
| **Review Settings and Create Report** | Click **Create** to create the diagnostic report. |
| **Confirmation** | The wizard closes automatically, and the diagnostic report appears. |

Review the diagnostic report created for the Tools replication group. In particular, take a look at the following sections:

- Note the DFS Replication efficiency savings. This savings will change over time as files are added and changed.
- Review any errors or warnings, if any, for the members. These are typically event log errors that appear in the member's respective DFS Replication event log.
- In the informational section for each member, review the replicated folder status (the status will be "Normal" after initial replication is

complete) and other information. Notice that the primary member will show different statistics from the non-primary member; this is because data originated from the primary member and replicated to the non-primary member during initial replication.

# Extending Your Active Directory Schema in Windows Server 2003 R2

Applies To: Windows Server 2003 R2

The schema defines objects and attributes and the types of data they can store for Active Directory. You can extend the schema to support new operating system features and applications, or to add RFC-defined attributes that are commonly found in other Lightweight Directory Access Protocol (LDAP) directories. You might also extend the schema so that the directory can store information that is interesting to your organization.

Extending the schema for a new operating system version is a two-phase operation that consists of a one-time schema extension on the domain controller that hosts schema operations master role (an operations master is also known as flexible single master operations or FSMO), and a one-time update on the domain controller that holds infrastructure master role in each domain in the forest. Both operations are performed with the ADPREP tool located on Windows Server 2003 R2 Disc 2.

These topics focus on using the adprep /forestprep command to add the Windows Sever 2003 R2 schema extensions that are required to support the following Windows Server 2003 R2 features or server roles:

- Distributed File System (DFS) Replication Service
- Domain controllers running Windows Server 2003 R2
- Identity Management for UNIX
- The Deployed Printers functionality of the Print Management console

These schema additions are automatically installed when you use Windows Server 2003 R2 installation media to create the first domain controller in a new Active Directory forest. However, if you are planning to add a domain controller that runs Windows Server 2003 R2 to an existing forest, you must extend the schema first. The following topics explain the Windows Server 2003 R2 schema update, interoperability considerations for x86-based versions and x64-based versions of Windows Server 2003 R2, and the steps for extending the schema:

- Active Directory Schema Update
- Interoperability of Adprep for x86-based Versions and x64-based Versions of Windows Server 2003 R2
- Steps for Extending the Schema

# Active Directory Schema Update

Applies To: Windows Server 2003 R2

Updating the Active Directory schema is an irreversible operation that must be performed on the schema master. The adprep /forestprep command adds Windows Server 2003 R2 object classes and attributes to Active Directory so that they can be used by the operating system, server roles, and applications.

You must update the schema before you upgrade an existing domain controller to Windows Server 2003 R2 (using Winnt32.exe) or before you add the Active Directory domain controller role on a computer running Windows Server 2003 R2 by using the Active Directory Installation Wizard (Dcpromo.exe). You must extend the schema before you perform either of these actions for the first time in an existing forest.

Typically, schema updates are approached cautiously because they can only be reversed by a forest recovery. However, Windows Server 2003 R2 schema updates have been designed and tested for compatibility with Windows client, server, and domain controller roles. Adding the Windows Server 2003 R2 schema updates does not affect the compatibility of client or server operating systems that are deployed inside or outside the forest.

You should test the Windows Server 2003 R2 schema updates in a lab environment to ensure they will not conflict with any applications that run in your environment. There should not be any conflicts if your applications use RFC-compliant object and attribute definitions.

Adprep skips redundant updates. Conflicting updates, such as the introduction of duplicate object identifiers, cause Adprep to stop until the conflicts are reconciled by an administrator.

In Windows Server 2003 R2, three new features, and the domain controller server role if you are adding a Windows Server 2003 R2 domain controller to an existing forest, require that you extend the existing schema before you attempt to deploy them. The following table explains why each of these features requires a schema extension.

| **Note** |
| --- |
| Microsoft recommends that you add the Windows Server 2003 R2 schema updates to your existing Active Directory installation before you deploy computers running Windows Server 2003 R2, regardless of whether you plan to use these new Windows Server 2003 R2 features or not. |

| | |
| --- | --- |
| DFS Replication Service | Requires that new object classes be added to the domain directory partition to contain replication groups and content sets. Also requires that new object classes be added to the **computer** object class in the domain directory partition to contain computer-specific settings to support Distributed File System (DFS) replication. |
| Domain controller server role | Requires new object classes be added to support objects that are defined for new features in Windows Server 2003 R2. |
| Identity Management for UNIX | Requires new object classes to represent items in a Network Information Service (NIS) map. |
| The Deployed Printers functionality of the Print Management console | Requires a new object class to contain information about printers so that their connections can be deployed through Group Policy. |

When you run adprep /forestprep to add the Windows Server 2003 R2 schema updates, you do not have to upgrade your existing domain controllers to Windows Server 2003 R2; they can continue to run Windows NT® Server 4.0, Windows® 2000 Server, or Windows Server 2003. Note, however, that Identity Management for UNIX must be installed on a Windows Server 2003 R2 domain controller. DFS Replication Service and Print Management Console can run on any computer that runs Windows Server 2003 R2.

The new object classes and attributes for the Windows Server 2003 R2 schema update are defined in a file named Sch31.ldf, which is located in the \cmpnents\R2\adprep folder on the Windows Server 2003 R2 Disc 2 (not in the \I386 folder of the Windows Server 2003 R2 Disc 1). You can view Windows Server 2003 R2 .ldf files in a text editor, but under no circumstances should their contents be modified. Modification of the .ldf files can cause irreversible changes and forest-wide failure. Use the

A**dprep** command to make all schema updates. Do not use import tools such as LDIFDE to import the Windows Server 2003 R2 .ldf files.

# Interoperability of Adprep for x86-based Versions and x64-based Versions of Windows Server 2003 R2

Applies To: Windows Server 2003 R2

You must run the version of Adprep that is compatible with the version of the Windows server operating system that is running on the schema operations master. Specifically, you must run the x86-based version of Adprep on an operations master that runs an x86-based version of Windows. Similarly, you must run the x64-based version of Adprep on an operations master that runs an x64-based version of Windows.

| **Windows server version running on the schema master** | **Version of Windows Server 2003 R2 Adprep that must be run to extend the schema** |
|---|---|
| x86-based version | x86-based version of Windows Server 2003 R2 Adprep.exe |
| x64-based version | x64-based version of Windows Server 2003 R2 Adprep.exe |
| IA64-based version | IA64-based version of Windows Server 2003 R2 Adprep.exe |

Windows Server 2003 R2 Disc 2 includes a single version of Adprep that is compatible with the operating system architecture for that version of Windows (either x86-based or x64-based).

If you have another domain controller that runs a compatible version of Windows but that domain controller does not hold the schema operations master role, transfer the role to that domain controller and then run the adprep /forestprep command that is on Windows Server 2003 R2 Disc 2.

If the version of Adprep on the Windows Server 2003 R2 Disc 2 is not compatible with your current schema master or your other domain controllers that might host the role, see article 919151 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82345) to obtain a version of Adprep that is compatible with the version of Windows that runs on your schema master.

**Example**

An administrator attempts to deploy the first Windows Server 2003 R2 x64-based domain controller, or a Windows Server 2003 R2 feature, in an existing forest that contains domain controllers that run only x86-based versions of Windows 2000 and Windows Server 2003.

When the administrator runs x64-based version of Windows Server 2003 R2 adprep /forestprep from Disc 2 on the x86-based schema master, the adprep /forestprep command fails with the error "Adprep.exe is not a valid 32 bit application."

Because the x64-based version of Windows Server 2003 R2 Disc 2 only contains the x64-based version of Adprep and there is no x-64-based domain controller that can host the schema master role, the administrator must run an x86-based version of Adprep. In this case, the administrator must obtain hotfix that contains a compatible version of Adprep, as described in article 919151 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82345). There are no charges associated with obtaining the hotfix.

Files with the .ldf file name extension do not depend on the type of processor (x86-based or x64-based) on the schema master. These files run on all versions of Windows Server 2003 R2.

# Steps for Extending the Schema

Updated: September 28, 2009

Applies To: Windows Server 2003 R2

Before you install one of the new features that is described in Active Directory Schema Update or before you add a domain controller running Windows Server 2003 R2 to a forest for the first time (unless it is the first domain controller in a new forest), you must first extend the schema with the Adprep tool. Perform the following steps to extend the schema:

- Verify Active Directory functionality before you apply the schema extension
- Apply the schema extension
- Verify the schema extension

**Verify Active Directory functionality before you apply the schema extension**

Verify Active Directory functionality before you update the schema to help ensure that the schema extension proceeds without error. At a minimum, ensure that all domain controllers for the forest are online and performing inbound replication.

**To verify Active Directory functionality before you apply the schema extension**

1. Log on to an administrative workstation that has the Windows Support Tool Repadmin.exe installed.

   | Note |
   | --- |
   | The Support Tools are located on the operating system installation media in the Support\Tools folder. |

2. Open a command prompt, and then change directories to the folder in which the Windows Support Tools are installed.
3. At a command prompt, type the following, and then press ENTER:

   **repadmin /replsum /bysrc /bydest /sort:delta**

   All domain controllers should show **0** in the **Fails** column, and the largest deltas (which indicate the time that has elapsed since the last successful replication) should be less than or roughly equal to the replication frequency of the site link that is used by the domain controller for replication. The default replication frequency is 180 minutes.

For more information about additional steps that you can take to verify Active Directory functionality before you apply the schema extension, see article 325379 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=71057).

**Apply the schema extension**

Use the following procedure to apply the Windows Server 2003 R2 schema extension to the Active Directory schema. In this procedure, you run the version of Adprep.exe that is included in the Windows Server 2003 R2 installation media on an existing domain controller (the schema operations master) in your forest.

**To apply the Windows Server 2003 R2 schema extension to the Active Directory schema**

1. Log on to the computer that holds the schema master operations role (also known as flexible single master operations or FSMO) as a member of the Schema Admins group and the Enterprise Admins group. If you are not sure which computer holds the schema master operations role, type the following at a command prompt, and then press ENTER:

   **netdom query FSMO**

   | Note |
   | --- |
   | The built-in Administrator account in the forest root domain is a member of the Schema Admins group by default. |

2. Verify that the schema master has performed inbound replication of the schema directory partition since the last time that the server restarted. Type the following at a command prompt, and then press ENTER:

   **repadmin /showrepl**

3. Locate the version of Adprep, either in the \cmpnents\R2 folder of the Windows Server 2003 R2 Disc 2 or from Microsoft hotfix 919151, that is compatible with the version of Windows that runs on your schema master.

   Each version of Windows Server 2003 R2 (x86-based or x64-based) ships with a single version of Adprep on Disc 2 that is compatible only with operation masters that run that version of Windows Server 2003 R2 (x86-based or x64-based).

   If your schema master is running run an x86-based version of Windows, run the x86-based version of Adprep.

   If your schema master is running run an x64-based version of Windows, run the x64-based version of Adprep.

   If your schema master does not run a version of Windows that is compatible with the version of Adprep that you plan to run, but your forest contains a domain controller that does run a compatible version of Windows, transfer the schema master role to that domain controller. Continue to step 4, and transfer the role back to the original role holder after the schema update is complete.

   If you do not have a compatible domain controller, obtain the hotfix described in article 919151 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82345).

   To determine the version of the Windows operating system that is running on the schema master, type the following at a command prompt, and then press ENTER:

   **winver**

| **Important** |
| --- |
| Be sure to use the version of Adprep that is on Windows Server 2003 R2 Disc 2 or hotfix 919151, not the version of Adprep that is on Windows Server 2003 R2 Disc 1. |

4. Run **adprep /forestprep**. Change directories to the location that contains the appropriate Adprep version. Type the following command at the command prompt, and then press ENTER:

   **cd cmpnents\R2\ADPREP**

   **adprep /forestprep**

| **Note** |
| --- |
| When you change the schema on the schema master, the changes are automatically propagated to all other domain controllers in the forest. Therefore, it is not necessary to perform this operation on other domain controllers. Also, there is no need to run **adprep /domainprep** in any child domain where you have already installed a domain controller running Windows Server 2003 with Service Pack 1 (SP1). The necessary domain partition updates were performed when the domain controller running Windows Server 2003 SP1 was installed. |

**Verify the schema extension**

After you run Adprep, you can use the Windows Support tool ADSI Edit to verify the schema extension.

**To verify the schema extension**

1. Log on to an administrative workstation that has ADSI Edit installed.
2. Click **Start**, click **Run**, type **adsiedit.msc**, and then click **OK**.
3. Double-click **Configuration Container**, and then double-click **CN=Configuration,DC=***forest_root_domain*

   where *forest_root_domain* is the fully qualified domain name (FQDN) of your forest root domain.
4. Double-click **CN=ForestUpdates**.
5. Right-click **CN=Windows2003Update**, and then click **Properties**.
6. Verify that the **Revision** attribute value is **9**, and then close the **Properties** dialog box.
7. Double-click **Schema**.
8. Right-click **CN=Schema,CN=Configuration,DC=***forest_root_domain*

where *forest_root_domain* is the FQDN of your forest root domain.

9. Click **Properties**.

10. On the **Attribute Editor** tab, for **Select a property to view**, select **objectVersion**, and verify that the attribute **Value(s)** equals **31**.

# File Server Management Overview

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**File Server Management Overview**
File Server Management provides a centralized tool for managing your file server. A file server provides a central location on your network where you can store and share files with users across your network.

Using File Server Management, you can perform many file server management tasks, such as formatting volumes, creating shares, defragmenting volumes, creating and managing shares, setting quota limits, creating storage utilization reports, replicating data to and from the file server, managing Storage Area Networks (SANs), and sharing files with UNIX and Macintosh systems.

The tasks you can perform depend on the features selected when you installed the file server role. For information about how to install the file server role or to add optional features, see File server role: Configuring a file server in the Configure Your Server online Help (CYS.chm).

The following features are typically loaded with File Server Management:

**Share Folder Management**
Share Folder Management includes:

- **Shared Folders**

  Shared Folders enables you to manage shared resources over a network. With Shared Folders, you can:

  - Control user access permissions, session activity, and shared resource properties.
  - Create, view, and set permissions for shared resources.
  - View a summary of connections and resource use for local and remote computers.
  - View a list of all users who are connected over a network to the computer and disconnect one or all of them.
  - View a list of files that are opened by remote users and close one or all of the open files.

**Disk and Volume Management**
Disk and Volume Management includes:

- **Disk Defragmenter**

  Disk Defragmenter analyzes local volumes and consolidates, or defragments, fragmented files and folders so that each occupies a single, contiguous space on the volume. As a result, your system can access files and folders and save new ones more efficiently. By consolidating your files and folders, Disk Defragmenter also consolidates a volume's free space, making it less likely that new files will be fragmented. The process of consolidating fragmented files and folders is called defragmentation. Disk Defragmenter can defragment volumes that are formatted with the file allocation table (FAT) file system, the FAT32 file system, and the NTFS file system.

- **Disk Management**

  Disk Management is a system utility for managing hard disks and the volumes or partitions that they contain. With Disk Management, you can initialize disks, create volumes, format volumes with the FAT, FAT32, or NTFS file systems, and create fault-tolerant disk systems. Disk Management enables you to perform most disk-related tasks without restarting the system or interrupting users; most configuration changes take effect immediately.

**File Server Resource Manager**
File Server Resource Manager includes:

- **Quota Management**

  Quota management allows you to create quotas to limit the space allowed for a volume or folder and generate notifications when the quota limits are approached or exceeded. You can also define quota templates that can be easily applied to new volumes or folders and that can be used across an organization and auto apply quota templates to all existing folders in a volume or folder, as well as to any new subfolders created in the future.

- **File Screening Management**

  With File Screening Management you can create file screens to control the types of files that users can save and to send notifications when users attempt to save blocked files, define file screening templates that can be easily applied to new volumes or folders and that can be used across an organization, and create file screening exceptions that extend the flexibility of the file screening rules.

- **Storage Reports Management**

  Storage Reports Management enables you to schedule periodic reports that help you to identify trends in disk usage. You can also monitor attempts to save unauthorized files for all users or a selected group of users.

**DFS Management**

DFS Management includes:

- **DFS Management snap-in**

  You can use the DFS Management snap-in to configure and manage the two technologies in the Distributed File System solution: DFS Namespaces and DFS Replication. Together, you can use these technologies to collect and distribute data and for loose collaboration.

- **DFS Namespaces**

  You can create a namespace to group shared folders located on different servers and present them to users as a virtual tree of folders. A namespace provides numerous benefits, including increased availability of data, load sharing, and simplified data migration. When browsing the namespace, users see a single folder and are not aware the folder is hosted by multiple servers. When a user opens the folder, the client computer is automatically referred to a server in its own site; if no same-site servers are available, you can configure the namespace to refer the client to a server that has the lowest connection cost as defined in the Active Directory® directory service.

- **DFS Replication**

  DFS Replication is a new multimaster replication engine that is used to keep folders synchronized on multiple servers. Replicating data to multiple servers increases data availability and gives users in remote sites fast, reliable access to files. DFS Replication uses a new compression algorithm known as remote differential compression (RDC). RDC is a “diff over the wire” protocol that can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, re-arrangements of data in files, enabling DFS Replication to replicate only the deltas (changes) when files are updated.

# IIS 6.0 Content Revision Summary

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1

This topic summarizes the changes made to the content in the IIS 6.0 Deployment Guide, the IIS 6.0 Operations Guide, and the IIS 6.0 Technical Reference since the original release of the documentation.

The table below gives a description of the area that each change affects.

| Area | Description |
|---|---|
| Application Configuration | Provides information about changes made to IIS 6.0 content about configuring applications. |
| Architecture | Provides information about changes made to IIS 6.0 content about IIS architecture. |
| Error Messages | Provides information about changes made to IIS 6.0 content about error messages. |
| Installation | Provides information about changes made to IIS 6.0 content about installation of IIS. |
| Introduction/Overview | Provides information about changes made to introductory content about IIS 6.0. |
| Logging | Provides information about changes made to IIS 6.0 content about logging. |
| Performance | Provides information about changes made to IIS 6.0 content about performance and scalability. |
| Reference | Provides information about changes made to IIS 6.0 reference content, such as metabase properties, registry entries, etc. |
| Security | Provides information about changes made to IIS 6.0 content about security. |
| Server Administration | Provides information about changes made to IIS 6.0 content about administering an IIS server. |
| Site Administration | Provides information about changes made to IIS 6.0 content about Web sites, Web directories, File Transfer Protocol (FTP) sites, Network News Transfer Protocol (NNTP) sites, and Simple Mail Transfer Protocol (SMTP) sites. |
| Troubleshooting | Provides information about changes made to IIS 6.0 troubleshooting content. |
| Web Applications | Provides information about changes made to IIS 6.0 content about Web applications. |

**Application Configuration**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Deployment Guide | Appendix D: Running 32-bit Applications on 64-bit Windows | Added new appendix with information about using the WOW64 emulator to run 32-bit Web applications on 64-bit Windows. |
| IIS 6.0 Operations Guide | Configuring IIS to Run 32-bit Applications on 64-bit Windows and subordinate topics | Added new topic about configuring IIS to run 32-bit Web applications on 64-bit Windows. |
| IIS 6.0 Operations Guide | Configuring the Maximum Number of Concurrent CGI Requests | Added topic with information about configuring the maximum number of Common Gateway Interface (CGI) requests allowed to run at one time by setting the MaxConcurrentCgisExecuting registry key. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Configuring CGI Application Timeouts | Added topic with information about configuring CGI application time-out values. |
| IIS 6.0 Operations Guide | Configuring ASP.NET Applications in Worker Process Isolation Mode | Updated which **processModel** settings still apply in worker process isolation mode. |
| IIS 6.0 Operations Guide | Configuring Applications to Use COM+ Services | Clarified that some configurations of launch permissions may prohibit COM+ objects from being created, which may affect the running of the app/extension/etc. in which the object resides. |
| IIS 6.0 Operations Guide | Configuring Applications to Use COM+ Services | Corrected list of Windows Components that support Side-by-Side assemblies. |
| IIS 6.0 Operations Guide | Configuring Applications to Use COM+ Services | Added note that batch Logon is required for COM+ server-activated application identities. |
| IIS 6.0 Operations Guide | Installing ISAPI Filters | Added notes for the following issues:<br>• In IIS 6.0, an Internet Server API (ISAPI) filter added at the site level will not load until the Web server has served at least one request to that site, so the filter's status won't display anything until that time.<br>• At the Web site level, you will not see any global filters inherited from the Web server's master properties. |
| IIS 6.0 Operations Guide | Recycling Worker Processes with IIS 6.0 and subordinate topics | Added information about worker process recycling including how it works, when to use it, how to configure it, and logging the recycling events. |

**Architecture**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Technical Reference | Evaluating Application Isolation Modes | Added information about how SF_NOTIFY_READ_RAW_DATA notifications work depending on the application mode in which the server is running. |
| IIS 6.0 Technical Reference | HTTP Protocol Stack | Added a note about improvements made to HTTP.sys for Windows Server 2003 SP1 and a link to the HTTP API in Windows Server 2003 SP1 white paper. |

**Error Messages**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Operations Guide | Configuring Custom Error Messages | Added note that the following errors are not customizable: 400, 403.9, 411, 414, 500, 500.11, 500.14, 500.15, 501, 503, 505. |
| IIS 6.0 Operations Guide | Error Messages in IIS 6.0 | Added note that HTTP.sys does not serve custom errors, so standard HTTP 1.1 error messages will be returned to the browser if a request does not reach user mode. |

**Installation**

| Content Type | Topic | Description |
|---|---|---|

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Installing IIS | Added link to information about answer files and unattended setup parameters in the IIS 6.0 Technical Reference. |
| IIS 6.0 Technical Reference | Creating an Answer File | Documented the following unattended setup parameters:<br>• *InetPrint*<br>• *SvcManualStart*<br>• *ExtensionFile* |

**Introduction/Overview**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Deployment Guide | IIS 6.0 Benefits and Features | Added information about HTTP compression. |
| IIS 6.0 Deployment Guide | Appendix C: Choosing a Cluster Technology for IIS 6.0 and subordinate topics | Added topics with information about the different clustering technologies available for IIS 6.0, and included links for additional information. |
| IIS 6.0 Operations Guide | What's Changed | Clarified the meaning of "extension" in the context of the Known Extensions feature of IIS 6.0, and added information about how to lock down DLLs, executables, and file name extensions. |
| IIS 6.0 Operations Guide | What's Changed<br>Does ASP debugging work in IIS 6.0 worker process isolation mode?<br>Important Changes in ASP | Added information about configuring Launch and Access permissions to enable ASP debugging for Script Debugger and Visual InterDev when using IIS 6.0 Worker Process Isolation mode. |

**Logging**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Operations Guide | Enabling W3C Centralized Logging | Added topic describing how to enable W3C centralized logging. |
| IIS 6.0 Operations Guide | Auditing the Metabase | Added new topic with information about auditing in the IIS metabase. |
| IIS 6.0 Operations Guide | Auditing in IIS 6.0 | Added link to information about disabling auditing of successful logons in the security event log. |
| IIS 6.0 Technical Reference | W3C Centralized Logging | Added topic about the new W3C centralized logging feature. |
| IIS 6.0 Technical Reference | Metabase Auditing | Added new topic with information about auditing in the IIS metabase. |

**Performance and Scalability**

| Content Type | Topic | Description |
|---|---|---|

| | | |
|---|---|---|
| IIS 6.0 Deployment Guide | Enabling HTTP Compression IIS 6.0<br><br>Configure Compression | Added topics with information about HTTP compression. |
| IIS 6.0 Operations Guide | Using HTTP Compression<br><br>Enabling HTTP Compression<br><br>Customizing the File Types IIS Compresses | Added topics with information about HTTP compression. |
| IIS 6.0 Operations Guide | Throttling Bandwidth | Clarified that the value in the **Maximum bandwidth (in kilobytes per second)** box must be at least 1024 Kbps. |
| IIS 6.0 Technical Reference | Events and Conditions That Disable HTTP.sys Response Caching | Added information about uncached responses when accessing a Web site by requesting the root folder with no specific file, and about Web sites with IP Restriction lists. |
| IIS 6.0 Technical Reference | Using HTTP Compression for Faster Downloads | Added information about configuring HTTP compression for individual sites and site elements. |

**Reference**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Operations Guide | NTAuthenticationProviders Metabase Property | Added information about the state of the Integrated Windows Authentication setting following installation of Windows Server 2003 Service Pack 1 (SP1) as part of a slipstream installation of a Windows Server 2003 operating system. |
| IIS 6.0 Operations Guide | MD_ETAG_CHANGENUMBER Metabase Property | Added information about setting this property in an environment with clustered Web servers. |
| IIS 6.0 Operations Guide | AppPoolQueueLength Metabase Property | Added note that the default value of this property changed with Windows Server 2003 Service Pack 1 (SP1) from 4000 to 1000, with a recommendation to lower the value if IIS is already installed on the server prior to applying the service pack. |
| IIS 6.0 Operations Guide | FTP Service Events | Added new FTP Service event message 14401: "The server failed to create a data channel connection to a client on local interface *ip_address*. The FTP data port *port_number* may be in use by another service or application." |
| IIS 6.0 Operations Guide | ConnectionTimeout Metabase Property | Added information about the reasons a connection can be considered inactive and disconnected by IIS. |
| IIS 6.0 Operations Guide | LogEventOnRecycle Metabase Property | Clarified that the flags for this property only determine whether or not IIS will log the type of recycle event in the flag. |
| IIS 6.0 Operations Guide | AspSxsName Metabase Property<br><br>AspAppServiceFlags Metabase Property | Corrected list of Windows Components that support Side-by-Side assemblies. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | ASP Registry Entries | Created the topic ASP Registry Entries and documented the following ASP registry keys:<br>• AspMaxPropertyStringLength<br>• AspMaxResponseHeaderLength<br>• DisableCachedResponseOnUNCAccessFailure<br>• DisableComPlusCpuMetric<br>• DisableOOMRecycle<br>• EnableChangeNotificationForUNC<br>• F5AttackDetectionEnabled<br>• FileMonitoringEnabled<br>• FileMonitoringTimeoutSeconds<br>• HangDetConsecIllStatesThreshold<br>• HangDetEnabled<br>• HangDetRequestThreshold<br>• HangDetThreadHungThreshold<br>• MaxCPU<br>• MaxCSR<br>• ThreadMax |
| IIS 6.0 Operations Guide | MaxProcesses Metabase Property | Removed erroneous information about setting the value of this property to zero in order to create an unmanaged application pool. |
| IIS 6.0 Operations Guide | FTP Service Registry Entries | Documented the following FTP service registry keys:<br>• AnonymousHomeDirInfoGrace<br>• AnonymousHomeDirInfoInterval<br>• CacheAnonymousHomeDirInfo |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Global Registry Entries | Documented the following global registry keys:<br>• DataSetCacheSize<br>• DoDirMonitoringForUNC<br>• ErrorLoggingDir<br>• FileAttributeCheckThreshold<br>• ThreadPoolMaxCPU<br>• ThreadPoolStartDelay<br>• ThreadPoolStartupThreadCount<br>• ThreadPoolMaxContextSwitch<br>• ThreadPoolRefTraceCounter<br>• ThreadPoolExactThreadCount |
| IIS 6.0 Operations Guide | WWW Service Registry Entries | Documented the following World Wide Web Publishing Service (WWW Service) registry keys:<br>• EnableTraceMethod<br>• LogErrorRequests<br>• MaxConcurrentCgisExecuting<br>• UseSharedWPDesktop |
| IIS 6.0 Operations Guide | DisableSocketPooling Metabase Property | Clarified that setting this metabase property has no effect in IIS 6.0, and included link to information about how to use the new utility, Httpcfg.exe, to allow applications to use the same port on different IP addresses. |
| IIS 6.0 Operations Guide | ServerListenTimeout Metabase Property<br><br>ConnectionTimeout Metabase Property<br><br>HeaderWaitTimeout Metabase Property<br><br>MinFileBytesPerSec Metabase Property | Clarified that **ServerListenTimeout** metabase property is not used by the WWW service, but is used by the FTP, SMTP, and NNTP services.<br><br>Added information about using the **ConnectionTimeout**, **HeaderWaitTimeout**, and **MinFileBytesPerSec** metabase properties instead of **ServerListenTimeout** for Web service nodes. |
| IIS 6.0 Operations Guide | SMPProcessorAffinityMask Metabase Property | Added note to warn that setting the **SMPProcessorAffinityMask** property to zero can create an error condition. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Metabase Property Reference | Documented the following metabase properties:<br>• **ServerID**<br>• **LogInUTF8**<br>• **IsapiRestrictionList**<br>• **CgiRestrictionList**<br>• **RestrictionListCustomDesc**<br>• **SuppressDefaultFTPBanner**<br>• **WebDAVMaxAttributesPerElement** |
| IIS 6.0 Operations Guide | Metabase Property Reference | Corrected documentation for the following metabase properties:<br>• **DoDynamicCompression**<br>• **DoStaticCompression**<br>• **HcDoDynamicCompression**<br>• **HcDoStaticCompression**<br>• **IdleTimeout**<br>• **NotDeletable**<br>• **PeriodicRestartTime**<br>• **RevocationURLRetrievalTimeout**<br>• **RevocationFreshnessTime** |
| IIS 6.0 Operations Guide | NotDeletable Metabase Property | Clarified that the **NotDeletable** metabase property is invalid in IIS 6.0. |
| IIS 6.0 Technical Reference | Global Registry Entries | Corrected the following registry key references:<br>• DigestContextCacheTTL<br>• DigestPartialContextCacheTTL<br>• MaxConcurrency<br>• MaxPoolThreads<br>• PoolThreadLimit<br>• ThreadTimeout |

**Security**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Deployment Guide | Reviewing Security Policies, Processes, and Procedures | Corrected Table 3.16, "Firewall and Router Security," to refer to port 445 instead of 455 for NetBIOS/SMB. |
| IIS 6.0 Operations Guide | Using Isolation to Secure Applications | Added topic with information about giving each application pool its own account identity to isolate applications on the Web server. |
| IIS 6.0 Operations Guide | Configuring Subauthentication and subordinate topics | Corrected references to the **AnonymousPasswordSync** metabase property. |
| IIS 6.0 Operations Guide | Encrypting Data When Running WMI–Based Remote Administration Scripts | Added important note that Windows Management Instrumentation (WMI) based scripts must be edited to encrypt authentication credentials and data after upgrading to SP1. |
| IIS 6.0 Operations Guide | Configuring Constrained Delegation for Kerberos | Added information about Kerberos authentication failing with a 401.3 error if not configured properly. |
| IIS 6.0 Operations Guide | Integrated Windows Authentication in IIS 6.0<br><br>Configuring Integrated Windows Authentication in IIS 6.0<br><br>Windows Authentication Provider in ASP.NET<br><br>Authentication in ASP.NET | Added information about the state of the **Integrated Windows Authentication** setting following installation of Windows Server 2003 Service Pack 1 (SP1) as part of a slipstream installation of a Windows Server 2003 operating system. |
| IIS 6.0 Operations Guide | Securing Sites with IP Address Restrictions | Added note about the disabling of the HTTP.sys cache when IP address restriction is used on a Web site. |
| IIS 6.0 Operations Guide | Enabling Kernel-Mode SSL | Added new topic about kernel-mode Secure Sockets Layer (SSL). |
| IIS 6.0 Operations Guide | Basic Authentication in IIS 6.0 | Added information about administering users and adding them to groups with specific permissions when using Basic authentication. |
| IIS 6.0 Operations Guide | Requesting a New Server Certificate from an Online CA<br><br>Configuring SSL on a Web Server or Web Site | Clarified the following issues:<br>• The Web Server Certificate Wizard is used to request new server certificates.<br>• The request file generated by the Web Server Certificate Wizard is saved by default as C:\Certreq.txt.<br>• SSL can be configured for a Web server or a Web site. |
| IIS 6.0 Operations Guide | Installing Server Certificates | Added note that a password must be specified before the certificate can be assigned to a Web server. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Configuring SSL on a Web Server or Web Site | Added note explaining that users will receive an error message when browsing to a site that does not have SSL completely setup and the **Require Secure Channel (SSL)** check box is selected for the site. |
| IIS 6.0 Operations Guide | IIS 6.0 Security Best Practices | Added recommendation to use an encrypted remote connection with WMI-based administration scripts. |
| IIS 6.0 Operations Guide | Mapping Client Certificates with Directory Service Mapping | Added procedure for enabling directory sService mapping. |
| IIS 6.0 Operations Guide | Encrypting Data When Running WMI–Based Remote Administration Scripts | Added topic about establishing an encrypted connection when running WMI-based administration scripts on an IIS server over a remote connection. |
| IIS 6.0 Operations Guide | Configuring Subauthentication and subordinate topics | Corrected references to **AnonymousPasswordSync** metabase property and added IIsWebService node as recommended configurable location. |
| IIS 6.0 Operations Guide | Anonymous Authentication in IIS 6.0 | Clarified that the IUSR_*Computername* account, which is a member of the **Guests** group on computers running IIS, has the same access as members of the **Users** group by default. |
| IIS 6.0 Operations Guide | Configuring SSL on a Web Server or Web Site | Added note that users will receive an error when browsing to a Web site that requires SSL if the process of setting up SSL is not complete. |
| IIS 6.0 Operations Guide | Enabling and Disabling Dynamic Content in IIS 6.0 | Added reminder to disable Web service extensions when features are no longer required. |
| IIS 6.0 Operations Guide | Enabling Web Service Extensions<br><br>Enabling and Disabling Dynamic Content in IIS 6.0 | Added important note that allowing unknown ISAPI extensions or CGI extensions to run on a Web server can leave the server susceptible to attack. |
| IIS 6.0 Operations Guide | Configuring Subauthentication on a New Installation of IIS 6.0<br><br>Configuring Subauthentication in IIS 5.0 Isolation Mode | Added node at which the **AnonymousPasswordSync** metabase property should be set. |
| IIS 6.0 Operations Guide | Creating an Authorization Policy Store in Authorization Manager<br><br>Setting the Scope for the Application | Clarified items in the procedure that must be typed exactly as shown in order for the authorization policy store for IIS 6.0 URL Authorization to be configured successfully. |
| IIS 6.0 Operations Guide | Setting Metabase Properties for URL Authorization | Removed semi-colons from sample script. |
| IIS 6.0 Operations Guide | Adding Urlauth.dll as a New Web Service Extension | Added procedure for adding Urlauth.dll as a new Web service extension. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Adding the IIS Worker Process to the Readers Role | Added procedure for adding the IIS worker process to the **Reader** role. |
| IIS 6.0 Operations Guide | Exporting a Client Certificate for One-to-One Mapping | Added note that client certificate mapping programs for IIS 6.0 and Windows Active directory services accept certificates formatted as either binary or Base-64 encoded. |
| IIS 6.0 Operations Guide | Setting NTFS Permissions for Directories or Files and subordinate topics | Clarified that IIS Manager is used to set permissions on Web sites, directories, and virtual directories, and that to set permissions for individual files you must use a programmatic solution, such as Adsutil.vbs. |
| IIS 6.0 Operations Guide | Advanced Digest Authentication in IIS 6.0<br><br>Digest Authentication in IIS 6.0<br><br>UseDigestSSP Metabase Property | Added note that the WWW service must be restarted for a change in the **UseDigestSSP** metabase property to take effect. |
| IIS 6.0 Operations Guide | Configuring SSL Host Headers<br><br>Obtaining and Installing a Wildcard Server Certificate<br><br>Configuring Server Bindings for SSL Host Headers<br><br>Advanced Digest Authentication | Added new topics that explain how to obtain and install a wildcard server certificate that can be used for Web sites that have the same IP address:port binding, as well as how to use Adsutil.vbs to configure SSL host headers and how to ensure that secure content is not served for an HTTP request. |
| IIS 6.0 Technical Reference | Advanced Digest Authentication | Added information about configuring the registry keys DigestPartialContextCacheTTL and DigestContextCacheTTL. |
| IIS 6.0 Technical Reference | .NET Passport Authentication | Added information about configuring Web sites to conform to .NET Passport privacy guidelines. |
| IIS 6.0 Technical Reference | Digest Authentication | Added information about the issue where logging on with a user principal name (UPN) in the form *username@domain.top-leveldomain* fails. |
| IIS 6.0 Technical Reference | Integrated Windows Authentication | Added information about the state of the **Integrated Windows Authentication** setting following installation of Windows Server 2003 Service Pack 1 (SP1) as part of a slipstream installation of a Windows Server 2003 operating system. |
| IIS 6.0 Technical Reference | Authentication Methods Supported in IIS 6.0 | Added information about the importance of using authentication with IIS when resources on the Web server need to be restricted to approved users, and clarified that IIS goes in order from the most secure to the least secure authentication method when multiple authentication methods are configured. |
| IIS 6.0 Technical Reference | Integrated Windows Authentication | Added information that a user logged on to the local computer as a domain user will not be prompted to authenticate if they access a network computer in that same domain. |
| IIS 6.0 Technical Reference | Controlling Access to a Database on a Web Server | Added topic with information about controlling access to databases from Web applications. |
| IIS 6.0 Technical Reference | Access Control Lists | Added three tables outlining the default Access Control Lists (ACLs) and privileges for the **IIS_WPG** group. |

| | | |
|---|---|---|
| IIS 6.0 Technical Reference | Kernel-Mode SSL | Added topic about running SSL in kernel mode instead of user mode (the default) in Windows 2003 Server SP1. |
| IIS 6.0 Technical Reference | Configuring Application Pool Identity in IIS 6.0 | Added section about the **IIS_WPG** group. |
| IIS 6.0 Technical Reference | SSL and SF_NOTIFY_READ_RAW_DATA Filters | Added information about how SF_NOTIFY_READ_RAW_DATA works with SSL when running worker process isolation mode. |
| IIS 6.0 Technical Reference | Using URL Authorization | Removed semi-colons from sample script. |
| IIS 6.0 Technical Reference | Digest Authentication<br><br>Advanced Digest Authentication | Added note that the WWW service must be restarted for a change in the **UseDigestSSP** metabase property to take effect. |

**Server Administration**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Operations Guide | Configuring Launch Permissions for COM+ Server Objects | Added important note about the IUSR_*computername* and IWAM_*computername* accounts no longer being granted launch permissions to COM+ objects by default after installations of IIS on Windows Server 2003 SP1. |
| IIS 6.0 Operations Guide | Implementing Incremental Web Site Numbering | Added new topic with information about incremental Web site numbering. |
| IIS 6.0 Operations Guide | Renaming a Web Service Extension | Added topic with information about renaming Web Service extensions. |
| IIS 6.0 Operations Guide | Administering Servers Remotely in IIS 6.0 | Mde references to the Remote Administration (HTTP) Tool consistent. |
| IIS 6.0 Operations Guide | Uninstalling IIS | Added topic with procedure on uninstalling IIS. |
| IIS 6.0 Operations Guide | Configuring Application Pool Identity with IIS 6.0 | Added JScript code example to show how to programmatically change the account under which an application pool runs. |
| IIS 6.0 Operations Guide | Setting Active Directory User Isolation Using lisftp.vbs | Changed references to the following parameters:<br>From *FTPDir\|FTPRoot* to *msIIS-FTPDir\|msIIS-FTPRoot*. |
| IIS 6.0 Operations Guide | Reliability Features<br><br>Configuring Web Gardens with IIS 6.0 | Clarified information about how web gardens benefit reliability and performance. |
| IIS 6.0 Operations Guide | Listing IIS Backup Configurations Using lisback.vbs | Added note that **iisback /list** uses Coordinated Universal Time (UTC) for date and time stamps. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Enabling ASP.NET | Added note to clarify the difference between using the Configure Your Server wizard or Add or Remove Programs to install IIS 6.0 and enable ASP.NET. |
| IIS 6.0 Operations Guide | Configuring Application Pool Identity with IIS 6.0 | Added the following procedures:<br>• To change the account under which an application pool runs using the Adsutil.vbs administration script<br>• To programmatically change the account under which an application pool runs |
| IIS 6.0 Operations Guide | Enabling and Disabling Dynamic Content in IIS 6.0 | Added information about needing to enable FrontPage Server Extensions and ASP in order for Visual Studio .NET 2003 applications to work on IIS 6.0. |
| IIS 6.0 Operations Guide | Setting Up Virtual Servers for Clustering | Corrected the procedure step explaining how to copy IIS configuration from one node to other nodes in a server cluster. |
| IIS 6.0 Technical Reference | Configuring Rapid-Fail Protection | Updated information about Rapid-Fail Protection. |
| IIS 6.0 Technical Reference | Creating Application Pools | Removed erroneous reference to an unmanaged application pool. |

**Site Administration**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Deployment Guide | Creating Web Sites and Home Directories<br>Create a Web Site | Added information about storing Web site content in a location where "/bin" will not be part of the requested URL or a 404 error will be returned. |
| IIS 6.0 Operations Guide | Creating Global MIME Types | Added information about creating Multipurpose Internet Mail Exchange (MIME) types for files without extensions, and corrected steps in the procedure. |
| IIS 6.0 Operations Guide | Creating MIME Types for a Web site or directory | Added information about creating MIME types for files without extensions. |
| IIS 6.0 Operations Guide | Editing Global MIME Types<br>Editing MIME Types for a Web site or directory<br>Removing Global MIME Types | Created topics with procedures to edit and remove MIME types. |
| IIS 6.0 Operations Guide | Removing Global MIME Types<br>Removing MIME Types from a Web site or directory | Added information about removing MIME types from the registry at HKEY_CLASSES_ROOT\extension after removing the MIME type mapping. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Renaming Virtual Directories | Added new topic about renaming virtual directories. |
| IIS 6.0 Operations Guide | Setting FTP Messages and Directory Output Style | Added procedure for suppressing the default FTP banner using the **SuppressDefaultFTPBanner** metabase property. |
| IIS 6.0 Operations Guide | Redirecting FTP Requests to Directories or Network Shares | Added information and procedure about configuring an FTP site so that users browsing the site can see a directory entry for a virtual directory. |
| IIS 6.0 Operations Guide | Creating FTP Sites Using lisftp.vbs | Added an example and changed references to the following parameters:<br>• From **/domain** *DomainName* to **/ADdomain** *DomainName*.<br>• From **/Admin** [*Domain*\]*User* to **/ADadmin** [*Domain*\]*User*.<br>• From **/AdminPwd** *Password* to **/ADpass** *Password*. |
| IIS 6.0 Operations Guide | Using FrontPage Server Extensions to Extend Web Sites | Clarified that the _vti_bin virtual directory of new FrontPage Server Extensions virtual servers must be assigned to the MSSharePointPool application pool in order to remotely administer a Windows® SharePoint® Services (STS) Web site. |
| IIS 6.0 Operations Guide | Working with MIME Types and subordinate topics | Added important note about not using wildcard MIME types on production servers, and revised wording in procedures about providing valid MIME types. |
| IIS 6.0 Operations Guide | Setting FTP Messages and Directory Output Style | Added note that although the FTP exit message box can contain up to 30,000 characters, the message size is limited to 1024 characters (including the reply code, blank, carriage return, and null). |
| IIS 6.0 Operations Guide | Hosting Multiple Web Sites<br>Naming Web Sites | Added note that host headers for Web sites cannot contain Unicode characters because the Domain Name System (DNS) standard doesn't recognize Unicode characters. |
| IIS 6.0 Technical Reference | Metabase Structure in IIS 6.0 | Added important note about enabling sequential numbering of Web sites in IIS 6.0. |

**Troubleshooting**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Operations Guide | FTP server terminates user connections and returns MSFTPSVC event message 8 | Added topic with information about hosting a high-load FTP site with the FTP anonymous home directory on a UNC share, and receiving FTP service message 8. |
| IIS 6.0 Operations Guide | Cannot launch COM objects with IUSR_computername or IWAM_computername accounts | Added topic with information about the IUSR_*computername* and IWAM_*computername* accounts no longer being granted launch permissions by default on installations of IIS on Windows Server 2003 SP1. |
| IIS 6.0 Operations Guide | UPN logons not accepted by IIS 6.0 server in Windows 2000 domain | Added topic with information about the correct format for logins when the IIS 6.0 server is a member of a Windows 2000 domain, and is configured for both Digest authentication and subauthentication. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Install certificate after deleting the pending certificate request | Added topic with information about how to install a certificate if the pending certificate request was deleted from the server. |
| IIS 6.0 Operations Guide | CGI Processes Will Not Start | Added information about the default anonymous user account, IUSR_*computername*, being denied access to executable programs in the *windir*\System32 folder and how to resolve the problem if failures occur when attempting to call external programs from CGI code. |
| IIS 6.0 Operations Guide | Cannot make immediate request for a Web server certificate | Added topic with information about not being able to request a Web server certificate immediately after installing Certificate Services on a server and configuring it to be either an Enterprise Root certification authority (CA) or a stand-alone certification authority. |
| IIS 6.0 Operations Guide | Client cannot renegotiate request and returns an HTTP 413 error | Clarified that clients may receive an HTTP 413 error when uploading large files if client certificates are enabled on a Web server, Web site, or on individual directories or files on the site. |
| IIS 6.0 Operations Guide | Configuring Custom Error Messages | Added information about storing a custom error URL in the application pool that directs the request to the custom error URL so that the worker process can serve the custom error page successfully. |
| IIS 6.0 Operations Guide | Clients browsing to a Web site receive HTTP 403.4 - Forbidden: SSL is required to view this resource error, but the Web site is not configured to use SSL | Added information about troubleshooting an issue where clients receive an error message about requiring SSL when the Web site is not required to use SSL. |
| IIS 6.0 Operations Guide | Client requests receive a "503: Service Unavailable" error | Updated information about the "503: Service Unavailable" error message, which occurs when the server is unable to process a request, and linked to a topic with more information about increasing the application pool queue length limit when the Httperr.log file includes the 503 error code along with the message "QueueFull". |
| IIS 6.0 Operations Guide | When adding a new Web site, the Web site is not added, and the error message "No more memory is available for security information updates" is displayed (also, error 1131 might appear in the system Event Log) | Added information about issue and steps to correct the problem. |
| IIS 6.0 Operations Guide | All requests with /bin in the URL are rejected and return a 404 error | Added information about issue and steps to correct the problem. |
| IIS 6.0 Operations Guide | Client requests time out or error out | Clarified that **ServerListenTimeout** metabase property is not used by the WWW service, but is used by the FTP, SMTP, and NNTP services. |

| | | |
|---|---|---|
| IIS 6.0 Operations Guide | Requests for static files return 404 error | Added content outlining the following options for serving files with unknown file name extensions:<br>• Add the file name extension to the MIME map on specific Web sites or directories.<br>• Turn off the Known Extensions feature on the specific Web sites or directories.<br>• Turn off the Known Extensions feature on the Web server.<br>• Added important note that turning off Known Extensions on the Web server lessens the security of the server. |
| IIS 6.0 Operations Guide | When attempting to download a file from an FTP site that is hosted on IIS 6.0, a "File not found" or similar error is returned, and the file name in the error message contains a caret (^) character | Added information about issue and steps to correct the problem. |
| IIS 6.0 Operations Guide | Applications are denied access to resources | Added note that when IIS 6.0 worker processes run under the default low-privileged Network Service user account, application events, including CGI events, are written to the Application event log not the System event log. |
| IIS 6.0 Operations Guide | Client receives 403.16 error when IIS cannot process a complete certificate chain | Added information about adding a certificate to the Intermediate Certification Authorities folder on the local computer when the client receives a 403.16 error. |
| IIS 6.0 Operations Guide | Computer runs slowly when scripts using ADSI scripts to query IIS 6.0 | Added information about memory usage when running a program that uses multiple threads and Active Directory Service Interfaces (ADSI) scripts to query Internet Information Services (IIS). |
| IIS 6.0 Operations Guide | Advanced Troubleshooting with IIS Tracing and subordinate topics | Added multiple topics that describe how to configure and execute new IIS tracing features. |
| IIS 6.0 Operations Guide | Tracing Events Reference | Added new topic that describes tracing events available with IIS Admin tracing, IIS Request-based Tracing, and IIS Currently-executing request tracing. |

| | | |
|---|---|---|
| IIS 6.0 Technical Reference | Advanced IIS Troubleshooting with Tracing and Debugging and subordinate topics | Added multiple topics that address the new tracing features in IIS 6.0 SP1. These features include the following:<br>• Currently-executing requests tracing: allows tracing of all requests executing on the IIS server. This tracing feature is helpful when requests have become slow or unresponsive and it is unclear which Web site or application is processing the requests.<br>• Request-based tracing: allows tracing of requests for a specific site or for a specific component of IIS, such as ASP pages. This tracing feature helps narrow troubleshooting efforts to a specific site or IIS component.<br>• IIS Admin tracing: allows tracing of the IIS Admin service during startup and shutdown events. If the IIS Admin service hangs during startup and shutdown, this tracing feature can help determine why. |
| IIS 6.0 Technical Reference | Enabling Debugging for IIS | Replaced the script for OrphanActionExe. |

**Web Applications**

| Content Type | Topic | Description |
|---|---|---|
| IIS 6.0 Operations Guide | ASP.NET Settings Schema Reference | Linked topic to MSDN for information about the individual elements in the schema and removed the subordinate topics. |
| IIS 6.0 Operations Guide | Process Model Modes | Updated which **processModel** settings still apply in worker process isolation mode. |
| IIS 6.0 Operations Guide | What's New in ASP | Corrected list of Windows Components that support Side-by-Side assemblies. |

# IIS 6.0 Typographical Conventions

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1

The following graphics and text conventions are used throughout the IIS 6.0 Deployment Guide and the IIS 6.0 Technical Reference.

**Flowchart Symbols**

Use the following table of symbols as a resource for understanding the flowcharts included in the IIS 6.0 Deployment Guide.

| Symbol | Meaning | Symbol | Meaning |
|---|---|---|---|
| | Step or component process | | Data stored to a database |
| | Predefined process or subroutine | | Flowchart beginning or end |
| | Decision point | 1 | Intra-chart connector: Flow continues to next page |
| | Output to a document or input from a document | 1 | Intra-chart connector: Flow continues from previous page |
| | Data transfer to a file on disk | A | Inter-chart connector: Indicates an exit point to another flowchart |
| | Data transfer to a data store | B | Inter-chart connector: Indicates an entry point from another flowchart |

**Art Symbols**

Use the following table of the art symbols as a resource for understanding the graphics included in this guide.

| Symbol | Meaning | Symbol | Meaning |
|---|---|---|---|
| | Workstation | | Macintosh client |
| | Portable computer | | Tablet computer |
| | Terminal | | Cellular phone |
| | Portable digital assistant (PDA) | | Document |
| | File folder | | E-mail |
| | Chart | | Wireless network adapter |
| | Modem | | Video camera |
| | Network adapter | | Digital camera |
| | Facsimile | | Printer |
| | Telephone | | Scanner |
| | Hard disk | | Tape drive |
| | Database | | Tape |
| | Compact disc | | Security key |
| | Digital certificate | | Padlock |
| | Padlock | | Uninterruptible power supply |

| | | | |
|---|---|---|---|
| | Access token | | Hub |
| | Modem bank | | Automated library |
| | Windows NT–based server | | Generic server |
| | Mainframe computer | | Host |
| | Data jack | | Input/output (I/O) filter |
| | Shadowed router | | Windows 2000–based router |
| | Router | | Switch |
| | Server farm | | Clustered servers |
| | Interface | | Packets |
| | Transceiver | | Script |
| Internet | Internet | Intranet | An intranet |
| | Firewall | | Tunnel |
| | Process or communication failure | “ · ” | DNS root |
| | Directory tree root | | Root |
| | Organization | | Organizational unit |
| | Active Directory domain | | User group |
| | Common name | | Generic node |
| Windows 2000 Domain | Windows 2000 domain | | Site or Windows NT 4.0 domain |
| | Active Directory™ | | |

# Windows Server 2003 Terminal Server Capacity and Scaling Abstract

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Microsoft Windows Terminal Server lets users run Windows-based applications on a remote computer running one of the Windows Server 2003 operating systems. This white paper contains testing methodologies, results, analysis, and sizing guidelines for Windows Server 2003 Terminal Server. See Windows Server 2003 Terminal Server Capacity and Scaling.

# Microsoft IT SP1 Deployment Case Study Abstract

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This case study provides an inside look at how Microsoft Information Technology (Microsoft IT) deployed Microsoft® Windows Server™ 2003 Service Pack 1 (SP1) into the Microsoft global environment. This document describes Microsoft IT's high-level processes for deploying SP1 and the best practices they learned as a result. Microsoft IT minimized the cost of the deployment by planning carefully, creating a ramped rollout schedule, and using an installation sequencer to deploy a standardized software package. IT architects can use this case study to help plan their SP1 deployments.

To view this document, see the Microsoft IT SP1 Deployment Case Study.

# Mixed Workload Consolidation Guide Abstract

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This document provides detailed information you can use to identify appropriate applications for mixed workload consolidation, validate compatibility of applications, and plan for a mixed workload consolidation deployment. This document discusses mixed workload consolidation processes primarily as they pertain to Microsoft Windows Server 2003 Enterprise Edition and Microsoft Windows Server 2003 Data Center Edition, which are the preferred operating systems for mixed workload consolidation.

For information about this topic, see Mixed Workload Consolidation Guide.

# Domain Isolation Planning Guide for IT Managers

Updated: June 8, 2005

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1

Plan your domain isolation using the step-by-step planning information in this guide. This guide is designed to help you work with your IT staff to gather the necessary information, design your IPsec polices, and to create a deployment plan.

This document is intended for IT professionals who are investigating using IPsec in Microsoft® Windows® to deploy domain isolation in their environments. This guide is designed to help you work with your IT staff to gather the necessary information, design your IPsec polices, and to create a deployment plan.

This guide includes an overview of the deployment process, a step-by-step guide to the planning process, and links to other resources that you can use in the planning and design process. The material in this guide covers the planning of the deployment but not the actual deployment process itself.

This guide provides material relevant only to Windows-based computers and is not intended as a guide for deploying domain isolation on operating systems other than Windows. This guide does not provide background information about IPsec and related technologies.

#### Terminology Used in This Guide

These terms are defined so that you can more clearly understand how they are used in this guide:

**Domain isolation** - The use of Internet Protocol security (IPsec) to require authentication, encryption, or both, among members of a Windows domain as well as between members of the domain and unknown or unauthorized computers.

**Isolated host** - A computer that is a member of an isolated domain.

**Non-isolated computer** - A computer that is not a member of an isolated domain.

**Isolated domain** - A domain or network that requires authentication, encryption, or both, by using IPsec before allowing any domain member to communicate with any other computer.

**Boundary computer** - A computer in the boundary group of an isolated domain that accepts secure communication from members of the isolated domain and unsecured communication from computers that are not members of the isolated domain.

**Proxy server** - A firewall component that manages Internet traffic to and from a local area network (LAN) and that can provide other features, such as document caching and access control. A proxy server can improve performance by supplying frequently requested data, such as a popular Web page, and it can filter and discard requests that the owner does not consider appropriate, such as requests for unauthorized access to proprietary files.

#### IT Roles Used in This Guide

The IT roles used in this guide are generalizations derived from the IT industry and should closely approximate those in your IT structure. Your roles might differ from these, but they are offered to help you assign tasks to your staff members.

| Role | Primary Responsibilities |
|---|---|
| IT Manager | Coordinates the deployment effort and communicates status to upper management. Manages the IT staff responsible for the infrastructure, desktop and server deployment, and server administration and operations. Evaluates the impact of the technology solution on core business and IT resources. Uses this guide to assign tasks to staff members, collect and collate information, guide the overall process of planning, and make the major decisions. |
| Systems Architect | Provides information and assists in IPsec policy design. Responsible for designing the overall server infrastructure for all systems. Develops server deployment strategies and policies. Contributes to networking connectivity design. Ensures that deployment policies are followed. Provides overall architectural guidance and assists in designing the isolated domains and policies for establishing these segments. |

| | |
|---|---|
| Security Manager | Provides information, assists in IPsec policy design, and assists IT Manager in planning. Responsible for determining and implementing server security policy. Evaluates new technology and its effects upon security and availability. Responsible for security issues and solutions. Is the primary source of information about what security levels are needed for segments, how segments might be designed around security needs, what current security policies and tools can be made obsolete by domain isolation, and what security concerns might arise in the design and implementation of domain isolation. |
| Windows Systems Administrator | Provides information and implements polices on Windows-based computers. Responsible for determining and implementing server security policy. Evaluates new technology and its effects upon security and availability. Responsible for security issues and solutions. Is the primary source of information about what security levels are needed for segments, how segments might be designed around security needs, what current security policies and tools can be made obsolete by domain isolation, and what security concerns might arise in the design and implementation of domain isolation. |
| UNIX Systems Administrator | Provides information and assists Helpdesk and Security Managers in planning. Responsible for configuration and administration of UNIX servers, including upgrades, backups, capacity monitoring, and planning and interoperability issues with Windows systems. Is the primary source of information about IPsec interoperability between UNIX and Windows. |
| Network Administrator | Provides information and assists in IPsec policy design and implementation. Responsible for overall connectivity for the entire network, including hardware. Manages connectivity between heterogeneous systems (Windows and UNIX). Troubleshoots all performance issues across the network. Provides significant input regarding how the network will influence the design of, or be affected by, IPsec policies. |
| Database Administrator | Provides information and assists in IPsec policy design. Also assists in the configuration and management of database solutions. Evaluates build images, deploys new databases and changes, and conducts server integration testing. Is the primary source of information about how domain isolation might affect database access and performance. |
| Desktop Configuration Manager | Provides information and assists in IPsec policy design and implementation. Responsible for provisioning desktop PCs and deploying service packs and updates to these PCs. Involved in setting the strategic direction for the desktop operating system and applications. Is the primary source of information about how IPsec polices might affect desktop configuration. |
| Helpdesk Manager | Provides information and creates user education and notification materials. Responsible for all Helpdesk operations. Is the primary contact for information about how users might be affected, or respond to, access issues during or after deployment, and how user education can help mitigate any issues that might arise. |

**Introduction to Deployment Planning Phases**

This section provides a brief overview of the different phases involved in the domain isolation planning process. This process is suggested as a way of making domain isolation deployment as effective and efficient as possible and to suggest how you can work with your IT team to gather the needed information, discuss domain isolation issues, create a deployment plan, design IPsec policies, and test/refine these polices to reduce any user and operations issues that might arise from domain isolation.

**Collect Information About Your IT Environment**

You and your team will gather information about network topology, security policy and implementation, server operating systems and applications, service level agreements (SLAs), user types, any interoperability issues or concerns, and regulations or other external constraints. This information will be used along with other information, such as IT polices and guidelines and any business needs, to determine what domain isolation needs you have and then to design the IPsec policies that will be used to fulfill these domain isolation needs.

**Determine Your Domain Isolation Needs**

You and your team will use the collected information and determine what kind of isolation needs you have, based upon business needs, regulatory influences, security requirements, Service Level Agreements, the IPsec technology, user needs, and other factors.

**Design Your IPsec Policies**

This is probably the most crucial phase and requires close attention to the details for designing IPsec filter lists, filter actions, rules, and policies for each segment. Carefully-designed policies will make the deployment process smooth and efficient, the isolation effective, the protection of your assets solid, and it will keep user problems to a minimum while still meeting all SLAs, regulatory requirements, and other criteria.

**Deploy the Policies in a Test Environment**

Your team can test the domain isolation deployment and discover any refinements that should be made to the IPsec policies and the deployment process before deploying to a large or business-critical segment. The test environment can be designed specifically for deployment testing, or it can be a small, non-business-critical domain environment.

**Refine Policies**
The test phase might highlight some connectivity, security, or administration issues that can be addressed by refinements to your IPsec policies, by adjustments in operations and administration, or by improvements in user education. This information is important for a smooth and effective deployment.

**Create a Deployment Schedule**
Once you have completed your plans and IPsec policies, your team can discuss and solidify how, when, and where you will implement domain isolation. This phase is where you can discuss any potential problems with the schedule and agree on the best plan for actual deployment.

**Prepare for User and Infrastructure Support**
Before deployment you can develop plans, documents, and tools to assist your Helpdesk staff to deal with pre-deployment notification and education, user issues during deployment, and any post-deployment issues that might arise as a result of domain isolation deployment.

**Inform Team Members About IPsec**
The planning and design of domain isolation will be more efficient and effective if your team has a good understanding of what IPsec is and how it can be used for domain isolation. The following table lists the type of IPsec information that might be useful before you begin the domain isolation planning phases.

| Action | Owner |
|---|---|
| Review IPsec concepts. | As needed |
| Review examples of domain isolation deployment. | IT Manager, Systems Architect, Security Manager |
| Review IPsec limitations. | IT Manager, Systems Architect, Security Manager, others as needed |
| Review IPsec interoperability information. | IT Manager, Systems Architect, Security Manager, others as needed |

**Phase 1: Collect Information About Your IT Environment**
**Collect Computer Information**
Because not all computers in your environment will implement IPsec the same way, you must document the operating systems and service pack versions on your computers, both servers and desktop computers.

| Action | Owner |
|---|---|
| Identify IPsec-compatible Windows-based computers (Microsoft Windows 2000, Microsoft Windows XP, and Microsoft Windows Server™ 2003). | Windows Systems Administrator |
| Identify IPsec-incompatible Windows-based computers (Microsoft Windows 98, Microsoft Windows Millennium Edition, and Microsoft Windows NT® 4.0). | Windows Systems Administrator, Desktop Configuration Manager |
| Identify IPsec-incompatible computers using operating systems other than Windows (UNIX, BSD UNIX, Macintosh OS X, Linux, IBM OS390, Sun Microsystems Solaris 8, etc.). | UNIX Systems Administrator, Desktop Configuration Manager |

**Collect Network Device Information**
Network devices, such as routers or firewalls, are also involved in the domain isolation, and their IPsec capabilities must be documented to ensure that deployment planning takes them into account.

| Action | Owner |
|---|---|
| Identify IPsec-compatible network devices (Cisco IOS, Lucent VPN Firewall Bricks, Lucent Access Point IP services routers, 3Com SuperStack 3 Firewall, Nortel VPN Gateways, etc.). | Network Administrator |
| Identify IPsec-incompatible network devices - these devices cannot allow IPsec-protected packets to traverse the network. | Network Administrator, Systems Architect, UNIX Systems Administrator |

**Collect Active Directory/Domain Information**
Your IPsec policy design will be strongly influenced by your domain structure. Document your domain structure to identify

organizational and business units that might require different levels of security and other information.

| Action | Owner |
|---|---|
| Document your domain structure. | Systems Architect |
| Document your organizational units (OUs). | Systems Architect, IT Manager |
| Document your global security groups. | Security Manager |

**Collect Regulation and Other External Constraint Information**

Your organization might be affected by regulations that require enhanced security, access to information, or other actions. By being aware of these impacts during the IPsec policy design, you can ensure compliance or plan for compliance issues.

| Action | Owner |
|---|---|
| Identify any government regulations that might affect planning and design. | IT Manager, Security Manager |
| Identify any business partner regulatory requirements that might affect planning and design. | IT Manager |
| Identify any international regulatory requirements that might affect planning and design. | IT Manager |
| Identify any company policies that might affect planning and design. | IT Manager |

**Collect Security Information**

Your IPsec policy design will be strongly influenced by your current security policies and practices, such as firewall configurations. IPsec policies will also affect and expand your security policies.

| Action | Owner |
|---|---|
| Document your firewall configurations. | Security Manager |
| Document logon scripts or policies that might affect IPsec policies. | Security Manager |
| Document your software update policies and processes. | Security Manager |
| Document your application deployment policies. | Security Manager |
| Document your security response plan. | Security Manager |

**Collect Service Level Agreement Information**

Your domain isolation planning process must be designed and deployed in a way that complies with your SLAs. By being aware of these SLAs during the planning and design process, you can ensure compliance or make plans for mitigating and dealing with any compliance problems.

| Action | Owner |
|---|---|
| Identify any internal/direct SLA requirements that might affect planning and design. | IT Manager, UNIX Systems Administrator, Database Administrator, Desktop Configuration Manager, Network Administrator |
| Identify any business partner SLA requirements that might affect planning and design. | IT Manager |
| Identify any international SLA requirements that might affect planning and design. | IT Manager |

**Collect User and Partner Connectivity Information**

You need to consider how domain isolation will affect user connectivity during and after the deployment. This information can guide you in designing and deploying IPsec policies or in training staff and informing users before and after deployment.

| Action | Owner |
|---|---|
| Identify IT administrative staff that must have uninterrupted connectivity. | IT Manager |

| | |
|---|---|
| Identify knowledge workers. | Desktop Configuration Manager |
| Identify Helpdesk staff members that require detailed knowledge of the deployment. | Helpdesk Manager |
| Identify internal or external partners that require uninterrupted connectivity. | IT Manager |
| Document any applications that require uninterrupted connectivity. | Desktop Configuration Manager, Windows Systems Administrator, Database Administrator |
| Identify security personnel that must monitor security during the deployment. | Security Manager |

**Collect Interoperability Information**

Understanding how your IPsec policy design and deployment might affect IPsec-incompatible computers and computers with other implementations of IPsec will help you to plan the security for these computers and to determine how they will connect to IPsec-incompatible computers.

| Action | Owner |
|---|---|
| Identify any servers that are incompatible with the Microsoft implementation of IPsec but must access resources on Windows servers. | UNIX Systems Administrator, Desktop Configuration Manager |
| Identify any Windows servers that are incompatible with servers configured for a non-Microsoft implementation of IPsec but must access resources on these servers. | Windows Systems Administrator |
| Identify any applications that might require IPsec policy exemptions for business reasons. | Desktop Configuration Manager, Windows Systems Administrator |

**Phase 2: Determine Your Domain Isolation Needs**

**Business Needs**

Your IPsec policies must also take into account your business needs and the financial impact that the deployment might have.

| Action | Owner |
|---|---|
| Document how knowledge workers, internal customers, and partners will be affected by domain isolation deployment and the business impact of this. Document how these effects will be mitigated. | Helpdesk Manager, Desktop Configuration Manager, Security Manager |
| Document how the operations infrastructure will be affected by domain isolation deployment and the business impact of this. | Security Manager, Systems Architect, IT Manager |

**Regulation Needs**

Government and international regulations might influence your IPsec policy designs. You should enumerate the regulations and restrictions you must comply with and take these into account during the design phase.

| Action | Owner |
|---|---|
| Document the regulations you must comply with. | IT Manager, Security Manager |
| Determine the time-frame you have to comply. | IT Manager |
| Determine how you can use domain isolation to comply with these regulations. | IT Manager, Security Manager, Systems Architect |

**Security Management Needs**

You might have sensitive data or servers that require additional security in your environment. You should enumerate these and take into account what levels and types of security you want domain isolation to provide.

| Action | Owner |
|---|---|

| | |
|---|---|
| Document any effects of deploying domain isolation upon current security polices. | Security Manager |
| Identify whether any additional security administration will be required. | Security Manager, Desktop Configuration Manager, IT Manager |
| Determine whether any of your current security technologies are incompatible with domain isolation. | Security Manager, Network Administrator, Systems Architect |
| Identify where you will need boundary computers. | Security Manager, Network Administrator, UNIX Systems Administrator |
| Determine and document what additional security methods will be used to protect boundary hosts. | Security Manager, Network Administrator, Systems Architect |

**Service Level Agreement Needs**

During the planning process, determine whether the deployment will negatively affect your SLAs.

| Action | Owner |
|---|---|
| Determine how domain isolation will affect deployment and administration of SLAs. | IT Manager |
| Document how any effects on deployment and administration of SLAs will be measured. | IT Manager |
| Document how any effects on deployment and administration of SLAs will be mitigated or corrected. | IT Manager, Security Manager |
| Determine how any effects upon SLAs will be communicated to the appropriate parties. | IT Manager, Helpdesk Manager |

**IPsec Technology Needs**

Some of the policy design decisions are based on the IPsec technology itself and how it secures traffic and data.

| Action | Owner |
|---|---|
| Document which of the four IPsec-negotiated security modes will be used, where they will be used, and why.<br><br>The four modes are:<br><br>• **Request Mode**. A host responds to both IPsec and unauthenticated (non-IPsec) requests. It initiates communications with IPsec and, if that fails, allows unauthenticated communications.<br><br>• **Secure Request Mode**. A host responds to requests secured by IPsec and ignores unauthenticated requests. It initiates communications with IPsec and, if that fails, returns to unauthenticated communication.<br><br>• **Secure Require Mode**. A host requires IPsec-secured communications for both incoming and outgoing requests.<br><br>• **Default Response**. A host responds to IPsec requests, but never initiates IPsec. | Security Manager |
| Identify where IPsec tunnel mode will be needed. | Security Manager, Network Administrator |
| Identify where data integrity using Authenticated Header (AH) will be needed. | Security Manager, Systems Architect |
| Identify where data integrity and encryption (using ESP) will be needed. | Security Manager, Network Administrator |

| | |
|---|---|
| Document which forms of encryption will be used and where. | Security Manager |
| Document which forms of authentication will be used and where. | Security Manager |
| Identify which infrastructure applications or servers, such as DNS and DCHP servers, will need to be added to the default exemptions so that all clients can access them. | Security Manager, Systems Architect |
| Identify which ports/protocols will need to be opened in firewalls for IPsec. | Security Manager, Network Administrator |
| Identify where no IPsec protection will be needed. | Security Manager, Network Administrator, UNIX Systems Administrator, Desktop Configuration Manager |

**User and Partner Needs**

Your domain isolation design and deployment plans should also take into account how the process might affect the ability of users and partners to access information stored on your network.

| Action | Owner |
|---|---|
| Determine how users might be affected by the deployment. | Helpdesk Manager |
| Determine what user education steps can be taken to prepare users for the deployment and any possible issues resulting from it. | Helpdesk Manager |
| Determine how partners might be affected by the deployment. | IT Manager |
| Determine what steps can be taken to prepare partners for the deployment and any possible issues resulting from it. | IT Manager, Helpdesk Manager |

**Interoperability Needs**

If your environment includes computers that either cannot implement IPsec or whose implementation of IPsec is not the same as the Microsoft implementation, then you need to determine how, or even if, you will allow these computers to communicate with IPsec-incompatible computers.

| Action | Owner |
|---|---|
| Determine how IPsec-incompatible servers and Macintosh clients will communicate. | UNIX Systems Administrator, Security Manager |
| Determine how IPsec-compatible computers will communicate with IPsec-incompatible Windows clients. | Desktop Configuration Manager, Security Manager |
| Document how any effects of denied communications will be mitigated or corrected. | UNIX Systems Administrator, Desktop Configuration Manager, Security Manager |
| Determine which Windows services cannot be used with higher levels of IPsec protection. | Security Manager, Windows Systems Administrator |
| Determine whether there are any current IPsec policies (local or global) that might conflict with ones being designed. | Security Manager |

**Phase 3: Design Your IPsec Policies**

**Review IPsec Policy Design Documentation**

| Action | Owner |
|---|---|
| Designing IPSec Policies | Security Manager, Systems Architect |
| Understanding Default IPSec Policies | Security Manager, Systems Architect |
| Determining Your IPSec Needs | Security Manager, Systems Architect |

| | |
|---|---|
| Special IPSec considerations | Security Manager, Systems Architect |
| Weighing IPSec Tradeoffs | Security Manager, Systems Architect |
| Establishing an IPSec security plan | Security Manager |

**Create a Naming Convention**

You can create a naming convention for policies, filter lists, and filter actions. A naming convention can make backing up, restoring, and managing changes to policies, much easier.

Policy names should include the isolated domain and the date issued, for example, "Accounting_3.28.2005." Filter list names should describe the type of network traffic they match, for example, "All ICMP Traffic." Filter action names should describe the level of security they provide and the type of negotiation they use, for example, "Request Security."

| Action | Owner |
|---|---|
| Determine a naming convention for policies. | Security Manager, Systems Architect |
| Determine a naming convention for filter lists. | Security Manager, Systems Architect |
| Determine a naming convention for filter actions. | Security Manager, Systems Architect |

**Create an IPsec Policy Management Process**

A policy management process can reduce confusion and make backing up, restoring, and managing changes to policies much easier.

If you plan to create policies for a Windows Server 2003-based computer, you should keep in mind that Windows Server 2003 incorporates some new features that are not available in Windows XP or Windows 2000. For more information, see "IPsec Policy Compatibility Considerations" in Using Microsoft Windows IPsec to Help Secure an Internal Corporate Network Server.

| Action | Owner |
|---|---|
| Document how policies will be created. | Systems Architect |
| Document where policies will be backed up. | Systems Architect |
| Document how policies will be backed up. | Systems Architect |
| Document how policies will be changed, adjusted, and deployed. | Systems Architect |
| Determine how changes and backups will be documented. | Systems Architect |
| Determine how policies will be secured. | Security Manager |

**Review Example IPsec Policies**

Microsoft provides default IPsec policies with Windows, and also in the Windows Server 2003 Security Guide, that you might be able to use, with modifications, in your environment. These can also be used as examples in your policy design process.

| Action | Owner |
|---|---|
| Review the default policies. | Security Manager |
| Determine whether any of these policies can be used with modifications for your environment. | Security Manager |
| Review the policies provided in the Windows Server 2003 Security Guide. | Security Manager |
| Determine whether any of these policies can be used with modifications for your environment. | Security Manager |

**Design IPsec Filter Actions**

If the intranet traffic is to be secured, filter actions specify an ordered set of security methods (such as which integrity and encryption methods are used) and other settings. A combination of a filter action and a filter list make up a rule in an IPsec policy.

Try to create the fewest filter actions that meet your needs. For example, Microsoft IT was able to use only three for its environment. Your environment might be more diverse and might require more.

| Action | Owner |
| --- | --- |
| Determine where encryption of packet contents is required. | Security Manager |
| If encryption is used, determine which encryption algorithm is appropriate. | Security Manager |
| If encryption is not being used, determine whether packet integrity (signing) is necessary or desired. | Security Manager |
| Determine whether the correct action is to block, permit, or negotiate security. | Security Manager, Systems Architect |
| Determine whether the negotiation allows unsecured connections with IPsec-incompatible computers or IPsec-compatible computers with which IPsec negotiations fail. | Security Manager, Systems Architect |

**Design IPsec Filters and Filter Lists**

IP filters define matching criteria for a computer or a group of computers by specifying source and destination IP addresses, IP protocols, and source/destination TCP or UDP ports. Filter lists are a collection of one or more IP filters that logically belong together as a unit and that should have only one filter action associated with them. A rule combines a filter list with a filter action.

As a best practice use the **Any IP address** setting rather than the **My IP address** setting to mitigate problems with DHCP changing IP addresses. Additional best practices are provided in Improving Security with Domain Isolation.

| Action | Owner |
| --- | --- |
| Determine which IP addresses or subnets should be included in the filter lists. | Systems Architect, Security Manager |
| Determine which protocol/port combinations belong in the filter lists. | Systems Architect, Security Manager |
| Determine where the filters within the filter lists should and should not be mirrored. | Systems Architect, Security Manager |

**Design IPsec Policy Rules**

An IPsec policy rule combines a filter list with a filter action. If the filter action requires security, then the rule also specifies authentication methods, tunnel mode settings, and the types of interfaces to which this rule applies.

| Action | Owner |
| --- | --- |
| Pair the filter lists with the appropriate filter actions to define the set of rules for the IPsec policy. | Systems Architect, Security Manager |
| Determine whether the default response rule needs to be enabled or disabled. | Systems Architect, Security Manager |
| For rules requiring security, determine which authentication methods the rule uses to establish trust. | Systems Architect, Security Manager |

**Design IPsec Policies**

IPsec policies are a collection of one or more rules. Policies should group together all the rules that are appropriate for distribution to an organizational unit (OU), domain, or security group of the Active Directory® directory service.

Each segment will typically have an associated IPsec policy. The same policy might apply to many segments. Each computer can have only one policy assigned (active) at a time.

| Action | Owner |
| --- | --- |
| Determine where the policy will be deployed. | Security Manager, Systems Architect |
| Determine which rules need to added to the policy. | Security Manager, Systems Architect |
| Determine which computers or subnets will need to be added to an exemption list. | Security Manager, Systems Architect |

**Phase 4: Deploy the Policies in a Test Environment**

**Determine the Appropriate Test Environment**

The test environment will help you find and resolve any issues that could arise from your domain isolation deployment. The

more closely the test environment represents your actual IT environment, the more effective this testing will be.

| Action | Owner |
|---|---|
| Determine whether the current test environment is appropriate for testing domain isolation. | Security Manager, Systems Architect, Network Administrator |
| If the test environment is not appropriate, determine what changes need to be made to the test environment to properly test policy design and deployment. | Security Manager, Systems Architect, Network Administrator |
| Determine the cost/benefit of making changes to the test environment. | IT Manager, Security Manager, Systems Architect, Network Administrator |
| Determine whether testing can be accomplished in a smaller, non-critical domain or subdomain. | IT Manager, Security Manager, Systems Architect, Network Administrator |

**Deploy the Policies to the Test Environment**

You should deploy the policies using the plan you have created. If you are also deploying non-Microsoft IPsec solutions, such as those for UNIX or Apple Macintosh computers, you should deploy the one with the largest operating base first and refine and stabilize it before deploying the other solutions. If you are using these solutions, be sure to test them all together before deploying to your IT environment.

| Action | Owner |
|---|---|
| Deploy the least restrictive policy. | Security Manager |
| Monitor the communications in this segment for failures, etc. | Network Administrator |
| Correct any policy design issues (see "Refine Policies" below). | Security Manager, Systems Architect, Network Administrator |
| Continue to deploy, monitor, and correct until the deployment is successful. | Security Manager, Systems Architect, Network Administrator |
| Deploy other policies in order of increasing restriction. | Security Manager, Systems Architect, Network Administrator |

**Phase 5: Refine Policies**

During your test deployment, you might have issues that require a change to existing policies or the addition of new policies. The testing and refining process might require more than one cycle to find all the issues and redesign your policies to fit your environment.

For more information about troubleshooting IPsec issues, see "Testing and Monitoring Successful IPsec Operation" in Using Microsoft Windows IPsec to Help Secure an Internal Corporate Network Server.

| Action | Owner |
|---|---|
| Determine whether any computers that should be able to connect are blocked. | Network Administrator, Windows Systems Administrator, Desktop Configuration Manager |
| Determine whether any computers that should be blocked can connect. | Network Administrator, Security Manager |
| Determine whether any computer's performance is significantly affected by the policies. | Network Administrator, Database Administrator, Windows Systems Administrator |
| Determine whether any computers already have a conflicting IPsec policy implemented. | Network Administrator, Security Manager, Windows Systems Administrator, Desktop Configuration Manager |

| | |
|---|---|
| Determine whether any computers need to be updated so they can implement IPsec properly (for example, computers running Windows 2000, Windows XP with no service packs installed, and Windows XP with SP1 need to be updated for IPsec NAT-T support). | Network Administrator, Security Manager, Windows Systems Administrator, Desktop Configuration Manager |
| Determine whether any computers or network devices that were thought to be IPsec-compatible are not. | Network Administrator, Security Manager |
| Determine whether any computers that can use IPsec must have policies changed to work correctly (for example, any VPN servers that are not domain members, and therefore cannot use Kerberos v5 authentication, must use a certificate or preshared key). | Network Administrator, Security Manager |
| Determine where VPN or other remote connections do not work with IPsec. | Network Administrator, Security Manager |
| Determine whether there are any features or configurations that will not work with IPsec. | Network Administrator, Security Manager |

**Phase 6: Create a Deployment Schedule**

The policy testing and refinement processes will provide you with valuable information about how the deployment is best implemented for a given segment. You can also use the answers to the planning questions earlier to help you determine the best sequence of, and time frame for, IPsec deployment to your environment. Information based on the actions listed below might help you determine your deployment schedule.

As a best practice, Microsoft IT found that it worked for them to deploy to smaller, non-critical domains first, then to larger domains, and finally to mission-critical domains. They also deployed "Request Mode" first and then "Secure Mode." Additional best practices are provided in Improving Security with Domain Isolation.

| Action | Owner |
|---|---|
| Document the order in which the segments will be deployed. | IT Manager, Systems Architect, Security Manager |
| Document the best date and time for the deployment. | IT Manager, Systems Architect |
| Document how you will monitor the segment to make sure it is working properly. | Systems Architect, Security Manager |
| Document a contingency plan if connectivity is blocked. | Systems Architect, Security Manager |
| Document how you will back-out a change if something goes wrong. | Systems Architect, Security Manager |
| Determine when all parties should be informed of a pending change. | Helpdesk Manager |
| Determine how you will know that the deployment is sound enough to be implemented on the next segment. | Systems Architect, Security Manager, Helpdesk Manager |
| Determine how you will know that the entire deployment is sound and the goals have been achieved. | IT Manager, Systems Architect, Security Manager, Helpdesk Manager |

**Phase 7: Prepare for User and Infrastructure Support**

After you have finalized your deployment schedule, you can finalize when and how you will inform the operations staff, department heads, server owners, application owners, users, and partners of the pending changes. The availability of information about the process is important to a smooth deployment and the information should be available online (and in written form) well ahead of the actual deployment. The actions listed below might help you determine your Helpdesk needs.

| Action | Owner |
|---|---|
| Inform the Helpdesk staff of the changes, what they need to do to prepare for them, what they can expect to experience, and who to contact in case of problems. | Helpdesk Manager |

| | |
|---|---|
| Train Helpdesk staff using simulation drills with problems that are likely to arise. | Helpdesk Manager |
| Inform the Helpdesk staff about IPsec and the deployment process, possible problems that might arise, resources for helping users with these problems, and escalation of problems. | Helpdesk Manager |
| Inform the following groups of the changes, what they need to do to prepare for them, what they can expect to experience, and who to contact in case of problems:<br>• Department heads<br>• IT Operations staff<br>• IT Security staff<br>• Server owners<br>• Application owners<br>• Users<br>• Partners | Helpdesk Manager, Windows Systems Administrator |
| Document confirmation of compliance from all parties, signifying that they understand and have made all changes necessary for compliance. | Helpdesk Manager, IT Manager |

# A Guide to Domain Isolation for Security Architects

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Vista

Learn how to assess the enterprise environment, plan domain isolation, and assess the implications of deploying domain isolation in an enterprise environment. Designed for security architects of enterprise organizations that are investigating using IPsec in Microsoft Windows to deploy domain isolation.

*Domain isolation* is the use of Internet Protocol security (IPsec) to require authentication, encryption, or both, among members of a Windows domain as well as between members of the domain and unknown or unauthorized computers. The goal of domain isolation is to isolate secured computers from unsecured computers by providing an additional level of protection for the traffic that is sent on a network. By using IPsec you add an additional defense-in-depth layer to the mechanisms that currently secure your network. IPsec-based communication changes the format of the TCP/IP packets transmitted over your network, which requires careful study and planning to mitigate risks and ensure success. This paper presents an overview of the three steps a security architect should follow to prepare for IPsec deployment:

1. Determine the current state of your IT infrastructure
2. Plan isolation groups
3. Consider operational issues for IPsec-based traffic

**Knowledge Prerequisites**

Prior to reading this paper you should read Domain Isolation with Microsoft Windows Explained at http://go.microsoft.com/fwlink/?LinkId=44642.

In addition, make sure that you have a thorough understanding of the following topics before you begin IPsec domain isolation:

- TCP/IP and core networking principles.
- Windows authentication, including use of the Kerberos V5 protocol and public key infrastructure (PKI).
- Active Directory concepts, including Active Directory structure and tools; users, groups, and other Active Directory objects; and Group Policy.
- Windows system security, including security concepts such as users, groups, auditing, and access control lists (ACLs).
- A thorough understanding of Windows Server 2003 IPsec policies. For more information, see the Windows Server 2003 Technical Reference at http://go.microsoft.com/fwlink/?LinkId=21711.

**Determining the Current State of Your IT Infrastructure**

Before starting the planning process for a domain isolation project, you need to collect and analyze up-to-date information about the current state of your IT infrastructure. A thorough and accurate assessment of your infrastructure provides the basis for planning what to isolate and how isolation should be implemented. Perform your data collection in three phases:

- Identify network configuration
- Map Active Directory infrastructure
- Identify host configuration

**Identifying Network Configuration**

Determining the current state of your network involves gathering information about network segmentation and infrastructure devices, and then performing an analysis of network communication.

**Network Segmentation**
Determine what networks are in place and what hosts exist on those networks. Typically, this information is illustrated by using schematic diagrams.

Figure 1 shows a very simple network diagram.

**Network Infrastructure Devices**
Next in your assessment, review the devices that make up the network infrastructure — routers, switches, load balancers, and firewalls. These devices are required to process IPsec-based traffic after the isolation solution is implemented. For this reason, it is important to determine whether these devices can handle the technical and physical requirements of the isolation design. Some of the characteristics to examine include:

- **Response to datagram change**. IPsec without encryption changes the offset for the destination ports and protocols within the TCP/IP packet. These changes might limit the functionality of traffic analysis applications, such as Cisco NetFlow.

- **Normal and peak utilization**. Peak use information can help determine whether the device is capable of using IPsec or if a memory or firmware upgrade is needed. If problems arise after IPsec is implemented, normal utilization data can assist in determining if the cause is related to high utilization of the device.

- **Whether the device is performing network address translation (NAT)**. To allow IPsec-based traffic to pass through a NAT device, you must ensure that IPsec NAT-T is supported on your IPsec peer computers.

- **Internal vs. external subnets and firewall configuration**. When a firewall or filtering router exists between IPsec peers, it must be configured to forward IPsec traffic on UDP source and destination port 500 for Internet Security Association and Key Management Protocol (ISAKMP), UDP source and destination port 4500 (IPsec NAT-T), IP protocol 50 for Encapsulating Security Payload (ESP), or IP protocol 51 for Authentication Header (AH).

For specific considerations for network infrastructure devices, see “Considering Operational Issues for IPsec-based Traffic" in this paper.

**Network Communication**
A thorough analysis of the communication flow on your network will provide three vital pieces of information:

- What communication is currently taking place between hosts

- What communication should be restricted

- What communication is at risk of failing when secured with IPsec

When you examine traffic flow, look closely at how all network devices interact. Keep in mind the following questions:

- What protocols and ports do servers and clients use to communicate with each other?

- Are there any security devices or projects that are implemented or planned that could impact the isolation project?

- Are certificates used to provide authentication?

- Do you have subnets that are dedicated to specific types of traffic (for example, Macintosh workstations and UNIX

workstations, or mainframe-to-terminal connections)?

**Mapping Active Directory Infrastructure**

Active Directory is the next source from which to gather information. Make sure that you understand the forest structure, including domain layout, organizational unit (OU) architecture, Group Policy, and site topology. This information provides the logical placement of computers, their configuration, and the impact to Active Directory as a result of implementing IPsec. For Active Directory, determine the following:

- **Number of forests**. The forest is the security boundary in Active Directory. Therefore, make sure that you understand the current Active Directory architecture because IPsec communication across forests is possible only if external trusts are configured.

- **Names and number of domains**. Active Directory domains are the building blocks of domain isolation. Therefore, computers that are domain members are assumed to support IPsec using Kerberos V5 authentication.

- **Number and types of Active Directory trusts**. Trusts affect the logical boundaries of isolation and can define how IKE authentication occurs. Active Directory trusts can affect Kerberos-based IKE authentication.

- **Names and number of sites**. Site architecture should be aligned with network architecture.

- **OU structure and Group Policy**. Organizational units can be used to apply IPsec policy. Review the OU structure to determine how Group Policy is used and how OUs are organized.

- **Existing use of IPsec policy**. Multiple IPsec policies that are assigned in different Group Policy objects (GPOs) are not merged. The IPsec policy applied is the one assigned to the GPO that is closest to the computer in the Active Directory domain structure. More IPsec policies in your environment means more complexity in your domain isolation design.

**Host Configuration**

The final piece of your current network environment assessment is a review of client and server host computers. IPsec-based communication depends on host systems meeting specific operating system and application requirements. Useful host information to gather includes:

- **Operating system, service pack, and hotfix versions**. The operating system version is a key factor in determining the ability of a host to communicate with IPsec. It is also important to track the current state of service packs and hotfixes that can be installed because these are often used to confirm that the minimum security standards have been met.

- **Domain membership**. This information is used to determine whether a computer can obtain IPsec policy from Active Directory or whether it must use a local IPsec policy. Hosts that are not domain members can use a local IPsec policy applied via scripts.

- **Physical location**. This information is simply the location of the device in your organization. It can be used to determine whether a device should participate in a particular isolation group based on its location or the location of the hosts that it communicates with regularly.

- **Hardware type and role**. This information can help determine the eligibility of a particular computer to participate in isolation and the isolation group in which to place the computer.

**For More Information**

Various methods can be used to gather data from the devices on your network. These methods range from high-end, fully automated systems to completely manual data collection. Generally, the use of automated methods to gather data, such as Microsoft® Systems Management Server, is preferred over manual methods for reasons of speed and accuracy. For more information about how SMS 2003 can help perform asset management, see the demonstration and the asset management datasheet on the SMS 2003 Asset Management page at http://go.microsoft.com/fwlink/?LinkId=45078.

For more information about determining your current network configuration, see "Chapter 3: Determining the Current State of Your IT Infrastructure" available at http://go.microsoft.com/fwlink/?LinkId=45130.

**Planning Domain Isolation**

With a good understanding of your company's network and host configuration, you are ready to specify your isolation domain. You can do this in four phases:

- Define isolation
- Determine isolation groups
- Specify communication paths and IPsec policies
- Complete implementation steps

**Defining Isolation**

*Domain isolation* is the use of Internet Protocol security (IPsec) to require authentication, encryption, or both, among members of a Windows domain as well as between members of the domain and unknown or unauthorized computers. In order to be a member of an isolated domain, a host must meet these minimum requirements:

- **Domain membership**. The host must be a member of an Active Directory domain.
- **Ipsec-compatible operating system.** The host must run an operating system that is IPsec-compatible such as Windows 2003, Windows XP, or Windows 2000 SP4.

Your organization might decide to add further requirements for security such as:

- A properly installed and configured antivirus program with up-to-date signature files
- Current security updates
- Current service packs

Hosts failing to meet minimum requirements — and whatever additional requirements your organization adds — cannot be included in the isolated domain. These hosts will be restricted from communicating with domain isolation members.

**Determining Isolation Groups**

The primary goal of domain isolation is to restrict the communication between isolated and non-isolated hosts. For planning purposes, it is useful to combine hosts into logical groups called isolation groups. An isolation group is a device for grouping host computers that share the same inbound and outbound network traffic requirements.

In Windows, isolation groups are implemented by placing hosts in organizational units (OUs) or security groups, and then by applying policy or by assigning access permissions. An isolation group's inbound and outbound access controls can be implemented by IPsec policy using permit/block actions, or by using IPsec policy in combination with Group Policy network access rights.

Figure 2 illustrates a simple isolation group design.

In this example, four groups are created for domain isolation:

- **Isolation domain**. This is the default group for all isolated computers and will likely be the group with the largest number of hosts. If the domain includes bidirectional trusted domains, members of those domains would be part of the isolation domain. All host-to-host communication within this group is secured by using IPsec.

- **Non-isolated hosts**. This group contains all non-isolated computers not capable of IPsec-based communication, such as Macintosh and UNIX computers.

- **Boundary isolation**. This group contains isolated hosts that will be allowed to communicate with non-isolated and isolated hosts. These computers will be exposed to a higher level of risk because they can receive incoming communications directly from unsecured computers. For example, you might want your Remote Installation Services (RIS) servers, which support downloading operating system images to computers that are not yet IPsec-compatible, to be boundary hosts.

- **Exemption lists**. This group contains computers that are by default in your isolated domain, but that must be available to all systems on the network. For example, you might want your domain controllers, and DNS, DHCP, and WINS servers to be exempted.

All computers on your network that share the same communications security policy are assigned to one of the isolation groups. After the groups are designed and host membership decided, you're ready to plan the network traffic between the isolation groups.

**Specify Communication Paths and IPsec Policies**

At this point in the planning process, the communications traffic requirements that will be allowed to pass between the groups need to be documented, along with the form the communications will take. Figure 3 illustrates communication paths for the isolation groups.

After IPsec policies are in place for the isolation groups, communication between the groups will proceed as shown in the following table.

| Path | Groups | Communication |
|---|---|---|
| 1 | From non-isolated hosts to hosts in the boundary group | Unsecured, plaintext TCP/IP connections. |
| 2 | From boundary group hosts to non-isolated hosts | Hosts attempt to communicate with IPsec-based traffic but can fall back to non-IPsec-based communication (the **Fall back to clear** option). |
| 3 | Between hosts in the isolation domain and boundary groups | Hosts attempt to use IPsec to protect the traffic. This traffic might require encryption, depending on the security requirements. If the IKE negotiation fails, the communications will fail because there is no **Fall back to clear** option when IKE negotiation fails. |
| 4 | From isolated hosts to non-isolated hosts | Hosts attempt to communicate with IPsec-based traffic but will fall back to non-IPsec-based communication. |
| 5 | From non-isolated hosts to isolated hosts | Blocked from initiating communication. |

Though not included in the diagram or table, all hosts are allowed to communicate with hosts in the exemption lists group using unsecured, plaintext connections.

#### Implementation Steps

With a complete understanding of your network and a plan for controlling traffic with isolation groups, you are now ready for the next steps in your utilization of IPsec to secure your network. These steps include:

- **Create IPsec policies**. Creating IPsec policies involves creating filter lists, filter actions, and IPsec policies containing rules that match filter lists with filter actions. For more information about these tasks, see "Chapter 5: Creating IPsec Policies for Isolation Groups" at http://go.microsoft.com/fwlink/?LinkId=45132.

- **Create a test lab**. To ensure that IPsec policy functions as expected and provides the appropriate level of security, test specific IPsec policy configurations on clients and servers in a lab environment, and then conduct pilot or beta tests in a limited operational environment before conducting a full-scale deployment. For more information about creating a test lab, see Setting Up IPsec Server and Domain Isolation in a Test Lab at http://go.microsoft.com/fwlink/?LinkId=44646.

- **Deploy IPsec Policies Across Your Network**. For more information about IPsec deployment, see Deploying IPsec in the Windows Server 2003 Deployment Kit at http://go.microsoft.com/fwlink/?LinkId=31789.

#### Considering Operational Issues for IPsec-based Traffic

IPsec provides greater security at the expense of network and processing performance and compatibility with other services, tools, and features. The following section describes these and other important operational considerations for managing IPsec policies.

#### The Impact of IPsec on Performance

IPsec has some costs in network and processor performance. The exact cost cannot be predicted because it depends on many factors, such as the level of application traffic and the number and configuration of IPsec filters deployed. However, the following factors should be understood and reviewed for your deployment.

#### Network Performance

IPsec impacts network performance in two ways.

**IKE SA establishment slows connection establishment**.

When a security association (SA) is initially established between two computers, a delay of up to three seconds occurs while security is negotiated. This time might vary depending on policy design, the authentication method that is selected, network roundtrip time, and the load placed on the servers required to establish the connection. Accordingly, end users might notice brief initial delays when IPsec-based connections are established. Typically, after SAs are established, no further delays occur.

**Large packet headers reduce throughput and increases network utilization**.

For each IPsec-based packet, the AH and ESP headers add an additional 24 to 36 bytes of data, depending on which method of encapsulation is used and whether IPsec tunneling is used. This decreases the effective IP payload size for upper-layer protocols such as TCP and UDP. As a result, traffic that is secured by IPsec uses more packets than traffic that is not secured by IPsec. The Microsoft IT department observed a mean bandwidth usage increase of 3 percent when they deployed IPsec (ESP-Null) across their network.

Different enterprise environments might experience a different amount of increased usage, depending on the mix of applications present. The increase in bandwidth usage is likely to have a more significant effect in a WAN scenario where the traffic is already near capacity, than in a LAN over Fast Ethernet connections.

#### Processor Performance

IPsec impacts processor performance in two ways.

**SA maintenance affects scalability and increases CPU and memory overhead**.

Performance degradation and lower throughput might be experienced by servers that must establish IPsec-based communications with many clients. In particular, full ESP-encrypted traffic places the highest burden on server CPU and can gain the most benefit from the use of offload network adapters. Typically, for each active IPsec client, 5 to 20 kilobytes (KB) of memory is used on a server. The IKE authentication method has the greatest impact on memory usage for each active IPsec client. For example, Kerberos V5 authentication typically requires less memory per SA than certificate authentication.

**Per-packet processing overhead increases CPU and memory overhead**.

Each IPsec-based packet creates additional performance overhead for encryption, authentication, and other packet processing functions. Each packet that is not secured by IPsec must still pass through all IPsec filters. Therefore, when you configure an IPsec policy, make sure that you create the minimum number of filters required for your environment. The impact of IPsec on throughput varies in proportion to the rate at which traffic is sent or received. Typically, active IPsec policies with 500 or fewer filters result in only a minor impact on throughput. In IPsec for Windows XP and Windows Server 2003, the per-packet processing performance is significantly improved, compared to the per-packet processing performance in IPsec for Windows 2000.

The effects of IPsec on CPU performance are typically negligible on clients because clients often have ample, spare CPU processing power and memory to accommodate IPsec. However, servers that have highly loaded CPUs might incur a significant increase in load, depending on the amount of traffic that must be secured by IPsec, the number of SAs that must be processed, and the cryptographic algorithms that are selected.

If your servers already have high loads on their CPUs, consider using IPsec offload network adapters before deploying IPsec. IPsec offload network adapters accelerate cryptographic operations used to secure IPsec packets. However, these adapters do not accelerate filter processing time. IPsec-enabled network adapters can be used with Windows 2000, Windows XP, and Windows Server 2003. Such network adapters typically complete IPsec operations at such a high rate that there is minimal change in transmission speeds, resulting in minimal performance degradation. However, such adapters generally have a maximum number of SAs that they can support, after which additional SAs are processed by Windows IPsec.

**Crossing Security Boundaries with IPsec Traffic**

When you design an IPsec policy, it is important to consider security boundaries, such as NATs, firewalls, and forests, that IPsec-based traffic must cross. Within a TCP/IP packet, IPsec changes the offsets for the destination ports and protocols. These changes might adversely affect the transmission of data over network devices and should be researched prior to IPsec deployment.

**NAT Traversal**

If traffic between the client and a server must pass through a network address translator (NAT), then IPsec cannot secure the traffic (the IKE negotiation will fail when translated by a network address translator). IPsec NAT traversal (NAT-T) allows IPsec peers that are behind NATs to detect the presence of NATs, negotiate IPsec SAs, and send ESP-protected data, despite the fact that the addresses in the IPsec-protected IPv4 packets change. IPsec NAT-T does not support the use of AH across network address translation. For more information about how IPsec NAT-T works, see IPsec NAT Traversal Overview, the August 2002 Cable Guy article at http://go.microsoft.com/fwlink/?LinkId=45080.

IPsec NAT-T is supported by Windows Server 2003, Windows XP with Service Pack 2 (SP2). IPsec NAT-T is also supported by Windows XP with Service Pack 1 (SP1) and Windows 2000 if used in combination with a free Web download. However, due to the behavior of IPsec and NATs, Windows XP SP2 by default no longer supports establishing IPsec NAT-T SAs to servers that are located behind NATs to avoid a perceived security risk.

If you must send IPsec-based communication across a NAT device, it is recommended that public IP addresses be used for all servers that can be connected to directly from the Internet. If this configuration is not possible, then the default behavior of Windows XP with SP2 can be changed to enable IPsec NAT-T security associations to servers that are located behind a network address translator.

In addition, servers running Windows Server 2003 also require a hotfix so that they can be reached by hosts on the other side of a NAT device. The hotfix will be included in the Windows Server 2003 SP1 release. (This hotfix can currently be obtained from Microsoft Product Support Services.)

To ensure that a server is reachable behind a NAT for IPsec traffic, you must configure the NAT with static translation entries that map UDP port 500 (IKE) and UDP port 4500 (IPsec NAT-T) traffic to the server.

For additional information, see the following articles:

- Problems with Using Network Address Translators – The Cable Guy, October 2004 at http://go.microsoft.com/fwlink/?LinkId=45081.

- IPsec NAT-T is not recommended for Windows Server 2003 computers that are behind network address translators on the Microsoft Support Site at http://go.microsoft.com/fwlink/?LinkId=45083.

- L2TP/IPsec NAT-T update for Windows XP and Windows 2000 on the Microsoft Support Site at http://go.microsoft.com/fwlink/?LinkId=45084.

**Creating Firewall Filters to Permit ISAKMP, AH, and ESP Traffic**
In some cases, IPsec-based traffic might need to pass through a router, firewall, or other filtering device. In the case of a router, unless the router filters TCP and UDP traffic or other upper-level protocol headers, no special configuration is required to permit the IPsec-based traffic to be forwarded. In the case of a filtering router or a firewall, you must configure these devices to allow IPsec-based traffic to be forwarded.

In order for IPsec-based communications to pass through a firewall or other filtering device, you must configure the firewall to permit IPsec traffic on UDP source and destination port 500 (ISAKMP), UDP source and destination port 4500 (IPsec NAT-T) and IP Protocol 50 (ESP). You might also need to configure the firewall to permit IPsec traffic on IP protocol 51 (AH) to permit troubleshooting by IPsec administrators and to allow the traffic to be inspected while it is still IPsec-protected.

For more information, see How to Enable IPsec Traffic Through a Firewall on the Microsoft Support Site at http://go.microsoft.com/fwlink/?LinkId=45085.

**Different Trust Environments**
When you design an IPsec policy, consider any logical boundaries that might affect IPsec-based communications. For example, your domain and trust environment is critical in determining an appropriate IKE authentication method.

Kerberos V5 authentication is recommended for use in a two-way (mutual) domain and forest trust environment. You can use Kerberos V5 for IKE authentication across trusted domains whether the domains are in the same forest or in different forests. If the two domains are in different forests, you must configure two external trusts, one for each direction, between the domains. The external trusts must use the fully qualified domain name (FQDN) of the domains, and you must configure the IPsec policy to allow an IKE initiator to communicate to any domain controller in the other forest, so the initiator can obtain a Kerberos ticket from a domain controller in the responder's domain. If the domains are on opposite sides of a firewall, then you must configure the firewall to allow Kerberos traffic over UDP destination port 88, TCP destination port 88, as well as UDP destination port 389.

For more information, see Active Directory in Networks Segmented by Firewalls, available at http://go.microsoft.com/fwlink/?LinkId=45087.

If the use of Kerberos is not possible because two-way trusts across forests cannot be established as in some large enterprise environments, you can use a PKI and digital certificates to establish IPsec-based communication. For an example of how Microsoft deployed their PKI, see Deploying PKI Inside Microsoft at http://go.microsoft.com/fwlink/?LinkId=45088.

**Operational Considerations**
In addition to the impact of IPsec on security boundaries, other operational areas of your network will likely be affected by an IPsec deployment. These areas include: non-IPsec-compatible support, NLB clusters, and network inspection technologies.

**Support for IPsec-Incompatible Hosts**
In most organizations, some workstations or servers cannot communicate by using IPsec. Such hosts include:

- Non-Windows-based computers and devices, such as Macintosh computers, UNIX computers, and personal digital assistants (PDAs).
- Hosts running older versions of the Windows operating system. Computers running Windows NT, Windows 95, Windows 98, and Windows Millennium Edition do not support Group Policy or IPsec policies.
- Windows-based computers that are not domain members. Stand-alone computers cannot perform IKE authentication using the Kerberos V5 protocol. A computer that is joined to a domain that is not trusted by the forest being used as the trust boundary for IKE authentication cannot participate in a domain isolation solution.
- Other non-Windows-based remote access or VPN clients. If a non-Windows-based IPsec virtual private network (VPN) client is being used for an organization's remote access solution, it typically is not compatible with Windows IPsec. If Windows IPsec cannot be used, the host cannot participate in an IPsec domain isolation solution.

In an IPsec-based network, these hosts would likely be considered non-isolated and communication with them would be blocked. However, business requirements often exist for these computers to communicate with isolated hosts in the isolation domain.

To deal with this situation, you can create a boundary group that contains hosts that will be allowed to communicate with non-isolated hosts. These boundary hosts will be exposed to a higher level of risk because they can receive incoming unsecured communications directly from non-isolated computers. Computers in the boundary group are isolated hosts that can communicate both with other isolated hosts and with non-isolated hosts.

Boundary hosts will attempt to communicate using IPsec by initiating an IKE negotiation to the originating computer. If no IKE response is received within three seconds, the host will use plaintext without IPsec. Because plaintext communication is allowed, these hosts must be secured in other ways or monitored for acceptable risk. For more information about planning and deploying boundary groups, see Chapter 4: Designing and Planning Isolation Groups available at http://go.microsoft.com/fwlink/?LinkId=45131.

**NLB Clusters**

There are challenges in implementing IPsec on Network Load Balancing (NLB) clusters and server clusters. NLB allows multiple servers to be clustered together to provide high availability for a service by providing automatic failover to other nodes in the cluster if an individual server fails. IPsec directly opposes NLB in that it prevents different computers from handling the same client connection. Because IPsec is negotiated between individual hosts before any data is transmitted, the same node in the cluster must respond to established IPsec connections or the traffic will be dropped.

If the particular node in the cluster fails, existing IPsec connections to that server cannot detect the failover and attempt to rebuild the security association until the preset time-out period expires. In Windows 2000 and Windows XP, IPsec must be idle for five minutes before the client attempts to re-authenticate. This results in a two-to-six minute interruption in service for that client.

Windows XP SP1 (with the NAT-T update), Windows XP SP2, and Windows Server 2003 reduce the preset time-out period to one minute. There will always be a delay if a client happens to be connected to a cluster node that fails.

For more information about IPsec and configuring NLB clusters, see the following articles on the Microsoft Support Site:

- How to Configure Network Load Balancing to Work with IPsec at http://go.microsoft.com/fwlink/?LinkId=45089
- IPsec is not designed for failover at http://go.microsoft.com/fwlink/?LinkId=45091
- How to Configure IPsec on an Exchange Server 2003 Back-End Server That Is Running on a Windows Server 2003 Server Cluster at http://go.microsoft.com/fwlink/?LinkId=45092.

**Network Inspection Technologies**

Within a TCP/IP packet, IPsec changes the offsets for the destination ports and protocols. These changes adversely affect many applications running on network devices like routers that monitor and manage traffic on the network.

Some network applications are updated to support IPsec, but many are not yet compatible:

- Router access control lists (ACLs) cannot examine protocol and port fields in ESP-encrypted packets, and therefore the packets are dropped. ACLs based only on IP address are forwarded as usual.
- Cisco NetFlow on routers cannot analyze packets between IPsec members based on protocol or port. Analysis based only on IP address is unaffected.
- Router-based Quality of Service (QoS) cannot use ports to classify packets. Host-based classification of packets supported by Windows is unaffected, as is router-based QoS using only IP addresses.
- Weighted Fair Queuing (WFQ) and other flow-based router traffic prioritization methods might not queue packets as intended resulting in suboptimal network utilization.
- Network monitoring tools might be unable to parse ESP packets that are not encrypted (ESP-Null).

In general, IPsec defeats network-based prioritization and port- or protocol-based traffic management. For encrypted packets, there is no workaround—the host itself must handle any traffic management functions. For unencrypted, authenticated-only packets, the devices and applications must be aware of how IPsec changes packets to be able to do anything with them other than route them to the correct host. If it is not possible to upgrade monitoring or management devices to support IPsec, it is vital that this information be recorded and figured into your isolation design.

Network Monitor added an ESP parser in version 2.1 to aid troubleshooting of unencrypted IPsec packets. Network Monitor is available in a light version in Windows Server 2003 and a full version for SMS. The SMS version adds formatting of data, advanced diagnostic capabilities, and other features for capture management.

The version of Network Monitor that is provided with Windows Server 2003 includes parsers for the ISAKMP (IKE), AH, and

ESP protocols. Network Monitor parsers for ESP can parse inside the ESP packet only if ESP null-encryption is being used. Network Monitor cannot parse the encrypted portions of IPsec-based ESP traffic when encryption is performed in software. However, if encryption is performed by an IPsec hardware offload network adapter, the ESP packets are decrypted when Network Monitor captures them on either the source or the destination and, as a result, they can be parsed and interpreted into the upper-layer protocols. If you need to diagnose ESP software-encrypted communication, you must disable ESP encryption and use ESP-null encryption by changing the IPsec policy on both computers.

**Summary**

The use of IPsec to isolate computers that belong to an Active Directory domain requires careful planning. Three steps presented in this paper will prepare the security architect for the necessary research and cross-team communication. The three steps presented in this paper are: Determine the current state of your IT infrastructure, plan isolation groups, and consider operational issues for IPsec-based traffic.

# Setting Up IPsec Domain and Server Isolation in a Test Lab

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This document is intended for network architects who are investigating the use of Internet Protocol security (IPsec) in Microsoft® Windows® operating systems to deploy domain and server isolation in their environments. The procedures in this document demonstrate how to set up IPsec domain and server isolation in a limited test environment, which you can use as a basis for your own deployment.

The objective of setting up domain isolation in a test lab is to configure a test lab network in which isolated domain member computers accept only authenticated communications initiated from other domain member computers, while ignoring communications initiated from non-isolated computers outside the isolated domain.

The objective of setting up group-specific server isolation in a test lab is to configure a test lab network in which a server computer accepts only authenticated communications initiated from domain member computers that are members of a specific security group, while ignoring communications initiated from non-isolated computers outside the isolated domain and isolated computers that are not members of a specific security group.

**Overview of the Domain and Server Isolation Test Lab**

The following steps are required for the successful setup and demonstration of the domain and server isolation lab:

1. Setting up four computers that make up the test lab network: two server computers and two client computers.
2. Demonstrating that the clients have full, unrestricted access to the servers.
3. Creating an IPsec policy to isolate the computers in the isolated domain from computers outside of the isolated domain.
4. Demonstrating, after the domain isolation policy is in place, that the isolated computers in the domain can access other isolated computers in the domain, but that non-isolated computers outside of the isolated domain do not have access to domain members.
5. Demonstrating, after the server isolation settings are in place, that specific, authorized isolated computers can access the isolated server, and that unauthorized isolated computers are denied access.

This lab is designed to demonstrate the basic capabilities of IPsec domain and group-specific server isolation in a limited test environment. It does not explore every possible configuration, but rather outlines a specific set of procedures to get you started. If you plan to deploy IPsec server and domain isolation in your production environment, see the "Other Resources" section at the end of this paper for links to IPsec planning and deployment documentation that may address the specifics of your network.

| **Note** |
| --- |
| The procedures in this document use the Microsoft Windows Server™ 2003, Standard Edition operating system. Your server might function differently based on the version and edition of the Windows operating system that is installed, your account permissions, and your menu settings. For example, the steps to open an item in Control Panel vary slightly based on how a server is configured. |

**Domain and Server Isolation Lab Setup**

The following illustration shows the configuration of the IPsec test lab.

Figure 1. Test lab configuration.

The following four computers make up the test lab network:

- **DC1**: a computer running Windows Server 2003 that is used as a domain controller and a Domain Name System (DNS) server.
- **FS1**: a computer running Windows Server 2003 that is used as a file sharing server.
- **CLIENT1**: a computer running Windows XP that is used as a client.
- **CLIENT2**: another computer running Windows XP that is used as a client.

The lab requires one network segment that represents a private network. All computers on the private network are connected to a common hub or Layer 2 switch. Private IP addresses are used throughout the test lab configuration. The private network of 172.16.0.0/24 is used for the test lab network.

In addition, each computer is manually configured with an IP address, subnet mask, and DNS server IP address. Dynamic Host Configuration Protocol (DHCP) and Windows Internet Name Service (WINS) servers are not used.

The following sections describe the configuration for each of the computers in the test lab.

**Setting Up DC1**

DC1 is a computer running Windows Server 2003 that is functioning as:

- The domain controller for the contoso.com Active Directory® domain.
- The DNS server for the contoso.com DNS domain.

| **Note** |
| --- |
| The domain name, contoso.com, is used here for example purposes only. You can use any domain name in your test lab configuration. |

To configure DC1 for these services, perform the following steps.

1. Install Windows Server 2003 as a stand-alone server.
2. Using Network Connections, configure the TCP/IP protocol for the Local Area Network connection with the IP address of **172.16.0.1** and the subnet mask of **255.255.255.0**.
3. Run the **Active Directory Installation Wizard** (**dcpromo.exe**) for a new domain named **contoso.com** in a new forest. Install the **DNS** service when prompted.

**Setting Up FS1**

FS1 is a computer running Windows Server 2003 that is providing file and print sharing services. To configure FS1 as a file server, perform the following steps.

1. Install Windows Server 2003 as a stand-alone server.

2. Using **Network Connections**, configure the TCP/IP protocol for the Local Area Network connection with the IP address of **172.16.0.2**, the subnet mask of **255.255.255.0**, and the DNS server IP address of **172.16.0.1**.

3. Using **System**, join FS1 to the contoso.com domain.

4. After restarting the computer, in **Windows Explorer**, share the root directory of **Local Disk (C:)** using the share name **ROOT**.

**Setting Up CLIENT1**

CLIENT1 is a computer running Windows XP Service Pack 1 (SP1) or SP2 that is acting as a client and member of the contoso.com domain. To configure CLIENT1 as a client, perform the following steps.

1. Install Windows XP SP1 or SP2 as a workgroup computer.

2. Turn off Windows Firewall.

3. Using Network Connections, configure the TCP/IP protocol for the Local Area Network connection with the IP address of **172.16.0.3**, the subnet mask of **255.255.255.0**, and the DNS server IP address of **172.16.0.1**.

4. Using System, join CLIENT1 to the contoso.com domain.

5. After restarting the computer, in Windows Explorer, share the root directory of Local Disk (C:) using the share name ROOT.

**Setting Up CLIENT2**

CLIENT2 is a computer running Windows XP SP1 or SP2 that is acting as a client but is not a member of the contoso.com domain and does not have a local IPsec policy. To configure CLIENT2 as a client, perform the following steps.

1. Install Windows XP SP1 or SP2 as a workgroup computer.

2. Turn off Windows Firewall.

3. Using Network Connections, configure the TCP/IP protocol with the IP address of **172.16.0.4**, the subnet mask of **255.255.255.**0, and the DNS server IP address of **172.16.0.1**.

4. In Windows Explorer, share the root directory of Local Disk (C:) using the share name ROOT.

**Configuring the Domain**

Now that the domain is set up, move the computers to which the domain isolation IPsec policy should be applied from the Computers folder in Active Directory Users and Computers into a new organizational unit (OU). On DC1, perform the following steps using Active Directory Users and Computers.

1. In **Active Directory Users and Computers**, create the **Isolate** OU within the contoso.com domain.

2. In **Active Directory Users and Computers**, move the **FS1** and **CLIENT1** computer accounts to the **Isolate** OU.

**Testing CLIENT1 and CLIENT2 Access to FS1**

Before configuring and assigning IPsec policy, confirm that hosts can successfully communicate.

1. On CLIENT2, from a command prompt, type **net view \\FS1.**

   You should be able to successfully connect to the shared folder on FS1.

2. On CLIENT1, from a command prompt, type **net view \\FS1.**

You should be able to successfully connect to the shared folder on FS1.

**Configuring IPsec Domain Isolation Policy**

Now that your domain computers are configured, you can configure an IPsec domain isolation policy to apply to the contoso.com domain. In the following steps, you will create a domain isolation policy that will allow only isolated computers to be accessed by other isolated computers within the isolated domain. Non-isolated computers outside the isolated domain, making communications requests to isolated computers inside the isolated domain, will be ignored. Perform the following steps using Group Policy.

1. Configure filter lists.
2. Configure policy filter actions.
3. Configure IPsec policy.
4. Assign IPsec policy.
5. Propagate IPsec policy to domain members.

**Configuring Filter Lists**

You will create the following IP filter lists:

- **Domain Controller**
- **Secure Subnet**

**To create the Domain Controller filter list**

1. On DC1, click **Start**, point to **Administrative Tools**, and then click **Domain Controller Security Policy**.
2. Under **Security Settings**, right-click **IP Security Policies on Active Directory**, and then click **Manage IP filter lists and filter actions**.
3. On the **Manage IP Filter Lists** tab, click **Add**.
4. In **IP Filter List**, clear the **Use Add Wizard** check box.
5. In **Name**, type **Domain Controller**, in **Description**, type **Permits all traffic between DC1 and any other computer**, and then click **Add** to add filter properties.
6. In the **Source address** list on the **Addresses** tab, confirm that **Mirrored** is enabled.
7. In **Source address**, select **My IP Address**. In **Destination address**, select **A specific IP Address**.
8. In **IP address**, type the address of DC1, **172.16.0.1**, click **OK**, and then click **OK** again.

**To create the Secure Subnet filter list**

1. On DC1, on the **Manage IP Filter Lists** tab, click **Add**.
2. In **IP Filter List**, confirm that the **Use Add Wizard** check box is cleared.
3. In **Name**, type **Secure Subnet**, in **Description**, type **Matches all traffic between computers on the 172.16.0.0 subnet**, and then click **Add** to add filter properties.
4. On the **Addresses** tab, confirm that **Mirrored** is enabled.

5. In **Source address**, select **My IP Address**. In **Destination address**, select **A specific IP Subnet**.

6. In **IP address**, type the private network ID, **172.16.0.0.** In **Subnet mask**, type **255.255.255.0**, click **OK**, and then click **OK** again.

#### Configuring Policy Filter Actions

IPsec Policy Filter Actions specify how the resulting IPsec policy negotiates security between computers. They indicate whether security will be negotiated, by what means it will be negotiated, and how to handle requests from non-IPsec-compatible computers.

You will create the following IP filter action:

- **Isolate Domain**

**To create the Isolate Domain filter action**

1. On DC1, click the **Manage Filter Actions** tab, clear the **Use Add Wizard** check box, and then click **Add**.

2. On the **Security Methods** tab, in New **Filter Action Properties**, click **Add**.

3. In **New Security Method**, click **Integrity only**, and then click **OK**.

4. In **New Filter Action Properties**, click the **General** tab. In **Name**, type **Isolate Domain**, and in **Description**, type **Prohibits communication between isolated and non-isolated hosts**.

5. Click **OK**, and then click **Close**.

#### Configuring IPsec Policy

Create an IPsec policy with the name "Domain Isolation." Use the following settings.

- IP Filter Lists: Secure Subnet, Domain Controller, All ICMP Traffic

- Filter Actions: Isolate Domain, Permit

- Authentication method: Kerberos

- Tunnel setting: This rule does not specify an IPsec tunnel

- Connection type: All network connections

1. On DC1, under **Security Settings**, right-click **IP Security Policies on Active Directory**, and then click **Create IP Security Policy**. Click **Next**.

2. In **Name**, type **Domain Isolation**, and in **Description**, type **Provides domain isolation**. Click **Next**.

3. Clear the **Activate the default response rule** check box, click **Next**, and then click **Finish**.

4. Clear the **Use Add Wizard** check box, and then click **Add**.

5. On the **IP Filter List** tab, select **Secure Subnet**. On the **Filter Action** tab, select **Isolate Domain**, and then click **OK**.

6. Click **Add**. On the **IP Filter List** tab, select **Domain Controller**. On the **Filter Action** tab, select **Permit**, and then click **OK**.

7. Click **Add**. On the **IP Filter List** tab, select **All ICMP Traffic**. On the **Filter Action** tab, select **Permit**, click **OK**, and then

click **OK** again.

#### Assigning IPsec Policy

Assign the Domain Isolation IPsec policy to the Isolate OU using Group Policy.

1. On DC1, click **Start**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.

2. Expand contoso.com, right-click **Isolate**, and then click **Properties**.

3. Click the **Group Policy** tab, and then click **New**.

4. Type **Domain Isolation** for the new policy name, and then click **Edit**.

5. Under **Computer Configuration**, expand **Windows Settings**, and then expand **Security Settings**.

6. Click **IP Security Policies on Active Directory (contoso.com)**, right-click **Domain Isolation**, and then click **Assign**.

   There should now be a small green diamond on the lower-right corner of the container for the Domain Isolation policy. This diamond indicates that the policy is currently assigned.

7. Close the Group Policy Object Editor, and then click **Close** to close **Isolate Properties**.

#### Propagating IPsec Policy to Domain Members

IPsec policy is updated through the standard Group Policy refresh intervals. To immediately update changes in IPsec policy settings, from a command prompt, run the following commands on FS1 and CLIENT1:

- **gpupdate /force**

- **net stop policyagent**

- **net start policyagent**

#### Verify IPsec Policy Is Applied

To verify that IPsec policy is applied to the isolated domain hosts, FS1 and CLIENT1, do the following:

1. Click **Start**, click **Run**, type **MMC**, and then click **OK**.

2. In **MMC**, click **File**, click **Add/Remove Snap-in**, and then click **Add**.

3. In the **Add Standalone Snap-in** dialog box, click **IP Security Monitor**, and then click **Add**.

4. Click **Close**, and then click **OK**.

5. Expand **IP Security Monitor**, expand computer name, and then expand **Quick Mode**.

6. Click **Specific Filters** and verify that three filters are applied to this host. If the filters do not appear, restart FS1 or CLIENT1.

For more information about IPsec Security Monitor, see "Monitor IPSec Activity" on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=52598).

Figure 2. IP Security Monitor

**Testing Isolated and Non-Isolated Host Communication**

After configuring and assigning IPsec policy, FS1 and CLIENT1 should be isolated from communication with CLIENT2.

1. On CLIENT2, from a command prompt, type **net view \\FS1.**

   You should not be able to successfully connect to the shared folder on FS1. You will see the following message:

   "System error 53 has occurred. The network path was not found."

2. On CLIENT2, from a command prompt, type **net view \\CLIENT1.**

   You should not be able to successfully connect to the shared folder on CLIENT1.

3. On CLIENT1, from a command prompt, type **net view \\FS1**.

   You should be able to successfully connect to the shared folder on FS1.

Figure 3. Result of domain isolation.

**Configuring Group-Specific Server Isolation**

Now that the entire domain is secured with an IPsec policy, you may want to further isolate specific servers so that only certain isolated computers can communicate with them. Group-specific server isolation requires that a computer that is requesting IPsec authentication belongs to an Active Directory security group. If the requesting computer is a member of the group, it is allowed access to the server. If it is not a member of the group, the IPsec authentication fails.

The following steps build on the domain isolation lab steps, showing how to further isolate server FS2 so that only authorized client computers can communicate with it.

1. Join CLIENT2 to the domain.
2. Create an Active Directory security group named Authorized Computers.
3. Add CLIENT2 to the Authorized Computers group.
4. Configure the "Access this computer from the network" local Group Policy user right on FS1 for the Active Directory group.
5. Determine that CLIENT2 can access FS1 but CLIENT1 cannot.

**Joining CLIENT2 to the Domain**

Using System, join CLIENT2 to the contoso.com domain.

1. On CLIENT2, click **Start**, click **Control Panel**, click **Performance and Maintenance**, and then click **System**.
2. On the **Computer Name** tab, click **Change**.
3. Under **Member of**, click **Domain**, type **contoso.com**, and then click **OK**.
4. You will be prompted to provide a user name and user password to join the computer to the domain.
5. Click **OK** to close the **System Properties** dialog box. You will be prompted to restart your computer to apply your changes.
6. Reboot and log on to the **contoso** domain.
7. On DC1, in **Active Directory Users and Computers**, move the **CLIENT2** computer account to the **Isolate** OU.
8. On CLIENT2, reboot and log on to the **contoso** domain.
9. From a command prompt, type **net view \\FS1.**

You should be able to successfully connect to the shared folder on FS1.

**Creating an Active Directory Security Group Named "Authorized Computers"**

1. On DC1, click **Start**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
2. In the console tree, right-click **contoso.com**.
3. Click **New**, click **Group**, type **Authorized Computers** in **Group Name**, and then click **OK**.

**Adding CLIENT2 to the Active Directory Security Group Named "Authorized Computers"**

1. On DC1, double-click the **Authorized Computers** security group, click the **Members** tab, and then click **Add**.
2. In **Select Users, Contacts, Computers, or Groups**, type **client2; administrator**.
3. Click **Object Types**, click **Computers**, and then click **OK**.
4. Click **Check Names** to verify the object names, click **OK**, and then click **OK** again.

**Configuring the "Access this computer from the network" Local Group Policy Right**

1. On DC1, right-click the **Isolate** OU, click **Properties**, and then click the **Group Policy** tab.

2. Click **New**, type **Restricted FS1 Access**, and then click **Edit**.

3. In the console tree, under **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **User Rights Assignment**.

4. In **Policy**, double-click **Access this computer from the network**.

5. Click **Define these policy settings** to enable this setting.

6. Click **Add User or Group**, and then click **Browse**.

7. Type **Authorized Computers**, click **Check Names** to verify the object name, and then click **OK**.

8. Click **OK** to close the **Add User or Group** properties.

9. Click **OK** to close the **Access this computer from the network** properties.

10. Click **Yes** to accept the warning, and then click **Close** to close **Isolate Properties**.

11. On FS1, from a command prompt, run the following command: **gpupdate /force**.

12. Reboot FS1, CLIENT1, and CLIENT2.

**Testing CLIENT1 and CLIENT2 Access to FS1**
After configuring group specific isolation, FS1 should now be isolated from communication with CLIENT1, even though CLIENT1 is a host in the isolated domain.

1. On CLIENT1, from a command prompt, type **net view \\fs1**.

   You should **not** be able to successfully connect to the shared folder on FS1.

2. On CLIENT2, from a command prompt, type **net view \\fs1**.

   You should be able to successfully connect to the shared folder on FS1.

Figure 5. Result of server isolation.

**Conclusion**
This step-by-step guide has shown how to set up domain isolation and server isolation in a test lab by performing the following steps:

1. Setting up the four computers that make up the domain.

2. Demonstrating that the clients have full access to the servers.

3. Creating an IPsec policy to isolate computers in the isolated domain from computers outside the isolated domain.

4. Demonstrating that computers in the isolated domain can access other computers in the isolated domain, but that computers outside the isolated domain do not have access to members of the isolated domain.

5. Creating an IPsec policy that builds on the domain isolation policy by further isolating a server using group-specific server isolation.

6. Demonstrating that specific, authorized computers can access the isolated server and that unauthorized computers are denied access.

# Network Load Balancing: Security Best Practices for Windows 2000 and Windows Server 2003

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

**In This White Paper**

- General Assumptions
- Deployment and Operational Management
- Summary of Security Attributes

**General Assumptions**

There are a number of general assumptions that need to hold around the infrastructure and operational best practices to ensure a secure environment in which to run NLB clusters:

1. Servers and storage are in physically secure locations.
2. Practical security implementations such firewalls, network probes and management tools to detect irregular traffic are in place.
3. Best practices and common sense in terms of security are adhered to in areas like administration, storage of logs, backup and restore, etc.
4. Platform level security best practices are adhered to in terms of assigning administrative permissions, Access Control Limiting resources, and other housekeeping roles.
5. The network infrastructure services such as Active Directory, DNS, DHCP, WINS, etc. must be secure. Any compromise of these infrastructure services can lead to a compromise of the NLB itself.
6. Administration tools or other applications that administer NLB clusters can be run from remote workstations. The administrator must ensure that the applications are run from trusted computers. Any compromise on the computers on which the applications are executing (that the cluster administrator runs), can compromise the cluster. For example, if there are untrusted users with elevated privileges on the workstation where the administration tools are run, untrusted or malicious code can be run against the cluster by the cluster administrator without the cluster administrator realizing.
7. NLB creates and maintains a set of objects in the operating system such as files, devices, registry keys, etc. These objects have a default security setting that ensures non-privileged users cannot impact the cluster configuration or the applications running on the cluster. Changing these security settings to less restrictive security settings can lead to the cluster being compromised and application data being corrupted.

# Deployment and Operational Management

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

**Cluster administrators**
Administrators can specify groups or individuals that are allowed to manage the cluster. Because NLB does not implement a cluster-wide administrative account, the cluster administrator must ensure that an appropriate administrative account with Administrator privileges has been enabled on all cluster hosts. This account is used by NLB management tools, such as NLB Manager and the NLB control program, wlbs.exe, to administer individual NLB hosts. To simplify this process and ensure uniform access on all hosts, it is preferable to use a single domain or global group account for this purpose.

**Using the cluster administrative tools through a firewall**
The NLB control program, wlbs.exe, should only be used on NLB hosts or, when remote control operations have been enabled, only on a trusted, internal computer within the firewall. By default, remote control operations are disabled, and they must only be enabled if the NLB cluster has been protected by a firewall that blocks UDP control ports 1717 and 2504. Otherwise, unauthorized remote control packets could be delivered to NLB hosts and thereby cluster operations.

The NLB Manager administrative tool can safely be used on trusted computers outside the firewall. This tool uses a secure method of communication to access NLB hosts. NLB Manager uses WMI interface to manage NLB hosts. Please refer to WMI/DCOM documentation to see what ports to unblock to allow WMI/DCOM access from outside the firewall. Nevertheless, make sure that this tool is only executed on a trusted, remote computer.

**Using Kerberos Authentication in an NLB Cluster**
NLB does not use its own cluster-wide authentication mechanism for cluster administration. Instead, NLB management tools use an appropriate administrative account, which must be enabled with administrative privileges on each NLB host. If a domain account is used for this purpose, it will use Kerberos authentication to control access to NLB hosts.

**Using NLB to support VPN connections**
NLB can be used to load balance virtual private network connections using the PPTP protocol in Windows 2000 and using both the PPTP or IPSec protocols in Windows Server 2003. When using IPSec, some client sessions may be disrupted when a new NLB host joins the cluster. This issue has been corrected in Windows XP SP1 and in Windows Server 2003.

**Network Security**
To coordinate their actions, all NLB hosts communicate with each other by periodically exchanging heartbeat messages on a common subnet, which is also used to receive incoming client requests. This subnet must be physically protected from intrusion. Otherwise, unauthorized heartbeat messages could be delivered to NLB hosts and disrupt cluster operations. Note that NLB heartbeat messages use a uniquely assigned Ethertype (0x886F) which is not normally routed across subnets. However, the cluster administrator must ensure that unauthorized computers and devices which could emit invalid NLB heartbeat packets are not placed directly on the NLB subnet. The effects of these disruptions are described below in the subsection "Rogue Servers".

**Network Flooding**
NLB cluster hosts may be affected by denial of service attacks, which flood the cluster with invalid network packets. These attacks can create additional CPU and network load on the cluster hosts and thereby delay the handling of valid client requests. In addition, they can cause NLB hosts to increase their memory usage up to parameterized limits. These limits are adjustable by setting registry variables on each NLB host, as described in the Windows 2000 Resource Kit. In extreme cases, a high volume of invalid network packets can disrupt extant client connections and require affected clients to reconnect to the cluster. Note that the Windows network protocol stack and server applications, such as Web servers, also may be affected by denial of service attacks.

**Rogue Servers**
Rogue NLB servers on an NLB subnet could emit heartbeat packets that disrupt cluster operations. Disruptions can include impeding NLBs convergence process such that cluster hosts cannot be added and recovery for a failed host cannot be completed. In addition, disruptions can block some or all of NLBs service to clients. NLB subnets must be physically protected from intrusion by unauthorized computers and devices.

**Best practices**
To summarize, best practices for NLB cluster administrators:

- Cluster administrators should establish a common administrative account on all NLB hosts that have Administrator privileges. To simplify cluster management, it is preferable that a single domain or global group account be used for this

purpose.

- The NLB subnet must be physically protected from intrusion by unauthorized computers and devices to avoid interference from unauthorized heartbeat packets.

- NLBs remote control mechanism is disabled by default. It should remain disabled unless the administrator can ensure that the NLB subnet has been physically protected from intrusion and that UDP control ports 1717 and 2504 have been firewalled to prevent unauthorized remote control.

- If remote control has been enabled, remote control operations using the NLB control program wlbs.exe must only be performed from a trusted computer within the firewall.

- NLB Manager provides a secure method for remote cluster management and should be used instead of wlbs.exe whenever possible. NLB Managers optional host list file should only be saved to a file that is accessible by user accounts (such as the NLB cluster administrators account) that have local Administrator privileges.

# Summary of Security Attributes

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section outlines the various objects and their associated security attributes needed to ensure that NLB runs successfully. This section lists the minimum security requirements. If the security attributes are made more restrictive, NLB may not run. If the security attributes are less restrictive, it may result in malicious attacks being able to compromise the cluster or corrupt end-user data. We recommend that the security attributes on the objects not be changed from the default settings.

**Directory and file protection**

| Object | Description | Minimum recommended security attributes |
|---|---|---|
| **<filespec>** | **NLB Manager host list file** | **BUILTIN\Administrators: Full control** |

**System resources**

The cluster service uses other system resources that are protected by default.

| Object | Description | Minimum recommended security attributes |
|---|---|---|
| **HKLM*** | **HKLM registry hive** | **SYSTEM:Full control**<br><br>**BUILTIN\Administrators: Full control** |

# Kerberos Protocol Transition and Constrained Delegation

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

This document refers to features that are included with Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. You can run most of the features that are discussed in this document on the Windows Server 2003, Web Edition operating system, except for Active Directory and Kerberos Key Distribution Center (KDC).

**In This White Paper**

Introduction (Kerberos Protocol Transition and Constrained Delegation)

Authenticating Web Application Users

Windows Server 2003 Kerberos Extensions

Sample Scenario Source Files

Summary (Kerberos Protocol Transition and Constrained Delegation)

Conclusion (Kerberos Protocol Transition and Constrained Delegation)

# Introduction (Kerberos Protocol Transition and Constrained Delegation)

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

The number of security threats to Web applications that are deployed on the Internet increase every day. An enterprise that deploys a Web application on the Internet has to deal with security issues, such as denial of service attacks, identity spoofing, unauthorized access to program functions, and so on. You can mitigate certain types of security risks, such as unauthorized access to data, through the process of user authentication and authorization. This document examines the requirements that you can use to authenticate the users of Web applications and discusses how the new extensions to the Kerberos authentication protocol in Microsoft Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition can satisfy these requirements. Note that this document is not a specification of the protocol extensions and, therefore, detailed explanations of the protocol message flows and data structures are outside of the scope of this document. If you are familiar with the features of the extensions and want a summary of the implementation of the extensions, you can skip to the "Summary" section at the end of the document.

This article assumes that you have a basic understanding of the Kerberos authentication protocol and Windows security concepts, such as user privileges and tokens. For a Kerberos protocol primer, see "Exploring Kerberos, the Protocol for Distributed Security in Windows 2000" at the Microsoft Web site (http://www.microsoft.com/msj/0899/kerberos/kerberos.aspx).

The sample scenario and sample code in this document assumes some basic knowledge of Microsoft ASP.NET programming.

# Authenticating Web Application Users

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

This section discusses certain characteristics of Web applications emphasize some of the key requirements for Web application authentication protocols.

Web applications can use a variety of protocols to authenticate users. For example, Web applications can use the authentication protocols that are supported by HTTP or Web applications may depend on custom authentication mechanisms that are used with the existing Web server infrastructure (such as form and cookie-based authentication). However, not all of the authentication mechanisms have the same security attributes; some of the authentication mechanisms have stronger security properties than others. For example, Kerberos supports mutual authentication, while cookie-based authentication schemes do not.

Designers of scalable and reliable Web applications often follow design principles that advocate a tiered-application approach. For example, a Web-based line of business (LOB) application may consist of presentation, business logic, and data tiers. Frequently, the tiered approach introduces the delegation requirement that should be supported by the underlying network and operating system security infrastructure. Delegation allows a service to act on another security principles behalf to gain access to resources throughout the network. N-tiered applications may use delegation to satisfy various application requirements (for example, auditing or making authorization decisions in the original users context).

A more specific example is a Web-based bank account withdrawal application with a business component that resides in the business tier. The application verifies whether the Web user has permissions to withdraw the requested amount of $1,000 US from a given bank account. That business component needs to know the identity of the application user to allow the transaction. In the ideal scenario, the authentication protocol would propagate the original user context throughout the end-to-end application flow, even though the flow may cross physical computer boundaries. Application components that are in the respective tiers can then retrieve the original user context and perform authorization accordingly.

At the time that this document was published, Kerberos was the only widely-adopted authentication protocol that was capable of performing delegation. When n-tier applications are not using an authentication protocol that enables delegation, they typically design in user identifiers that are passed through application message bodies. Without further security measures to protect the application message while it is in transit, this approach is susceptible to message modification which could result in the identifier being modified and, subsequently, result in a security breach (such as identity spoofing). In addition to delegation, Kerberos also offers the benefits of mutually-authenticating communicating parties, as well as protecting the application message when it is in transit by using data encryption.

Kerberos is not the default authentication protocol that is used by Web applications because Kerberos uses port 88, a port that is typically blocked by corporate firewalls. Because of this port restriction, it is difficult to successfully deploy Kerberos in an Internet environment.

Note that:

- Web applications require firewall-friendly authentication at the authentication tiers
- Delegation is a frequently desired security feature for n-tier Web applications

Ideally, Web applications would use an authentication protocol with all of the desired security attributes of Kerberos, while offering ease of deployment over the Internet. To work around some of these limitations, consider the following engineering approaches:

- Fix the existing authentication protocols (like Basic, Digest, and SSL) so that they support delegation and mutual authentication. This is not a viable option because of the breadth of design and engineering work that is required for every authentication protocol that is supported.
- Fix the Kerberos protocol so that it can traverse corporate firewalls. This approach (or at least its functional equivalent) is not available.
- Do enough engineering work so that the Kerberos protocol becomes the default authentication protocol that is used behind corporate firewalls, independent of the protocol that is used at the Web server authentication tier to authenticate the Internet user. This approach has been adopted in the Windows Server 2003 family to help address delegation issues

that Web applications encounter. The new Kerberos protocol extensions provide significant security benefits to Web applications without modifying the functions of Web authentication protocols that are already deployed.

# Windows Server 2003 Kerberos Extensions

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

There are two new extensions in the implementation of the Kerberos protocol in Windows Server 2003:

- **Protocol transition**: The protocol transition extension allows a service that uses Kerberos to obtain a Kerberos service ticket on behalf of a Kerberos principal to the service without requiring the principal to initially authenticate to the Kerberos Key Distribution Center (KDC) with a credential.

- **Constrained delegation**: The constrained delegation extension allows a service to obtain service tickets (under the delegated users identity) to a subset of other services after it has been presented with a service ticket that is obtained either through the TGS_REQ protocol, as defined in IETF RFC 1510, or in the protocol transition extension.

  For more information about RFC 1510, see the IETF Web site (http://www.ietf.org).

| **Note** |
| --- |
| Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here. |

The extensions that are included in Windows Server 2003 are described in the following sections of this document.

**The Protocol Transition Extension**

As mentioned in the previous section, the protocol transition extension allows a service to obtain a Kerberos service ticket to the service on behalf of a Kerberos security principal. No user credential is required for the transition. Applications may transition into Kerberos through two mechanisms that are described in this section.

The first method that you can use to transition to the Kerberos protocol is to call the **LsaLogonUser** Win32 function or directly instantiate a **WindowsIdentity** class object. The new **KerbS4ULogon** logon message type and **KERB_S4U_LOGON** logon information structure have been defined to support protocol transitioning through the **LsaLogonUser** function. A successful call to the **LsaLogonUser** function returns a Windows user token.

There is a new **WindowsIdentity** class constructor in the Microsoft .NET Framework assembly that s the **LsaLogonUser** function to help managed code applications use the Kerberos protocol extension features. The sample in this article uses this new **WindowsIdentity** class.

Two variations of user tokens may be returned, depending on whether the caller process has the **Act as part of the operating system** privilege. When the call is made from a process without the **Act as part of the operating system** privilege, an identification token is returned. When the caller process is assigned the **Act as part of the operating system** privilege, an impersonation token is returned. The Windows Server 2003 family includes a new **SeImpersonatePrivilege** privilege. Only processes that have this privilege can obtain impersonation-level tokens and use the tokens to impersonate the users to perform certain operating system functions. To use the full feature of the impersonation-level token that is obtained through protocol transition, the caller process that uses protocol transition must have both the **SeImpersonatePrivilege** and **Act as part of the operating system** privileges. If the caller process has only the **Act as part of the operating system** privilege, the impersonation-level token is downgraded to an identification-level token when it tries to impersonate by using the token. Basically, an identification token allows the process to determine the identity and privileges that are associated with a user, but an impersonation token also allows the process to take on the token users identity and operate in that users identity. The user token level does not directly determine whether the caller process can subsequently use constrained delegation to call other services. The caller process may use the service ticket that was obtained through protocol transition to obtain service tickets to other services if you correctly configure the service account to use the Kerberos constrained delegation extension. (The constrained delegation extension is discussed in more detail in the next section.)

The programmatic mechanism that is described above allows applications to initiate protocol transition. In addition, you should also configure the applications to run as services that use Kerberos. Programming and configuration tasks are discussed in more details later in this document.

The second method that you can use for applications to transition into Kerberos is through other existing Windows-integrated authentication protocols, such as HTTP basic, digest, or Secure Sockets Layer/Transport Layer Security (SSL/TLS). Some applications are designed to use non-Kerberos, Windows-integrated authentication protocols when the Kerberos protocol may

not be the best option at the user-authentication tier. Subsequent application tiers may switch to Kerberos when it is needed and possible to do so. This concept is illustrated in Figure 1:

- In step 1, an application user is authenticated through a non-Kerberos authentication protocol that is integrated into the Windows operating system.
- In step 2, the security package creates a Windows user token for the authenticated user when the authentication is completed. Note that the user token is indirectly linked to a Kerberos service ticket for the user if the user is authenticated by the Kerberos protocol. If the user is not authenticated by Kerberos, no service ticket is associated with the user token.
- In step 3, the application impersonates the user and connects to a database server that requires Kerberos for authentication.
- In step 4, the Kerberos security package detects that there is no Kerberos ticket in the user token.
- In step 5, the Kerberos Security Support Provider (SSP) automatically initiates protocol transition by requesting a service ticket for the impersonated user.

**Figure 1: Protocol Transition from Windows-Integrated Authentication Protocols**

| **Note** |
| --- |
| Two sample Web scenarios that you can use for Kerberos protocol transition are discussed later in this document. |

The following network and operating system requirements must be met if you are using protocol transition in an Active Directory forest:

- You must run the operating system process that initiates protocol transition on a computer that is running Windows Server 2003
- All domain controllers that are used for protocol transition in the service and user account trust path domains must be running Windows Server 2003. There are two ways to accomplish this, and you can use either one:
    - You can upgrade all domain controllers in the domain to computers that are running Windows Server 2003
    - You can upgrade all domain controllers in Active Directory sites where domain controllers are used for protocol transition to computers that are running Windows Server 2003

To use protocol transition across Active Directory forests, the following additional requirements must also be satisfied:

- Both Active Directory forests must be running at the Windows Server 2003 forest functional level
- The forests must have established two way trusts across forests

**The Constrained Delegation Extension**

The reason why the constrained delegation extension is introduced in Windows Server 2003 can be best explained by describing the limitations in the Windows 2000 implementation of Kerberos delegation. In the Windows 2000 Kerberos delegation model, the Kerberos Key Distribution Center (KDC) does not limit the scope of services to which a Kerberos principal's identity can be delegated. In other words, after a service account is trusted for delegation, it can request service tickets on behalf of an authenticated user to any other service accounts. (See the Windows 2000 Kerberos Authentication white paper on the MSDN Web site for more technical information about the mechanics of delegation at http://www.microsoft.com/technet/prodtechnol/windows2000serv/deploy/confeat/kerberos.mspx.) This delegation method does not provide precise mechanisms for an application to specify a subset of service accounts that it determines to be trustworthy for delegation. Essentially, applications are exposed to broader impersonation risks that may span across resource domains that have different levels of security policy requirements; some of the security policies may not be as strict as the applications security requirements. From the domain administrators point of view, it is too risky to enable unconstrained Kerberos delegation in the enterprise because there is no way to exclude untrusted servers from participating in delegation.

With constrained delegation, domain administrators can configure service accounts so that they delegate only to specific sets of service accounts. On Active Directory that is running Windows Server 2003, a new **Allowed-to-Delegate-to** (**A2D2**) Active Directory attribute is added to service accounts to help enforce constrained delegation. The **A2D2** attribute lists the service principal names (SPNs) of other service accounts to which a given service account is allowed to delegate. When a Windows Server 2003 KDC processes a service ticket request by using the constrained delegation extension, the KDC verifies that the target service account is listed in the **A2D2** attribute. With the addition of constrained delegation, computers that are running Windows Server 2003 support two modes of delegation: Kerberos unconstrained delegation and Kerberos constrained delegation. Kerberos unconstrained delegation is supported if the user initially provides a user credential to obtain a ticket-granting ticket (TGT) that can be forwarded to a service that is trusted for delegation. This behavior is the same as the Windows 2000 behavior for Kerberos implementations. Constrained delegation can be used by a service if the service can obtain a Kerberos service ticket to itself for the user whose security context is to be delegated. It does not matter whether the user obtained the service ticket directly by authenticating through Kerberos, or whether the service obtained a service ticket on behalf of the user through the protocol transition extension. Note that constrained delegation works only in the boundary of a domain.

For a service account to use protocol transition in conjunction with constrained delegation, you must set a new control flag, **Trusted-to-Authenticate-for-Delegation** (**T2A4D**), on the service account in Active Directory. Only domain administrators can change the value of the control flag. If you set the flag for a service account, the account can use the protocol transition extension to obtain a service ticket that it can then use to obtain service tickets to a preconfigured subset of services that use Kerberos. In addition, you must not mark the impersonated user account as a sensitive account that cannot be delegated.

**Enabling User Identification, Impersonation, and Delegation Through Extension Configurations**

You can perform several security-related operations by using the extensions that have been discussed in this document. You can perform these security-related operations, even when a users Kerberos authentication credential is not available. For example, you can:

- Obtain both privilege and authorization information for a user.
- Impersonate a user by running an application request in a users identity.
- Make remote calls to a set of preconfigured Kerberos service instances in a given users identity.

Whether an application can perform one or all of the above operations is based on how you configure the service account. As discussed earlier in this paper, an application can initiate protocol transition by using two mechanisms: by programmatically invoking the **LsaLogonUser** function or automatically through the Kerberos SSP. The necessary conditions for protocol transition to take place are different for the two mechanisms.

Scenario A, Scenario B, Scenario C, and Scenario D in Figure 2a, Figure 2b, Figure 2c, and Figure 2d illustrate the successful results that can occur when you call the **LsaLogonUser** function with different service account configurations.

In Scenario A in Figure 2a, protocol transition allows a service without the **Act as part of the operating system** privilege to obtain an identification-level token that works only for making application authorization decisions. In this scenario, the **Act as part of the operating system** service account does not have the **Trusted-to-Authenticate-for-Delegation** (**T2A4D**)

permission and the service ticket that is issued does not have the Forwardable flag set. A ticket that does not have the Forwardable flag set cannot be used for a constrained delegation operation.

1. The program calls the **LsaLogonUser** function or instantiates the **WindowsIdentity** class object.
2. The Kerberos **Protocol Transition** service ticket.
3. KDC checks the delegation policy for the T2A4D flag on the service account.
4. The Kerberos Protocol Transition service ticket reply.
5. An identity or impersonation-level user token is created when the **LsaLogonUser** function or the **WindowsIdentity** class constructor call returns to the program.

**Figure 2: a Scenario A: Service Account Does Not Have TCB and the T2A4D Flag Is Not Set**

In Scenario B in Figure 2b, the service account has the **Act as part of the operating system** privilege and protocol transition allows the service to obtain an impersonation token. As noted previously, the service process must also have the **SeImpersonatePrivilege** privilege to use the impersonation token so that it can run in the users identity. You do not want any arbitrary service to be able to impersonate and run as other users. Because of this, the service must have both the **Act as part of the operating system** and **SeImpersonatePrivilege** privileges that can be assigned only by members of the local administrators group. Only local administrators can give those services the ability to impersonate users on the computers where the services are running. Like Scenario A in Figure 2a, the Kerberos service ticket that is obtained by the service account in Scenario B does not have the Forwardable flag set and therefore the ticket cannot be used for constrained delegation.

1. The program calls the **LsaLogonUser** function or instantiates the **WindowsIdentity** class object.
2. The Kerberos **Protocol Transition** service ticket.
3. KDC checks the delegation policy for the T2A4D flag on the service account.
4. The Kerberos Protocol Transition service ticket reply.
5. An identity or impersonation-level user token is created when the **LsaLogonUser** function or the **WindowsIdentity** class constructor call returns to the program.

*Impersonation is enabled if the process has the **SeImpersonatePrivilege** privilege.

**Figure 2: b Scenario B: Service Account Has TCB and the T2A4D Flag Is Not Set**

The **T2A4D** control flag is set for the service account on Active Directory by domain administrators and is independent of **Act as part of the operating system** privileges on the local computer. In Scenario C in Figure 2c, the KDC that issues the service ticket does not check to see if the calling process has either the **Act as part of the operating system** or **SeImpersonatePrivilege** privileges when processing a service ticket request by using the protocol transition extension. Because of this, the KDC issues a service ticket with the Forwardable flag set if the **T2A4D** control flag is set. This service ticket is accepted by a KDC for constrained delegation requests if both the requesting and target services are in the same domain and the target service (SPN) is listed in the requesting services **A2D2** attribute in Active Directory.

1. The program calls the **LsaLogonUser** function or instantiates the **WindowsIdentity** class object.
2. The Kerberos **Protocol Transition** service ticket.
3. KDC checks the delegation policy for the T2A4D flag on the service account.
4. The Kerberos Protocol Transition service ticket reply.
5. An identity or impersonation-level user token is created when the **LsaLogonUser** function or the **WindowsIdentity** class constructor call returns to the program.

*Impersonation is enabled if the process has the **SeImpersonatePrivilege** privilege.

**Figure 2: c Scenario C: Service Account Has TCB and the T2A4D Flag Is Set**

In Scenario D in Figure 2d, the service ticket is issued with the Forwardable flag set and the created user token is an identification-level token because the service does not have the **Act as part of the operating system** privilege. Although the service ticket allows constrained delegation, the service cannot use the identification-level token to impersonate the user. Most practical applications require an impersonation-level token to perform network-related operations before authenticating as the delegated user. Because of this, the service cannot impersonate the user and use the service ticket for constrained delegation for most applications.

1. The program calls the **LsaLogonUser** function or instantiates the **WindowsIdentity** class object.
2. The Kerberos **Protocol Transition** service ticket.
3. KDC checks the delegation policy for the T2A4D flag on the service account.
4. The Kerberos Protocol Transition service ticket reply.
5. An identity or impersonation-level user token is created when the **LsaLogonUser** function or the **WindowsIdentity** class constructor call returns to the program.

**Figure 2: d Scenario D: Service Account Does Not Have TCB and the T2A4D Flag Is Set**

In situations where protocol transition is initiated by the Kerberos Security Support Provider (SSP) as in the scenario shown in Figure 1(for example, not by directly calling the **LsaLogonUser** function or the **WindowsIdentity** class object), an impersonation-level user token must already exist for that user before the Kerberos SSP tries to perform protocol transition. The impersonation-level user token could be created previously by any of the Windows-integrated SSPs. The service must also have the **SeImpersonatePrivilege** privilege to impersonate the user and initiate the protocol transition extension through the Kerberos SSP. Subsequently, the services ability to perform constrained delegation is determined by the Active Directory policies and the state of the Forwardable flag in the service ticket that is issued through protocol transition. The Active Directory policy checks that are used by the KDC to issue service tickets that are enabled for constrained delegation are the same as the flags that were previously described (for example, the **T2A4D** and **A2D2** flags).

**Sample Web Service Scenarios**

Figure 3 displays two simple Web service scenarios that illustrate how the Kerberos features work.

The first sample scenario illustrates where protocol transition is initiated by the Kerberos SSP. The scenario consists of a browser client that invokes an ASP.NET Web service that, in turn, calls a stored procedure on a computer that is running Microsoft SQL Server.

The second sample scenario illustrates how protocol transition works by programmatically instantiating a **WindowsIdentity** class object. In this scenario, the browser client is used to navigate through an ASP.NET Web application that invokes the same SQL Server stored procedure that is invoked in the first sample scenario.

Both scenarios are configured to use an Active Directory forest with a single-domain Kerberos Key Distribution Center (KDC). Note that you can run both the ASP.NET Web service and application from different virtual directories of the same computer that is running Microsoft Internet Information Services (IIS).

For the sample scenarios to work, Active Directory must run on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. Also, IIS must run on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows Server 2003, Web Edition. The computer that is running SQL Server 2000 must run Windows 2000 Professional, Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or a later version of Windows.

**Sample Scenario One**
Sample scenario one illustrates the following authentication flow:

1. The user is initially authenticated to the Web service through a non-Kerberos Windows authentication protocol. This sample scenario uses Hypertext Transfer Protocol (HTTP) digest authentication.

2. The Web service impersonates the authenticated Windows user before connecting to the SQL server.

3. The Web service tries to open a connection to the SQL server, and is challenged to prove its identity.

4. The Kerberos authentication package that is running on the same computer as the Web service cannot find a Kerberos ticket for the impersonated user and, therefore, uses protocol transition to obtain a service ticket to the Web service in the impersonated user context.

5. The Web service uses constrained delegation to obtain a service ticket to the SQL server. When this occurs, the authentication is completed in the impersonated user identity.

For demonstration purposes, the Web service uses HTTP digest authentication for initial user authentication. Although the sample uses digest authentication, you can easily modify the sample to support protocol transitioning from other Windows-integrated authentication protocols by changing the IIS directory security configuration.

The sample Web service supports the public **TestKerbSfu** method that the browser client invokes. This Web service method then invokes the **GetUserInfo** SQL server stored procedure that returns the identity of the user who invoked the stored procedure. The Web methods final return value is a string that contains the caller identities of the Web service and stored procedure. If you set up the sample that is described in this document, the two user identities that are in the return string are identical and they reflect the domain user account under which the Web service and stored procedure code operates.

In this scenario:

1. The browser gains accesses to the Web service with a URL such as http://www.fabrikam.com/KerbExtWebSvc/authxws.asmx?op=TestKerbSfu.

2. The browser displays an authentication dialog box that prompts for the user name and password to authenticate to the Web server.

3. The user name and authentication credential is sent to the server on which IIS is running to host the Web service.

4. IIS performs the HTTP digest authentication before forwarding the Web service request to the .NET Framework .asmx handler.

5. Before establishing the connection to the SQL server, the Web service impersonates the authenticated user and transitions into the Kerberos protocol by obtaining a Kerberos service ticket to the Web service.

The Web service uses Kerberos constrained delegation to obtain a service ticket to the SQL server in the authenticated browser users identity.

**Figure 3: Sample Scenarios**

**Sample Scenario Two**

Sample scenario two illustrates a slightly different method that you can use to use the Kerberos protocol transition extension. In this scenario, the Web service is replaced by an ASP.NET Web application that uses ASP.NET form-based authentication to authenticate users. The Web application goes through a series of interactive steps to show you how an application can use an authentication protocol that is not integrated in the Windows operating system to authenticate the Web users and then transition into Kerberos to authenticate to backend services, such as the SQL server that was used in sample scenario one.

The Web application illustrates the following authentication flow:

1. The browser client navigates to the virtual directory of the sample and is redirected to the login Web form.

2. The user types a user name and password in the login Web form, and then clicks **Login**.

3. The login Web page authenticates the user by using a custom authentication mechanism (for example, by checking a hashed password that is stored in a SQL server database), and then issues a login cookie to the browser when the authentication is successful. The user is then redirected to the default Web page for the Web application.

4. The user types a unique principal name (UPN) to be used for Kerberos protocol transition, and then the user clicks **Do protocol transition**.

5. The Web application transitions into Kerberos by using the specified UPN, and then saves the Kerberos security context in the Web application session state.

6. The user has the option to connect to the SQL server if they click **Invoke SQL Server**. When the user clicks this option, the Web application retrieves the user context from the application session state, and then the Web application impersonates the user before connecting to the SQL server.

7. When the Web application is challenged by SQL server to authenticate, the Web application uses Kerberos constrained delegation to obtain a service ticket to the SQL server in the impersonated user identity.

8. The Web application returns a response string that shows the impersonated user identity and the user identity that is authenticated on the SQL server.

# Sample Scenario Source Files

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

The sample in this section uses Microsoft Visual Studio .NET and refers to the Windows Server 2003 implementation of the .NET Framework runtime. The version of the .NET Framework runtime in Windows Server 2003 is different than the runtime that is included with Visual Studio .NET.

You can obtain the source code and setup programs in the sample scenario from the Microsoft Download Center Web site at http://download.microsoft.com/download/8/9/7/89734348-63AB-4F55-B11B-8C0AC50612B1/KerberosProtocolExtensions.msi. The file contains the following items:

| Files and folders | Descriptions |
|---|---|
| Authxws* | Contains the implementation of the ASP.NET Web service. You need to create an IIS /Authxws virtual directory that points to the Authxws folder so that the Visual Studio .NET project can successfully start. |
| WebApp* | Contains the implementation of the ASP.NET Web application. You need to create a WebApp IIS virtual directory that points to the WebApp folder so that the Visual Studio .NET project can successfully start. |
| KerbExtWebSvc* | Contains the Visual Studio .NET Deployment project that builds the setup program that you can use to create the ASP.NET Web service. |
| KerbExtWebApp* | Contains the Visual Studio .NET deployment project that builds the setup program that is used to create the ASP.NET Web application. |
| Sql* | Contains a SQL script that sets up a sample database and a stored procedure. |
| SfuIdentity* | Contains managed C++ code that illustrates Kerberos protocol transition through the **LsaLogonUser** function. Note that the rest of the sample does not use code in this folder. This code is sample code for applications that need to use native Win32 functions instead of the **WindowsIdentity** class. |

**Sample Scenarios Configuration Tasks**

| **Note** |
|---|
| To complete the following configuration steps, you must have domain administrator privileges to Active Directory, local administrator privileges to the ASP.NET Web service, and administrative privileges on the SQL server. |

To set up the sample:

1. Configure the domain to run at the Windows Server 2003 functional level:

    a. Open the Active Directory Users and Computers Microsoft Management Console (MMC) Snap-in.

    b. In the console tree, right click **Active Directory User and Computers** *server_name* , point to **All Tasks**, and then click **Raise Domain Functional Level**.

    c. In the **Select an available domain functional level** box, click **Windows Server 2003**.

2. Create two domain user accounts for the IIS process pools that host the ASP.NET Web service and application:

| **Note** |
|---|

| |
|---|
| Although you can run the sample Web service and application in the default Network Service account that all newly-created Web applications use on the server on which IIS is installed, the Network Service account is generally used to run other services and Web applications. This means that other processes that run in this account can also exploit the extra Kerberos extensions-related privileges if you give the Network Service account the ability to use both the protocol transition and constrained delegation extensions. This is not the desired behavior, so you should isolate the ability to use Kerberos extensions to a specific domain user account on computers that are running Windows Server 2003. |

a. Open the Active Directory Users and Computers MMC Snap-in.

b. In the console tree, double-click **Active Directory Users and Computers** *server_name* .

c. In the details pane, right-click **Users**, point to **New**, and then click **User**.

d. In the **New Object User** box, type the appropriate information , and then complete the procedure.

e. Repeat step c and step d for the second user account.

3. Create a domain user account for the SQL server service. To do this, repeat the instructions in step 2.

4. Register Kerberos Service Principal Names (SPNs) for the user accounts that you created in the previous two steps.

   To use the domain account that you created as a Kerberos service account, you must use the Setspn (Setspn.exe) command-line tool to create an SPN for the account. For example, to add an SPN named ws/kerbsfuidentity for the kerbsfuidentity domain account, type the following command at a command prompt:

   **setspn a ws/kerbsfuidentity kerbsfuidentity**

   To create an SPN for the SQL Server service that is running on sqlcomputer.devdomain.fabrikam.com by using the sqlservice service account, type the following command at a command prompt:

   **setspn a MSSQLSvc/sqlcomputer.devdomain.fabrikam.com:1433 sqlservice**

| **Note** |
|---|
| For more information about how to configure SQL Server service for Kerberos authentication, see Microsoft SQL Server 2000 Security on the MSDN Web site. |

5. Create a domain user account that will be used as the user account for Web browser user authentication in scenario one and for protocol transition in scenario two. To create a domain user account, repeat the procedure that is described in step 2.

6. Configure the service accounts that will be trusted for constrained delegation to the SQL Server.

   In the sample scenario, you want to constrain the ability of the service accounts to present delegation credentials to only the specific SQL Server service account. Use the following procedure to add the specified service to the **A2D2** attribute on the service accounts that you created in step 2:

   a. Right-click the user account, and then click **Properties**.

   b. In the **Properties** dialog box, click the **Delegation** tab,, and then click **Trust this user for delegation to specified services only**.

   c. Click **Use any authentication protocol**, and then click **Add**.

   d. Click the SQL Server service SPN that you registered in step 4.

| Note |
| --- |
| The **Delegation Property** tab for a user account is available only if you have created an SPN for the user account. Step 4 describes how to create an SPN. |

7. Give service accounts Read access to the **tokenGroupsGlobalAndUniversal** user object attribute in Active Directory.

   The service accounts that is performing the protocol transition procedure must have Read access to the **tokenGroupsGlobalAndUniversal** user object attribute in Active Directory. To give the service accounts Read access:

   a. Open the Active Directory Users and Computers MMC Snap-in.

   b. In the console tree, click **Builtin**.

   c. In the results pane, right-click **Windows Authorization Access Group**, and then click **Properties**.

   d. Click the **Members** tab, and then click **Add**.

   e. In the **Enter the object names to select (examples)** box, type the name of the first service account that you created in step 2, and then click **OK**.

   f. Repeat step 7d and step 7e for the second service account that you created in step 2.

8. Add the service accounts to the IIS worker process group on the computers that are running the ASP.NET Web service and the application:

   a. Click **Start**, point to **Administrative Tools**, and then click **Computer Management**.

   b. In the console tree, click **Local Users and Groups**, and then click **Groups**.

   c. In the results pane, right-click **IIS_WPG**, and then click **Add to Group**.

   d. Click **Add**, in the **Enter the object names to select (examples)** box, type the name of the service account, and then click **OK**.

| Note |
| --- |
| At the time that this document was published, you also need to manually configure the service account to have access to the %SystemRoot%/Temp folder so that you can run ASP.NET. Confirm that the service account has both **List Folder\Read Data** and **Delete** permissions to the %SystemRoot%/Temp folder. |

9. Deploy the ASP.NET Web service:

   a. Create a new IIS process pool:

      Click **Start**, point to **Administrative Tools**, and then click **Computer Management**.

      In the console tree, double-click **Services and Applications**, and then double-click **Internet Information Services (IIS) Manager**.

      In the console tree, right-click **Application Pools**, point to **New**, and then click **Application Pool**.

      In the **Application Pool ID** box, type a name for the new application pool, and then click **OK**.

   b. Set the process pool identity to one of the user accounts that you created in step 2 for the process pool that hosts

the ASP.NET Web service:

In the **Application Pools** pane, right-click the application pool that you created in the previous step, and then click **Properties**.

Click the **Identity** tab, click **Configurable**, and then type the appropriate user name and password.

10. Create a new virtual directory for the ASP.NET Web service. To do this, run the Setup.exe program in the KerbExtWebSvc folder to start the wizard that will help you set up a virtual directory for the Web Service.

11. Configure the Web service to use digest authentication:

    a. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.

    b. Right-click the Web service virtual directory, and then click **Properties**.

    c. Click the **Directory Security** tab, and then click **Edit** in the **Authentication and access control** box.

    d. In the **Authentication Methods** box, confirm that the **Digest authentication for Windows domain servers** check box is the only check box that is selected, click **OK**, and then click **Apply**.

12. Configure the Web service to use the process pool that you created in step 9a:

    a. In IIS Manager, right-click the Web service virtual directory, and then click **Properties**.

    b. Click the **Virtual Directory** tab, click **Application Pool**, and then click the application pool that you created in step 9a.

13. Configure the name of the computer that is running SQL Server in the Web services Web.config file.

    The Web service uses the application configuration section in Web.config file to find the name of the computer that is running SQL Server. Because of this, you need to modify the value of the **sqlServer** key (in the <appSettings> section) in the Web.config file to point to the computer that is running SQL Server. For example, if the name of the computer that is running SQL Server is *computer_name*, open a text editor, such as Notepad, and then open the Web.config file that is located in the folder where the Web service is installed. Search for <appSettings>, and then make the following changes to the file:

    <**appSettings**>

    <**add key="sqlServer" value="***computer_name***" /**>

    <**/appSettings**>

14. Deploy the ASP.NET Web application:

    a. Assign the **Act as part of the operating system** privilege to one of the user accounts that you created in step 2. This account should be different from the account that you used in step 9b:

    On the computer that is hosting the Web application, click **Start**, point to **Administrative Tools**, and then click **Local Security Policy**.

    In the console tree, double-click **Local Policies**, and then double-click **User Rights Assignment**.

    Right-click the **Act as part of the operating system** policy, point to **Properties**, and then click **Add user or Group**.

Type the user account that you created in step 2 for the IIS process pool that is hosting the ASP.NET Web application, and then click **OK**.

b. Create a new IIS process pool for the Web application. To do this, repeat the procedure in step 9a.

c. Set the process pool identity to the user account that was assigned the **Act as part of the operating system** privilege in step 14a. To set the identity of the process pool that you created in the previous step, repeat the procedure in step 9b.

d. Create a new virtual directory for the ASP.NET Web application. To do this, run Setup.exe in the KerbExtWebApp folder to start the wizard.

e. Enable anonymous access to the Web application:

   Using IIS Manager, right-click the Web application virtual directory, and then click **Properties**.

   Click the **Directory Security** tab, and then, in the **Authentication and access control** box, click **Edit**.

   Confirm that the **Enable anonymous access** check box is the only check box that is selected in the **Authentication Methods** dialog box, click **OK**, and then click **Apply**.

f. Configure the Web application to use the process pool that you created in step 14b. To do this, repeat the procedure in step 12, and then specify the process pool that you created in step 14b when you are prompted to do so.

15. In the Web applications Web.config file, configure the name of the computer that is running SQL Server.

16. Configure the computer that is running SQL Server:

    a. Configure SQL Server to use Integrated Windows Authentication:

       Click **Start**, point to **Programs**, point to **Microsoft SQL Server**, and then click **Enterprise Manager**.

       Right-click the instance of the SQL Server that you want to manage, and then click **Properties**.

       Click the **Security** tab, and then click **Windows only**.

       Click **This account**, type the domain user name and password to configure the startup service account to use the user account that you created in step 3, and then click **OK**.

    b. Set up the sample database and stored procedure by running the Kerbs4u.sql script file:

       To run the Kerbs4u.sql script file, click **Start**, point to **Programs** point to **Microsoft SQL Server**, and then click **Query Analyzer**.

       To connect to the target SQL Server computer, in the **Connect to SQL Server** box, click the SQL Server to which you want to connect, and then click **OK**.

       On the **File** menu, click **Open**. Navigate to the sample folder that contains the Kerbs4u.sql file, click the **Kerbs4u.sql** file, and then click **Open**.

       Press F5 to run the SQL Server script.

       When you run the script, both a KerbS4uDB database and a **GetUserInfo** stored procedure are created. SQL Query Analyzer returns output that is similar to the output that is in Figure 4 when you successfully run the script.

       Grant rights to the user account that you created in step 5.

**Figure 4: Setting up the Sample Database and Stored Procedure**

In the following configuration steps, you will grant the user account login rights to KerbS4uDB, and then you will add permissions so that the user has permissions to run the **GetUserInfo** stored procedure:

1. Open the SQL Server Enterprise Manager MMC Snap-in.

2. Right-click **Logins**, and then click **New Login**.

3. In the **SQL Server Login Properties New Login** dialog box, click **Windows Authentication**, in the **Domain** box, click the user login domain, in the **Name** box, type the user account that you created in step 5, click **Grant access**, and then, in the **Database** box, click **KerbS4uDB** in the **Database** box.

4. Click the **Database Access** tab, select the **KerbS4uDB** check box, in the **Database roles for KerbS4uDB** box, click the **public** row , and then click **Properties**.

5. In the **Database Role Properties public** dialog box, click **Permissions**.

6. In the **Exec** column, select the **GetUserInfo** check box, and then click **OK**.

**Running the Samples**

The following sections describe how to test the sample scenarios.

**Running Sample Scenario One**

To run sample scenario one:

1. Start Internet Explorer, and then type the URL for the Web service method in the **Address** box. For example, type **http://www.fabrikam.com/kerbextwebsvc/authxws.asmx?op=testkerbsfu**.

2. In the **Enter Network Password** dialog box for digest authentication, type the domain user name and password, and then click **OK**.

3. Click **Invoke** to send a test call to the **TestKerbSfu** Web method. When the call successfully runs, you receive a return string that is similar to the following return string:

```
<?xml version="1.0" encoding="utf-8" ?>
<string xmlns=http://fabrikam.com/>web method user context:
FABRIKAM\jeffpike; AuthenticationType: Digest; Sql server user
context: FABRIKAM\jeffpike</string>
```

**Note**

For security reasons, you can invoke the Web method only if the browser client is running on the same computer that is running the Web service in Windows Server 2003.

The return string indicates that the fabrikam\jeffpike domain user has been authenticated by the **Digest** authentication protocol. The user account that is used to authenticate the SQL Server connection is returned by the **GetUserInfo** stored procedure. To confirm that you successfully used constrained delegation to connect to the SQL Server, view the Security event log on the computer that is running SQL Server to verify that the user account successfully logged on to the network by using the Kerberos authentication package. To view the Security event log, right-click **My Computer**, click **Manage**, click to expand **Event Viewer**, and then click **Security**. Figure 5 shows an example of this logon event. At the bottom of the **Event Properties** dialog box, Transitted Services information is displayed. The Transitted Services information displays the identity of the service that uses constrained delegation. Note that the computer must be configured to audit successful logons to capture this event. You can enable this configuration through the **Audit Policy** option in the Local Security Policy MMC Snap-in.

**Figure 5: Kerberos User Logon Event Log**

**Sample Scenario One Code Walkthrough**

In sample scenario one, the user is authenticated through HTTP Digest authentication. The ASP.NET Framework runtime automatically instantiates a **WindowsIdentity** object for the authenticated user. Subsequently, the Web service method impersonates the user before authenticating to the SQL server. The following code sample provides an example for how you can perform protocol transition with programming code for sample scenario one:

```
[WebMethod]
public string TestKerbSfu()
{

    //
    // impersonate the user before connecting to the SQL database
    //

    WindowsIdentity userIdentity = Context.User.Identity as WindowsIdentity;
    WindowsImpersonationContext impContext = userIdentity.Impersonate();

    string userName = ConnectToSql( sqlServer );

    if( impContext != null )
    {
        impContext.Undo();
    }

}

private string ConnectToSql( string sqlServer )
{
```

```
    ...
    try
    {
        string connString = "integrated security=SSPI;initial
catalog=KerbS4uDB;data source=" + sqlServer + ";Connect Timeout=30";
        connection = new SqlConnection( connString );
        connection.Open();
        ...
     }
}
```

Multiple processing steps occur when the **SqlConnection.Open** function is called:

1. The Kerberos SSP is invoked when the Web service connects to the SQL server. The Kerberos SSP finds an impersonation-level user token for the impersonated user; however, the Kerberos SSP does not find a Kerberos ticket that is available for the user.

2. The Kerberos SSP initiates protocol transition, and then obtains a service ticket to the Web service on behalf of the impersonated user.

3. The Kerberos SSP obtains a service ticket to SQL Server through constrained delegation.

**Running Sample Scenario Two**

To run sample scenario two, start Internet Explorer, type the URL for the Web application in the **Address** box (for example, type **http://www.fabrikam.com/KerbExtWebApp**), and then press ENTER.

The Web application redirects the browser to the user logon page. Note that the sample code does not validate the user and password information that is typed in at the logon page. Typically, your Web application that uses ASP.NET form-based authentication verifies that the user name and password are valid before allowing the user to use the Web application. After the user logs on, the browser is redirected to the Web applications default page. The default page is where you type the user account that you want the Web application to use for protocol transition. When protocol transition is successful, the next Web page allows you to connect to the SQL server through constrained delegation. When the SQL stored procedure returns, the browser displays both the impersonated and delegated user identities. Similar to sample scenario one, you can examine the Security event log on the computer that is running SQL server to look at the Kerberos-related events that were logged during the SQL connection authentication.

**Sample Scenario Two Code Walkthrough**

There are two code samples that you should examine for scenario two. The first code sample is used to initiate protocol transition into Kerberos and the second code sample demonstrates how to use constrained delegation to connect to the SQL server.

The following code sample shows how you can initiate protocol transition by creating a new instance of the **WindowsIdentity** class object:

```
private void DoProtocolTransition_Click(
object sender, System.EventArgs e)
{
    ...
    WindowsIdentity newIdentity = new WindowsIdentity( UserAccount.Value );

    if( null == newIdentity )
    {
        Msg.Text = "Cannot do protocol transition, please try again";
        return;
    }

    //
    // Store this user as part of the HTTP session state
    //

    HttpContext.Current.Session.Add( "KerberosIdentity", ( object )newIdentity );
    ...
}
```

Note that the Web browser user can specify the Kerberos security principal for protocol transitioning in this Web application. Typically, a Web application may use a user mapping table to determine the Kerberos security principal that will be used as the user identity for Kerberos protocol transition. The previous code shows that a new **WindowsIdentity** class object is created

for the user that you specify in the **UserAccount.Value** variable. After the class object is created, the **WindowsIdentity** object is stored in the ASP.NET HTTP session state. The Web application can retrieve this **WindowsIdentity** object from the HTTP session state when it needs to impersonate the user and use constrained delegation to authenticate the connection to the SQL server. The following code sample shows how the Web application performs protocol transition and constrained delegation:

```
...
//
// Get the user's Kerberos identity from the HTTP session state
//
WindowsIdentity user = ( WindowsIdentity )HttpContext.Current.Session[
                       "KerberosIdentity" ];
...
//
// impersonate the user before connecting to the SQL database
//

WindowsImpersonationContext impContext = user.Impersonate();
string userName = ConnectToSql( sqlServer );

Identity.Text = "Impersonated user identity = " + user.Name + "; SQL
Server user identity = " + userName;
if( impContext != null )
{
    impContext.Undo();
}
...
```

# Summary (Kerberos Protocol Transition and Constrained Delegation)

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

This section summarizes and defines some of the key points for the new protocol extensions.

**Protocol Transition**
The following items summarize the protocol transition implementation details that are described in this document:

- The protocol transition extension can be initiated in two ways:

    - Programmatically through the **LsaLogonUser** function or the **WindowsIdentity** class object. This approach is recommended when the initial user-authentication mechanism is not one of Windows-integrated authentication protocols. The process must have the **Act as part of the operating system** privilege for the function to create an impersonation-level token. If the process does not have the **Act as part of the operating system** privilege, an identification-level token is created.

    - Using existing Windows-integrated authentication protocols for the initial user logon procedure with credentials, and using Kerberos protocol transition for subsequent user authentication to other services. The Kerberos SSP initiates the protocol transition extension if the user token that you created for initial logon is an impersonation-level token.

- You must run the operating system process that initiates protocol transition on a computer that is running Windows Server 2003.

- You can use protocol transition both in and across Active Directory forests.

- When you use protocol transition in an Active Directory forest, all domain controllers that are located in the user and service accounts trust path and that are used for the protocol transition process must be running Windows Server 2003. To meet this requirement, use one of the following methods:

    - Upgrade all of the domain controllers that are in the domain that is participating in protocol transition to computers that are running Windows Server 2003. This approach requires that all of the domain controllers in the domain are running Windows Server 2003.

      **-or-**

    - Upgrade all of the domain controllers in the Active Directory sites that are participating in protocol transition to computers that are running Windows Server 2003. This approach does not require that all domain controllers that are in the domain are running Windows Server 2003. This approach is recommended if you cannot upgrade all of the domain controllers in the domain to Windows Server 2003, and if you can isolate the applications that require the protocol transition extension to a certain number of Active Directory sites for which you can upgrade all of the domain controllers.

- When you use protocol transition across Active Directory forests, both forests must be operating at the Windows Server 2003 forest functional level and two-way forest trust must be established between the forests.

**Constrained Delegation**
The following items summarize the constrained delegation implementation details that are described in this document:

- The constrained delegation extension is affected by the following domain policies that are set in Active Directory:

    - The requesting service must be trusted for constrained delegation (the T2A4D flag must be set for the requesting service) if Kerberos is not used as the initial user authentication protocol.

    - The requesting service must be authorized to delegate to the target service (the target service must be on the requesting services A2D2 list).

- You cannot use constrained delegation between services whose accounts are in different domains. All domain controllers in the domain must be running Windows Server 2003, and the domain must be operating at the Windows Server 2003 functional level. The accounts of users accessing the services do not have to be in the same domain as the services.

# Conclusion (Kerberos Protocol Transition and Constrained Delegation)

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Delegation is a security pattern that occurs frequently in n-tier applications. At the time when this document was published, Kerberos was the only widely-adopted authentication protocol that possessed the delegation property. In this document, the Kerberos extensions on computers that are running Windows Server 2003 are discussed. The document also describes how the extensions allow many applications to use the authentication protocol. The sample code illustrates how n-tier Web services and applications can use the new feature.

Protocol transition provides application designers with increased flexibility and security by enabling applications to support different authentication mechanisms at the user authentication tier, and by switching to the Kerberos protocol for security features, such as mutual authentication and constrained delegation, in the subsequent application tiers.

Constrained delegation gives administrators the ability to specify and enforce application trust boundaries by limiting the scope where application services can act on a users behalf. This flexibility to constrain a services authorization rights helps improve application security design by reducing the opportunities for compromise by untrusted services.

# Role-Based Access Control for Multi-tier Applications Using Authorization Manager

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

**Author:** Dave McPherson, Microsoft Corporation

**Acknowledgements:** Thanks to Jason Rush, Praerit Garg, Don Schmidt, Paul Leach, and Doug Bayer for their support.

In the Windows Server 2003 family, Authorization Manager introduces a new model for application authorization on the Windows platform. Authorization Manager provides an easy-to-use authorization framework for line-of-business applications where you must grant access to users according to the users role within an organization or application. To address this need, applications often create custom implementations of authorization mechanisms, which increases development costs and administrative complexity because of divergent authorization models. Authorization Manager gives applications a role-based access control framework that provides manageable administration and natural development for Web-based or line-of-business applications.

Environment-specific Design Issues

Internet Information Services 6.0 URL Authorization

Scenario: Web Expense Application

Scenario: Using Authorization Manager with Custom Principals

**ACLs and line-of-business applications**

Windows operating systems have supported the use of ACLs in access control for applications since the introduction of the Private Object Security API in Microsoft Windows NT Server 4.0. In the ACL model, you can attach discretionary access control lists (DACLs) to a securable object and you make access decisions by calling the **AccessCheck** application programming interface (API), which looks at a users group memberships in a token and compares them to the contents of the ACL to determine if the user has the requested access. The ACL model is ideal for many types of applications. Resource managers that have well-defined persistent objects, such as the NT system registry, use the ACL model appropriately to provide object-level access control. In these types of applications, access control decisions can always be made in terms of a user requesting access to an existing object. In the future, applications that use the ACL model should use AuthzAPI, which was introduced in Windows XP and the Windows Server 2003 family. It provides performance and flexibility enhancements, compared to the Windows NT Private Object Security APIs. For more information about AuthzAPI, see the Microsoft Platform Software Development Kit.

A distinct authorization problem exists for some line-of-business (LOB) applications, such as a Web expense reporting application or a shopping application. For these applications, the authorization decisions do not determine access to well-defined persistent objects. Instead, they verify a workflow or perform multiple distinct operations, such as querying a database and sending mail. In LOB applications, access decisions are often made on business logic, such as the amount submitted in an expense application or verification of workflow completion, and not just based on token group membership. Applications that don't have well-defined persistent objects have no place to put an ACL, so the ACL model can be harder to apply in these applications.

**Role-based access control**

Traditional access control administration models are based on objects. In these models, access control is specified at the object or object container (for example, in an ACL), and the administrator must go to the object to query and specify access to the object. These models require administrators to translate the organizational authorization policy into permissions on objects:

Each object has a list of access permissions that is granted to various users and groups within an organization. Role-based access control (RBAC) simplifies access control administration and provides better manageability in enterprise environments by allowing permissions to be managed in terms of user job roles.

Some of the goals of role-based access control can be accomplished using groups. A group corresponds to an employee role, and application administrators can specify the permissions that are needed by the role by granting the group permission in a DACL for the object. As object collections grow, the number of places where administrators need to manage permissions grows. Diligent use of resource groups and user groups can help minimize this effort, but this requires consistent practice and coordination among administrators and precise definitions of resource groups. These processes slow down the administrative process, so administrators often avoid them.

Additionally, querying the granted access to a particular group or role across an application becomes more difficult as the number of objects grows. To accurately determine what permissions are granted to a user or group, administrators have to examine the permissions on every object. While inheritance appears to simplify this, the ability of each object to avoid inheriting permissions still makes it necessary to look at each object to fully understand the authorization policy. Since there are too many objects to query, the state of access control with respect to a particular group or user is sometimes rarely verified.

Role-based access control attempts to allow administrators to specify access control in terms of the organizational structure of a company. RBAC does this by creating a new object called a role. You assign a user to a role to perform a job function. Unlike groups, however, a role defines the authorization permissions on some set of resources. In the RBAC model, the administrator uses the role to manage permissions and assignments. For example, a company may create a role called Sales Manager that has the permissions that a sales manager needs for their job. When sales managers are hired, they are assigned the Sales Manager role and instantly have all required permissions for that job. When they leave the position of sales manager, they are removed from the Sales Manager role and no longer have Sales Manager access. Since the role allows access to be granted in terms of a company's organizational model, it is more intuitive and natural for administrators to specify access control. Figure 1 identifies the relationship between the role, the users, and the permissions. In this model, the role is the object to which permissions are granted, and the users are assigned to the role.

**Figure 1: Role-based access**

RBAC maps user job roles to application permissions so that access control administration can be accomplished in terms of a users job role. The RBAC system translates a users role membership to application permissions. Since the permissions are granted at the role, permissions can be queried and changed at the role without examining the specific resources. In most environments, once the role permissions are established, changes to a roles permissions will be rare, compared to changes in assignments to the role. This means that administrators will have to set up roles, such as Employee, Manager and Administrator, but once roles are created, administrators will manage membership in the roles; not permissions on objects.

**Authorization Manager conceptual model**

Authorization Manager is a set of COM-based runtime interfaces that allows applications to easily manage and verify a clients requests to perform application operations. Additionally, Authorization Manager provides a Microsoft Management Console (MMC) snap-in that application administrators can use to manage user roles and permissions.

Authorization Manager:

- Simplifies application access control administration in line-of-business applications.
- Provides a simplified and natural development model.
- Enables flexible and dynamic authorization decisions.

Typically, you define access control models with the terms Subject, Resources, and Permissions. A subject is often a user operating upon resources. Access is controlled by a set of permissions that allow the subject to perform specific operations on the resource. Administration of access control rarely deals directly with these constructs but more often involves management of collections of subjects, resources, and permissions. You usually manage subjects or users in groups, but you manage resources in application-specific collections, such as directories or organizational units. Permissions may be granted directly, but are often grouped into higher level permissions such as Full Control. These collections make authorization management possible in environments where there are many subjects, resources, or permissions. Application administrators must use these collections to make an authorization policy for the application so that each subject has the appropriate permissions to use the application resources.

Traditional resource manager applications store authorization policy with the resources that the policy applies to. For example, an ACL on a file is stored by the resource manager and is logically associated with the file. In the Authorization Manager model, authorization policy data is stored separately from the object in an authorization policy store. An application identifies the operations or tasks that the application can perform and declares them in the authorization store when the application is installed. Administrators manage the authorization policy by defining roles in terms of the tasks and operations that are needed to perform a job in an organization. The definitions of roles, tasks and operations, and the assignment of users and groups to the roles are all stored in the authorization store. Applications query the authorization policy at run time to confirm that a client is authorized to perform a requested operation on a resource. Authorization Manager provides APIs for managing authorization policy and validating access control and a user interface for administrators so that they can manage the authorization policy store. The following figure illustrates the composition of the authorization store that Authorization Manager provides for querying applications and managing the authorization store. It also illustrates the relationships between each Authorization Manager object.

**Figure 2: Authorization Manager object relationships**

**Definitions**

This section introduces the objects that Authorization Manager uses to manage authorization policy.

**Operation.** A low-level permission that a resource manager uses to identify security procedures. Several operations may be required to perform a meaningful task. Operations are often not exposed or meaningful to administrators. An example of an operation could be WriteAttributes or ReadAttributes.

**Task.** A collection of low-level operations. The purpose of the task is to determine which low-level operations are required to do some unit of work that is meaningful to administrators. An example of a task might be Change Password. Tasks can also contain other tasks. For example, a task called Manage User Accounts may include the tasks Change Password, Reset Password, Disable Account, and so on.

**Role Definitions.** A collection of permissions that are needed for a particular role, where permissions can be tasks or operations. Notice that this definition is similar to that of a task.

**Role.** The set of permissions that users must have to be able to do their job. The role is applied to a set of objects and users are assigned to the role.

**BizRules.** Also called authorization scripts. Scripts that are attached to a task object that is run at the time of the access request. It can use information that is only available at runtime, such as "time of day" or "dollar amount requested," to make an authentication decision.

**Scope.** A collection of objects or resources with a distinct authorization policy. A scope can represent a physical collection, such as a folder, or a more flexible collection of resources, such as *.doc. Applications can use the scope as necessary to group resources, and must be able to map the requested resource to its scope at the time the application checks the access for a user.

**Application groups.** Groups that are applicable only to an authorization store, an application within an authorization store, or a scope within an application. Authorization Manager implements two types of application groups.

**Application basic groups.** A subset of application groups. A list of members (Active Directory Users or groups or other application groups) that is maintained for a specific set of applications, a single application, or a scope within an application. Application groups also can identify non-members, which allows for exceptions where a large group can be used with a smaller group or particular user excluded.

**LDAP-query groups.** A subset of application groups. Groups that are defined by an Lightweight Directory Access Protocol (LDAP) query on a given Active Directory users account attributes. These provide flexible group membership to be defined in terms of user account attributes and that remains up to date with the users account object.

# Authorization Policy Storage

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

When an application that uses Authorization Manager is initialized, it loads the authorization policy information from the store. Authorization Manager provides support for storage of authorization policy in Active Directory or in .xml files.

| **Important** |
| --- |
| Because the authorization policy information is stored by Active Directory or in an NTFS file, it is secured with the security capabilities of either Active Directory or NTFS, and the auditing support for changes that are made directly against the storage (without using the Authorization Manager runtime interfaces) is handled by the system on which the store is located. Additionally, administrators on the system that contains the authorization policy store have a high degree of access to the store. For this reason, the authorization policy store must be located on a trusted system. |

**Active Directory Authorization Manager storage**

To use Active Directory to store the Authorization Manager policy, the domain must have a functional level of Windows Server 2003. Active Directory in the Windows Server 2003 family contains schema updates for the Authorization Manager objects. When using the Active Directory store, Authorization Manager creates Active Directory objects for the store itself and child objects for each application group, application, operation, task, role, and scope. The scope object can contain tasks, roles, and groups that were created in that scope.

When using the Active Directory authorization policy store, applications control when application objects are loaded. When an application connects to the policy store, the stores global attributes (including store-level groups) are cached locally, along with header information for each application. When an application initializes its authorization policy using the **OpenApplication** method, the applications attributes, roles, tasks, operations, application groups, and header information for each scope are loaded into memory. Once an application is loaded, it remains cached in memory until the application object is freed. Scopes are loaded on demand; either the first time the scope is specified in a call to **AccessCheck** or when the scope is explicitly loaded using the **OpenScope** method. Once a scope is loaded, it remains cached in memory until the application object is freed.

Active Directory does not support enforcement of transactional writes on multiple objects or attributes, so it is possible that the store could be edited simultaneously by two administrative applications. In this situation, a store could become corrupted. Because of this, it is recommended that applications regularly back up their authorization store. For more information about Active Directory backup and restore tools, see "Active Directory" in the Windows Server 2003 Help.

**Deployment considerations for Active Directory administrators**

Application administrators can benefit from using Active Directory to store the authorization policy. The Active Directory store allows applications to take advantage of the existing domain infrastructure to provide the application with storage, availability, redundancy, and distribution of the authorization policy. Active Directory administrators who deploy Authorization Manager should consider the following information.

**Domain mode requirements**

The Authorization Manager Active Directory Store requires that the domain be in Windows Server 2003 functional level.

**Authorization Manager Active Directory impact on infrastructure**

Authorization Manager is a runtime that runs on the application server. It does not run any applications or services on domain controllers. Active Directory can be used to store the authorization policy data.

Applications that use the policy download application policy information when it initializes and downloads application scope policy as needed. When the application reads the policy information, the impact of the read on a domain controller will vary. The size of the authorization policy for an application or scope will vary with the number of roles, tasks, operations, and groups in the scope. Application groups vary in size, but it is recommended that you do not use application groups for large groups so that application performance is not affected. The size of the groups and roles can vary, but may be similar to Active Directory groups. The read of a group or role costs as much in processing time as the read for the members of an Active Directory group with the same amount of members. Application groups can have the same maximum size as Active Directory groups but are usually smaller than Active Directory groups because they are only used by an application. When possible, we recommend that people use Active Directory groups instead of application groups when groups with more than 5000 members are needed.

**Proximity requirements**

Applications need high-quality access to Authorization Manager policy. Even though individual applications may perform

acceptably in low-bandwidth scenarios, unless they have small authorization stores, domain controllers should generally be within the local area network (LAN) of the application server.

**Replication**
The authorization policy store is replicated to all domain controllers in the domain in which the authorization policy is stored and Authorization Manager objects are referenced in each global catalog server in the forest.

A separate domain or forest could be used to store an Authorization Manager policy. You may choose to do this to minimize replication traffic within a domain, to minimize load on domain controllers in an account domain, or to have separate administrators manage the Authorization Manager policy store. Using a separate domain or forest requires that appropriate trust be established between the domain where user accounts are stored (the account domain) and the domain the Authorization Manager policy is stored in (the Authorization Manager storage domain.) The trust configuration that is required depends on what domain the accounts of the administrators of the Authorization Manager policy are in and which domain the application server and any back-end resource servers are in.

**Deploying an Authorization Manager store in Active Directory**
The following gives step-by-step instructions on deploying an Authorization Manager store in Active Directory.

1. Choose the Authorization Manager Active Directory store location.

   To deploy Authorization Manager in an Active Directory store, you must choose a location for the store. It is recommended that the administrator create a new organizational unit (OU) in the domains Program Data container and create a store object in the new OU. This recommendation is not enforced. If the application has data in a container other than Program Data, you can put the Authorization Manager store there.

   Authorization Manager cannot be placed in a non-domain naming context, which is also called an application partition.

2. Create an Authorization Manager store.

   Applications can create the Authorization Manager policy store in Active Directory themselves through the Authorization Manager API, or administrators can create a store using the Authorization Manager MMC. In order to do this, the user or application attempting to create a store must have Create Child Object permissions in the container that was chosen in the previous step and they must know the distinguished name of that container.

   For more information about creating a store using the Authorization Manager MMC snap-in, see Work with Authorization Stores in Authorization Manager Help.

3. Roles and authorization store access

   If the application administrator creates the store using a program, then they should already have permission to manage the store. If the store is created manually by an Active Directory administrator, permission to manage the store must be given to the application administrator who is using the store. Use the Authorization Manager MMC to grant the application administrator access to manage the authorization policy store. The authorization policy within the store is managed by the application administrator. The Authorization Manager Active Directory store allows the application administrator to delegate management of applications and scopes within the store.

   Since application service accounts that use the authorization policy must be able to read the policy store, the application service account must be included in the Readers role in for the appropriate store or application or scope within a store.

4. Enable the Windows Authorization Access group.

   | **Note** |
   | --- |
   | This step is only needed if the application designers use either the **InitializeClientContextFromName** and **InitializeClientContextFromStringSID** methods to create client context objects within the application. Applications that use **InitializeClientContextFromToken** do not require this step. If you are not sure which APIs the application server will use, the application administrator or designer should know. |

   These methods attempt to read the users token-groups-global-and-universal attribute in Active Directory to get the user's Active Directory group membership information. To read this information, the application service account must

have Read access on this attribute on each user object.

If the domain is configured for Pre-Windows 2000 Compatible Access mode (that is, the Everyone group is in the in the Pre-Windows 2000 Compatible Access group), then the Authenticated Users group will have access to call the **InitializeClientContextFromName** or **InitializeClientContextFromStringSID** methods by default. If the domain is set for Windows 2000 and Windows Server 2003 Compatible Access then, by default, only the Authenticated Users group will be in the Pre-Windows 2000 Compatible Access group. In this case, application service accounts will have the required access to call the **InitializeClientContextFromName** or **InitializeClientContextFromStringSID** methods. If the domain has been locked down (that is, Active Directory administrators have made the default access permissions more restrictive) it is possible that the Pre-Windows 2000 Compatibility Access group will be empty, in which case application servers may fail when calling the **InitializeClientContextFromNameOfSID** interfaces.

In this situation, to grant access to the service account, it is recommended that, first, you add the service account to the Windows Authorization Access group, and then grant the Windows Authorization Access group access to each users token-groups-global-and-universal attribute if it does not already have that access. For more information about the Windows Authorization Access group (which is new for the Windows Server 2003 family), search for the term in the Microsoft Knowledge Base at http://support.microsoft.com.

**Authorization Manager storage with XML files**

Authorization Manager supports storage of the authorization policy in an .xml file that is stored on an NTFS volume. The XML store can be kept on the same computer as the server application using Authorization Manager APIs or it can be stored remotely.

In order to support renaming of objects, the XML format contains globally unique identifiers (GUIDs). Because of this, you should not edit the .xml file directly. Furthermore, the XML schema is not published currently. You can edit the store through the Authorization Manager MMC or through the Authorization Manager interfaces which are available to scripting languages, such as Microsoft Visual Basic Scripting Edition (VBScript) and JScript. The XML store does not support delegation because access to the XML file is controlled by the discretionary access control list (DACL) on the file which grants or restricts access to the entire contents of the file.

It is recommended that application administrators back up their authorization store regularly. The NTFS file system does not support applications issuing a sequence of separate write operations as a single logical write to a file when multiple applications write to the same file. (These operations are sometimes known as transactional operations.) Since an Authorization Manager policy store could be edited simultaneously by two administrative applications, a store could become corrupted.

# Application Administration

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

After installing an application, the job of the administrator is to add any new roles required, verify the permissions on the initial roles (if present), and assign users to roles. If the application creates a complete set of tasks with meaningful names, the administrator's job of setting up initial roles is much easier.

The point of role-based access control is make administration more intuitive and manageable. To do so, administrators must devise a strategy for deploying roles within the application that resembles the user job descriptions. Once the roles are established, the administrative focus is primarily managing memberships within the roles, so it is very important that you verify each role's permissions. Generally, it is safer to grant each role only those permissions that are needed immediately and then add permissions as needed, rather than granting too many permissions and then removing unneeded permissions later.

**Managing scopes**

Often, the applications manage the creation of scopes and the administrator then creates and manages the roles within a scope. This way, the administrator does not have to know the applications scope syntax and the application logic that is used to associate user access request to a scope.

When applications allow administrators to create scopes, the application must provide documentation so that the administrator understands how to create scopes that are named correctly, since scopes are defined by each application and the application will map each access request to the appropriate scope.

Scopes allow administrators to group application resources into physical or logical collections and specify different authorization policy in each scope. Since tasks and role definitions can be created so that they are global to the application (in other words, visible to all scopes), roles that are created for different scopes can use the same global role definition and have different memberships. This prevents the need to redefine the permissions in each scope. Such a technique is useful when a role or task, such as Administrator or Full Control will have the same permissions in each scope but different people assigned to it.

| **Important** |
| --- |
| Authorization Manager applications have a default scope. Permission that is granted to roles in the default scope apply in all scopes in the application. For this reason, the applications default scope should only be used for role assignments that apply to all scopes in the application. |

**Role inheritance**

Since the process of establishing roles involves assigning user permissions, it requires special attention. To minimize the validation and analysis that is required, a hierarchal role model can be designed that leverages the work that was done on establishing existing roles when creating new roles.

**Figure 3: Role hierarchy**

Role definition involves tasks and operations that define the permissions for a role. Using role definitions allows roles to be defined hierarchically, using existing roles to create new ones.

**Delegation of administration**

When using the Active Directory Authorization Manager policy store, Authorization Manager supports delegation of administration at the authorization store, application, and scope levels. This allows higher-level administrators to give limited

access to others to manage some subset of the authorization policy. The store, application, and scope objects can each have a set of Administrators and Readers. Administrators of a store, application, or scope can perform all operations that are needed to manage the authorization policy within the delegated scope, and Readers can only read the authorization policy. Additionally, users who have been delegated authority of a scope or application must be added to the Delegated User administrative role of the store. This allows the delegated user to view groups that are created at both the application and the store level.

When a scope has been delegated (because one or more principals are in the scopes Administrator role), BizRules cannot be added to tasks or role definitions that were created in the scope. Delegated scopes can use BizRules that are attached to tasks and role definitions at the application level. Store-level administrators can also globally prevent all BizRules from running by setting the ScriptEngineTimeout store level value to 0. After doing this, **AccessCheck** assumes that existing BizRules will return as false and access will not be granted through task or role definitions containing a BizRule.

**Using Authorization Manager application groups**

Authorization Manager introduces two types of groups which can be used by Authorization Manager applications to facilitate applications that need to maintain groups of security principals: application basic groups and LDAP query groups. (These are discussed in more detail later in this paper.) Authorization Manager application groups can be global to an Authorization Manager policy store and can be used by all applications within the store, specific to an application and used by all scopes in the application, or specific to a single scope. Some applications need to manage groups of users without having to depend on updates to domain groups that may be managed by different people. Domain administrators may have requirements to keep the number of groups low without managing application-level groups. Latency may exist between the application administrators request and the actual changes to the Active Directory groups. Additionally, some groups are only needed for certain applications and, if the application can manage the group memberships, the domain administrators does not have to.

**Application basic groups**

An application basic group is similar to a traditional Windows domain group in that it is a collection of member security principals, but it is unlike traditional groups in that it also contains a non-member or subtractive list of security principals. This allows for exceptions that traditionally use Deny access control entries (ACEs) on objects. Security principals that are added to the non-member list will never be a member of the group, even if they are directly or indirectly granted membership in the member list. Application basic groups store security identifiers (SIDs) for each member and nonmember, so growing application groups will result in growth of the Authorization Manager store. Since applications load portions of the authorization store into memory, large group and role memberships can increase the time required to initialize an Authorization Manager store, application, or scope object.

As application groups become very large:

- Performance for initialization of stores, initialization of applications, and calls to **AccessCheck** are affected.
- The application requires more memory.
- There is more load on domain controllers when applications initialize and refresh the loaded policy.
- The membership of the application groups tend to change, which requires more frequent refreshing of the cache.

Because of this, it is strongly recommended that, as application groups grow to around 2000 members, that they be converted to Active Directory groups. (For more information about performance, see Performance, later in this paper.) A users Active Directory group memberships are determined when the user logs on or when the user context is created and do not affect the time required to initialize an Authorization Manager store, application, or scope.

**LDAP query groups**

Often, groups are maintained in Active Directory for collections of users that have similar attributes on their Active Directory accounts. For example, users who work in a given cost center may be in a group for the cost center, even though the cost center information is maintained as an attribute on each users account in Active Directory. When the user moves from one cost center to another, the administrator must update both the cost center group and the cost center attribute on the user object. To leverage the users properties and relieve administrators of maintaining the same information in multiple places, Authorization Manager provides the LDAP query group.

Membership in an LDAP query group is determined by using an LDAP query on a given user object. This allows applications to use these user attributes as groups in roles and frees administrators from managing memberships of these groups. Application administrators control membership by creating an LDAP query group in terms of the properties on user accounts. The following are some examples of coding for LDAP query groups.

All members of the Managers group:

```
(memberOf= CN=Managers,OU=Distribution Lists,DC=nwtraders,DC=com)
```

All members over 18 years old.

```
(age>=18)
```

All users in Germany

```
(country=Germany)
```

All users over 18 years old in Germany

```
(&(age>=18)(country=Germany))
```

LDAP query groups require that the connected users account is maintained in Active Directory, but they are also supported when using the XML-based Authorization Manager policy store. LDAP query groups are evaluated when **AccessCheck** is called, therefore, the **AccessCheck** call will take more time to complete when the LDAP query is used to populate roles, because evaluating the query will require a LDAP search in Active Directory. While membership in an LDAP query group is cached for the life of the client context, initial **AccessCheck** calls are slower if many LDAP query groups must be evaluated.

**Enterprise-wide roles**

Since Authorization Manager roles are defined in terms of the permissions that a role will require within an application, a role cannot span across applications. To have roles in distinct applications have the same memberships, use common groups to populate application roles. This can be done using Windows groups or application groups if the applications are managed in the same Authorization Manager policy store. These groups are visible to each application and can contain the members for roles that are defined in multiple applications. Then, in each application, these groups can be assigned as members of the roles. By using Active Directory global or universal groups to contain role membership, application roles can have similar memberships across applications and Authorization Manager policy stores in an organization.

# Auditing

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Authorization Manager provides two types of auditing.

- Authorization Manager runtime auditing
- Authorization Manager policy store change auditing.

**Authorization Manager runtime auditing**
Authorization Manager runtime auditing audits:

- Application initialization
- Client context initialization or deletion
- All calls to **AccessCheck** with pass and fail audits

Auditing can be configured at the store or application layers. Authorization Manager runtime auditing is enabled through the **GenerateAudits** property of the **AzAuthorizationStore** interface, which is stored in the Authorization Manager policy store.

In order to use Authorization Manager runtime auditing, the system that is running Authorization Manager must have enabled auditing, and the context that calls the Authorization Manager interfaces must have the SE_AUDIT_NAME or the Generate Audits privilege. If an application requires that auditing is enabled, it can require the audit privilege by passing the AZ_AZSTORE_FLAG_AUDIT_IS_CRITICAL flag to IAzAuthorizationStore::Initialize. This requires the calling application to have SE_AUDIT_PRIVILEGE or else IAzAuthorizationStore::Initialize fails.

**Authorization Manager policy store change auditing**
Authorization Manager policy store change auditing triggers audits when there is a change to the Authorization Manager auditing policy. The Active Directory supports auditing of Active Directory objects so that the Active Directory store changes can be audited using the Active Directory system auditing where auditing settings can be configured at the store, application, and scope levels. Changes to the XML store can be audited as a whole by using the system access control list (SACL) that is on the objects.

# Application Design Process

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Part of application design is making good choices for roles, tasks and operations. This section gives you information that will help you in your design.

**Identifying operations**
An operation is a low-level permission that represents privileged actions or capabilities of an application. Operations should be created for each routine, query, method, and so on that comprises a discrete application function which requires access control. An operation alone may not be enough to perform a high-level task and may be required for more than one high-level task, but the operation itself is always executed as a unit and must be secured.

For example, an operation such as **ReadOrderInfo** alone may not be enough for the high-level task Process Order, but the same routines may be needed for another high-level task, such as Query Order Status. Creating an operation for the set of routines that are required to use the order controls allows finer permission specification. The more precisely the operations are defined, the more flexibility you have when managing permissions. However, operations that are defined too precisely make administration more complex.

For many resource managers, operations correspond to securable routines, procedures, or queries that operate on data or resources. The operations may be low-level and meaningful only to the application developer. To create permissions that are meaningful to administrators, the application developer can group low-level operations into Authorization Manager task objects.

**Figure 4: Operations and tasks**

**Defining tasks**
As stated above, the application should define operations for each routine that will run as a single unit and must be secured. While this allows the application to grant access more precisely, multiple operations may be required to perform a high-level task that the application exposes to the user. In this case, you should determine which operations are required to perform the high-level task and create an Authorization Manager task object for it. This requires some research on the part of the administrator. Task objects are designed to simplify role management by providing meaningful, high-level permission sets that correspond to the application tasks that an administrator would grant a user permission to perform. Therefore, it is important for applications to install with a complete set of tasks required to control access for all uses of the application. Figure 4 illustrates how you can use task objects to combine permissions into high-level tasks.

**BizRules**
The Authorization Manager task object has the additional ability of dynamically qualifying the permissions granted in a task, based on the result of an attached VBScript or JScript associated with the task. This allows for the access control decision to take into account runtime data, such as the dollar amount of an expense that has been requested or the inventory of a requested item. BizRules are run during the **AccessCheck** call, and will run in the context of the Web application in the thread calling **AccessCheck**. If the BizRule returns success, the user receives the requested operations which were associated with the task. If the BizRule fails, the client is not allowed to perform the operations that are associated with the task. The user may be able to perform those operations through a separate task. Parameters are sent to the BizRule through the **AccessCheck** call, which takes corresponding name and value arrays as its parameters. For example, the first element in the *varParameterNames* array is the name corresponding to the first element in the *varParameterValues* array. The BizRule parameter's names array

(*varParameterValues*) must be ordered accordingly so that names and values have the same index.

An applications authorization policy can have many tasks. Each task may or may not have associated BizRules, and new tasks and BizRules may be added by application administrators. At design time, application developers do not know if a call to **AccessCheck** will need to specify BizRule parameters (since BizRules may not be used for any given call to **AccessCheck**), so the application must send in the parameters potentially needed by BizRules. To facilitate BizRule developers, applications should define and publish the set of BizRule parameters that are sent into each **AccessCheck** call.

The type of data that **AccessCheck** should send as BizRule parameters includes information such as user name and restriction data. Restriction data may include items such as amount limits, account or ID numbers, or a users manager. Any data that may be useful in determining whether or not to grant access at runtime can be used in each **AccessCheck** call and must be included in the applications list of published BizRules parameters.

BizRules require some scripting knowledge, and therefore it is not appropriate for most administrators to create and modify them. Usually, BizRules should be developed and shipped with the application or provided by the application vendor or other developer later. Since each BizRule that is run invokes the Windows Script Engine, BizRules should be computationally small tasks, such as comparing given parameters or querying a database.

**Sample BizRules**

Here is a BizRule written in JScript that insures that the time of day is between 9:00 and 17:00, using a 24-hour clock:

```
AzBizRuleContext.BusinessRuleResult = false;
dt = new Date();
hour = dt.getHours();
if (hour > 9 && hour < 17)
{
   AzBizRuleContext.BusinessRuleResult = true;
}
```

To improve performance of BizRules that are called frequently, the results of the BizRule are cached for the life of a client context. Because of this, BizRules are time-sensitive, as in the above example. Applications cache client contexts for appropriately short amounts of time.

Here is a Microsoft Visual Basic Scripting Edition (VBScript) BizRule to make sure an amount that is passed into the BizRule as a parameter named ExpAmount is less than 500:

```
Dim Amount
AzBizRuleContext.BusinessRuleResult = FALSE
Amount = AzBizRuleContext.GetParameter("ExpAmount")
if Amount < 500 then AzBizRuleContext.BusinessRuleResult = TRUE
```

When a BizRule refers to a parameter, **AccessCheck** caches the parameters, values, and result for a particular BizRule for the life of a client context. This allows improved performance in subsequent **AccessCheck** calls on the same client context that references the same BizRule with identical values. This means that, if BizRule results can change in subsequent **AccessCheck** calls without changing the BizRule parameters (as in the time of day BizRule described above), then the cached value may not be the correct value. For this reason, applications using BizRules should free the client context periodically.

**Initial roles**

Some applications have a small number of hard coded roles, such as Administrator, Reader, and Writer. Such applications would call the Authorization Manager API to create these initial roles at startup time.

**Scoping**

Authorization Manager scope objects are collections of resources, and can be either simple collections such as C:\My Documents or more collections, such as *.doc. The application must take into consideration what scoping logic it will use. A scope provides great flexibility to the application in how to apply different access control to different resources. Depending on what the application is controlling access to, the collections may vary considerably in form. For example, if an application performs operations on other computers, then a scope may represent collections of computer objects and be named something like Computers in Sales Dept or "Computers Running Windows XP. The only requirement is that the application must be able to map a user request for access to a resource to the scope containing the resource when the access validation is performed.

In addition to logical collections of resources, scopes give applications the flexibility to address complex authorization problems, such as incorporating a "work on behalf" feature into an application. A "work on behalf" feature allows a user to grant other users permission to do work on their behalf. For example, suppose Bob wants to allow James to do work on their behalf. In an application, this could be implemented by creating a scope for Bob in which a role would be defined that specifies the subset of Bobs permissions that James is allowed to use. (James would be assigned to this role.) When James connects and

requests permission to perform an operation on behalf of Bob, an **AccessCheck** operation is performed against the Bob Work on Behalf scope to verify that James has permission to perform the operations on behalf of Bob.

Since scopes are defined by each application and the application will map each access request to the appropriate scope, the application must provide documentation to allow the administrator understand how to create scopes that are named correctly.

**Installation**

When an application is installed, it can install authorization policy information into a new or existing authorization store by calling the Authorization Manager API. If the application installs its authorization policy into an existing store, the installation process must give the installing user a way to specify the location of the existing store. After initializing the authorization policy store, the install application uses the **CreateApplication** method to create an application object in the policy store. Then, for each operation, the installation application calls the **CreateOperation** method. Initial tasks, scopes and roles are installed using the **CreateTask**, **CreateScope**, and **CreateRole** methods, respectively. The following VBScript creates a store and installs the authorization policy for a simple expense application.

```
'--- Initialize the admin manager object
Dim pAzManStore
Set pAzManStore = CreateObject("AzRoles.AzAuthorizationStore")
'--- Create a new store for expense app
' 0 = Open store for Access Checking.
' AZ_AZSTORE_FLAG_CREATE   = 0x1,
' AZ_AZSTORE_FLAG_MANAGE_STORE_ONLY = 0x2, // cannot do access
checking.
' AZ_AZSTORE_FLAG_BATCH_UPDATE      = 0x4,
pAzManStore.Initialize 1+2+4, "msxml://C:\AzPolicy.xml"
pAzManStore.Submit
Dim App1
Set App1 = pAzManStore.CreateApplication("Expense")
App1.Submit
'--- Create operations -----------------------
Dim Op1
Set Op1=App1.CreateOperation("RetrieveForm")
Op1.OperationID = CLng(61)
Op1.Submit
Set Op1=App1.CreateOperation("EnqueRequest")
Op1.OperationID = CLng(62)
Op1.Submit
Set Op1=App1.CreateOperation("DequeRequest")
Op1.OperationID = CLng(63)
Op1.Submit
Set Op1=App1.CreateOperation("UseFormCotnrol")
Op1.OperationID = CLng(64)
Op1.Submit
Set Op1=App1.CreateOperation("MarkFormApproved")
Op1.OperationID = CLng(65)
Op1.Submit
Set Op1=App1.CreateOperation("SendApprovalNotify")
Op1.OperationID = CLng(66)
Op1.Submit
'--- Create tasks ------------------------------
Dim Task1
Set Task1=App1.CreateTask("Submit Expense")
Task1.AddOperation CStr("RetrieveForm")
Task1.AddOperation CStr("EnqueRequest")
Task1.AddOperation CStr("UseFormCotnrol")
Task1.Submit
Set Task2 = App1.CreateTask("Approve Expense")
Task2.AddOperation CStr("MarkFormApproved")
Task2.AddOperation CStr("SendApprovalNotify")
Task2.AddOperation CStr("DequeRequest")
Task2.BizRuleLanguage = CStr("VBScript")
Task2.BizRule = "Dim Amount" & vbnewline  & _
           "AzBizRuleContext.BusinessRuleResult= FALSE" & vbnewline &_
           "Amount = AzBizRuleContext.GetParameter( " & Chr(34) &_
                             "Amount" & Chr(34) & ")"  & vbNewLine &_
           "if Amount < 500 then AzBizRuleContext.BusinessRuleResult=
TRUE"
Task2.Submit
'--- Create role definitions ------------------------------
Set Task3 = App1.CreateTask("Expense Admin")
Task3.AddTask CStr("Approve Expense")
```

```
Task3.AddTask CStr("Submit Expense")
Task3.IsRoleDefinition = TRUE
Task3.Submit
Set Task4 = App1.CreateTask("Expense User")
Task4.AddTask CStr("Submit Expense")
Task4.IsRoleDefinition = TRUE
Task4.Submit
'--- Create initial scopes and roles ------------------------------
'--- only one scope in this app (we may instead choose to use no scope)
Dim Scope1
Set Scope1 = App1.CreateScope("AllRoutines")
Scope1.Submit
Set RoleA=Scope1.CreateRole("Expense Administrator")
RoleA.AddTask("Expense Admin")
RoleA.Submit
Set RoleB=Scope1.CreateRole("Expense User")
RoleB.AddTask("Expense User")
RoleB.Submit
'--- Demo - add everyone to ExpenseUser Role --------------------------
RoleB.AddMemberName("Everyone")
RoleB.Submit
```

**Application model**

Applications that use Authorization Manager use the trusted subsystem application model described below. Note that, while the two models imply distinct application designs, based on the tradeoff, a particular application may choose to use a hybrid model that contains a trusted subsystem middle tier design and use impersonation to maintain back-end auditing or to interface with legacy back-end resource managers.

**Impersonation model**

Windows 2000 and earlier versions of Windows NT Server supported the Windows NT impersonation model. In this model, server applications obtain a token for the connected client and impersonate the client token before attempting a secure operation, such as opening a file. The ACL on the file is compared to the users token groups to determine whether or not a user has permission to open the file. While the Windows Server 2003 family enhances support for the impersonation model through the Kerberos extensions of protocol transition and constrained delegation.

**Trusted subsystem application model**

Authorization Manager adds support for a new trusted subsystem application model to the Windows security infrastructure.

**Figure 5: Impersonation model and trusted subsystem model**

In the trusted subsystem model, the application server account only has enough access so that it can perform all the operations it exposes to clients. When a client requests an operation, the middle-tier application server authorizes the client request based on authorization policy that is specific to the application. If the client has permission to perform the requested operation, the server performs the operation on behalf of the client. In this model, clients do not have direct access to resources. While the impersonation model has its strengths and is appropriate in many cases, the trusted subsystem model has some advantages over the impersonation model.

**Management of permissions**

In the impersonation model, each client users account is used to access the back-end resource, so the DACLs of all resources

must be maintained by granting each user the appropriate level of access. When the number of resources that are secured separately grows, especially when stored on separate back-end computers, management of the DACLs becomes more tedious. For example, you might organize resources into units that are secured in the same way, such as protecting all files in a subtree the same way or organizing users into groups with similar permissions.

In the trusted subsystem model, only the middle-tier service account is used to access the back-end resources; therefore, the DACLs can be simplified by granting only the service account sufficient access to perform all required operations on the objects. A service account should not be given Full Control rights or be a local administrator, but should have just enough permission to perform the applications complete set of operations. Application designers can document the level of permissions the application need on back-end resources. This reduces the management of DACLs, because only the service account requires access to them. The service is given permissions to the resources, so you must trust that the service will not accidentally let one user access resources of another.

**Rights ion**

With the impersonation model, assigning DACLs to resources to grant users the ability to perform high-level tasks can be difficult. High-level tasks such as Submit Expense or Query Inventory may require several operations on back-end resources. *Rights ion* is the process of determining precisely which low-level resource permissions are required for high level application operations. It can be time consuming, particularly when many secured resource types are used.

In practice, administrators sometimes grant excessive access to resources to save time. A trusted subsystem application model allows the administrator to grant access only to the service account. Since the access to the resources is broadly given to the service account, determining the correct access is easier: usually the server gives just enough access to perform all operations that the server application may need (as defined by the application designer). The administrator does not have to define and maintain different levels of permissions on DACLs.

**Connection pooling**

You often can achieve better scalability by connection pooling. Since the impersonation model maintains the user context through the request to a resource server, a separate connection to the resource server is usually required for each user request. If you create a connection for every client, you prevent reuse of a single connection to a resource server, such as a SQL database. A trusted subsystem server application authorizes the client's request and accesses the remote resource for the client in the context of the applications service account. Since a new connection is not required, the application server can use the same connection with resource servers to service requests from different clients.

**Controlled access points**

Some applications enforce rules and workflow in the application server. In the impersonation model, each client is given appropriate access to each resource. Since the client has access to directly to the resource, they could potentially access the resource though a method other than through the intended applications which could cause undesired access and manipulation of resources.

In the trusted subsystem model, only the application service account has access to resources. This means that users cannot directly gain access to resources through a tool or API. In this model, the application server has more control over how the user sees and manipulates the resources.

**Auditing**

Auditing allows administrators to examine which users have attempted to gain access to particular resources. Auditing is most authoritative if the audits are generated by the same application that manages the resources. The impersonation model does this by maintaining the users context when it requests access on each system. This allows the remote system to authoritatively log the user and the requested access.

When you use a trusted subsystem application model, the back-end resource managers generate audits that log the servers service account as the account requesting access, not the client user on whose behalf the operation was performed. Authorization Manager provides runtime auditing when the access validation is performed (in other words, when the **AccessCheck** API is called), but these audits are generated at the application server. Because of this, mapping an access audit on a back-end resource to the user who made the request requires that the audit logs on the application server be correlated with back-end audits. The application server audits can often be more informative than audits made on the back-end resource. From the application server, you can know more about the high-level task that the client is requesting, so a greater degree of the users intent can be recorded in the audits. On the back-end resource managers, only low-level operation requests can be audited, so it may be difficult to determine the users higher-level activities.

**Other differences**

In the impersonation model, the service account in which the application server runs may have little or no access to resources. To access resources on behalf of the client, the application server must impersonate the clients security context, which the application server can obtain when the client connects to it. When you limit the permissions of the server context, the server is limited to the permissions of the connected client when a successful attack takes place which compromises the server. If an attacker wants to gain broad access to back-end data, they must compromise the server and wait for users to connect. As each

user connects to a compromised server, the access of the attacker grows in proportion to the connected users permissions. If a highly-privileged account logs on to the server, such as the applications administrator, the attacker quickly gains permissions to the application data. If client users who have access to resources other than the applications log on to the server, the attacker also gains access to those resources because of the ability to impersonate the client to those resources.

A trusted subsystem server starts out with a high degree of access to application resources so, if the server is compromised, the attacker has broad access to these resources. But since the client is not impersonated, the attacker is limited to the access of the service context (the application's resources). While the attacker gains broad access to application resources, the attacker cannot access non-application resources.

# Developing Authorization Manager Applications

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Server applications use Authorization Manager runtime interfaces to manage connections to the authorization policy store and validate client requests

**Initialization**
When the application runs, it initializes the Authorization Manager policy store using the **IAzAuthorizationStore::Initialize** interface. The application should have Read access to the authorization store, but does not need Write access. After connecting to the store, the application calls **IAzApplication::Initialize** to initialize an interface to its specific application within the policy store.

**Client connection**
When a client connects to the application, an Authorization Manager context must be created for the user. To do this, use the **IAzApplication::IntiializeClientContextFromToken**, **IAzApplication::AzInitializeClientContextFromStringSID**, or the **IAzApplication::InitializeClientContextFromName** method. Generally, if a token is available, you should use a token when creating a context. A token is usually the result of a Windows logon and will contain logon information, such as whether it was an interactive or a network logon. Context creation from a token is usually faster because it does not have to query a domain controller for group information. In rare cases, it is possible that role assignment may have been given depending on these logon properties, so when possible, use the FromToken form of InitializeClientContext APIs. For example, when a user logs on to the network interactively, the NT AUTHORITY\INTERACTIVE group is added to the resulting token. Using the **InitializeClientContextFromName** (or **SID**) method, an **IAzClientContext** object is created by looking up the users group assignments in Active Directory. Since the user has not logged on, the context will not contain groups such as the NT AUTHORITY\INTERACTIVE group that identifies the logon type. In this case, if membership in a group or role is given to the interactive group, a user context that is created using **InitializeClientContextFromName** does not receive the membership. It is recommended that you do not use these logon property groups to secure resources or specify memberships in groups or roles, in which case **InitializeClientContextFromName** and **InitializeClientContextFromSID** can be used.

The **AzInitializeClientContextFromStringSID** method creates an Authorization Manager context from a given SID in textual form. This behaves in a similar manner as the **InitializeClientContextFromName** method. When the AZ_CLIENT_CONTEXT_SKIP_GROUP flag is used, the **AzInitializeClientContextFromStringSID** method does not attempt to determine the group memberships of the given SID. The resulting client context only contains the specified SID. If the **IAzAccessCheck** method is called from this client context instance, role membership is only granted if the specified SID is used as a member of a role or group assigned to a role.

**Roles query and authorization**
After a client context is created, applications have the option of querying role information about the user in order to present a user interface based on the users role memberships. For example a Web-based application may render a Manager user interface for people in the Manager role, and an employee role for everyone else. The **IAzClientContext::GetRoles** method enumerates the users role memberships. The set of roles that is returned from **GetRoles** is based only on explicit membership assignment; **GetRoles** does not evaluate BizRules.

When the user makes a request, the application maps the request to the required operations and determines the scope in which the user is making the request. Then the application calls **AccessCheck** sending the scope, requested operations, BizRule parameters, and object name. The scope determines the users role membership, which determines whether or not access is granted to the user.

# Performance

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Application initialization and access validation performance can vary, depending on how applications use features such as XML storage, BizRules, and LDAP query groups. Application designers have several options to consider in meeting performance requirements.

**Application initialization performance**
Load times for large stores improve when you use the Active Directory store rather than the XML Authorization Manager storage provider. When an application initializes a connection to an Authorization Manager policy store, authorization policy is loaded into the address space of the application. The amount of policy that is loaded depends on the store type.

- The Active Directory Authorization Manager policy store allows Authorization Manager application objects to be loaded and unloaded on demand and allows the Authorization Manager scope objects to be loaded only when needed. (For more information, see Active Directory Authorization Manager Storage, earlier in this paper.)

- The XML Authorization Manager storage provider loads the entire authorization policy into memory.

Additionally, the time it takes to initialize increases as the number of objects within the Authorization Manager policy store increases or as the number of members in Authorization Manager application basic groups increases. To minimize the size of application groups, use Active Directory groups when possible and then use these Active Directory groups in Authorization Manager application groups or roles.

**AccessCheck performance**
Using the Authorization Manager **AccessCheck** method provides a flexible way to optimize performance using BizRules and LDAP query groups.

The **AccessCheck** method:

1. Identifies scopes that apply to the **AccessCheck** routine, both within the specified scope and the global scope.

2. Enumerates the set of roles in the scopes from step 1.

3. Discards roles that do not refer to requested operations. If **RoleForAccessCheck** is specified, all roles other than those specified are discarded.

4. Verifies the client security contexts membership in each role.

5. If the client is a member of the role in step 4, **AccessCheck** records all requested operations that are assigned to the role as granted.

6. Repeats steps 3-5 for each role in applying scopes.

The above logic is repeated a maximum of three times.

1. On the first pass, **AccessCheck** ignores any tasks containing BizRules and application groups containing LDAP queries. Both BizRules and LDAP queries can take a long time to compute and can require network operations, so the first pass takes place in case they are not needed.

2. In the second pass, **AccessCheck** processes BizRules, but still ignores LDAP query groups. BizRules are supposed to be simple and may not involve network operations, so they are likely to be faster to process than LDAP queries.

3. The third pass processes all data, including LDAP queries, using the cached results from previous iterations. **AccessCheck** terminates as soon as access is granted to all of the requested operations.

Since **AccessCheck** is optimized to evaluate static memberships ahead of dynamic memberships, and tasks without BizRules ahead of tasks with BizRules, you can optimize performance by using static assignments where possible.

Authorization Manager application groups are not evaluated until **AccessCheck** is called and membership in a role is queried. (This process of group evaluation is also called late-bound.) For LDAP query application groups, once membership in an application group is established for a user, the users membership in that LDAP query group is cached for the life of the user context object. Because of this, future **AccessCheck**s that involve group evaluations speed up as group memberships are resolved and cached.

As a best practice, BizRules should be kept computationally small. BizRules offer the greatest degree of flexibility in an **AccessCheck** call, and therefore offer the greatest potential to decrease performance. Network bound BizRules decrease the performance of **AccessCheck**. Often, this cannot be avoided, for example, if a database needs to be queried to check a credit history, but such queries will delay the result to the user.

# Environment-specific Design Issues

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Authorization Manager is designed for applications using the trusted subsystem application model, where access checks are done in the context of the server, and ACLs on back-end server resources only need to grant access to the application server service account. (For more information, see Trusted Subsystem Application Model, earlier in this paper.) To use a trusted subsystem model, usually the application server will run in the context of a dedicated service account. Since the application needs to read Authorization policy information from the Authorization Manager policy store, the security context that the application runs in needs Read permission to the store. You can do this by designating the dedicated service account as a Reader of the Authorization Manager policy store. To do this, you can use the Authorization Manager MMC (Microsoft Management Console).

If impersonation is used in the application, you should not impersonate a client while calling Authorization Manager API. The only exception to this is when you wish to initialize a client context from the impersonated thread context. In that case, call the **IAzApplication::InitializeClientContextFromToken** method and specify 0 for the *ullTokenHandle* parameter. The other Authorization Manager interfaces read the Authorization Manager authorization policy store (which contains user role information) and the **IAzApplicatin::AccessCheck** function runs BizRules and resolves LDAP query groups. Since a user requires a high degree of access to be able to read authorization policy and perform BizRule script actions, you should not call these functions while impersonating the security context of the user. Each Windows programming environment gives you different options to use to manage impersonation and call Authorization Manager from a service account for the application.

**ASP.NET**

Application servers written in ASP.NET can use the Authorization Manager API through the .NET Interop assembly that ships in the \AuthMan directory in the .NET Framework. To create a trusted subsystem model in ASP.NET, you need to run the application server in a service account. To configure your ASP.NET application server to run in a service account, you create a separate IIS 6.0 worker process which runs in the security context of the service account created for the application server. You can then configure your ASP.NET application to use this dedicated IIS worker process. For more information about IIS 6.0 worker processes, see the Microsoft Internet Information Services page on the Microsoft Web site at http://www.microsoft.com/technet/prodtechnol/windows2000serv/technologies/iis/default.mspx. Alternatively, you can use ASP.NET to configure the context in which an application runs using the Web.config file for your ASP.NET application. In that case, you should configure the ASP.NET application to run as the dedicated service account.

When your ASP.NET application is initialized, it can call **AzAuthorizationStore.Initialize** to connect to the Authorization Manager store. It then calls **AzApplication.Initialize** to load an initial percentage of the applications authorization policy.

At run time, when a client connects, you have the option of initializing a user context from the clients account name or from a token representing the client. The token can be retrieved in ASP.NET by way of the ASP.NET **HttpWorkerRequest** object. Authorization Manager can also initialize a context from a clients SID, though that is not usually available in ASP or ASP.NET. It is recommended that you initialize the Authorization Manager context from a token when possible because, when initializing from a token, you do not have to potentially query the users account object. That may require network-bound queries to Active Directory.

The following code calls the Authorization Manager API through ASP.NET, using a .NET Interop assembly to approve an expense approval. This code is a simple Web expense application that runs in a dedicated service account. The Authorization Manager policy store for this application can be created from the VBScript install script that appeared earlier in this paper.

```
<%@ Page Language="C#" Debug="True"%>
<%@ Assembly Name ="Microsoft.Interop.Security.AzRoles"%>
<%@ Import Namespace="Microsoft.Interop.Security.AzRoles"%>
<%@ Import Namespace="System.Runtime.InteropServices" %>
<html>
   <head>
   </head>
   <body>
      <%
      Microsoft.Interop.Security.AzRoles.AzAuthorizationStoreClass
AzManStore =
            new
Microsoft.Interop.Security.AzRoles.AzAuthorizationStoreClass();
      // Keep the authorization store in a safe place out of the Web
space.
      AzManStore.Initialize(0,
```

```
@"msxml://D:\SecureDir\MyWebAppsAzStore.xml",
                           null);
      IAzApplication azApp =
AzManStore.OpenApplication("expense",null);
      HandleRef token = new HandleRef(this, ((HttpWorkerRequest)
((IServiceProvider)Context).GetService(typeof(HttpWorkerRequest))).GetU
serToken());
//-------------- Create Client Context --------------
      IAzClientContext context =
azApp.InitializeClientContextFromToken(
                       (UInt64)token.Handle,
                       0);
      object[] scope = new Object[1];
      scope[0] = "";
      object[] operations = new Object[1];
      operations[0] = 55;
//--------------- Do access check --------------------
//Set up BizRule params. To optimize performance, name/value pairs must
//be placed in array alphabetically
      Object[] BRNames = new Object[1];
      BRNames[0] = "ExpAmount";
      Object[] BRValues = new Object[1];
      BRValues[0] = Convert.ToInt32(Request.QueryString["Amount"]);
      object[] results = (object[]) context.AccessCheck("Approve",
                                                        scope,
                                                        operations,
                                                        BRNames,
                                                        BRValues,
.null,null,null);
      bool bAuthorized = true;
      foreach (int iResCode in results)
      {
         if ( iResCode != 0 ) // zero = no error
         {
           bAuthorized = false;
           break;
         }
      }
      Response.Write((string)context.UserSamCompat + "<br>");
      Response.Write(
             "Approval of " + Convert.ToString(BRValues[0]) + " was");
      if (bAuthorized) {
         %><font color="#008000"><b>APPROVED</b></font><%
      } else {
         %><font color="#FF0000"><b>DENIED</b></font>.<%
      }
      %>
   </body>
</html>
```

**ASP**

Applications that use Authorization Manager usually use the trusted subsystem model. By design, IIS Application Service Providers (ASP) applications impersonate the context of each connected client. To use a trusted subsystem model in ASP, you have two options:

**Option 1: Use Internet Information Services 6.0 URL authorization and impersonate the Web expense service account.**

Create a separate IIS 6.0 worker process which runs in a security context that is created for the ASP application. This runs an instance of IIS and ASP in a dedicated service account for the ASP application. Normally, ASP applications run impersonating the authenticated user. IIS 6.0 URL authorization allows you to configure the ASP application to run in the context of the IIS worker process. Since you set up the IIS worker process to run in the application service account, we can use IIS 6.0 URL authorization to run the ASP application in that security context. IIS integrated authentication still authenticates the client, but instead of impersonating the client, IIS 6.0 URL authorization causes the ASP application to run in the service account. When a client connects and is authenticated by IIS, you can use the ASP server variable AUTH_USER to retrieve the authenticated name of the client and call **AzApplication.InitializeClientContextFromName** to create an Authorization Manager context for the client. For more information about IIS 6.0 URL authorization, see IIS 6.0 URL Authorization later in this paper.

The following code is an ASP application, using Authorization Manager to validate an expense approval. This code assumes that the ASP application is impersonating a dedicated service account, not the client security context. The application is configured to impersonate the IIS worker process using IIS 6.0 URL authorization, as described above.

```
<%@ LANGUAGE="VBSCRIPT" %>
<HTML>
<HEAD>
</HEAD>
<BODY>
<%
Dim CCHandle
Dim Results
Dim Names(5)
Dim Values(5)
Dim Scopes(5)
Dim Operations(10)
Dim AzManStore
Dim App
Dim UserName
Set AzManStore = CreateObject("Azroles.AzAuthorizationStore")
'Set myUser = Session.GetObject("LDAP")
UserName = Request.ServerVariables("LOGON_USER")
AzManStore.Initialize 0,
"msxml://D:\Inetpub\wwwroot\MyWebAppsAzStore.xml"
set App = AzManStore.OpenApplication ("Expense")
'--------------- Create Client Context --------------
Set CCHandle = App.InitializeClientContextFromName(UserName)
'--------------- Do access check --------------------
'Set up BizRule params. To optimize performance, name/value pairs must
be
'placed in array alphabetically
Names(0) = "ExpAmount"
Values(0) = 0
Names(1) = "Param2 for BizRule - Name"
Values(1) = "Param2 for BizRule - value"
Scopes(0) = Empty
Operations(0) = 55
If Len(Request.QueryString("amount")) > 9 Then
    Response.Write "Amount field is too long, please try again."
Else
   Set reg = New RegExp
   reg.Pattern = "\D+" ' Look for something other than 0-9's.
   if reg.Test(Request.QueryString("amount")) = False then
      Values(0) = Clng(Request.QueryString("amount"))
      '-------- AccessCheck ----------------------------------------
      Results = CCHandle.AccessCheck("Approve",
                                     Scopes, Operations, Names, Values)
      If Results(0) = 0 Then ' Zero = NO_ERROR
         Response.Write "Approval of " & Values(0) & " was accepted."
      Else
         Response.Write "Approval of " & Values(0) & " was denied."
      End If
      '-------------------------------------------------------------
   Else
      Response.Write "Must enter number, please try again"
   End if
End If
Set CCHandle = Nothing
set App = Nothing
Set AzManStore = Nothing
%>
</BODY>
</HTML>
```

**Option 2: Create custom COM objects and interfaces to control impersonation.**

Create a custom COM object that allows you to control impersonation from your ASP application. After that, set up the IIS worker process to run in a service account as described above and use the custom COM object to call the RevertToSelf API to return to the IIS worker process context (the ASP applications service account). Then, call the ImpersonateSelf API to impersonate the context of the IIS worker process. (ASP expects to run applications under impersonation.) It is important to save the client token in this step because it will be used later.

By impersonating the IIS worker process from the custom COM object you can call Authorization Manager APIs to initialize the Authorization Manager policy store and the Authorization Manager application in the context of the ASP applications service account (the security context that you configured the worker process to use). This process of initializing the Authorization Manager policy store and application objects might only be done once when the ASP application initializes.

When a client request is made, you must create an Authorization Manager client context to use for checking the clients access. To do this, you can use the ASP server variable AUTH_USER to get the clients user name and call **AzApplication.InitializeClientContextFromName**. But you have the option of using your custom COM object to create a client context using the logon token that was created when IIS authenticated the client user. To do this, expose a function in your custom COM object to retrieve the token that you stored above and call the ImpersonateLoggedOnUser API. This will impersonate the client security context. Then, create an Authorization Manager client context using the **AzApplication.InitializeClientContextFromToken** method with (0,0) as parameters to create an Authorization Manager context from the current thread token. Since you are impersonating the client, the current thread token represents the client and the Authorization Manager client context created from this token will also represent the client. After doing this, use your custom COM object to re-impersonate the ASP application service account process again, as explained above.

This works because, when **AzApplication.InitializeClientContextFromToken** is called with the value of **0** for the token handle, the API creates an Authorization Manager context that is derived from the token of the calling thread. Since, in this case, we are impersonating the client user, the Authorization Manager context that is created represents the client.

Implementing a custom COM interface to manage impersonation requires additional work, but using a custom COM object to control impersonation has the benefit of using the clients token that is maintained in IIS to create a context as described. Methods that use the **AzApplication.InitializeClientContextFromName** interfaces result in querying the user account object in Active Directory. This can result in slower performance than when you use a token, because the token already has this information.

**C, C++, and Visual Basic**

You can control impersonation in native C, C++, or Visual Basic by calling various context management APIs, such as ImpersonateLoggedOnUser, OpenThreadToken, or RevertToSelf. In these languages, the application server can be installed as a Windows System service and run in a dedicated account for the service application. When the application initializes, it first calls **AuthorizationStore.Initialize** to connect and load information from the Authorization Manager policy store, and then **AzApplication.Initialize** to create a COM interface to the application policy within the policy store

When a user logs on to the application, it authenticates the client using whatever means it chooses. If a native Windows authentication mechanism is used, such as Security Service Provider Interface (SSPI), Distributed Component Object Model (DCOM), Remote Procedure Call (RPC), or Named Pipes, then the application server can use the resulting token to create an Authorization Manager context with one of two methods:

- Impersonating the client by using the appropriate impersonation API, such as ImpersonateNamedPipeClient or ImpersonateSecurityContext in SSPI, and calling **IAzApplication::InitializeClientContextFromToken**, specifying **0** for the token handle value.

- Querying the clients token handle, such as **QueryContextAttributes** in SSPI, and using that handle in the call to **IAzApplication::InitializeClientContextFromToken**.

If non-native Windows authentication is used, then applications can map the authenticated client to a Windows account and then use the IAzApplication::InitializeClientContextFromName API, specifying the Windows account name that the client was mapped to after authentication.

# Internet Information Services 6.0 URL Authorization

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Internet Information Services (IIS) 6.0, which comes with the Windows Server 2003 family, integrates with Authorization Manager to implement IIS 6.0 URL authorization. This provides Web application administrators with the ability to control access to URLs based on custom user roles, LDAP queries, and BizRules.

Authorizing user access to Web pages in IIS can require management of many DACLs on resources used by Web applications. Resources for Web applications may include Web page files, database records, registry keys, and so on. Maintaining DACLs requires administrators to know precisely what back-end permissions are needed on each object to perform meaningful tasks in the Web application. IIS 6.0 URL authorization allows administrators to simplify access management by authorizing user access to the URLs that comprise a Web application. When a client requests a URL, IIS 6.0 URL authorization validates the users access based on the user roles. This allows administrators to simplify access control management by controlling all user access to URLs instead of each DACL on each object. The Web application can further restrict access to resources and operations by using the Authorization Manager role-based framework.

IIS 6.0 URL authorization is implemented as an ISAPI interceptor .dll, which is configured as a wildcard extension for an application, virtual directory, or URL. When an application, virtual directory, or URL is configured to use IIS 6.0 URL authorization, each request to a URL is routed to the URL authorization ISAPI interceptor. The IIS 6.0 URL authorization ISAPI interceptor will use the Authorization Manager runtime to authorize access to the requested URL. To do this, the URL (application, virtual directory, or single URL) must be associated with an Authorization Manager policy store that contains the authorization policy for the URL. Once the client has been authorized to access the URL, the IIS 6.0 URL Authorization ISAPI passes the request to the appropriate handler for the URL, such as ASP, ASP.NET ISAPIs, or the static file handler.

**Figure 6: IIS URL authorization**

Using IIS 6.0 URL authorization, an administrator can control access to URLs based on information that is only available at runtime. For example, if you had a Web page that is only viewable to employees in a given cost center or to employees of a certain age, you can assign roles to the correct users based on LDAP queries that check the cost center or age attributes on a users object. If employees can only access certain pages on certain days of the week or during a certain time of day, a BizRule can be created which grants access to the URL based on these values or any value that can be asserted at runtime, including IIS server variables.

**Setting up IIS 6.0 URL authorization**

To use IIS 6.0 URL authorization, set the following metabase attributes on the application, virtual directory, or URL:

- **AzEnable.** Enables URL authorization for the virtual directory, application, or URL that corresponds to the entry in the metabase.

- **AzStoreName.** Associates an Authorization Manager store with the virtual directory, application, or URL.

- **AzScopeName.** Associates the virtual directory, application, or URL with a scope. This scope will be the name of a scope in the IIS 6.0 URL authorization application in the Authorization Manager policy store that the **AzStoreName** attribute refers to. If it specifies either an empty string or no scope at all, the default scope of the IIS 6.0 URL authorization is used.

- **AzImpersonationLevel.** Determines the impersonation behavior for the application. This allows you to configure the Web application to impersonate the client user, the IIS worker process, or the IUSER_* account for the worker process. Each setting significantly changes the environment and implied design of the Web application. Set the value to 0, 1 or 2 corresponding to the desired impersonation style.

  **0** Authenticated client is impersonated. Some applications require client impersonation, such as ASP 2.0 applications. Use this if you want to use URL authorization for applications that expect to run while impersonating the client, such as ASP 2.0 applications.

  **1** The IIS worker process identity is impersonated. This is used when the application runs as a service account, authorizes each client request itself, and performs requested operations on behalf of the client in the trusted service context. For more information, see Trusted subsystem application model, earlier in this paper.

  **2** The anonymous user account is impersonated. This allows you to use URL authorization to authorize the clients access to the URL while still running the Web application as the anonymous account to limit all access of the client through the Web application.

The following script uses ADSI to set these properties on the IIS metabase entry for an application, virtual directory, or URL.

```
'  SetUrlAuth.vbs
'  Configuring UrlAuth with a Vdir.
'  This script uses ADSI to configure a vdir in the IIS 6.0 metabase.
to use
'  IIS 6.0 URL authorization.
'
'  This script assumes that the IIS vdir corresponding to the
application has
'  already been created.
'
'  After running this script to verify the settings, use the Adsutil
tool like so
'
'  inetpub\adminscripts\adsutil enum w3svc/1/root/MyApp
'  (where MyApp is the app name)
'  Use the Authorization Manager MMC snap-in to do the following:
'     Create an application called "IIS 6.0 URL Authorization"
'     Create an operation called "AccessURL" with an operation ID of 1
'     Create a scope corresponding to the AzScopeName specified to this
script.
'       This scope name will be used to manage access to URLs in this
Vdir
'     Make sure that the IIS worker process has read access to the
'       AzMan policy store. You can do this using the AzMan UI (right
click
'       store and select options and then the security tab
Set objArgs = WScript.Arguments
If objArgs.count < 4 then
  wscript.echo "Usage: SetUrlAuth VDirPath AzScopeName AzStoreName AzEnable
[ImpersonationLevel]"
  wscript.echo ""
  wscript.echo "Example:"
  wscript.echo " SetUrlAuth w3svc/1/root/MyApp MyApp
msxml://d:\inetpub\wwwroot\AzStore.xml True 1"
  wscript.echo ""
  wscript.echo "Run with 'cscript' command in cmd.exe to avoid msg
boxes"
Else
wscript.echo objargs(0)
'
' Get interface to the Vdir object
'
```

```
DIM iis
set iis = GetObject("IIS://localhost/" & objArgs(0))
' Set scope name - this scope will preside over URLs referring to this vdir
' This scope must exist in the corresponding Authorization Manager store.
'
iis.AzScopeName = objArgs(1)
'
' Specify location of Authorization Manager policy store
'
iis.AzStoreName = objArgs(2)
'
' Enable urlauth for this Vdir
'
iis.AzEnable = objArgs(3)
'
' Set Impersonation Level
'
If objArgs.count > 4 then
   iis.AzImpersonationLevel = objArgs(4)
End if
'
' Write settings to Metabase
'
iis.SetInfo
End if
```

When Web pages are requested, URL authorization will authorize the client based on the Authorization Manager authorization policy, if the client is allowed to access the URL. The security context that is configured by the **AzImpersonationLevel** attribute to retrieve the URL data (such as an .htm file) requires the correct IIS directory security and NTFS permissions. IIS URL authorization allows the IIS directory security and NTFS permissions to be more easily maintained using the trusted subsystem model. For more information, see "Trusted Subsystem Application Model," earlier in this paper.

When IIS 6.0 URL authorization is configured, you can identify an Authorization Manager policy store by the **AzStoreName** attribute in the IIS metabase entry for the application, virtual directory, or URL. To manage the authorization policy, us the following procedure.

1. Click the **Start** button, click **Run**, type **Azman.msc**, and then press ENTER.

2. In the console tree, right-click **Authorization Manager**, and then click **Open Authorization Store**.

3. In **Store Name**, type the path to the authorization store location, which is identified by the **AzStoreName** attribute, and then click **OK**.

For more information about opening an authorization store, see Authorization stores and applications in the Authorization Manager MMC Help.

IIS 6.0 URL authorization for this store is managed with the IIS 6.0 URL Authorization application. The **AzScopeName** attribute in the metabase entry will be an Authorization Manager scope in the IIS 6.0 URL Authorization application. Use this scope to manage access to the corresponding URL. When configuring an application, virtual directory, or URL for URL authorization, a scope must be created in the authorization policy store with the same name as that specified in the corresponding metabase entry's **AzScopeName** attribute.

The following figure shows the Authorization Manager MMC with an authorization policy store that is used to manage access to a Web Expense application and Web Application 2. This store also contains authorization policy for these applications.

**Figure 7: Authorization Manager managing two Web applications**

Authorization policy for IIS 6.0 URL authorization is stored in an Authorization Manager policy store in either Active Directory or in an .xml file. IIS 6.0 URL authorization allows the authorization policy for URLs to be maintained in the same authorization policy store as that of Web applications that use Authorization Manager to control access to application tasks and operations. Maintaining the authorization policy in the same store allows administrators to manage access to URLs and Web application resources from the same Authorization Manager MMC or custom user interface. This provides a common point of access control administration for URLs and applications and allows for the same Authorization Manager groups and LDAP queries to be used to populate roles for both URL authorization and application authorization.

**Configuring IIS 6.0 URL Authorization Step by Step**

The following steps set up IIS 6.0 URL Authorization for a Web application called WebApp, which is installed and configured in IIS as an application in the *Systemroot*\InetPub\WWWroot\WebApp folder:

| **Note** |
| --- |
| Integrated Windows Authentication is required for URLs using IIS URL Authorization. By default, IIS Web applications and virtual directories enable Integrated Windows Authentication. For information about configuring Integrated Windows Authentication, see Integrated Windows Authorization in Internet Information Services online Help. |

**Set up IIS: Create your application folder under Default Web Site, and then disable anonymous access to the site.**

1. Click **Start**, click **Run**, type **%systemroot%\System32\InetSrv\IIS.msc**, and then press ENTER.

   You can also click **Start**, click **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.

2. In the console tree, double-click **Internet Information Services**, double-click the computer name, double-click **Web Sites**, double-click **Default Web Site**, right-click the folder corresponding to your Web application, click **Properties**, and then click **Create**.

3. Click the **Directory Security** tab and then, in **Authentication and Access Control**, click **Edit**.

4. Confirm that the **Enable Anonymous Access** check box is cleared, confirm that the **Integrated Windows Authentication** check box is selected, click **OK**, and then click **OK** again.

**Set wildcard configuration properties to point to URLAuth.dll**

1. In **Internet Information Services (IIS) Manager**, right-click the folder for the Web application which you created, click **Properties**, and then click **Configuration**.

2. In **Wildcard application maps (order of implementation)**, click **Insert**.

3. In **Add/Edit Application Extension Mapping**, click **Browse** and, in **Files of type**, select **All files (*.*)**.

4. Browse to the *Systemroot*\System32\InetSrv folder.

5. Click **URLAuth.dll**, click **Open**, click **OK**, click **OK**, and then click **OK** again.

   If you get an error saying This executable path is already used then URLAuth.dll is already configured as a wildcard application extension mapping.

**Add URLAuth.dll as a new Web service extension**

1. In the console tree, double-click **Internet Information Services**, double-click the computer name, and then click **Web Service Extensions**.

2. In the details pane, click **Add a new Web service extension**.

3. Click **Add**, click **Browse**, browse to *Systemroot*\System32\InetSrv\, click **URLAuth.dll**, click **Open**, and then click **OK**.

4. In **Extension Name**, type **URL Authorization**.

5. Select the **Set extension status to Allowed** check box, and then click **OK**.

**Set up an authorization policy store in Authorization Manager**

1. Click the **Start** button, click **Run**, type **Azman.msc**, and then press ENTER.

2. In the console tree, right click **Authorization Manager**, and then click **Options**.

3. Confirm that **Developer mode** is selected, and then click **OK**.

   Now we will create a new store. For this example, we will put the store in C:\ and name the store "MyStore.xml."

4. In the console tree, right-click **Authorization Manager** and click **New Authorization Store**.

5. Click **XML file** and, in **Store name**, type **C:\MyStore.xml**.

6. (Optional) In **Description**, type information about the new store.

7. Click **OK**.

8. In the console tree, right-click **MyStore.xml** and click **New Application**.

9. In **New Application**, in **Name**, type **IIS 6.0 URL Authorization**.

10. (Optional) In **Description**, type information about this usage of IIS URL Authorization.

11. Click **OK**.

12. In the console tree, double-click **Authorization Manager**, double-click the store name, double-click the application name, double-click **Definitions**, right-click **Operation Definitions**, and then click **New Operation Definition**.

13. In **New Operation Definition**, in **Name**, type **AccessURL**, and then, in **Operation number**, type **1**.

**Set up the scope for the application**

1. In the console tree, right click **IIS 6.0 URL Authorization**, and click **New Scope**.

2. In **Name**, type **WebApp**, and then click **OK**.

3. In the console tree, double-click **IIS 6.0 URL Authorization**, double-click **Definitions**, right-click **Role Definitions**, and then click **New Role Definition**.

   This role definition could also be created in the WebApp scope.

4. In **Name**, type **Viewer**, and then click **OK**.

5. In the console tree, double-click **Role Definitions**.

6. In the details pane, right-click **Viewer**, and then click **Properties**.

7. Click the **Definition** tab, click **Add**, and then click the **Operations** tab.

8. Select the **AccessURL** check box, click **OK**, and then click **OK** again.

9. In the console tree, under **IIS 6.0 URL Authorization**, under **WebApp**, right click **Role Assignments**, and then click **Assign Roles**.

10. Select the **Viewer** check box, and then click **OK.**

11. In the details pane, right click the role assignment you created above, and then click **Assign Windows Users and Groups**.

12. In **Enter the object names to select (examples)**, type your user name, and then click **OK**.

#### Add the IIS worker process to the store's Readers role

By default, IIS runs in the Network Service account. You can configure an IIS worker process to run in a different account. For this sample, we will add Network Service to the Readers role.

| **Note** |
| --- |
| If you use a remote authorization store (such as Active Directory or a remote XML file based store) and run IIS in the default Network Service context, then the Active Directory account of the Web server running IIS must be added to the store's Readers role. |

#### Add the IIS worker process to the store's Readers role

1. If the Authorization Manager MMC is not already open, click **Start**, click **Run**, type **Azman.msc**, and then press ENTER.

2. In the console tree, right-click **Authorization Manager**, click **Open Authorization Store**, click **Browse**, click **C:\MyStore.xml** (which, for this example, is the store you want to work with), click **OK**, and then click **OK** again.

3. In the console tree, right-click the name of the store, and then click **Properties**.

4. Click the **Security** tab and, in the **Authorization manager user role** list, click **Reader**, and then click **Add**.

5. In the **Enter the object names to select (examples)** box, type **Network Service**, click **OK**, and then click **OK** again.

#### Configure the IIS Metabase to use URL Authorization for the Web Application

1. Click **Start**, click **Run**, type **Cmd**, and press ENTER.

2. Use the above script to create the SetUrlAuth.vbs file and save the file to \InetPub\AdminScripts directory. (By default the

InetPub directory is in the root of the drive which IIS is installed on.)

3. Type the below command and press ENTER.

4. CScript SetUrlAuth.vbs *VDirPathAuthMgrScopeNameAuthMgrStoreNameEnabledImpersonationLevel*

   For example, you might type the following:

   **Cscript SetUrlAuth.vbs W3svc\1\Root\WebApp WebApp msxml://C:\MyStore.xml true 1**

   Now, IIS URL Authorization should be configured and running for the specified Web application. Users who are in the Viewer role should be able to browse to the pages within the application.

| **Important** |
| --- |
| You must append **msxml://** if you are using an .xml file or **msldap://** if you using the Active Directory Authorization Manager store. |

# Scenario: Web Expense Application

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

In this scenario, a Web-based expense application uses the following procedure.

1. A user goes to the URL of the expense application and chooses to enter a new expense report.
2. The user enters the expense report and submits it for approval.
3. The manager receives e-mail notification that the expense report is awaiting approval.
4. The manager goes to the approval URL, which allows the manager to inspect and approve or reject the expense report.
5. If the manager approves the expense report, it is added to a verification queue, where a verifier can inspect the report, collect receipts, mark the expense report Approval-verified, and request a reimbursement.

| **Note** |
| --- |
| For a sample application using Authorization Manager, see *MicrosoftSDKPath*\Samples\Security\Authorization\AzMan in the Microsoft Platform SDK. For information about how to install the Microsoft Platform SDK, see http://www.microsoft.com/downloads/details.aspx?FamilyId=A55B6B43-E24F-4EA3-A93E-40C0EC4F68E5&displaylang=en on the Microsoft Web site. |

**Operations**

In the above expense application scenario, the operations can be defined as:

- **ExecuteExpenseControls.** Use the controls that allow user to fill out the expense form.
- **ExecuteApprovalControls.** Use the controls that allow user to approve the expense.
- **RetrieveExpenseForm.** Retrieve requested expense form from database
- **SaveExpenseForm.** Save the expense form to local machine.
- **EnqueApproval.** Put a copy of the completed form in the approval queue.
- **DequeApproval.** Remove the expense from approval queue.
- **SendRequestNotification.** Send e-mail to the manager that requests approval.
- **SendApprovalNotification.** Send e-mail notification of approval.
- **ApproveDenyExpense.** Mark the expense as approved or denied.
- **VerifyApproval.** Mark the expense as Approval-Verified.
- **SetExpenseLimit.** Set the limit amount that various roles can approve.
- **FwdRembursment.** Send a message to Accounts Payable.
- **ReadApprovals.** Read the expense forms in the approval queue.
- **ReadArchive.** Read the expense forms in approval archive.

**Tasks**
Each of the above operations may be needed in several expense application tasks that a user may need to do. Applications that use tasks should test each task as a stand-alone requirement that does not require any other task or operations permission.

In the expense application scenario, the tasks could be:

- **Create Report.** Routines to fill out an expense report. Operations (ExecuteExpenseControls, RetrieveExpenseForm, SaveExpenseForm.)
- **Submit Report.** Routines that upload the expense report to pending state, Sends e-mail to manager. (EnqueApproval, SendRequestNotification)
- **View Report** Routines that display a pending report. Operations ([Create Report] + AddApprovalQueue + SendNotification )
- **Approve Report** Routines that cause report to move from Pending state to Approved state, Sends e-mail to submitter and notifies payment system.
- **Verify Approval** Operations required to mark expense as Approval-Verified and forward reimbursement request to Accounts Payable. Operations (ExecuteApprovalControls, ApproveExpense SendApprovalNotification, FwdRembursment)
- **Audit Report** Allows reading of reports in approval queue and approval archive (ReadApprovals)
- **Config Limits** Allows the setting of approval limits for employees and managers (SetExpenseLimit)

**BizRules**
In the Web expense application, an Approve Report task would have the following BizRule attached.

```
Dim Amount
BizRuleContext.BusinessRuleResult = FALSE
Amount = BizRuleContext.GetParameter("Amount")
Limit = BizRuleContext.GetParameter(Limit)
If Amount < Limit then BizRuleContext.BusinessRuleResult = true
```

Attaching the above BizRule to the Submit Report task requires that the given expense is less than the limit amount that has been passed. The *Amount* parameter is retrieved by the application from the expense report, while the *Limit* amount is configured by the administrator of the Web expense application.

| **Important** |
|---|
| Every BizRule should immediately set the value of **BusinessRuleResult** to FALSE. If the BizRule prematurely ends due to code error or an environment problem, it is possible that random data could assign the BizRule result value to TRUE, which would grant access. |

**Roles and role definitions**
For the Web expense application, the following roles are defined during installation.

| Roles | Tasks Submit Report | View Report | Approve Report | Verify Approval | Delete Report | Config Limits |
|---|---|---|---|---|---|---|
| User | Submit reports for themselves | Those personally submitted | No | No | No | No |
| Manager | Submit for direct reports | Submitted by direct report | Submitted by direct report | No | No | No |
| Verifier | No | Yes | No | Yes | No | No |

| | | | | | | |
|---|---|---|---|---|---|---|
| Expense Admin | No | All reports | No | No | Yes | Yes |

**Role assignments**
Role assignments are configured by the Web expense application administrator after installation. An administrator might use:

- **User:** A Windows Active Directory group for all employees.
- **Manager:** An LDAP query group that checks title and number of direct reports.

  ```
  (&(Title = Manager)(numReports > 0))
  ```

  The Active Directory schema may be extended to support these properties on the user object. These properties would be maintained by a separate human resources application.
- **Verifier:** An application basic group that lists each user who verifies each expense.
- **Expense Admin:** An Active Directory group that contains the users in the expense accounting department.

After using one of the above techniques to create an Authorization Manager client context, the Web expense application can then call the **AzClientContext.GetRoles** method on the client context interface to determine which roles the user is assigned. This allows you to use the clients role membership to determine what options to display for the user.

If the user is in the Employee role, then the expense controls are displayed, which allows the user to submit an expense. If the user is in the Manager role, the displayed page has an additional area that lists the pending expense forms that have been submitted.

Closely relating role names to application logic makes modifications difficult for administrators, so a convention must be used by the application to customize presentation, based on role memberships. In this example, Employee and Manager roles are not hard-coded into the application. Instead, the role name corresponds to a similarly-named HTML file. Additionally, the **ApplicationData** property of the AzRole object may be used to provide the application with presentation information.

When the user clicks a form button to create a new expense report, the Web expense application calls **AccessCheck**, sending in the operation values that correspond to the **ExecuteExpenseControls**, **RetrieveExpenseForm** and **SaveExpenseForm** operations. By doing this, you prevent restricted users from loading these controls and degrading performance. If the user has access to the controls, the controls are displayed, an expense form is retrieved from a SQL store and loaded into the control, and the user is allowed to enter the expense data. When completed, the user clicks **Submit** and the Web expense application calls **AccessCheck**, specifying the operations that are needed to submit an expense, for example, the operation number corresponding to EnqueApproval or SendRequestNotification. Additionally, the amount of the expense is sent into **AccessCheck** as a BizRule parameter called Amount. If access is allowed, the expense report is uploaded to a SQL queue of pending requests and an e-mail is sent that notifies the users manager of the pending request.

To be able to perform these operations, permissions are needed on several back-end resources. These include the NTFS directory from which the expense form is retrieved, the SQL database for submitted expense reports, and a Web expense Microsoft Exchange account which can be used to send e-mail notifications. Instead of impersonating and performing operations as the client, the Web expense service account should be granted enough access on back-end objects to perform the operations that the application needs. Therefore, back-end DACLs only grant access to the Web expense service account. (For more information, see "Trusted subsystem application model" earlier in this paper.)

When a manager sees the pending expense as described above), **AccessCheck** verifies the ability to use the approval controls. The manager then browses the expense details and clicks **Approve** or **Deny** and **AccessCheck** is called on the operations: **DequeApproval**, **ApproveDenyExpense** and **SendRequestNotification**. Additionally, the **Amount**, **ApprovingMgr**, and **Submitter** parameters are given the values of the amount of the submitted expense, the current user attempting to approve or deny the expense, and the name of the person who submitted the expense, respectively. During **AccessCheck**, a BizRule validates the calling user as a manager of the submitting user by checking the relationship in Exchange or SQL and verifies that the amount is within a specified limit for the current approving manager.

# Scenario: Using Authorization Manager with Custom Principals

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Applications that use custom or non-Windows principals (for example, SQL, Passport, Microsoft Commerce Server, or ADAM principals) can leverage most of Authorization Manager's runtime features.

Whether in Active Directory or in XML, Authorization Manager will store SIDs as members of groups and roles, except for LDAP query groups, which don't have static members. When a SID is added to a role or an application group, it is not verified as a SID corresponding to an Active Directory or Windows NT account. You can add a completely meaningless SID as a member of a role or a group. When **IAzClientContext::AccessCheck** is called, the SIDs in the client context are compared to SIDs in Authorization Manager roles and groups and there is no validation of the SID as an Active Directory account. If a client context has a custom SID and a role has the same custom SID assigned to iteither directly or by way of an application group that has the same custom SIDthe **AccessCheck** function will check if the SID is a member of a role or group with the requested operation and grant the permissions associated with the roles to which the SID is assigned. You can use this behavior to add custom principal types to roles or application basic groups in Authorization Manager by creating a custom SID for each custom principal and assigning that SID to appropriate roles and application basic groups

Textual SIDs have the structure **S**-*Version-AuthorityID-X-Y-Z*, where *Version* is the SID version number, *AuthorityID* is the security authority ID of the issuer of the SID, and *X*, *Y* and *Z* are sub-authority values. (Currently, all SIDs are version 1.) SIDs are variable in length because then number of subauthorites in SIDs can vary. SIDs can have up to **SID_MAX_SUB_AUTHORITIES** sub-authorities. (This is defined as 15 in winnt.h.) Custom SIDs use 1 for the version number, the SECURITY_RESOURCE_MANAGER_AUTHORITY for the AuthorityID value, and custom values for sub-authorities.

When creating custom SIDs you must establish a SID design for your application. For example, you might have **S-1-9-***AppInstanceGUID-UserGuid*, where 9 is the resource manager subauthority and *AppInstanceGUID* and *UserGUID* are each broken into four sub authorities. You can also use **S-1-9-***AppInstanceGuid-UserRID*, where *UserRID* is a unique number for the user in the scope of the application instance. For sample code that generates a GUID, see the Microsoft Windows Software Development Kit (SDK).

Once you have created a custom SID, you can add the SID to Authorization Manager roles or groups using the **AddMember** method of the IAzRole or IAzApplicationGroup interfaces.

To initialize a client context with a custom SID, you can call **IAzApplication::InitializeClientContextFromSID** and specify a custom SID in string form. This creates a valid client context that is suitable for performing access validation for the custom principal. In practice, after a custom principal authenticates, an application maps the authenticated principal to a custom SID that is previously created for the principal and calls **InitializeClientContextFromSID** to attain a Authorization Manager client context. When **AccessCheck** is called on this client context, this SID will be evaluated for membership in Authorization Manager roles and groups.

#### Drawbacks to custom principals

There are some drawbacks to using custom principals.

- You cannot use LDAP query groups. Since the user is not in Active Directory, it does not make sense to have LDAP query groups.
- You cannot use Active Directory groups or local machine groups.
- You cannot use the Authorization Manager MMC user interface. Since the user interface validates user SIDs when displaying role or group memberships, administrators see textual string SIDs in the user interface and not user names. More importantly, the user interface only obtains SIDs to enter into roles and application groups by way of Object Picker, which only allows you to pick valid accounts or groups.

#### Using custom principals

The following figure illustrates the process of authorizing custom principals.

**Figure 8: Authorizing custom principals**

1. Authenticate the custom principal user. and then map the custom principal to an Authorization Manager custom SID.

2. Use **InitializeClientContextFromSID** and pass the AZ_CLIENT_CONTEXT_SKIP_GROUP flag as the *loptions* parameter to build a client context with the custom SID.

After this is done, you can use **AccessCheck** to verify that the custom principal is authorized to perform the specified operations in the specified scope.

# Using Administrative Template Files with Registry-Based Group Policy

Updated: October 11, 2004

Applies To: Windows Server 2003

Published: October 11, 2004

This white paper explains the concepts, architecture, and implementation details for registry-based Group Policy in Microsoft® Windows® operating systems. It shows how to create custom Administrative Template (.adm) files and includes a complete reference for the .adm language. In addition, it includes information about changes in .adm files for Windows XP with Service Pack 2 (SP2).

**In This White Paper**

# Introduction (Using Administrative Template Files with Registry-Based Group Policy)

Applies To: Windows Server 2003

Administrators can use Group Policy to deliver and apply one or more desired configurations or policy settings to a set of targeted users and computers within an Active Directory® directory service environment. The majority of available policy settings are provided through Administrative Template files (.adm files) and are designed to modify specific keys in the registry. This is known as registry-based policy. For many applications, the use of registry-based policy delivered by .adm files is the simplest and best way to support centralized management of policy settings.

Intended for IT administrators and developers, this document describes how to implement registry-based Group Policy by using .adm files.

For detailed instructions about enabling applications for Group Policy, see "Group Policy" in the Microsoft Platform Software Development Kit at http://go.microsoft.com/fwlink/?LinkId=26258.

# Overview of Registry-Based Policy and Administrative Template Files

Applies To: Windows Server 2003

By using registry-based policy, operating system components and applications can respond to registry key settings that administrators can manage centrally with Group Policy. These policy settings determine the behavior of the application for targeted computers or users. As long as a component or application has been policy-enabled (that is, its behavior changes based on registry values indicated in the .adm file), you can manage its features and settings through registry-based policy.

.Adm files are UNICODE text files that Group Policy uses to describe where registry-based policy settings are stored in the registry. All registry-based policy settings appear and are configured in the Group Policy Object Editor under the Administrative Templates node. .Adm files do not apply policy settings; they simply enable administrators to view the policy settings in the Group Policy Object Editor. Administrators can then create Group Policy objects (GPOs) containing the policy settings that they want to use. For example, you might have one GPO that contains various policy settings for managing the Active Desktop feature.

With the release of Microsoft® Windows XP Service Pack 2 (SP2), IT administrators have more than 1,300 Administrative Template policy settings available for their use. In addition, administrators and developers can add their own custom settings.

Registry-based Group Policy uses .adm files in the following manner:

- The Group Policy Object Editor reads the .adm files. By default, when an administrator opens a GPO, a comparison is made between the timestamps of the .adm files stored in the GPO being edited and those on the local computer. If the local .adm files have a more recent timestamp then they are uploaded to the domain controller and replicated throughout the domain.

- The Group Policy Object Editor console (gpedit.msc) displays the settings, and, depending on the .adm file, the policy settings can be displayed in a localized language.

- The Group Policy Object Editor uses .adm files to configure user interface settings such as dialog boxes, radio buttons, and drop-down lists, thereby enabling administrators to manage these settings centrally.

- The Group Policy Management Console (GPMC) uses .adm files to display policy settings when using Group Policy Results or Group Policy Modeling, also known as Resultant Set of Policy (RSoP).

| **Note** |
| --- |
| Windows XP SP2 includes modifications to the LISTBOX ADDITIVE behavior in .adm files (implemented by a new version of gptext.dll, the .dll used by the Group Policy Object Editor.) For details about these changes, see the, "What's New for .Adm Files in Windows XP SP2" section later in this document |

For more information about the architecture of Administrative Templates, see Administrative Templates Extension Technical Reference at http://go.microsoft.com/fwlink/?LinkId=35291.

**Default .adm Files**

The Group Policy Object Editor displays the policy settings within the .adm files that are included with the operating system by default. These .adm files are:

- **System.adm.** Provides policy settings to configure the operating system. System.adm is installed by default in Windows Server™ 2003, Windows XP, and Windows 2000 Server operating systems.

- **Inetres.adm.** Provides policy settings to configure Internet Explorer. Inetres.adm is installed by default in Windows Server 2003, Windows XP, and Windows 2000 Server operating systems.

- **Wuau.adm.** Provides policy settings to configure Windows Update. Wuau.adm is installed by default in Windows Server 2003, Windows XP Service Pack 1 (SP1), and Windows 2000 Server Service Pack 3 (SP3) operating systems.

- **Wmplayer.adm.** Provides policy settings to configure Windows Media Player. Wmplayer.adm is installed by default in Windows Server 2003 and Windows XP operating systems. Wmplayer.adm is not available on 64-bit versions of the Windows Server 2003 operating system and Windows XP 64-Bit Edition.

- **Conf.adm.** Provides policy settings to configure NetMeeting. Conf.adm is installed by default in Windows Server 2003, Windows XP, and Windows 2000 Server operating systems. Conf.adm is not available on 64-bit versions of the Windows Server 2003 operating system and Windows XP 64-Bit Edition.

Most Group Policy settings are contained in the System.adm file. The .adm files that ship with Windows Server 2003, Windows XP Professional, and Windows 2000 Server operating systems are located in the %windir%\inf\ folder. (for example, C:\Windows\inf). For more information about .adm file maintenance, see the "Maintaining and Managing .Adm Files" in this document.

**When to Use Registry-Based Group Policy**

In general, if a policy setting can be configured using a simple user interface, and any configuration input can be stored in the registry as plain text, you should consider using registry-based policy. Specifically, registry-based Group Policy is an appropriate solution for the following scenarios:

- **Creating available and unavailable (on/off, or yes/no) functionality.** You can use registry-based policy as if it were a switch, to turn functionality on or off. For example, you can create a policy setting to allow administrators to control whether a certain item is displayed on the desktop.

- **Defining a set of static modes.** For example, you can set the language used on a computer. You can set up a static list of the possible language selections, and when the policy setting is enabled, the administrator can select a language from the pre-created list. This action is typically shown in the user interface as a drop-down list.

- **Creating a policy setting that requires simple input that can be stored in the registry as plain text.** For example, you can create a policy setting to define the screensaver or bitmap that is displayed on the user's desktop. With this policy setting enabled, Group Policy administrators are provided with a text dialog box into which they can enter the name and path of the bitmap file to be used. This information is then stored in the registry as plain text.

**True Policies vs. Preferences**

Group Policy settings that administrators can fully manage are known as "true policies." In contrast, settings that users configure or that reflect the default state of the operating system at installation time are known as "preferences." Both true policies and preferences contain information that modifies the registry on users' computers. True policy settings take precedence over preference settings.

Registry values for true policies are stored under the approved registry keys as listed in Table 1. Users cannot change or disable these settings.

**Table 1 Approved Registry Key Locations for Group Policy Settings**

| For Computer Policy Settings: | For User Policy Settings: |
|---|---|
| HKLM\Software\Policies (The preferred location) | HKCU\Software\Policies (The preferred location) |
| HKLM\Software\Microsoft\Windows<br>\CurrentVersion\Policies | HKCU\Software\Microsoft\Windows<br>\CurrentVersion\Policies |

Preferences are set by the user or by the operating system at installation time. The registry values that store preferences are located outside the approved Group Policy keys listed in Table 1. They are located in other areas of the registry. Users can typically change their preferences at any time. For example, users can decide to change the location of their local dictionary to a different location, or set their wallpaper to a different bitmap. Most users are familiar with setting preferences that are available to them through the operating system or application user interface.

It is possible for an administrator to write an .adm file that sets registry values outside of the approved Group Policy registry trees included in Table 1. In this case, the administrator is only ensuring that a given registry key or value is set in a particular way. With this approach, the administrator configures preference settings, instead of true policy settings, and marks the registry with these settings (that is, the settings persist in the registry even if the preference setting is disabled or deleted).

If you configure preference settings by using a GPO in this manner, the GPOs that you create do not have Access Control List (ACL) restrictions. As a result, users might be able to change these values in the registry. When the GPO goes out of scope (that is, it is unlinked, disabled, or deleted), these values are not removed from the registry. In contrast to this, true registry policy settings do have ACL restrictions to prevent users from changing them, and the policy values are removed when the GPO that set them goes out of scope. For this reason, true policies are considered to be policy settings that can be fully managed. By default, the Group Policy Object Editor only shows policy settings that can be fully managed. To view preferences in the Group Policy Object Editor, you need to click the **Administrative Templates** node, click **View**, then click **Filtering**, and then clear **Only show policy settings that can be fully managed**.

Although Group Policy settings take priority over preferences, they do not overwrite or modify the registry keys used by the preferences. If a policy setting is deployed that conflicts with a preference, the policy setting takes precedence over the preference setting. If a conflicting policy setting is removed, the original user preference setting is restored.

**How to Use Policy Settings and Preferences**

Applications commonly include a user preference and a policy setting that perform similar or related functions. For example, you might want to offer users the ability to configure part of a component through a user preference setting, and also centrally control this setting by using a registry-based policy setting.

An example of where both a policy and preference can co-exist is the configuration of the wallpaper on a Windows desktop. Users can set their desktop wallpaper to be displayed (or not displayed) by using the **Display** icon in Control Panel. You can also use a policy setting to configure desktop wallpaper. To specify the desktop wallpaper that displays on users' desktops, administrators can use the **Active Desktop Wallpaper** policy setting (found in the Group Policy Object Editor, under the **User Configuration\Administrative Templates\Desktop\Active Desktop**. As a result, the user can choose to display or not display the wallpaper, but the administrator can choose which wallpaper is displayed when the display setting is ON.

Table 2 lists the resultant behavior for Group Policy settings and preferences.

**Table 2 Results of Group Policy Settings and Preferences**

| Scenario | Policy Present | Preference Present | Resultant Behavior |
|---|---|---|---|
| No policy or preference | No | No | Default behavior. |
| Preference Only | No | Yes | Preference configures behavior. |
| Policy only | Yes | No | Policy configures behavior. |
| Both policy and preference | Yes | Yes | Policy configures behavior. Preference is ignored. In all cases, policy overrides preference. |

# Design Considerations for Creating Policy Settings

Applies To: Windows Server 2003

This section addresses essential issues for creating and configuring custom policy settings in .adm files.

Use the following questions as a guide to help you design Group Policy settings.

- What is the default behavior (that is, when the policy is set to **Not Configured**)?
- What is the behavior when the policy is **Enabled**, **Disabled**, or **Not Configured**? The **Enabled** behavior should always be the opposite of the default behavior (that is, **Not Configured**).
- Do administrators need to explicitly disable a feature?
- Do the proposed policy settings affect users or computers or both?
- What are some potential future ramifications of the new policy settings? When new products are released, you must continue to maintain the previous .adm settings to manage computers running legacy software. New products and settings must be able to co-exist with earlier versions.

**When to Create Policy Settings**

An administrator should consider creating a policy setting for the following purposes:

- To help administrators manage and increase security of their desktop computers.
- To hide or disable a user interface that can lead users into a situation in which they must call the helpdesk for support.
- To hide or disable new behavior that might confuse users. A policy setting created for this purpose allows administrators to manage the introduction of new features until after user training has taken place.
- To hide settings and options that might take up too much of users' time.

**Controlling Feature Releases to Users**

An administrator can use .adm files to provide policy settings to manage new features of a new or updated application. By creating a single GPO for all new features, or by creating a GPO for each logical grouping of new features, an administrator can reduce the need for support and potential user frustration. A GPO should also be considered for specific features that administrators need to control after the new features have been enabled.

By enabling policy settings in this area, the administrator can control how and when users get new product features. By grouping related features, the administrator can prevent users from using a new feature set until they have been trained.

**Create Policy Settings to Reduce Need for Support**

To reduce the need for support, administrators can start by determining the top issues that users have and considering ways in which they can use policy settings to prevent support calls. For example, you could use policy settings to control software settings in the following scenarios:

- When proper configuration settings require advanced knowledge of the application.
- When there are complicated or advanced configuration settings that the typical user does not need to use.

In these scenarios, it would be appropriate to use Group Policy to give an administrator the ability to control access to the configuration settings.

**Control Data**

You can create policy settings to populate data for your application. Such data usually exists in small sets in the form of numbers, text strings, and so on. For example, a phone dialer could use policy settings to enable administrators to mandate that certain items exist in the phone directory.

**When Not to Create a Policy**
Although registry-based Group Policy provides an effective way of managing components and applications, there are some circumstances where its use is not recommended. For example:

- Do not create a policy for *all* of your application settings because large applications typically contain hundreds or even thousands of settings, and only a subset of these needs to be managed through Group Policy. Be selective about the features you want to enable or disable. Because Group Policy provides centralized management of the setting, you should evaluate whether administrators would want this kind of management before adding the policy setting.

- Do not create a policy if you do not intend to provide support for the policy setting. Treat each policy as a feature that needs to be tested, validated, and supported.

**User Interface Design**
Effective policy settings should be clearly written and displayed. You must also ensure that the user interface is clear and easy to understand. For example, review these user interface design options for disabling **My Network Places**:

- **Create an error message.** For example, the user clicks My Network Places and the following error message appears: "This option has been disabled by your administrator." In response, the user calls the administrator or support desk to ask why this feature has been disabled.

- **Disable the user interface.** For example, a user interface feature in My Network Places is disabled (grayed-out). This implies to the user that there is a way to enable the user interface. In response, the user might spend a lot of time trying to get this feature to work. In the end, the user might either give up in frustration or call the support desk.

- **Hide the user interface feature.** For example, a user interface feature in My Network Places is hidden. In response, the user does not recognize that anything is missing or unavailable. This is the preferred choice in this scenario.

- **Do nothing.** For example, when a user clicks My Network Places, and the screen does not change (that is, nothing happens). In response, the user assumes that something is wrong and calls the support desk.

**Policy Names**
You set the name of the policy setting at the same time that you create it. The name of the policy setting is displayed in the Group Policy Object Editor. Use the following guidelines for creating policy names:

- Use a verb that reflects the effect of the policy setting. Examples of verbs commonly used in policy setting names include: allow, permit, turn on, prohibit, hide, and prevent.

- Do not use the terms "enabled" or "disabled" in your policy setting names. Instead, consider using the terms "turn on" and "turn off," or "allow" and "prevent."

- Avoid overly technical jargon that might not be understood by administrators who are not experts in a particular component. Include technical details of the policy setting in the Explain text.

- Use short, descriptive names that accurately reflect the function of the policy setting, for example, Turn off Internet File Association service.

| **Note** |
| --- |
| Policy names are limited to 256 characters. However, depending on the font used on the user's workstation, a smaller number of characters are displayed, and all others truncated. On most systems, you can assume that you have the ability to display policy names up to 65 characters. (Using a Resolution of 1024 / 768 with small fonts installed).<br><br>When Group Policy names are translated into additional languages, they typically require additional characters. Therefore, if you are using English to name a Group Policy, limit the name to 49 characters. This limitation allows your title to grow by 33 percent during translation, without causing any truncation issues. |

**Explain Text**
Explain text provides information about the behavior of the policy setting, its interaction with other policy settings, and can

include any other information that you would like administrators to be aware of. When an administrator selects a policy setting, and then clicks the **Explain** tab, the Explain text appears in the policy setting's **Properties** dialog box. Explain text is limited to a maximum of 4096 characters, and Category Explain text is limited to a maximum of 256 characters.

| **Note** |
| --- |
| Do not try to supplement a Group Policy setting title in the user interface with tip text that can be displayed in the user interface. Include any tips for using the policy setting in the Explain text. |

Use the following guidelines when you create the **Explain** text:

- Draft the **Explain** text soon after creating the specification document for the policy setting. This serves as a high-level roadmap for developers, and assists testers in creating a test plan for the policy.
- Make sure your documentation team is available to help create the Explain text.
- Target the Explain text to the Group Policy administrator, rather than the end user.

Use the following template for the Explain text, and make sure that you include the following items:

- Write a one- or two-line description of the policy setting.
- Write a one- or two-line description of the feature that the policy setting affects.
- Use separate paragraphs within your Explain text for each policy setting state, as follows:
- If you enable this policy setting...<describe enabled behavior>.
- If you disable this policy setting...<describe disabled behavior>.
- If you do not configure this policy setting...<describe default behavior>.
- Include tips for using the policy setting.
- Include notes or interactions that this policy has with other settings.

As a best practice, you should also provide information about the following:

- Items that are not covered by this policy setting.
- Any other policy settings that are required for your policy setting to function.
- Any other policy settings that are related to the same component that your policy setting affects and which may have a higher or lower priority. For example, if you have a policy setting to restrict access to the LAN settings for a computer. This policy setting takes priority over more specific policy settings regarding the actual items you can configure within a LAN connection.
- Any related policies that the administrator needs to be aware of.

The following Explain text is from the **Active Desktop Wallpaper** policy setting in the **User Configuration\Administrative Templates\Desktop\Active Desktop**. This policy setting controls the desktop background (wallpaper) that is displayed on users' desktops.

Specifies the desktop background ("wallpaper") displayed on all users' desktops.

This setting lets you specify the wallpaper on users' desktops and prevents users from changing the image or its presentation. The wallpaper you specify can be stored in a bitmap (*.bmp), JPEG (*.jpg), or HTML (*.htm, *.html) file.

To use this setting, type the fully qualified path and name of the file that stores the wallpaper image. You can type a local path, such as C:\Windows\web\wallpaper\home.jpg or a UNC path, such as \\Server\Share\Corp.jpg. If the specified file is not available when the user logs on, no wallpaper is displayed. Users cannot specify alternative wallpaper. You can also use this setting to specify that the wallpaper image be centered, tiled, or stretched. Users cannot change this specification.

If you disable this setting or do not configure it, no wallpaper is displayed. However, users can select the wallpaper of their choice.

Also, see the "Allow only bitmapped wallpaper" in the same location, and the "Prevent changing wallpaper" setting in User Configuration\Administrative Templates\Control Panel.

| **Note** |
| --- |
| You need to enable the Active Desktop to use this setting. |

| **Note** |
| --- |
| This setting does not apply to Terminal Server sessions. |

**Best Practices for Developing Registry-Based Policy Settings**

It is strongly recommended that you do not try to create a single policy setting to control all aspects of your component. Group Policy is easier to implement and use if you have several smaller policy settings. This approach gives you more flexibility in designing and modifying your policy settings.

All policy settings should have an associated behavior for each of the three possible states shown in Table 3:

**Table 3 Policy States and Associated Behaviors**

| Enabled | Disabled | Not Configured |
| --- | --- | --- |
| Turns on the behavior indicated by the policy name | Turns off the behavior indicated by the policy name | Has no effect – default behavior |

Consider the following guidelines when you design your policy settings:

- Policy settings are never removed from the .adm files supplied by Windows operating systems. Even if subsequent versions of Windows no longer support the policy setting, Microsoft will continue to include that policy setting in .adm files for all future Windows operating systems that support Group Policy.

- Computer policy settings should override user policy settings.

- The **Enabled** behavior should be the *opposite* of the default behavior. For example, if a feature is on by default, the policy setting should be named using something like "Turn off <feature>", for example, **Turn off reminder balloons**. By default, reminder balloons are displayed when the Offline Files feature is enabled; they are used to notify users when they have lost the connection to a networked file and are working on a local copy of the file. If **Turn off reminder balloons** is set to **Enabled**, the system hides the reminder balloons, and prevents users from displaying them.

- Consider whether administrators need to explicitly disable a feature. You must understand the differences between the **Not Configured** state (which implies that the administrator does not care) and the **Disabled** state (which means that the administrator cares and wants to implement a very specific behavior).

- Make sure that your documentation team is involved with creating the Explain text. Well-written Explain text can help reduce support calls.

- Each component should expose a user interface that always reflects the policy setting that is applied. For example, if a Group Policy setting removes the ability for the user to set a preference for a component, the user interface should clearly indicate this and access to that particular item in the component should be removed (for example, the item is disabled and grayed-out, or it is not visible to users).

**Creating Custom .Adm Files**

You can create custom .adm files to extend the use of registry-based policy settings to new applications and components. Creating and implementing custom .adm files involves the following tasks:

- The application or component must be enabled to use Group Policy-enabled. Many off-the-shelf applications for Windows are already Group Policy-enabled. For example, Microsoft Office is developed to work with Group Policy settings, and applicable .adm files are included in the Office Resource Kit. If a developer's application is not already Group Policy-enabled, the developer must write code that changes the application so that an administrator can apply the application-specific Group Policy settings. For more information, see Microsoft Platform Software Development Kit at http://go.microsoft.com/fwlink/?LinkId=20540.

- After the application or component is Group Policy-enabled, a developer or administrator must write an .adm file that includes the appropriate settings for that application. Custom .adm files are created as text files that describe policy settings. A framework language is provided for .adm files, as described in "Language Reference for Administrative Template Files" later in this document. When you create a new policy setting in a custom .adm file, it is more efficient if you copy and modify existing policy settings that are similar to the ones that you want to create, rather than write new policy settings from scratch. To use an existing .adm file as a template for a custom .adm file, first copy the original .adm file into a new file with a different file name, and then edit the new file. Similar policy settings can provide:

    - A model to use as a basis for your Group Policy settings.

    - Consistency with available policy settings.

    - Information about possible interactions between policies.

- Administrators use the Group Policy Management Console to view and manage GPOs and use the Group Policy Object Editor to view the **Administrative Templates** node under **Computer Configuration** or **User Configuration**.

| ⚠**Caution** |
| --- |
| Treat the .adm files that ship in the operating system as read-only files. These files are often updated when you install service packs or future releases of the product. Policy settings should never be removed from .adm files that are included in the operating system by default. |

Keep in mind that by itself, the .adm file does not actually apply Group Policy to the client computer. You must have a corresponding component or application that responds to the registry key that is affected by the policy setting.

The following code example illustrates a simple .adm file.

```
CLASS USER

CATEGORY !!DesktopLockDown

    POLICY !!DisableTaskMgr
       EXPLAIN !!DisableTaskMgr_Explain
       VALUENAME "DisableTaskMgr"
       VALUEON NUMERIC 1
       VALUEOFF NUMERIC 0
       KEYNAME "Software\Policies\System"
    END POLICY
END CATEGORY
[strings]
DisableTaskMgr="Disable Task Manager"
DisableTaskMgr_Explain="Prevents users from starting Task Manager"
DesktopLockDown="Desktop Settings"
```

This sample code exists in the System.adm file. It allows you to configure a policy called **Disable Task Manager**, which appears in the Group Policy Object Editor namespace in **User Configuration\Administrative Templates\Desktop Settings**.

This policy setting defines the following behavior:

- If an administrator enables this policy setting, it creates a registry key called **DisableTaskMgr** and set its value to 1. The **VALUEON** tag implements this behavior. In this case, users cannot start Task Manager.

- If an administrator disables this policy setting, it creates a registry key called **DisableTaskMgr** and set its value to 0. The **VALUEOFF** tag implements this behavior. In this case, users can start Task Manager.

- In both cases, the **DisableTaskMgr** registry key is created below **HKCU\Software\Policies\System** in the registry. Note that the key is created under **CLASS USER** and not under **CLASS MACHINE** because this is a user policy setting.

- If an administrator sets this policy setting to **Not Configured**, it deletes the registry key called **DisableTaskMgr.** In this case, users can start **Task Manager**.

Table 4 lists where registry-based policy settings are stored in any of the four approved registry locations for Group Policy.

**Table 4 Approved Registry Key Locations for Group Policy Settings**

| **Computer Policy Settings** | **User Policy Setting:** |
|---|---|
| HKLM\Software\Policies (The preferred location) | HKCU\Software\Policies (The preferred location) |
| HKLM\Software\Microsoft\Windows<br><br>\CurrentVersion\Policies | HKCU\Software\Microsoft\Windows<br><br>\CurrentVersion\Policies |

The registry keys are created when a GPO containing an enabled or disabled registry-based policy setting is applied. If the GPO is later removed (for example, unlinked from an OU in which a user resides), the registry keys associated with it are also removed. Security prohibits a standard user from changing the registry keys. A local administrator can overwrite these registry keys, and thus change or disable the behavior of the policy setting. For this reason, as a Group Policy administrator, you might want to enable the **Registry policy processing** policy setting (located in **Computer Configuration\Administrative Templates\System\Group Policy**) and select the following option: **Process even if the Group Policy objects have not changed**.

Selecting this option updates and reapplies the policy settings even if you -- the Group Policy administrator -- have not changed the policy settings. This provides an additional safeguard in the event that local administrators try to change policy settings through the registry. Policy settings are reapplied during the regular background refresh of Group Policy, which occurs by default every 90 minutes with a randomized delay of up to 30 minutes.

# How to Write a Simple .Adm File for Registry-based Group Policy

Applies To: Windows Server 2003

This section shows you how to create a simple .adm file for delivering registry-based Group Policy settings. The code samples provided are parts of a single .adm file. Please refer to "Language Reference for Administrative Template Files," later in this document for full details about the .adm language.

The sections of the sample .adm file illustrate how to set a registry value to:

- Turn a feature on or off.
- Allow the selection of one or more values from a list.
- Display a list with add and remove buttons.
- Enter EDITTEXT and static text.
- Display a numeric list to the administrator.
- Display a numeric list to the administrator, using a spin control.
- Display an actionable list to an administrator.

**To Set a Registry Value to Turn a Feature ON or OFF**

This sample code displays a check box. The value is set in the registry with the REG_DWORD type. By default, the check box is clear. If the check box is selected, it writes the value 1 to the registry. If the check box is clear, it writes the value 0 to the registry.

```
CLASS USER

CATEGORY!!SampleCategory
    KEYNAME "SOFTWARE\Policies\Microsoft\ADM_Samples"

    POLICY!!Sample_ADM_FeatureOnOff
        #if version >= 4
            SUPPORTED!!SUPPORTED_WindowsXPSP1
        #endif
        EXPLAIN!!Sample_ADM_FeatureOnOff_Help
        VALUENAME "ADM_Sample_FeatureOnOff"
            VALUEON 1
            VALUEOFF 0
    END POLICY
END CATEGORY
```

**To Set a Registry Value to Allow the Selection of One or More Values from a List**

You can use **DROPDOWNLIST** to display a combo box with a drop-down style list. You can pre-populate the list of items that are displayed in the list and the corresponding registry value to be written for each item in the list.

```
POLICY!!Sample_ADM_DropDownList
    #if version >= 4
        SUPPORTED!!SUPPORTED_WindowsXPSP1
    #endif
    EXPLAIN!!Sample_ADM_DropDownList_Help
    PART!!Sample_ADM_DropDownList DROPDOWNLIST REQUIRED
        VALUENAME "Sample_ADM_DropDownList"
            ITEMLIST
             NAME !!Sample_ADM_DropDownList_Always    VALUE NUMERIC 1 DEFAULT
             NAME !!Sample_ADM_DropDownList_WorkStationOnly    VALUE NUMERIC 2
             NAME !!Sample_ADM_DropDownList_ServerOnly    VALUE NUMERIC 3
         END ITEMLIST
    END PART
```

```
END POLICY
```

**To Set a Registry Value to Display a List with Add and Remove Buttons**
You can use registry-based Group Policy to display a list box that contains Add and Remove buttons.

By default, only one column appears in the list box, and for each entry, a value is created where the name and value are the same. For example, a name entry in the list box creates a value called *name* that contains data labeled *name*.

```
POLICY!!Sample_ADM_ListBox
    #if version >= 4
        SUPPORTED !!SUPPORTED_WindowsXPSP1
    #endif
    EXPLAIN!!Sample_ADM_ListBox_Help
    PART!!Sample_ADM_DropDownList LISTBOX
        KEYNAME "Sample_ADM_ListBox"
    END PART
END POLICY
```

**To Set a Registry Value for EDITTEXT and Static Text**
This setting allows the user to type alphanumeric text in an edit field. The text is set in the registry with the REG_SZ type.

The following code is an example of how you can use the **EDITTEXT PART** type.

```
POLICY!!Sample_ADM_EditText
    #if version >= 4
        SUPPORTED !!SUPPORTED_WindowsXPSP1
    #endif
    EXPLAIN!!Sample_ADM_EditText_Help
    PART!!Sample_ADM_EditText EDITTEXT
        VALUENAME "ADM_Sample_EditText"
    END PART
END POLICY
```

**To Set a Registry Value for Displaying a Numeric List to the Administrator**
To display a list of numbers from which administrators can select one of the predefined numeric values, you can use a NUMERIC PART type.

```
POLICY!!Sample_ADM_Numeric

    #if version >= 4

        SUPPORTED !!SUPPORTED_WindowsXPSP1

    #endif

    EXPLAIN!!Sample_ADM_Numeric_Help

    PART!!Sample_ADM_Numeric NUMERIC

        VALUENAME "ADM_Sample_Numeric"

    END PART

END POLICY
```

**To Set a Registry Value for Displaying a Numeric List to the Administrator, Using SPIN Control**
To display a list of numbers from which administrators can select one of the predefined numeric values, you can use a SPIN control.

```
POLICY!!Sample_ADM_Spinner
    #if version >= 4
        SUPPORTED !!SUPPORTED_WindowsXPSP1
    #endif
    EXPLAIN!!Sample_ADM_Spinner_Help
    PART!!Sample_ADM_Spinner NUMERIC
        VALUENAME "ADM_Sample_Spinner"
        MIN 5 MAX 23 DEFAULT 14 SPIN 3
    END PART
END POLICY
```

**To Set a Registry Value to Display an ActionList to an Administrator**

To specify a set of arbitrary registry changes to make in response to a control being set to a particular state, you can use the **ACTIONLIST** option.

```
POLICY!!Sample_ADM_ActionList
    #if version >= 4
        SUPPORTED !!SUPPORTED_WindowsXPSP1
    #endif
    EXPLAIN!!Sample_ADM_ActionList_Help
    ACTIONLISTON
        KEYNAME "SOFTWARE\Policies\Microsoft\ADM_Sample\ActionOnList"
            VALUENAME "Action1"
            VALUE NUMERIC 1
        KEYNAME "SOFTWARE\Policies\Microsoft\ADM_Sample\ActionOnList"
            VALUENAME "Action2"
            VALUE NUMERIC 7
        KEYNAME "SOFTWARE\Policies\Microsoft\ADM_Sample\ActionOnList"
            VALUENAME "Action1"
            VALUE NUMERIC 100
    END ACTIONLISTON
    ACTIONLISTOFF
        KEYNAME "SOFTWARE\Policies\Microsoft\ADM_Sample\ActionOnList"
            VALUENAME "Action1"
            VALUE NUMERIC 0
        KEYNAME "SOFTWARE\Policies\Microsoft\ADM_Sample\ActionOnList"
            VALUENAME "Action2"
            VALUE NUMERIC 0
        KEYNAME "SOFTWARE\Policies\Microsoft\ADM_Sample\ActionOnList"
            VALUENAME "Action1"
            VALUE NUMERIC 0
    END ACTIONLISTOFF
END POLICY
```

# Testing Administrative Template Files

Applies To: Windows Server 2003

This section provides recommended procedures for testing .adm files. You should always test policy settings before deploying them in GPOs. Your test plan should examine and document the following for each policy setting:

- The default behavior
- The behavior when the policy setting is enabled, disabled, or not configured
- Changes in the user interface when a policy setting is enabled, disabled, or not configured
- The possible settings that the policy setting can be configured as
- The associated behavior. For example, does configuring the policy setting affect other policy settings, or is one policy setting dependent on another?
- Any associated preferences
- The behavior of the associated preferences
- The behavior in the event of invalid input by an administrator

First, test your new policy settings individually. Next, test how each policy setting interacts with other policy settings that are similar, or policy settings that are also designed to manage the affected component.

Suppose for example that you create a policy setting to configure the wallpaper that is displayed on your clients' desktops. The list of policy settings that ship with Windows Server 2003 includes other wallpaper policy settings. In this scenario, you should test how these policy settings interact. Any issues that arise should be addressed or documented in the Explain text.

Testing should ensure that the user interface is policy-aware. If the user interface is not aware of the policy setting, the user experience might be confusing. For example, if your policy setting restricts access to a certain item in a component, then no access to this component and its configuration should be available in the user interface. Some ways to achieve this are:

- Removing the item completely visually
- Gray-out the item and disable it

**Creating an .Adm Test File**

To simplify testing, create a sample .adm file for your policy setting. By doing this step, you can isolate testing of the new policy settings until they are ready to be merged into a larger .adm file, if appropriate.

Your test plan should include the following validations:

- Your policy settings display and can be configured in Group Policy Object Editor, and can be set to all pertinent combinations of values.
- The settings are configured properly on the client when configured in a GPO, and the component responds appropriately to the policy setting.
- You can generate settings and Resultant Set of Policy (RSoP) reports for your policy settings by using Group Policy Management Console.
- The Explain text for the policy setting is accurate and thoroughly explains how your policy setting works. It should describe the behavior for all states of the setting: **Enabled**, **Disabled**, and **Not Configured**.

**Loading an .Adm File into the Group Policy Snap-in**

After you create an .adm file, you can load it into the Administrative Templates section of Group Policy Object Editor by performing the following procedure.

**To load your .adm file into Group Policy Object Editor**

1. Open Group Policy Object Editor.

2. Under either **Computer Configuration** or **User Configuration**, right-click **Administrative Templates**, and then click **Add/Remove Templates**.

3. In the **Add/Remove Templates** dialog box, click **Add**.

4. Navigate to the folder containing the .adm file that you would like to add. Select the file, and then click **Open**.

5. Do one of the following:

   - If your .adm file was successfully loaded, in the **Add/Remove Templates** dialog box, click **Close**. Your policy template has been added successfully.

   - If your .adm file was not successfully loaded, a dialog box is displayed, showing the error and line number of the error. Make a note of the errors that were found, and click **OK**. Although your .adm file was not successfully loaded, it still appears in the list of .adm files loaded. Select your .adm file, click **Remove,** and then click **Close**. Edit the .adm file and correct any problems.

# Maintaining and Managing .Adm Files

Applies To: Windows Server 2003

This section provides guidance to ensure that your .adm files are properly configured for your administrative workstations.

Each domain-based GPO maintains a single folder in the Sysvol folder of each domain controller. This folder, known as the Group Policy template, contains all of the .adm files that were used in the Group Policy Object Editor when the GPOs were last created or edited.

Each Windows Server operating system includes a standard set of .adm files that are loaded by default into the Group Policy Object Editor. By default, the following .adm files are pre-loaded with a Windows 2000 or later operating system:

- System.adm
- Conf.adm
- Inetres.adm

Windows Server 2003 and Windows XP include the following additional .adm files:

- Wmplayer.adm
- Wuau.adm

**Importance of Timestamps for .Adm Files**

Each administrative workstation that is used to run the Group Policy Object Editor stores its .adm files in the %windir%\Inf folder. When GPOs are created and first edited, the .adm files from this folder are copied to the Sysvol and replicated to all the domain controllers. This includes the standard .adm files and any custom .adm files that are created by the administrator.

| **Note** |
| --- |
| If you create a GPO and do not edit it, you will create a Group Policy template without any associated .adm files. |

By default, when you edit GPOs, the Group Policy Object Editor compares the timestamps of the .adm files in the workstation's %windir%\Inf folder (local .adm files) with those that are stored in the Sysvol (these are the .adm files used by the GPO that is being edited). If the local .adm files are newer, the Group Policy Object Editor copies these files to the Sysvol, overwriting any existing files of the same name. This comparison occurs whenever the Administrative Templates node (under Computer or User Configuration) is selected in the Group Policy Object Editor, regardless of whether the administrator actually edits the GPO.

| **Caution** |
| --- |
| Because of the importance of timestamps on .adm file management, it is recommended that you do not edit system-supplied .adm files. If a new policy setting is required, it is highly recommended that you create a custom .adm file. This prevents the override of system-supplied .adm files whenever service packs are released. |

**Duplicate CATEGORY Sections**

If the .adm file that you add includes a duplicate **CATEGORY** to one that is used in an existing .adm file, the policy settings are merged.

An error can occur when the existing and the added .adm file contain the same **CATEGORY**, and both of them have a default **KEYNAME** specified (regardless of whether it is the same name). If these conditions are met, the following error message appears.

Key name specified more than once. Likely causes are: 1) the KEYNAME tag is defined multiple times in this category, 2) this KEYNAME is already defined in another category with the same name, 3) this KEYNAME is already defined in another category with the same name in a different .adm file.

**.Adm Files Used by the Group Policy Object Editor**

By default, the first time the Group Policy Object Editor is started for a specified GPO, it copies the System.adm file from the current computer's %windir%\inf\ directory to the GPO.

Subsequently, only those .adm files specified in the list are displayed. Each time you open Group Policy Object Editor, the Group Policy Object Editor also checks the listed .adm files and copies any newer versions from the local computer's %windir%\inf\ directory to the GPO.

#### .Adm Files Used by GPMC

By default, GPMC always uses local .adm files, regardless of their time stamp, and it never copies .adm files to Sysvol. If an .adm file is not found locally, GPMC looks for the .adm file in the Sysvol. In GPMC, you can specify an alternative location for .adm files. If an alternative location is specified, this alternative location takes precedence.

#### Controlling .Adm File Replication

Because .adm files are stored in the Group Policy template by default, they increase the Sysvol folder size. The File Replication Service (FRS) replicates all of the .adm files for GPOs throughout the domain. If you edit GPOs frequently, you might experience a significant amount of replication traffic. You can use a combination of the **Turn off automatic updates of adm files** and **Always use local adm files for Group Policy Object Editor** policy settings to reduce the size of the Sysvol folder and policy-related replication traffic.

#### Turn Off Automatic Updates of .Adm Files

The **Turn off automatic updates of adm files** policy setting is available under **User Configuration\Administrative Templates\System\Group Policy** in Windows Server 2003, Windows XP, and Windows 2000 operating systems. When this policy setting is enabled, the updating of an existing GPO remains local to the administrative workstation, and .adm files are not sent from the local computer to the Sysvol.

| **Note** |
| --- |
| In Windows 2000 operating systems, when you edit a GPO for the first time the local .adm files are uploaded to the Sysvol, without regard to how this policy setting is set. If this policy setting is enabled in Windows XP, .adm files are not uploaded when a GPO is edited for the first time. The first time that the GPO is edited might or might not be when the GPO is created. |

#### Always Use Local .Adm Files for Group Policy Object Editor

The **Always use local ADM files for Group Policy Object Editor** policy setting is available under **Computer Configuration\Administrative Templates\System\Group Policy** in Windows Server 2003 and Windows XP Professional. When a GPO is created, this policy setting has no immediate effect, and the .adm files on the local computer are still uploaded to the Sysvol. However, when you edit an existing GPO, any .adm files that are stored in the Sysvol are ignored, and Group Policy Object Editor uses the .adm files from the local computer only. If a policy setting has been set in the GPO, but the corresponding .adm file that describes the policy setting is not available on the local computer, Group Policy Object Editor does not display that policy setting.

| **Note** |
| --- |
| If this policy setting is enabled, the Turn off automatic updates of adm files policy setting is also implied. |

### To clear the Sysvol folder of .adm files

1. Enable the **Turn off automatic update of adm files** policy setting for all Group Policy administrators who will be editing GPOs and verify that this policy has been applied.

2. Copy any custom .adm templates to the %windir%\Inf folder.

3. Edit existing GPOs, and right-click **Administrative Templates**, and then click **Add/Remove Template** to remove all .adm files from the Sysvol.

4. Enable the **Always use local adm files for Group Policy Object Editor** policy setting for administrative workstations.

#### Maintaining .Adm files on Administrative Workstations

When you use the **Always use local adm files for Group Policy Object Editor** policy setting, make sure that each workstation has the latest version of the default and custom .adm files. If all .adm files are not available locally, some policy settings that are contained in a GPO will not be visible to the administrator. Avoid this by implementing a standard operating system and service pack version for all administrators. If you cannot use a standard operating system and service pack, implement a process to distribute the latest .adm files to all administrative workstations.

**Note**

Because the workstation adm files are stored in the %windir%\Inf folder, any process that is used to distribute these files must run in the context of an account that has administrative credentials on the workstation.

**Multilanguage Administration Issues**

In some environments, policy settings must be presented to the user interface in several languages. Because the GPT folder can store only one set of .adm files, you cannot use the GPT folder to store .adm files for multiple languages.

For Windows 2000 operating systems, the use of local .adm files for the Group Policy Object Editor is not supported. If you are using Windows 2000, use the **Turn off automatic updates of adm files** policy setting. Because this policy setting has no effect on the creation of new GPOs, the local .adm files will be uploaded to the GPT folder in Windows 2000. Creating a GPO in Windows 2000 effectively defines the language of the GPO. If the **Turn off automatic updates of adm files** policy setting is in effect on all computers running Windows 2000, the language of the adm files in the GPT folder will be defined by the language of the computer that is used to create the GPO.

If you are using Windows 2000 workstations, use the **Turn off automatic updates of adm files** policy setting for administrators, and consider the adm files in the GPT folder to be the effective language for all Windows 2000 workstations.

For administrators who are using Windows Server 2003 and Windows XP operating systems, the **Always use local adm files for Group Policy Object Editor** policy setting can be used. For example, this policy setting allows a French administrator to view policy settings by using the French .adm files that are installed locally, regardless of the adm file that is stored in the GPT folder. Note that when you use this policy setting, it is implied that the **Turn off automatic updates of adm files** policy setting is also enabled, to avoid unnecessary updates of the adm files to the GPT folder.

Consider standardizing on Windows Server 2003 for administrative workstations in a multi-language administrative environment. Configure both the **Always use local adm files for Group Policy Object Editor** and **Turn off automatic updates of adm files** policy settings.

**Operating System and Service Pack Release Issues**

Each operating system or service pack release includes a superset of the .adm files provided by earlier releases, including policy settings that are specific to operating systems that are different to those of the new release. For example, the .adm files that are provided with Windows Server 2003 include all policy settings for all operating systems, including those that are only relevant to Windows 2000 or Windows XP Professional. This means that only viewing a GPO from a computer with the new release of an operating system or service pack effectively upgrades the .adm files. Because later releases are typically a superset of previous .adm files this will not typically create problems, assuming that the .adm files that are being used have not been edited.

In some situations, an operating system or service pack release includes a subset of the .adm files that were provided with earlier releases. This has the potential to present an earlier subset of the .adm files, resulting in policy settings no longer being visible to administrators when they use Group Policy Object Editor. However, the policy settings will remain active in the GPO--only the visibility of the policy settings in Group Policy Object Editor is affected. Any active (either **Enabled** or **Disabled**) policy settings are not visible in Group Policy Object Editor, but remain active. Because the settings are not visible, it is not possible for the administrator to view or edit these policy settings. To work around this issue, administrators must become familiar with the .adm files that are included with each operating system or service pack release before using the Group Policy Object Editor on that operating system, keeping in mind that the act of viewing a GPO is enough to update the .adm files in the GPT, when the timestamp comparison determines an update is appropriate.

To plan for this in your environment, it is recommended that you either:

- Define a standard operating system/service pack from which all viewing and editing of GPOs occurs, making sure that the .adm files being used include the policy settings for all platforms.
