**Description**
Stores configuration data for the policy setting **Show only specified Control Panel applets**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel.

# Policies\Explorer Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies

**Description**
The Explorer subkey contains entries that store Group Policy settings for Windows Explorer and for the Windows interface. These include policies for the Start menu, taskbar, desktop, and Control Panel. Group Policy creates and maintains the entries in this subkey, and Windows Explorer reads and interprets them.

This subkey in HKEY_LOCAL_MACHINE stores entries that apply to all users of this computer. The Software\Microsoft\Windows\CurrentVersion\Policies\Explorer subkey in HKEY_CURRENT_USER stores policy-related entries that are configured separately for each user.

**Concepts**
Policies\Explorer

# Btn_History

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer

**Description**
Stores configuration data for the policy setting **Configure Toolbar Buttons**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Toolbars.

# NoDFSTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove DFS tab**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Explorer.

# NoStartMenuMyMusic

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer

**Description**
Stores configuration data for the policy setting **Remove My Music icon from Start Menu**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Start Menu and Taskbar.

# RestrictRun

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run only allowed Windows applications**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# NoFileAssociate Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\Explorer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 (Terminal Services systems) 0 (All other Windows Server 2003 systems) |

**Description**
Disables the buttons on the **File Types** tab. As a result, users can view file type associations, but they cannot add, delete, or change them.

The **File Types** tab shows which programs open when a type of file is double-clicked. The file types are represented by their file name extension.

| Value | Meaning |
|---|---|
| 0 | Users can add, delete, and change file type associations. |
| 1 | Users cannot add, delete, or change file type associations. |

By disabling this tab, you might prevent malicious users from creating an association that starts a risky or destructive program. Also, users cannot use the buttons on the **File Types** tab to create less productive associations, such as associating the .doc file type with Wordpad instead of Microsoft Word. This is a particular risk on multi-user systems, such as Terminal Services clients.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Notes

- Although this entry is located in the Policies\Explorer subkey, it is not associated with a Group Policy setting. You can create a policy by adding this entry to an Administrative Templates file. For more information on creating custom .adm files, see Windows Server 2003 Help or Windows XP Professional Help.

- This entry applies to all users of the computer. To set this entry for particular users, use Explorer\NoFileAssociate in the HKCU subtree. If the settings of these entries conflict, the setting in HKCU takes precedence over the setting in HKLM.

### Caution

- This entry specifies only whether buttons on the **File Types** tab in **Folder Options** are available. Any other method of changing file type associations is unaffected by this entry.

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\NonEnum

**Description**
Stores configuration data for the policy setting **Remove My Documents icon on the desktop**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Desktop.

# {645FF040-5081-101B-9F08-00AA002F954E}

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\NonEnum

**Description**
Stores configuration data for the policy setting **Remove Recycle Bin icon from desktop**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Desktop.

# ConnectHomeDirToRoot

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Connect home directory to root of the share**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# DisableBkGndGroupPolicy

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Turn off background refresh of Group Policy**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# DisableChangePassword

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove Change Password**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Ctrl+Alt+Del Options.

# DisableLockWorkstation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove Lock Computer**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Ctrl+Alt+Del Options.

# DisableRegistryTools

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prevent access to registry editing tools**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# DisableTaskMgr

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove Task Manager**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Ctrl+Alt+Del Options.

# EnableProfileQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit profile size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# HideLegacyLogonScripts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run legacy logon scripts hidden**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# HideLogoffScripts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run logoff scripts visible**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# HideLogonScripts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run logon scripts visible**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# HideShutdownScripts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run shutdown scripts visible**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# HideStartupScripts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run startup scripts visible**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# IncludeRegInProQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit profile size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# LogonType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

**Description**
Stores configuration data for the policy setting **Always use classic logon**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Logon.

# MaxGPOScriptWait

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Maximum wait time for Group Policy scripts**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# MaxProfileSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit profile size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# NoColorChoice

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

**Description**
Stores configuration data for the policy setting **Prohibit Theme color selection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display\Desktop Themes.

# NoDispBackgroundPage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Hide Desktop tab**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display.

# NoDispCPL

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove Display in Control Panel**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display.

# NoSizeChoice

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

**Description**
Stores configuration data for the policy setting **Prohibit selection of font size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display\Desktop Themes.

# NoVisualStyleChoice

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

**Description**
Stores configuration data for the policy setting **Prevent selection of windows and buttons styles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display\Desktop Themes.

# ProfileQuotaMessage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Limit profile size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# RunLogonScriptSync Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run logon scripts synchronously**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# RunStartupScriptSync

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Run startup scripts asynchronously**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Scripts.

# SetVisualStyle

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

**Description**
Stores configuration data for the policy setting **Load a specific visual style file or force Windows Classic**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display\Desktop Themes.

# System\Shell

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Custom user interface**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# VerboseStatus

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Verbose vs normal status messages**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# Wallpaper

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |

| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Active Desktop Wallpaper**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Desktop\Active Desktop.

# WallpaperStyle

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Active Desktop Wallpaper**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Desktop\Active Desktop.

# WarnUser

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit profile size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# WarnUserTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit profile size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# Policies\System

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies

**Description**
The System subkey stores the entries created when you configure a Group Policy setting that affects a basic component of Windows Server 2003. Group Policy creates and maintains the entries in this subkey, and the component program reads and interprets them.

This subkey stores entries that apply to all users of this computer. The Software\Microsoft\Windows\CurrentVersion\Policies\System subkey in HKEY_CURRENT_USER stores policy setting related entries that are configured separately for each user.

**See Also**
**Concepts**
Microsoft\System Subkey
Windows\System Subkey

# DisableStatusMessages

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove Boot / Shutdown / Logon / Logoff status messages**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# Uninstall

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# DefaultCategory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\Uninstall

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Specify default category for Add New Programs**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Add or Remove Programs.

# NoAddFromCDorFloppy

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\Uninstall

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Hide the Add a program from CD-ROM or floppy disk option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Add or Remove Programs.

| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# CurrentVersion\Run

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion

**Description**
The Run subkey of HKEY_LOCAL_MACHINE\Software stores the names of programs that Windows Server 2003 runs for all users of the computer each time the system starts up.

Each entry in the subkey represents a program. The value of the entry is the name of the executable file for the program. The entries have the following format:

| Entry name | Data type | Value |
|---|---|---|
| *Program Name* | REG_SZ | *File name* |

# RunOnce

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion

**Description**

The RunOnce subkey stores the names of programs that will be run the next time that a user logs on. These programs are run only one time, and then the registry entries that specified them are deleted from the subkey.

However, if the account of the next user to log on does not have permissions to delete entries from the RunOnce subkey, then the specified programs will not be run. The operating system will not run the programs until a user with adequate permissions logs on.

Each entry in the subkey represents a program. The value of the entry is the name of the executable file for the program. These entries have the following format:

| Entry name | Data type | Value |
|---|---|---|
| *Program Name* | REG_SZ | *File name* |

# Telephony Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Telephony\Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Telephony

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# HighSecurity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Telephony\Server

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFF | (None) |

**Description**
Specifies whether High Security mode is enabled on a Telephony Server. In High Security mode, the Telephony Server will accept RPC connections only from remote clients connecting with RPC_C_AUTHN_LEVEL_PKT_PRIVACY. Client connections that do not use RPC_C_AUTHN_LEVEL_PKT_PRIVACY will be rejected. Enabling High Security mode enhances the security of the Telephony Server component.

| Value | Meaning |
|---|---|
| 0x0 | High Security mode is disabled. |
| 0x1–0xFFFFFFFF (or not present in the registry) | High Security mode is enabled. |

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Telephony service on the Telephony Server to make changes to this entry effective.

### Note

- Starting with Windows Server 2003 and Windows XP Professional Service Pack 2, the telephony clients connect to a remote Telephony Server with RPC_C_AUTHN_LEVEL_PKT_PRIVACY. Clients using earlier Windows operating systems do not use RPC_C_AUTHN_LEVEL_PKT_PRIVACY and will fail to connect to a Windows Server 2003 Telephony Server in High Security Mode, which is enabled by default. Disabling High Security mode on the Telephony Server ensures that clients running earlier versions of Windows can connect to the server.

### Caution

Setting the value of this entry to 0x0 disables High Security mode on the Telephony Server, which compromises the security of the Telephony Server by allowing connections from clients that do not use RPC_C_AUTHN_LEVEL_PKT_PRIVACY (the RPC parameters for these connections are not encrypted).

# Microsoft\Windows NT Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
The Windows NT subkey stores configuration data for components of Windows Server 2003. The subkeys of the Windows NT subkey represent versions of the operating system, such as CurrentVersion, which refers to the version currently running on the computer. Each version subkey contains subkeys representing components that run on that version of the system.

This subkey stores entries that apply to all users of the computer. The Windows NT subkey in HKEY_CURRENT_USER stores entries that apply only to the current user of the computer.

**See Also**
**Concepts**
Microsoft\Windows NT

# CurrentVersion Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Version number* | 5.2 |

**Description**

Stores the version number of the Windows NT operating system that is currently running on the system.

# AeDebug

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The AeDebug subkey stores user preferences for Dr. Watson and other debugging tools.

**Change Method**
Use the **Dr. Watson for Windows** dialog box to change the values of entries in this subkey. (Run drwtsn32 from the command prompt or use the Run command on the Start menu.) To disable Dr. Watson for Windows, delete the AeDebug subkey. To enable Dr. Watson for Windows, type **drwtsn -i** at the command prompt or from the Run command on the Start menu.

# Auto

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\AeDebug

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
Specifies whether the debugger specified in the value of the Debugger entry starts automatically when an application error occurs.

| Value | Meaning |
|---|---|
| 0 | The system displays a message box notifying the user when an application error occurs. |
| 1 | The debugger starts automatically. |

If the **Debugger** entry contains the name of a valid debugger (such as Drwtsn32, WinDbg, or NTSD), then the user can either terminate the application by clicking **OK** or can run the debugger by clicking **Cancel**. If no debugger is specified, then the message box has no **Cancel** button.

# Debugger

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\AeDebug

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Name of debugger and switch settings.* | drwtsn32 -p %ld -e %ld -g |

**Description**

Specifies the debugger that activates when an application error occurs. If the value of the Auto entry is 1, then this debugger starts automatically. If the value of **Auto** is 0, then the user must start the debugger.

Dr. Watson for Windows (drwtsn32) is the default debugger, but another debugger (such as WinDbg or NTSD) can be installed as the automatic debugger. The values following the debugger name are specific to the debugger. The default switches for Dr. Watson are set as follows:

| Value | Meaning |
|---|---|
| -p | Stores the Process ID for the running process at the location specified by **%ld.** |
| -e | Stores the Event ID for the running process at the location specified by **%ld.** |
| -g | Tells the debugger to go (start). |

**Change Method**

You can change the value of this entry only by editing the registry. However, you can restore default settings by typing **drwtsn32 -i** at the command prompt.

### Note

- For more information on Dr. Watson for Windows, see Windows Server 2003 Help or Windows XP Professional Help.

# UserDebuggerHotKey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\AeDebug

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFF | 0x0 |

**Description**

Specifies the key that, when pressed, establishes a breakpoint in code being debugged.

The debugger interrupts code processing at the breakpoint so the programmer can examine a suspected problem.

The key specified in this value only sets a breakpoint. It does not invoke the debugger (the debugger must be running before the key is pressed), and it does not switch the debugger to single-step mode.

The value of this entry is a keyboard scan code. The default value (0x0) represents the F12 key on a 101-key keyboard or the "-" (hyphen, VK_SUBTRACT) key on an 82-key keyboard.

The following table lists the scan codes and virtual key codes for a standard keyboard.

| Scan code | Virtual key code |
|---|---|
| 0x0 | VK_SUBTRACT (F12) |
| 0x1 | VK_LBUTTON |
| 0x2 | VK_RBUTTON |
| 0x3 | VK_CANCEL |
| 0x4 | VK_MBUTTON |
| 0x8 | VK_BACK |
| 0x9 | VK_TAB |
| 0xC | VK_CLEAR |
| 0xD | VK_RETURN |
| 0x10 | VK_SHIFT |
| 0x11 | VK_CONTROL |
| 0x12 | VK_MENU |
| 0x13 | VK_PAUSE |
| 0x14 | VK_CAPITAL |
| 0x15 | VK_KANA, VK_HANGEUL, VK_HANGUL |
| 0x17 | VK_JUNJA |
| 0x18 | VK_FINAL |
| 0x19 | VK_HANJA, VK_KANJI |

| | |
|---|---|
| 0x1B | VK_ESCAPE |
| 0x1C | VK_CONVERT |
| 0x1D | VK_NONCONVERT |
| 0x1E | VK_ACCEPT |
| 0x1F | VK_MODECHANGE |
| 0x20 | VK_SPACE |
| 0x21 | VK_PRIOR |
| 0x22 | VK_NEXT |
| 0x23 | VK_END |
| 0x24 | VK_HOME |
| 0x25 | VK_LEFT |
| 0x26 | VK_UP |
| 0x27 | VK_RIGHT |
| 0x28 | VK_DOWN |
| 0x29 | VK_SELECT |
| 0x2A | VK_PRINT |
| 0x2B | VK_EXECUTE |
| 0x2C | VK_SNAPSHOT |
| 0x2D | VK_INSERT |
| 0x2E | VK_DELETE |
| 0x2F | VK_HELP |
| 0x30–0x39 | VK_0–VK_9 (ASCII 0–9) |
| 0x41–0x5A | VK_A–VK_Z (ASCII A–Z) |

# DNS Server_DepKit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Zones

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\DNS Server

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Zone-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\DNS Server\Zones

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The *Zone-name* subkeys represent each of the authoritative zones on the server. They are named for the zone and store settings that apply only to the zone.

The entries in *Zone-name* can appear in any subkey in the HKLM\SYSTEM\CurrentControlSet\Services\DNS\Zones subkey.

**Activation Method**
The Domain Name System (DNS) reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, the changes are not effective until you restart the DNS server, but changes made by using the DNS console are effective immediately.

### Notes

- The subkey *Zone-name* is a placeholder representing the zone subkeys in the subkey HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\DNS Server\Zones. "Zone-name" does not actually appear in the registry. Also, the entries documented in this reference for the *Zone-name* subkeys can appear in any registry, but the actual entries in your registry depend on the configuration of the zone.

- Note that in Windows 2000, Zone subkeys are located in HKLM\SYSTEM\CurrentControlSet\Services\DNS\Zones. Only zone-specific entries are relocated for Windows Server 2003; server-specific entries remain in the same location (HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters).

# LocalMasterServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\DNS Server\Zones*Zone-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Contains the space-separated list of master servers to be used by this DNS server for the zone specified by this registry subkey. When the DNS server loads a stub zone, it checks the value of this entry for that zone. If this entry is empty or doesn't exist in the registry, then the server uses the master servers specified in Active Directory.

This entry is created when **Use local list of Master servers** is selected in the DNS snap-in of the Microsoft Management Console (MMC). When created, this entry is populated with the IP addresses of the master servers. When **Use local list of Master servers** is deselected, this entry is deleted from the registry.

**Change Method**
This entry is created and modified through the DNS snap-in of the Microsoft Management Console.

**Activation Method**
When this entry is modified through the DNS snap-in, changes take effect immediately.

### Note

- A stub zone is a type of DNS zone that contains the set of resource records necessary to enable the DNS server that is hosting the zone to send DNS queries for the zone directly to the DNS servers authoritative for the zone. Without the resource records of the stub zone, if the required resource records are not already in its cache, then the DNS server must perform an interative query for the records, starting with the name servers that are authoritative for the root zone.

# ScavengeServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\DNS Server\Zones*Zone-name*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *IP address[, IP address] ... (dotted decimal form)* | (None) |

**Description**
Limits the Domain Name System (DNS) servers that can scavenge the resource records for this zone to the servers listed in this entry.

When *scavenging*, the DNS server inspects the timestamps of resource records for this zone in the DNS database, and it deletes records that are out of date.

To enable scavenging, the value of the server's **Aging** entry must be set to 1.

By default, this entry does not appear in the registry and, therefore, all primary servers that are authoritative for this zone can scavenge its resource records. However, if this entry appears in the registry, only the servers specified in the value of this entry can scavenge the resource records for the zone.

**Change Method**
To change the value of this entry, use the *DNS Server Troubleshooting Tool* (Dnscmd.exe) included with Windows Server 2003. For more information, see Windows Server 2003 Tools Help.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Notes

- By default, scavenging is disabled on the DNS server and on all zones. To enable scavenging for any zone, you must enable it on the DNS server (as specified in **ScavengingInterval**) and on the zone (as specified by this entry). If scavenging is disabled on the DNS server, all entries that configure scavenging on any zone are ignored.

- If this entry appears in the registry, but its value is blank, no servers are authorized to scavenge the records of this zone. As a result, scavenging is effectively disabled on the zone.

- DNS adds this entry to the registry when you configure scavenging using the *DNS Server Troubleshooting Tool* (Dnscmd.exe) in the \Support\Tools\Support folder of the Windows Server 2003 operating system CD. You should not edit the registry to add, delete, or change this value.

# MasterServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\DNS Server\Zones*Zone-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *IP address[, IP address] ... (dotted decimal form)* | (None) |

**Description**
Specifies the Domain Name System (DNS) master servers from which the DNS secondary server pulls zone transfers. This entry is required for secondary zones.

**Change Method**
To change the value of this entry, use the DNS console. Right-click the name of a secondary zone, click **Properties**, and then click the **General** tab. This value corresponds to the **Masters IP addresses** boxes. You should not change this value by editing the registry directly.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS snap-in. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Note

- This entry is effective only the when it appears in the registry of a secondary Domain Name System (DNS) zone. Otherwise, it is ignored.

# Font Drivers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The Font Drivers subkey stores configuration data for external font drivers.

# driver-name Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Font Drivers

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *file name* | *file name* |

**Description**
Stores a list of external font drivers installed on the system.

The *driver-name* entry is a variable representing the entries in the Font Drivers subkey. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the Font Drivers subkey.

The Font Drivers subkey contains an entry for each font driver installed in Windows Server 2003. Each entry has the following format:

| Entry name | Data type | Value |
|---|---|---|
| *Driver name* | REG_SZ | *File name* |

For example, the following entry indicates that the driver for Adobe Type Manager is in the file atmfd.dll. The driver files are stored in *Systemroot*\WINNT\system32:

| Entry name | Data type | Value |
|---|---|---|
| Adobe Type Manager | REG_SZ | atmfd.dll |

**Change Method**
To change the value of this entry, use the program supplied by the font vendor for adding and removing drivers.

### Note

- The bitmap, vector, and TrueType drivers are built in to Windows Server 2003 and do not appear in the value of this entry. The Adobe Type Manager driver for PostScript fonts, which is included with Windows Server 2003, does appear in this entry.

# FontDPI

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The FontDPI subkey stores information about the size of the system fonts.

# LogPixels

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\FontDPI

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x13–0x1E0 *pixels per inch* | 96 |

**Description**
Specifies the size of fonts on the desktop and in menus. This entry also determines the bitmap resolution of icons and toolbar buttons.

**Change Method**
To change the value of this entry, double-click **Display** in Control Panel. Click the **Settings** tab, click the **Advanced** button, and on the **General** tab, select a font size from the list.

**Activation Method**
You must restart the computer for changes to this entry to take effect.

### Note

- The actual range of this entry depends on the installed monitor.

# Fonts Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The Fonts subkey stores the names of the files that support each font installed in Windows Server 2003. This information is used by applications running on Windows Server 2003.

Entries in this subkey are of data type REG_SZ and are named after the font stored in the file name specified by the entry. For example, the entry named **Arial (TrueType)**, if it exists in the registry, stores the string "ARIAL.TTF", the name of the file that has the Arial font. Entries can also store a combination of path and file name.

**See Also**
**Concepts**
Type 1 Fonts

# FontSubstitutes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
Stores the names of alternative fonts that can be used when a requested font or a font that appears in a document either is not available or is unsupported.

Entries in this subkey are of data type REG_SZ and are named after the fonts for which substitutes are defined. The value of an entry is the name of the font to be used in substitution for the font name matched by the name of the entry. For example, the entry **Helvetica**, if it exists in the registry, could store the string "Arial", which would configure Arial as a substitute for Helvetica.

# Font-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\FontSubstitutes

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *font name* | *substitute font* |

**Description**

Associates an alternative font with the actual font that a program requests or a document uses.

The substitute font can be used as the screen font, as the printer font, or as both. These entries have the following format:

| Entry name | Data type | Value |
|---|---|---|
| *Font name* | REG_SZ | *Substitute font name*[,*character set number*] |

For example, the following entry indicates that Arial can be substituted for Helvetica, if Helvetica is not available:

| Entry name | Data type | Value |
|---|---|---|
| Helvetica | REG_SZ | Arial |

The optional character set number must be one of the numbers in the following table.

| Character Set Number | Character Set Name |
|---|---|
| 0 | ANSI_CHARSET |
| 1 | DEFAULT_CHARSET |
| 2 | SYMBOL_CHARSET |
| 128 | SHIFTJIS_CHARSET |
| 129 | HANGEUL_CHARSET |
| 134 | GB2313_CHARSET |
| 136 | CHINESEBIG5_CHARSET |
| 161 | GREEK_CHARSET |
| 162 | TURKISH_CHARSET |
| 177 | HEBREW_CHARSET |
| 178 | ARABIC _CHARSET |
| 186 | BALTIC_CHARSET |
| 204 | RUSSIAN_CHARSET |
| 238 | EE_CHARSET |
| 255 | OEM_CHARSET |

**Note**

- The *Font-name* entry is a variable representing the entries in the FontSubstitutes subkey. It displays information that is

common to the entries in the FontSubstitutes subkey. It does not actually appear in the registry.

# GRE_Initialize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The GRE_Initialize subkey holds screen raster fonts, which command windows use.

The fonts are stored in the *Systemroot*\WINNT\system32\dllcache folder, and they are hidden to prevent their accidental deletion. All the entries in this subkey have the following format:

| Entry name | Data type | Value |
|---|---|---|
| *Font name* | REG_SZ | *File name* |

**Change Method**
These fonts are used by the system. Do not change the values of these entries.

### Note

- For more information on raster fonts in Windows Server 2003, see the *Windows Server 2003 Technical Reference*.

# CurrentVersion\Network Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support administration tools designed for Windows NT 4.0 or earlier.

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 or earlier.

# World Full Access Shared Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Network

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 or earlier.

# PDH

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The PDH subkey stores configuration data for the Performance Data Helper dynamic-link library (Pdh.dll). PDH is a library of performance data collection and processing functions used by performance monitoring programs, such as System Monitor.

This subkey does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# CollectTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\PDH

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 30–3600 | None. |

**Description**
Specifies the amount of time, in seconds, that the system waits before timing out and returning an error when accessing performance counter information via the RegQueryValueEX interface of the Performance Data Helper library (Pdh.dll). When this entry is absent from the registry, the system waits 300 seconds.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
Changes to this entry are effective the next time that Pdh.dll is loaded. It might be necessary to stop and restart any program that uses Pdh.dll.

**Tip**

Consider increasing the value of this entry on heavily loaded systems. When the processing resources of a computer are under heavy use, a PDH call that uses the registry interface as a data source might take a long time to complete, and performance tools that use this interface can seem unresponsive. Increasing the value of this entry increases the amount of time that PDH waits before declaring the call unsuccessful.

# DefaultNullDataSource

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\PDH

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 4 | 1 |

**Description**

Specifies the source from which the Performance Data Helper (PDH) functions retrieve performance counter data.

In all versions of Windows, the PDH functions use the registry to retrieve data collected by internal counters. In Windows 2000 and Windows Server 2003, PDH functions can also retrieve this data by using the Windows Management Instrumentation (WMI) interface.

| Value | Meaning |
|---|---|
| 1 | Registry. PDH functions retrieve performance counter data through registry interfaces. |
| 4 | WMI. PDH functions use WMI interfaces instead of registry interfaces to retrieve performance counter data. |

If the value of this entry is set to any value other than 4, the system behaves as if this entry is 1.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**

For changes to the entry to be effective, PDH must be reloaded.

# Perflib

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The Perflib subkey stores configuration data for the Windows Performance Library, which collects and organizes data for performance tools, such as System Monitor.

In addition to entries, the Perflib subkey contains a Language-code subkey for each spoken language you configure for Windows Server 2003. The *Language-code* subkey stores performance counter names and their descriptions in the specified language. The *Language-code* subkey is named for the language code for that language. For example, the counters and descriptions for the English language are stored in a subkey named 009, the language code for English (United States).

**Activation Method**
To make changes to entries in this subkey effective, restart Windows.

**Tip**

- If you cannot display particular performance counters, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib finds a disabling error in a performance counter dynamic-link library (DLL), it records an event in the log. Then it sets the value of Disable Performance Counters to 1 to disable the counters.

# Configuration Flags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x1F | 0x10 |

**Description**
Regulates the run-time test feature of the performance counter dynamic-link library (DLL).

The Performance Library (Perflib) tests performance counter DLLs whenever you select a performance counter in System Monitor or in a similar performance tool. It performs these reliability tests to identify and eliminate defective counter DLLs. A defective counter DLL can harm your Windows Server 2003 performance tools, preventing them from displaying any performance data and, in some cases, causing errors that shut down the system and start Dr. Watson for Windows.

Perflib can perform tests to detect the following errors:

- Slow procedure calls (non-trusted counter DLLs only).
- Data buffer alignment errors.
- Buffer integrity errors.
- Function errors.
- Program exceptions (critical).

The value of this entry determines which tests Perflib runs on trusted and non-trusted performance counter DLLs. It also determines how Perflib responds when a counter DLL fails a test. Perflib always records an error in the Application Log in Event Viewer (Source = Perflib). However, it can also disable the counter DLL so that the counters are not displayed in any performance tool until you manually re-enable the DLL.

By default, Perflib uses these test guidelines:

- Time the procedure calls of non-trusted counter DLLs. If a procedure call is slow, then record a message in the Application Log.
- Test trusted and non-trusted counter DLLs for data buffer alignment errors. If a counter DLL fails the test, then record a message in the Application Log.
- Thoroughly test the integrity of buffers that non-trusted counter DLLs return. If a counter fails the test, then disable the counter.
- Do not test the integrity of buffers that trusted counter DLLs return, unless the value of the ExtCounterTestLevel entry specifies otherwise. If a counter DLL fails a test that the **ExtCounterTestLevel** entry requires, then disable the counter.
- Detect errors in the function calls of trusted and non-trusted counter DLLs. If an error is detected, then record a message in the Application Log.
- Detect program exceptions in the function calls of trusted and non-trusted counter DLLs. If a DLL generates an exception, then disable the counters.

The value of this entry is a bitmask that you can use to change the default behavior. By default, only bit 0x10 (10000) is set. To

select a behavior, either set the bit representing that behavior to 1, or sum the values of all desired bits. For example, to prevent Perflib from testing for data buffer alignment (1 binary) and from disabling counters (10 binary), set the value of this entry to 0x3 (11 binary).

| Bit value | Test setting |
|---|---|
| 0x0 | Use default test behavior. |
| 0x1 (1 binary) | Do not test for data buffer alignment errors. (These are common errors that are not usually critical.) Perform all other tests. |
| 0x2 (10 binary) | Do not disable counters. Perform all tests, but if a counter generates a function error or a program exception, record a message in the Application Log. |
| 0x4 (100 binary) | Do not time procedure calls or perform buffer integrity tests. When set, the ExtCounterTestLevel entry and the entries that define a slow procedure call (see Notes below) are ignored. |
| 0x8 (1000 binary) | Disable counters if their procedure calls are slow. (Non-trusted counter DLLs only.) |
| 0x10 (10000 binary) | Collect debugging data. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to this entry effective, either restart the Remote Registry Service or restart Windows.

### Notes

- Bit 0x2 (10) takes precedence over bit 0x8 (1000). If bit 0x2 is set, then Perflib does not disable performance counters.
- Perflib disables a counter by setting the value of the Disable Performance Counters entry for that service to 1. After you have repaired or replaced the counter DLL, you must re-enable it manually by changing the value of Disable Performance Counters to 1.
- Perflib does not time the procedure calls of trusted counters. To determine whether the procedure call of a non-trusted counter is abnormally slow, Perflib uses the standards established by the values of the OpenProcedureWaitTime, Open Timeout, and Collect Timeout entries.

### Tip

- If particular performance counters do not appear in your performance counter display tool, check the Application Log in Event Viewer for events recorded by Perflib.

### Caution

- Run-time tests can perceptibly delay the appearance of performance data, but they protect the system's monitoring capability.

ExtCounterTestLevel

# Disable Performance Counters Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Enables and disables the registry-based performance counters on the system.

If the value of this entry is 1, then Perflib does not retrieve performance counter data from the registry. As a result, System Monitor and other tools that use the data cannot display it. Instead, when a program requests performance data from the registry, the system returns an error to the program explaining that the Performance Library (Perflib) service is disabled.

| Value | Meaning |
|---|---|
| 0 | Enables performance counters. Programs can retrieve performance data from the registry. |
| 1 | Disables performance counters. Programs cannot retrieve performance data from the registry. |

**Activation Method**
To make changes to this entry effective, restart Windows.

### Note

- This entry affects all performance counters on the system. To enable or disable the performance counters for a particular service, use Exctrlst.exe to add Disable Performance Counters to the Performance Subkey subkey for the service.

### Tip

- If you cannot display particular performance counters, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib finds a disabling error in a performance counter dynamic-link library (DLL), it records an event in the log. Then it sets the value of Disable Performance Counters to 1 to disable the counters.

### Caution

- If you change the value of this entry to 1, the **Performance object** and **Performance counter** lists in System Monitor will be empty. You will not be able to use System Monitor or any tool that uses Performance Library data to monitor your system.

**See Also**
**Concepts**
Disable Performance Counters

# EventLogLevel Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 3 | 1 |

**Description**
Specifies which events the Performance Library records in the Application Log in Event Viewer.

| Value | Meaning |
|---|---|
| 0 | No recording. |
| 1 | Errors only. |
| 2 | Errors and warnings. |
| 3 | Errors, warnings, information, and success/failure conditions. |

Consider increasing the value of this entry if you are encountering problems starting or running a performance tool. If you find Perflib errors in the Application Log, increase this value again to record more detail on future errors.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to this entry effective, either restart the Remote Registry Service or restart Windows.

### Note

- If a remote computer is using System Monitor to monitor the local computer, you must restart Windows on the local computer and stop and restart System Monitor on the remote computer before changes to this entry take effect.

### Tip

- If you cannot display particular performance counters, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib finds a disabling error in a performance counter dynamic-link library (DLL), it records an event in the log. Then it sets the value of the Disable Performance Counters entry to 1 to disable the counters.

**See Also**
**Concepts**
ExtCounterTestLevel

# ExtCounterTestLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 \| 3 \| 4 | 4 |

**Description**

Specifies the extent to which Perflib tests the data buffers of a trusted performance counter dynamic-link library (DLL).

If a counter DLL fails the buffer integrity test specified by the value of this entry, then, by default, Perflib records an error in the Application Log (Source = Perflib) and disables the counters. Perflib does not load the counters again until you have manually re-enabled them.

| Value | Meaning |
|---|---|
| 1 | High. The Performance Library thoroughly tests the pointers and buffers of returned trusted counter DLLs. To protect the user's buffer from damage, Perflib sends the DLL function a copy of the buffer, instead of the actual buffer. |
| 2 | Medium. The Performance Library checks pointers and buffer length, but it does not test pointer references or buffer contents. To protect the user's buffer from damage, Perflib sends the DLL function a copy of the buffer, instead of the actual buffer. |
| 3 | Low. The Performance Library does not test pointers or buffers. To protect the user's buffer from damage, Perflib sends the DLL function a copy of the buffer, instead of the actual buffer. |
| 4 | None. The Performance Library does not test pointers or buffers, and it sends the user's buffer, not a copy. This value minimizes System Monitor overhead, especially when monitoring applications that require large performance data buffers. |

Perflib tests the integrity of data buffers to identify and eliminate defective counter DLLs. One defective counter DLL can harm your Windows Server 2003 performance tools, preventing them from displaying any performance data and, in some cases, causing errors that shut down the system and start Dr. Watson for Windows.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**

To make changes to this entry effective, either restart the Remote Registry Service or restart Windows.

### Notes

- The data buffer integrity test is one of several Perflib run-time reliability tests. To configure the Perflib test feature, use the Configuration Flags entry.
- If the 0x4 bit (100) is set in the value of **Configuration Flags**, then Perflib does not perform data buffer integrity tests on any counters, including trusted counters.
- To prevent Perflib from disabling counters when they fail a test, set the 0x2 (10) bit in the value of the Configuration Flags entry. This bit prevents Perflib from disabling any counters that fail any tests. It is not specific to trusted counters or to data buffer integrity tests.
- Perflib disables a counter by setting the value of Disable Performance Counters for that service to 1. After you have repaired or replaced the counter DLL, you must re-enable it manually by changing the value of **Disable Performance Counters** to 1.
- This entry has a different effect on Windows 2000 and Windows Server 2003 than it has on Windows NT 4.0 and earlier.

In Windows NT 4.0 and earlier, it determines the testing level for extensible counters. For more information, see Regentry.hlp in the *Windows NT Resource Kit 4.0*.

**Tip**

- If a performance counter does not appear in your performance monitoring tool, check the Application Log in Event Viewer for events recorded by Perflib.

Disable Performance Counters

# OpenProcedureWaitTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xEE6B2800 *milliseconds* | 0x2710 (10 seconds) |

**Description**
Defines a slow Open procedure call for the performance counter dynamic-link libraries (DLLs) on the system.

When an Open procedure call takes longer to complete than the time specified in the value of this entry, then by default, Perflib records an error in the Application Log. However, if the value of Configuration Flags is 0x0, then Perflib disables the counter DLL and does not load the counters again until you have manually reenabled them.

Perflib times the procedure calls of non-trusted counters to identify counters that can delay or lock performance tools during initialization. While the Open procedure call proceeds, you cannot use the performance tools, and remote users cannot log on to the local computer.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to this entry effective, restart Windows.

### Notes

- Perflib disables counters by setting the value of Disable Performance Counters for that service to 1. After you have repaired or replaced the counters, you must re-enable them manually by changing the value of **Disable Performance Counters** to 1.
- Perflib does not time the procedure calls of trusted performance counter DLLs This entry applies only to non-trusted DLLs.
- This entry applies to all counter DLLs on this system. To adjust the Open procedure time for the counters of a particular service, use the Open Timeout entry.
- The value of this entry is also the default value of the Collect Timeout entry.
- This entry has a different effect on Windows 2000 and Windows Server 2003 than it has on Windows NT 4.0 and earlier. In Windows NT 4.0 and earlier, it determines the Open procedure wait time only for extensible counters. For more information, see Regentry.hlp in the *Windows NT Resource Kit 4.0*.

### Tip

- If you suspect problems with procedure calls, check the Application Log in Event Viewer. Perflib records an error in the log whenever a procedure call exceeds its limit.

Open Timeout
Configuration Flags
Collect Timeout

# TotalInstanceName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* | _Total |

**Description**
Specifies an alternate name for the **_Total** instance in performance tools, such as System Monitor.

The **_Total** instance represents the sum of values for all other instances of a performance object. For example, the **_Total** instance of Logical Disk: % Disk Time represents the sum of active time for all logical partitions on the computer. You can use this entry to change the name of the **_Total** instance as it appears in your performance tools.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to this entry effective, restart Windows.

**Tip**

- If particular performance counters do not appear in your performance monitoring tool, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib detects disabling errors in a counter dynamic-link library (DLL), it records an event in the log. Then it sets the value of Disable Performance Counters to 1 to disable the counters.

# Language-code

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib

**Description**
The *Language-code* subkey stores performance counter names and their descriptions in each spoken language you configure for Windows Server 2003. It is named for the language code associated with the language. For example, the counters and definitions for the English language are stored in a subkey named 009, the language code for English (United States).

The *Language-code* subkey is a variable representing the subkeys in the HKCU\Software\Microsoft\Perflib subkey. It does not actually appear in the registry. This variable subkey displays the entries that can appear in any of the language code subkeys in the Perflib subkey. The actual *Language-code* subkeys in the registry depend on the spoken languages chosen for the system.

**Activation Method**
To make changes to entries in this subkey effective, either restart the Remote Registry Service or restart Windows.

### Tip

- If you cannot display particular performance counters, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib finds a disabling error in a performance counter dynamic-link library (DLL), it records an event in the log. Then it sets the value of Disable Performance Counters to 1 to disable the counters.

### Caution

- This subkey is maintained by the Performance Library. If you change the values, the performance tools on your system might not operate properly.

# Counter

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib*Language-code*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Counter names and indices* | (None) |

**Description**
Stores the name and index of each performance counter installed on the system. The value of this entry comes from the .ini files for the counter.

**Activation Method**
To make changes to this entry effective, restart Windows.

**Tip**

- If you cannot display particular performance counters, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib finds a disabling error in a performance counter dynamic-link library (DLL), it records an event in the log. Then it sets the value of Disable Performance Counters to 1 to disable the counters.

**Caution**

- Do not change the value of this entry. This value is maintained by the Performance Library. If you change it, the performance tools on your system will not operate properly.

# Help Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib*Language-code*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Descriptions of counters* | (None) |

**Description**
Describes the performance counters installed on the system. The descriptions are designed for performance tools, such as System Monitor.

**Activation Method**
To make changes to this entry effective, either restart the Remote Registry Service or restart Windows.

**Tip**

- To view the description in System Monitor, in the **Add to Chart** dialog box, click **Explain**.
- For information about how to add descriptive text to the counters you develop, see the *Platform Software Development Kit* (SDK).

**Caution**

- Do not change the value of this entry. This value is maintained by the Performance Library. If you change it, the performance tools on your system will not operate properly.

# Print Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Printers Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print

**Description**
The Printers subkey contains information about the local printers.

### Note

- The printers listed in this subkey can be shared, or they can be accessible only to the host computer.
- The entries in this subkey are linked to the Print\Printers entries that appear in the SYSTEM key. Changes made in this subkey will be reflected in the SYSTEM key.

**See Also**
**Concepts**
server-name\Printers

# DefaultSpoolDirectory Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *path* | *Systemroot*\System32\spool\PRINTERS |

**Description**
Specifies the folder holding spooled files that the system is printing on a local printer.

This entry is backed up in the Printers subkey in the SYSTEM key. Any changes made to this entry in the SOFTWARE key will be reflected in the SYSTEM key.

**Change Method**
To change the value of this entry, from the **Print Server Properties** dialog box, click the **Advanced** tab, then type the new value in the **Spool folder** text box.

### Notes

- Before changing the spool folder, you should wait for all documents to finish printing.
- Do not set the value of this entry to be the root directory. If you do, then spooling reverts to the %Systemroot%\system32\spool\printer directory.

**See Also**
**Concepts**
Printers\DefaultSpoolDirectory

# printer-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Printers

**Description**
The *printer-name* subkey stores information about printers connected to the print server.

The subkeys and entries that appear in this subkey are backed up in the Control\Print subkey in HKEY_LOCAL_MACHINE\SYSTEM. Any changes made in the SOFTWARE\Printers subkey will be reflected in the SYSTEM\Printers subkey.

**Note**

- This subkey appears only on servers that host local printers. It does not appear on computers that connect only to network printers.

- The *printer-name* subkey is a placeholder representing the types of subkeys in the Printers subkey; "printer-name" does not actually appear in the registry.

# SpoolDirectory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Printers*printer-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *path* | (None) |

**Description**
Stores the location of a printer-specific location for spool files. The value of this entry takes precedence over the global default stored in the DefaultSpoolDirectory Entry entry.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Do not set the value of this entry to be the root directory. If you do, then spooling reverts to the %Systemroot%\system32\spool\printer directory.

# PrinterDriverData

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Printers*printer-name*

**Description**
The PrinterDriverData subkey contains configuration data for the specified printer.

**Change Method**
To change the value of entries in this subkey, use the SetPrinterData/GetPrinterData or the SetPrinterDataEx/GetPrinterDataEx APIs.

# Transparency

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Printers*printer-name*\PrinterDriverData

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | (blank) \| 1 | (None) |

**Description**
Specifies the background mode when the value of the Winprint_TextNoCRTranslation entry is set to 1. If the background mode is set to transparent, then the driver will not print the background of the document, regardless of color.

| Value | Meaning |
|---|---|
| (blank) | Background is opaque. |
| 1 | Background is transparent. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the SetPrinterData/GetPrinterData or the SetPrinterDataEx/GetPrinterDataEx APIs.

server-name\Providers

# LanMan Print Services

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Providers

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Servers Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Providers\LanMan Print Services

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# server-name Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Providers\LanMan Print Services\Servers

**Description**
The *server-name* subkey stores information about printers connected to the specified print server.

### Note

- The *server-name* subkey is a placeholder representing the types of subkeys in the Servers subkey; "server-name" does not actually appear in the registry.

# server-name\Printers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Providers\LanMan Print Services\Servers*server-name*

**Description**
The Printers subkey contains information about the individual network printers to which the local computer is connected.

# Providers\EventLog

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Providers\LanMan Print Services\Servers*server-name*\Providers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x1F (bitmask) | Windows XP Professional: 0x1B (11011) Windows Server 2003: 0x1F (11111) |

**Description**
Specifies the level of detail of events that the print spooler logs for the specified server.

The value of this entry is a bitmask. To direct the print spooler to log entries of the type specified, set the bit representing that type to 1, or sum the hexadecimal values of all desired types. For example, the default value for Windows Server 2003, 11111, indicates that the print spooler logs all events. The default value for Windows XP Professional, 11011, indicates that the print spooler logs all events except information.

| Value | Event type |
|---|---|
| 0x0 (0 binary) | Success |
| 0x1 (1 binary) | Error |
| 0x2 (10 binary) | Warning |
| 0x4 (100 binary) | Information |
| 0x8 (1000 binary) | Audit success |
| 0x10 (10000 binary) | Audit failure |

**Change Method**
To change the value of this entry, from the **Start** menu, point to **Settings**, and then click **Printers**. From the **File** menu, click **Server Properties**, click the **Advanced** tab, and then select or clear the check boxes representing each event type.

### Note

- This entry only appears in the registry after a connection has been made to the remote machine.

**See Also**
**Concepts**
EventLog Entry

# RestartJobOnPoolEnabled Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Providers\LanMan Print Services\Servers*server-name*\Providers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether a print job on the specified network printer can be restarted after an error.

If the value of this entry is set to 1, then a **Cancel/Retry** dialog box appears on the user's system for the duration specified in the value of the Providers\RestartJobOnPoolError entry.

| Value | Meaning |
|---|---|
| 0 | Print jobs cannot be restarted after an error. |
| 1 | Print jobs can be restarted after an error. |

### Notes

- This entry applies only to pooled printers.
- The print job cannot be restarted if it has been completely sent to the printer and deleted from the print queue.

**See Also**
**Concepts**
Providers\RestartJobOnPoolEnabled
Providers\RestartJobOnPoolError

# Providers\RestartJobOnPoolError

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Print\Providers\LanMan Print Services\Servers*server-name*\Providers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *number of seconds* | 0x258 (600 seconds = 10 minutes) |

**Description**
Specifies how long the print monitor for the specified network printer waits after an error occurs before starting a print job on another port in the print pool.

### Notes

- This entry applies only to pooled printers.
- Both the print monitor and the printer must support SNMP.
- The print job cannot be restarted if it has been completely sent to the printer and deleted from the print queue.

RestartJobOnPoolError Entry

# Type 1 Installer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
Contains subkeys that store information about the Type 1 fonts installed on the system.

# Type 1 Fonts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Type 1 Installer

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | | |

**Description**
The Type 1 Fonts subkey contains the names of the Type 1 fonts that are installed on the system.

The fonts are stored in the *Systemroot*\WINNT\Fonts folder, and the corresponding entries store the following string values:

- *String 0* – Specifies with "T" for true and "F" for false whether *String 2* exists.
- *String 1* – Specifies the name of the Printer Font Metrics (.pfm) file.
- *String 2* – Specifies the name of the Printer Font Binary (.pfb) file.

For example, if the font Arial is installed as a Type 1 font, the corresponding value, when viewed in the Registry Editor (regedit.exe), could appear as follows: **T arial.pfm arial.pfb**.

**Change Method**
This entry is maintained automatically by the installation and removal of fonts in the Fonts folder, located in Control Panel.

### Notes

- The operating system uses Printer Font Metrics files to display a font on the screen.
- Printer Font Binary files contain mathematical descriptions for each character. Applications and printers use this information to print text in the described font.

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *DLL file names* | (This entry has no default value.) |

**Description**

Specifies which dynamic-link libraries (DLLs) installed on the computer are loaded by Windows 3.*x*–based applications.

# DeviceNotSelectedTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Number of seconds* (in decimal) | 15 |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows 3.51 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# TransmissionRetryTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Number of seconds* (in decimal) | Windows NT 3.1: 45 Windows NT 3.51 and later: 90 |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

**Caution**

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# CurrentVersion\Winlogon

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
The Winlogon subkey stores configuration data for the Winlogon service. Winlogon provides support for interactive logon to Windows Server 2003.

This subkey stores data that applies to all users of the computer. The Winlogon Subkey subkey in HKEY_CURRENT_USER stores data that applies to a specific user.

**See Also**
**Concepts**
Winlogon Subkey

# AutoRestartShell

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**

Specifies whether the Windows user interface (typically, Explorer.exe) restarts automatically if it stops unexpectedly.

| Value | Meaning |
|---|---|
| 0 | If the Windows user interface or one of its components stops unexpectedly, the user must restart the interface. |
| 1 | If the Windows user interface or one of its components stops unexpectedly, the interface restarts automatically. |

**Note**

- The user can restart the interface either by logging off and logging on again, or by pressing Control-Alt-Del, selecting **Task Manager**, then from the **File** menu, selecting **Run** and typing "Explorer.exe".

# CachePrimaryDomain

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | (None) |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

**Caution**

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# DCacheMinInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 120–86,400 *seconds* | 120 (2 minutes) |

**Description**

Specifies how often the list of domains in the **Unlock Workstation** dialog box is updated. The list of domains is updated before it is displayed to the user if its age exceeds the value of this entry.

A memory cache on the local computer stores the domain list. When the value of this entry is set to the default of two minutes, and a user unlocks a workstation or server, then the system retrieves domain data and updates the list. The short update interval ensures that the domain list is current. However, refreshing the list can cause a noticeable delay.

You can use this entry to increase the time between domain list updates, eliminating some of the delay. However, if the domain list changes between updates, users still will not see the most current list of domains.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# DCacheUpdate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *Domain names in binary form* | (None) |

**Description**
Stores domain names in binary form for internal Winlogon programming code to use.

**Caution**

- Winlogon stores the value of this entry for its own use. Do not delete this entry or change its value. If you do, Windows Server 2003 might not operate properly.

# DebugServerCommand

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | (There is no range of values for this entry.) | (None) |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# DefaultDomainName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Domain-name* | NEWDOMAIN |

**Description**
Stores the name of the domain to which the user most recently logged on successfully. The value of this entry appears in the **Log On to Windows** dialog box the next time the dialog box is displayed.

**See Also**
**Concepts**
DefaultUserName

# DefaultUserName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *User-name* | Administrator |

**Description**
Stores the last user name entered in the **Log On to Windows** dialog box.

The value of this entry appears in the **Log On to Windows** dialog box the next time the dialog box is displayed. It is also used in automated logons and unattended setup.

### Note

- This entry is required if you have configured Windows Server 2003 to log on automatically by setting the value of the entry **AutoAdminLogon** to 1.

### Tip

- If you delete the value of this entry, then the system restores it the next time a user logs on to Windows Server 2003. To specify that the user-name field in the **Log On to Windows** dialog box be blank, set the value of the DontDisplayLastUserName entry to 1.

**See Also**
**Concepts**
DefaultDomainName
DontDisplayLastUserName

# DontDisplayLastUserName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ or REG_DWORD | 0 \| 1 (decimal only) | 0 |

**Description**
Specifies whether a user name appears in the **Log On to Windows** dialog box.

By default, Windows Server 2003 displays the user name of the last user who logged on successfully (as stored in the value of DefaultUserName) in the **Log On to Windows** dialog box. If the value of this entry is 1, then the **User name** box in the **Log On to Windows** dialog box is blank.

| Value | Meaning |
|---|---|
| 0 | The name of the last user who logged on successfully appears in the **Log On to Windows** dialog box. This setting is designed to make logging on faster and easier. |
| 1 | The **User name** field in the **Log On to Windows** dialog box is blank. This setting is designed to enhance the security of the system by not displaying a valid user name. |

**Note**

- A Group Policy setting in Windows Server 2003 can override the value of this entry. When the **Do not display last user name in logon screen** Group Policy setting (Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options) is configured, this entry is ignored.

**See Also**
**Concepts**
DefaultUserName

# KeepRasConnection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**
Specifies whether Windows Server 2003 closes all open dial-up (Routing and Remote Access) connections when a user logs off.

| Value | Meaning |
|---|---|
| 0 | RAS connections are closed. |
| 1 | RAS connections remain open. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# LogonPrompt

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* | (None) |

**Description**

Specifies a message for the **Log On to Windows** dialog box. By default, there is no logon prompt message.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Winlogon\ProfileDlgTimeOut

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 0x1E (30 seconds) |

**Description**
Defines the starting time for the User Environment Countdown Timer. This timer determines how long the system waits for a user response before it uses a default value. The value of this entry is used when either of the following occurs:

- The system detects a slow link between the client and the server that stores the client's profile.
- The system cannot access or update a server-based profile when the user logs on or off.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Notes

- The value of this entry can be overridden by a Group Policy setting. If your system does not respond as expected, the **Timeout for dialog boxes** Group Policy setting might be in effect. See the **ProfileDlgTimeout** entry in the **Policies** subkey.
- If you change this value by editing the registry, enter the value in decimal numbers.

**See Also**
**Concepts**
Winlogon\SlowLinkTimeOut

# RasForce

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**

Specifies whether the **Log on using dial-up connection** check box is selected by default when the system starts. This check box appears on the **Log On to Windows** dialog box that is displayed when the user logs on to Windows Server 2003.

The system uses the value of this entry only when you have created a dial-up connection by using Network and Dial-up Connections and the computer is a member of a domain.

| Value | Meaning |
|---|---|
| 0 | Cleared. The **Log on using dial-up connection** check box is cleared when displayed. Users can click it to select it. |
| 1 | Selected. The **Log on using dial-up connection** check box is selected when displayed. Users can click it to clear it. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# ReportBootOk

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
Specifies whether Winlogon declares startup to be successful. If you change the value of this entry to 0, then you must use another program (such as Bootok.exe or Bootvrfy.exe) to declare the startup successful.

| Value | Meaning |
|---|---|
| 0 | Winlogon does not declare startup to be successful. |
| 1 | Winlogon declares startup to be successful after at least one user has logged on successfully. |

**Note**

- If this entry is deleted from the registry, Winlogon does not declare the startup to be successful.

**See Also**
**Concepts**
BootVerificationProgram
BootVerification

# ReportControllerMissing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | TRUE or any string | (None) |

**Description**
Stores the computer setting for the domain controller message. (The user setting is stored in the value of the ReportDC entry.)

This entry determines, in part, whether the system displays the following message when it cannot contact the domain controller that stores a user's roaming user profile:

```
A domain controller for your domain could not be contacted. You have been logged on using cached account
information. Changes made to your profile since you last logged on might not be available.
```

When the value of this entry is equal to **TRUE**, the system displays the message. When the value is any other string, and when this value is absent from the registry, the system does not display the message.

Two entries manage the display of the domain controller message: ReportDC and **ReportControllerMissing.** The system displays this message only when both entries are set to the display setting—that is, when **ReportDC** is either set to 1 or does not appear in the registry, and when **ReportDomainController** appears in the registry with a value of TRUE. By default, the message does not display.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
This entry does not exist in the registry by default, and you must add it to the registry and set its value equal to **TRUE** to cause the system to display the message when the system cannot contact the domain controller that stores the user's roaming profile.

## Notes

- While the domain controller message is displayed, other elements of the user interface are disabled, but all processes continue to run normally. If the **OK** button accompanying the domain controller message is not clicked after two minutes, then the message box disappears.

- The value of this entry must be in all capital letters. Otherwise, the system ignores the value and behaves as though the value is FALSE.

# Winlogon\RunLogonScriptSync Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the system waits for the logon script to finish running before it starts Windows Explorer and creates the desktop.

| Value | Meaning |
|---|---|
| 0 | The logon script and Windows Explorer can run simultaneously. |
| 1 | Windows Explorer does not start until the logon script has finished running. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To establish a policy setting related to this entry, use Group Policy. The value of this entry can be overridden by using the **Run logon scripts synchronously** Group Policy setting (User or Computer Configuration\Administrative Templates\System\Logon).

### Notes

- This entry applies to all users of the computer. The Winlogon\RunLogonScriptSync entry in HKEY_CURRENT_USER is configured separately for each user.

- Group Policy settings included in Windows Server 2003 can supersede this entry. While the **Run logon scripts synchronously** Group Policy setting is enabled (in the Computer Configuration or User Configuration policy folders), the system ignores this entry. The **Run logon scripts synchronously** policy setting is stored in the values of the **RunLogonScriptSync** entry in HKEY_LOCAL_MACHINE and the **RunLogonScriptSync** entry in HKEY_CURRENT_USER.

**See Also**
**Concepts**
Winlogon\RunLogonScriptSync

# ScreenSaverGracePeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x20C49B (2,147,483) *seconds* (approximately 24 days) | 0x5 |

**Description**

Specifies when password protection of a screen saver becomes effective. This entry specifies the delay between the appearance of a password-protected screen saver and the enforcement of the password requirement.

Password protection of a screen saver is not effective immediately. By default, a brief period elapses within which the user can use the mouse or the keyboard to stop the screen saver without entering the password. This delay is designed to minimize the disruption that results when the screen saver starts while the user is working.

You can add this entry to the registry to adjust the length of the delay. To make password protection effective immediately, set the value of this entry to 0x0.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SfcBugcheck

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**

Windows Server 2003 does not use this entry. It might appear in the registry when you upgrade from a pre-release version of Windows Server 2003.

# Winlogon\SFCDllCacheDir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Fully qualified path* | *Systemroot*\System32\Dllcache |

**Description**
Specifies an alternate location for the Windows File Protection cache.

### Note

- This entry can be superseded by a Group Policy setting. While the policy setting **Specify Windows File Protection cache location** is enabled (which corresponds to registry entry SFCDllCacheDir Entry), the system ignores this entry. If the Windows File Protection cache does not appear in the expected location, check to see whether a policy setting is in effect.

SFCDllCacheDir Entry

# Winlogon\SfcScan

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 0 |

**Description**
Specifies when Windows File Protection scans protected files for changes. By default, it scans protected files only during setup.

| Value | Meaning |
|---|---|
| 0 | Windows File Protection scans files only during setup. |
| 1 | Windows File Protection scans files at setup and each time you start Windows Server 2003. This setting delays each startup. |
| 2 | Windows File Protection scans files the next time you start the system. |

**Change Method**
To change the value of this entry, use System File Checker (SFC.exe), a tool included in Windows Server 2003.

### Note

- This entry affects file scanning only. It does not affect the standard background file change detection that Windows File Protection provides.

- This entry can be superceded by a Group Policy setting included in Windows Server 2003. While the **Set Windows File Protection scanning** policy setting is enabled, the system ignores this entry. The configuration of the **Set Windows File Protection scanning** policy setting is stored in the value of **Sfcscan** in the Policies subkey. If Windows File Protection or System File Checker does not operate as expected, check to see whether a policy setting is in effect.

- Windows File Protection only scans when the current user is an administrator of the computer.

# SfcShowProgress Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Hides the file scan progress window. This window provides status information that might be helpful to advanced users, but it might confuse novices.

| Value | Meaning |
|---|---|
| 0 | The file scan progress window does not appear during file scanning. |
| 1 | The file scan progress window appears. |

**Notes**

- This entry can be superseded by a Group Policy setting included in Windows Server 2003. While the policy setting **Hide the file scan progress window** is enabled (which corresponds to registry entry Windows File Protection\SfcShowProgress), the system ignores this entry. If the scan progress window does not appear, check to see whether a policy setting is in effect.

- Windows File Protection only scans when the current user is an administrator of the computer.

**Concepts**
Windows File Protection\SfcShowProgress

# Shell Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Name of executable file* | Explorer.exe |

**Description**
Specifies the programs that provide the user interface to the operating system.

By default, Winlogon starts the programs specified in the value of **Userinit**, including Userinit.exe. Userinit.exe starts the user interface program. However, if Winlogon cannot start the programs specified in the value of **Userinit**, then Winlogon directly runs the programs specified in the value of this entry.

**See Also**
**Concepts**
Winlogon\System Subkey

# ShowLogonOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**

Specifies whether logon options are displayed in the **Log on to Windows** dialog box when the dialog box opens.

The **Log on to Windows** dialog box has an **Options** button that alternately hides and displays the **Domain** box and the **Log on using dial-up connection** options.

| Value | Meaning |
|---|---|
| 0 | The options are hidden when the dialog box opens, but users can click the **Options** button to display them. |
| 1 | The options are displayed when the dialog box opens, but users can click the **Options** button to hide them. |

# Winlogon\SlowLinkProfileDefault

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Directs the system to wait for the remote copy of the roaming user profile to load, even if the profile is loading slowly. Also, the system waits for the remote copy when the user is notified about a slow connection but does not respond in the time allowed.

| Value | Meaning |
|---|---|
| 0 | Use the local copy. When a remote profile is slow to load, the system loads the local copy of the roaming user profile. The local copy is also used when the user is consulted (as set in the entry **SlowLinkUIEnabled**) but does not respond in the time allowed (as set in the Winlogon\ProfileDlgTimeOut entry). |
| 1 | The policy is enabled. The system waits for the remote copy of the user profile to load. |

Waiting for the remote profile is appropriate when a user moves between computers frequently and the local copy of the profile is not always current. Using the local copy is desirable when logging on quickly is a priority.

**Note**

- This entry can be superseded by a Group Policy setting included in Windows Server 2003. When the **Wait for remote user profile** policy setting is enabled, the system ignores this entry. The setting of the **Wait for remote user profile** policy setting is stored in the value of **SlowLinkProfileDefault** in the Policies subkey. If the slow link feature does not operate as expected, check to see if a policy setting is in effect.

# Winlogon\SlowLinkTimeOut

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–120,000 *milliseconds* | 2000 (2 seconds) |

**Description**
Defines which connections Winlogon considers to be slow. If the server storing a user's profile does not respond before the time specified in the value of this entry, then Winlogon considers the link to the server to be slow, and it offers the user the option of using a profile stored on the local computer instead of waiting for the server.

This entry is used only when the value of **SlowLinkDetectEnabled** is 1.

You can increase the value of **SlowLinkTimeOut** to favor the server-based profile. This is particularly useful for clients using addresses assigned by Dynamic Host Configuration Protocol (DHCP), or for computers accessing server-based profiles over slow wide area network (WAN) connections, such as dial-up connections.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use Group Policy. This entry corresponds to the **Slow network connection timeout** Group Policy setting (Computer Settings\Software Policies\Windows NT User Profiles).

**See Also**
**Concepts**
Winlogon\ProfileDlgTimeOut

# Winlogon\System Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Names of executable files* | (None) |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# Welcome Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* | (None) |

**Description**
Specifies the text that appears in the caption bar beside the title of the **Log On to Windows**, **Windows Security**, **Computer Locked**, and **Unlock Computer** dialog boxes.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Tip**

- The system adds only one space between the dialog box title and your message. To further separate the title from your message, begin your message with leading spaces.

# WOW

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion

**Description**
Contains subkeys and entries that control startup parameters affecting MS-DOS-based applications and applications created for 16-bit Windows 3.*x*.

**Caution**

- Do not change any of the subkeys in this subkey.

# boot

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\WOW

**Description**
The boot subkey contains information about drivers and fonts that are loaded for each instance of the Windows on Windows (WOW) subsystem.

**Caution**

- Do not change any of the entries in this subkey.

# Microsoft\Windows Script Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Windows Script \Settings Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows Script

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

# Enabled Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Windows Script\Settings

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Windows Script Host (WSH) is disabled for all users of the machine. This entry disables all scripts that rely on WSH, including VBScript and Jscript. If WSH is disabled and the user attempts to run a WSH script, then a message alerts the user that WSH is disabled. The message appears even if the user attempts to run the script from a batch file or a designated script host.

| Value | Meaning |
|---|---|
| 0 | WSH is disabled for all users of the machine. |
| 1 | WSH is enabled for all users of the machine. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# NoTrueColorSharing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Conferencing

**Description**
Stores configuration data for the policy setting **Prevent Application Sharing in true color**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\NetMeeting\Application Sharing.

# NoVideoPage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Conferencing

**Description**
Stores configuration data for the policy setting **Hide the Video page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\NetMeeting\Options Page.

# NoWebDirectory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Conferencing

**Description**
Stores configuration data for the policy setting **Prevent viewing Web directory**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\NetMeeting.

# PersistAutoAcceptCalls

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Conferencing

**Description**
Stores configuration data for the policy setting **Allow persisting automatic acceptance of Calls**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\NetMeeting.

# Use AutoConfig

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Conferencing

**Description**
Stores configuration data for the policy setting **Enable Automatic Configuration**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\NetMeeting.

# Conferencing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

**Description**
The Conferencing subkey is one of two subkeys that store entries for Group Policy settings for NetMeeting. Group Policy creates and maintains these entries, and the NetMeeting program reads and interprets them.

This subkey stores entries that apply to all users of the computer. The system adds these entries when you configure a NetMeeting policy setting in the Computer Configuration folder in Group Policy.

The Conferencing subkey in HKEY_CURRENT_USER stores policy setting related entries that are configured separately for each user. The system adds these entries when you configure a NetMeeting policy setting in the User Configuration folder in Group Policy.

In Group Policy, the NetMeeting ploicy settings appear in the following folders:

- Computer Configuration\Administrative Templates\Windows Components\NetMeeting.
- User Configuration\Administrative Templates\Windows Components\NetMeeting.

The NetMeeting Group Policy settings appear only when the Conf.adm administrative template file is added to Group Policy. Conf.adm is included in Windows Server 2003 (at *Systemroot*\inf\conf.adm), but it is not loaded automatically. For instructions, see Help for Group Policy.

# Control Panel Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Control Panel\Desktop

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Control Panel

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# MultiUILanguageID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Restrict selection of Windows menus and dialogs language**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Regional and Language Options.

# Microsoft\Internet Explorer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

**Description**
The Internet Explorer subkey is one of several subkeys that store entries for Group Policy settings for Internet Explorer. Group Policy creates and maintains these entries, and the Internet Explorer program reads and interprets them.

The Internet Explorer Group Policy settings appear when the Inetres.adm file is added to Group Policy. By default, this file is added automatically.

In Group Policy, the Internet Explorer settings appear in the following folders:

- Computer Configuration\Administrative Templates\Windows Components\Internet Explorer
- User Configuration\Administrative Templates\Windows Components\Internet Explorer

# DisableImportExportFavorites

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer

**Description**
Stores configuration data for the policy setting **Disable importing and exporting of favorites**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Advanced Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable changing Advanced page settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# AdvancedTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable the Advanced page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel.

# ConnectionsTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable the Connections page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel.

# GeneralTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable the General page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel.

# HomePage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable changing home page settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# PrivacyTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable the Privacy page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel.

# ProgramsTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable the Programs page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel.

# SecurityTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable the Security page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel.

# ContentTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Control Panel

**Description**
Stores configuration data for the policy setting **Disable the Content page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel.

# Control Panel Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Internet Explorer

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Infodelivery

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Internet Explorer

**Description**
The Infodelivery subkey is one of several subkeys that store entries for Group Policy settings for Internet Explorer. Group Policy creates and maintains these entries, and the Internet Explorer program reads and interprets them.

The Internet Explorer Group Policy settings appear when the Inetres.adm file is added to Group Policy. By default, this file is added automatically.

In Group Policy, the Internet Explorer settings appear in the following folders:

- Computer Configuration\Administrative Templates\Windows Components\Internet Explorer
- User Configuration\Administrative Templates\Windows Components\Internet Explorer

# Restrictions Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Internet Explorer\Infodelivery

**Description**
The Restrictions subkey stores the entries created when you configure Group Policy settings that restrict the installation, updating, or presentation of Internet Explorer. Group Policy creates and maintains these entries, and the Internet Explorer program reads and interprets them.

# MaxSubscriptionCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Subscription Limits**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# MaxSubscriptionSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Subscription Limits**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# MaxWebcrawlLevels

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Subscription Limits**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# MinUpdateInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Subscription Limits**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoAddingChannels

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable adding channels**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoAddingSubscriptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable adding schedules for offline pages**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoBrowserClose

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **File menu: Disable closing the browser and Explorer windows**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoBrowserOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Tools menu: Disable Internet Options... menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoBrowserSaveWebComplete

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **File menu: Disable Save As Web Page Complete**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoChannelLogging

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable offline page hit logging**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoChannelUI

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable channel user interface completely**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoEditingScheduleGroups

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable editing and creating of schedule groups**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoEditingSubscriptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable editing schedules for offline pages**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoFavorites

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Hide Favorites menu**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoJITSetup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable Automatic Install of Internet Explorer components**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# NoRemovingChannels

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Infodelivery\Restrictions

**Description**
Stores configuration data for the policy setting **Disable removing channels**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Offline Pages.

# NoRemovingSubscriptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Internet Explorer\Persistence

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# 2\DomainLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Persistence\2

**Description**
Stores configuration data for the policy setting **File size limits for Trusted Sites zone**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Persistence Behavior.

# 2\DocumentLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Persistence\2

**Description**
Stores configuration data for the policy setting **File size limits for Trusted Sites zone**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Persistence Behavior.

# 3\DocumentLimit Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Persistence\3

**Description**
Stores configuration data for the policy setting **File size limits for Internet zone**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Persistence Behavior.

# 3\DomainLimit Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Persistence\3

**Description**
Stores configuration data for the policy setting **File size limits for Internet zone**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Persistence Behavior.

# 3

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Internet Explorer\Persistence

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# 4

Updated: March 28, 2003

HKLM\SOFTWARE\Policies\Microsoft\Internet Explorer\Persistence

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# 4\DocumentLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Persistence\4

**Description**
Stores configuration data for the policy setting **File size limits for Restricted Sites zone**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Persistence Behavior.

# 4\DomainLimit Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Persistence\4

**Description**
Stores configuration data for the policy setting **File size limits for Restricted Sites zone**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Persistence Behavior.

# No_LaunchMediaBar

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Configure Media Explorer Bar**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# NoBrowserContextMenu

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Disable Context menu**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoBrowserSaveAs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **File menu: Disable Save As... menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoExternalBranding

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Disable external branding of Internet Explorer**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# NoFileNew

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **File menu: Disable New menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoFileOpen

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **File menu: Disable Open menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoFindFiles

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Search: Disable Find Files via F3 within the browser**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# NoHelpItemNetscapeHelp

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Help menu: Remove 'For Netscape Users' menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoHelpItemSendFeedback

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Help menu: Remove 'Send Feedback' menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoHelpItemTipOfTheDay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Help menu: Remove 'Tip of the Day' menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoHelpItemTutorial

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Help menu: Remove 'Tour' menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoOpeninNewWnd

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Disable Open in New Window menu option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# NoSelectDownloadDir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Internet Explorer\Restrictions

**Description**
Stores configuration data for the policy setting **Disable Save this program to disk option**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer\Browser menus.

# Internet Explorer\Restrictions Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Internet Explorer

| Data type | Range | Default value |

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Client\PreventAutoRun

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Messenger\Client

**Description**
Stores configuration data for the policy setting **Do not automatically start Windows Messenger initially**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Messenger.

# PreventAutoRun Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Messenger\Client

**Description**
Stores configuration data for the policy setting **Do not automatically start Windows Messenger initially**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Messenger.

# Client\PreventRun

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Messenger\Client

**Description**
Stores configuration data for the policy setting **Do not allow Windows Messenger to be run**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Messenger.

# PreventRun Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Messenger\Client

**Description**
Stores configuration data for the policy setting **Do not allow Windows Messenger to be run**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Messenger.

# RestrictAuthorMode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\MMC

**Description**
Stores configuration data for the policy setting **Restrict the user from entering author mode**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Microsoft Management Console.

# RestrictToPermittedSnapins

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\MMC

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Restrict users to the explicitly permitted list of snap-ins**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Microsoft Management Console.

# Microsoft\MMC

# Group Policy for Active Directory Tools Run Restriction

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\MMC\{D70A2BEA-A63E-11D1-A7D4-0000F87571E3}

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Group Policy tab for Active Directory Tools**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Microsoft Management Console\Restricted/Permitted snap-ins\Group Policy.

# Active Directory Sites and Services Run Restriction

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\MMC\{D967F824-9968-11D0-B936-00C04FD8D5B0}

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Active Directory Sites and Services**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Microsoft Management Console\Restricted/Permitted snap-ins.

# {D967F824-9968-11D0-B936-00C04FD8D5B0}

Updated: March 28, 2003

# AllowExclusiveScriptsShareAccess

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Netlogon share compatibility**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# AllowExclusiveSysvolShareAccess

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Sysvol share compatibility**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# AllowSingleLabelDnsDomain

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Location of the DCs hosting a domain with single label DNS name**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# AutoSiteCoverage Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Automated Site Coverage by the DC Locator DNS SRV Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# Parameters\AvoidPdcOnWan Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Contact PDC on logon failure**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# BackgroundRetryInitialPeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Initial DC Discovery Retry Setting for Background Callers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# BackgroundRetryMaximumPeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Maximum DC Discovery Retry Interval Setting for Background Callers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# BackgroundRetryQuitTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Final DC Discovery Retry Setting for Background Callers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# BackgroundSuccessfulRefreshPeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Positive Periodic DC Cache Refresh for Background Callers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# DnsAvoidRegisterRecords

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **DC Locator DNS records not registered by the DCs**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# DnsRefreshInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Refresh Interval of the DC Locator DNS Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# DnsTtl Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **TTL Set in the DC Locator DNS Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# ExpectedDialupDelay Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Expected dial-up delay on logon**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# GcSiteCoverage Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Sites Covered by the GC Locator DNS SRV Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# LdapSrvPriority

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Priority Set in the DC Locator DNS SRV Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# LdapSrvWeight

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Weight Set in the DC Locator DNS SRV Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# MaximumLogFileSize Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Maximum Log File Size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# NdncSiteCoverage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Sites Covered by the Application Directory Partition Locator DNS SRV Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# NegativeCachePeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Negative DC Discovery Cache Setting**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# NonBackgroundSuccessfulRefreshPeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Positive Periodic DC Cache Refresh for Non-Background Callers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# ScavengeInterval Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Scavenge Interval**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# SiteCoverage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Sites Covered by the DC Locator DNS SRV Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# SiteName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Site Name**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# UseDynamicDns

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Dynamic Registration of the DC Locator DNS Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon\DC Locator DNS Records.

# dbFlag

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Netlogon\Parameters

**Description**
Stores configuration data for the policy setting **Log File Debug Output Level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Net Logon.

# PCHealth Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# ForceQueueMode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Report Errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# IncludeKernelFaults

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Report operating system errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting\Advanced Error Reporting settings.

# IncludeMicrosoftApps

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Default application reporting settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting\Advanced Error Reporting settings.

# IncludeShutdownErrs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Report unplanned shutdown events**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting\Advanced Error Reporting settings.

# IncludeWindowsApps

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Default application reporting settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting\Advanced Error Reporting settings.

# ShowUI

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Display Error Notification**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# PCHealth\ErrorReporting

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\PCHealth

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# AllOrNone

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Default application reporting settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting\Advanced Error Reporting settings.

# DoReport

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting

**Description**
Stores configuration data for the policy setting **Report Errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# ErrorReporting\DW

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\PCHealth\ErrorReporting

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# DWAllowHeadless

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting\DW

**Description**
Stores configuration data for the policy setting **Display Error Notification**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# DWFileTreeRoot

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting\DW

**Description**
Stores configuration data for the policy setting **Report Errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# DWNoExternalURL

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting\DW

**Description**
Stores configuration data for the policy setting **Report Errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# DWNoFileCollection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting\DW

**Description**
Stores configuration data for the policy setting **Report Errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# DWNoSecondLevelCollection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting\DW

**Description**
Stores configuration data for the policy setting **Report Errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# DWReporteeName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\ErrorReporting\DW

**Description**
Stores configuration data for the policy setting **Report Errors**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Error Reporting.

# Headlines

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\PCHealth\HelpSvc

**Description**
Stores configuration data for the policy setting **Do not allow Did you know content to appear**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Help and Support Center.

# HelpSvc

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\PCHealth

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Microsoft\System Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# DFSClient

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\System

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# DfsDcNameDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\System\DFSClient

**Description**
Stores configuration data for the policy setting **Sets how often a DFS Client discovers DC's**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network.

# NV PrimaryDnsSuffix

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\System\DNSClient

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Primary DNS Suffix**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# DNSClient Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\System

**Description**
The DNSClient subkey stores entries created when you configure a Group Policy setting for the Domain Name System (DNS) client. Group Policy creates and maintains the entries in this subkey, and DNS reads and interprets them.

# W32Time Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# W32Time\Config Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\W32Time

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# AnnounceFlags Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# EventLogFlags Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# Config\FrequencyCorrectRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# HoldPeriod Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# LargePhaseOffset Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# Config\LocalClockDispersion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# MaxAllowedPhaseOffset

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# MaxNegPhaseCorrection Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# MaxPollInterval Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# MinPollInterval Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# PhaseCorrectRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# PollAdjustFactor Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# SpikeWatchPeriod Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# UpdateInterval Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# MaxPosPhaseCorrection Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\Config

**Description**
Stores configuration data for the policy setting **Global Configuration Settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service.

# CrossSiteSyncFlags Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\Parameters

**Description**
Stores configuration data for the policy setting **Configure Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# Parameters\EventLogFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\Parameters

**Description**
Stores configuration data for the policy setting **Configure Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# NtpServer Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\Parameters

**Description**
Stores configuration data for the policy setting **Configure Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# ResolvePeerBackoffMaxTimes Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\Parameters

**Description**
Stores configuration data for the policy setting **Configure Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# ResolvePeerBackoffMinutes Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\Parameters

**Description**
Stores configuration data for the policy setting **Configure Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# SpecialPollInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\Parameters

**Description**
Stores configuration data for the policy setting **Configure Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# Parameters\Type

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\Parameters

**Description**
Stores configuration data for the policy setting **Configure Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# W32Time\Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\W32Time

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# TimeProviders Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\W32Time

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# TimeProviders\NtpClient Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\W32Time\TimeProviders

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# NtpClient\Enabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Enable Windows NTP Client**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# NtpServer\Enabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\W32Time\TimeProviders\NtpServer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Enable Windows NTP Server**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows Time Service\Time Providers.

# TimeProviders\NtpServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\W32Time\TimeProviders

# Windows Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# App Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**
The App Management subkey contains entries storing the Group Policy settings that determine how programs run. Group Policy creates and maintains the subkeys and entries in the Windows subkey, and the component that implements the subkeys and entries reads and interprets them.

### Note

- Policy setting entries in the App Management subkey override default settings in the SOFTWARE\Microsoft\Windows\CurrentVersion\App Management subkeys.

# App Management\COMClassStore

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\App Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Download missing COM components**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# App Management\COMClassStore Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\App Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Download missing COM components**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# DisableEngine

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\AppCompat

**Description**
Stores configuration data for the policy setting **Turn Off Application Compatibility Engine**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Application Compatibility.

# DisablePropPage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\AppCompat

**Description**
Stores configuration data for the policy setting **Remove Program Compatibility Property Page**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Application Compatibility.

# DisableWizard

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\AppCompat

**Description**
Stores configuration data for the policy setting **Turn Off Program Compatibility Wizard**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Application Compatibility.

# LogAppHelpEvents

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\AppCompat

**Description**
Stores configuration data for the policy setting **Turn On Application Help Log Events**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Application Compatibility.

# AppCompat\VDMDisallowed

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\AppCompat

**Description**
Stores configuration data for the policy setting **Prevent access to 16-bit applications**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Application Compatibility.

# AppCompat\VDMDisallowed Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\AppCompat

**Description**
Stores configuration data for the policy setting **Prevent access to 16-bit applications**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Application Compatibility.

|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Desktop Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\Control Panel

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Desktop\ScreenSaveActive

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Screen Saver**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display.

# ScreenSaverIsSecure

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Password protect the screen saver**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display.

# Desktop\ScreenSaveTimeOut

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Screen Saver timeout**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display.

# Desktop\SCRNSAVE.EXE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Screen Saver executable name**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Display.

# Windows\CurrentVersion Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**

The CurrentVersion subkey contains subkeys and entries that store Group Policy settings for components of Windows. The subkeys and entries in the CurrentVersion subkey are written and maintained by Group Policy, and they are read and interpreted by the component that implements them.

This subkey stores entries for policy settings that apply to all users of this computer. There is also a Software\Policies\Microsoft\Windows\CurrentVersion subkey in HKEY_CURRENT_USER, which stores policy setting related entries that are configured separately for each user.

# Identities

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\CurrentVersion\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Locked Down

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Identities

**Description**
Stores configuration data for the policy setting **Identity Manager: Prevent users from using Identities**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# Accessibility Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing accessibility settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Internet Settings Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\CurrentVersion

**Description**
The Internet Settings subkey is one of several subkeys that store entries for Group Policy settings for Internet Explorer. Group Policy creates and maintains these entries, and the Internet Explorer program reads and interprets them.

The Internet Explorer Group Policy settings appear when the Inetres.adm file is added to Group Policy. By default, this file is added automatically.

In Group Policy, the Internet Explorer settings appear in the following folders:

- Computer Configuration\Administrative Templates\Windows Components\Internet Explorer
- User Configuration\Administrative Templates\Windows Components\Internet Explorer

**Note**

- The Internet Explorer folder in Group Policy is created by the Inetres.adm administrative templates file. This file is included in Windows Server 2003, and it is loaded automatically when you start Group Policy.

# Autoconfig

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing Automatic Configuration settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Cache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing Temporary Internet files settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# CalendarContact

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing Calendar and Contact settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# Certificates Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing certificate settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Check_If_Default

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing default browser check**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# Internet Settings\Colors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing color settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Connwiz Admin Lock

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable Internet Connection wizard**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# DialupAutodetect

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Use Automatic Detection for dial-up connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# DisplayScriptDownloadFailureUI

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Display error message on proxy script download failure**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# EnableAutoProxyResultCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable caching of Auto-Proxy scripts**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Internet Settings\Fonts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing font settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# FormSuggest

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable AutoComplete for forms**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# FormSuggest Passwords

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Do not allow AutoComplete to save passwords**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# History

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing history settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Languages

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing language settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# links

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing link color settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Messaging

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing Messaging settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Profiles

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing Profile Assistant settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# Proxy

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing proxy settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# ProxySettingsPerUser

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Make proxy settings per-machine (rather than per-user)**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# Ratings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable changing ratings settings**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Explorer.

# ResetWebSettings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Disable the Reset Web Settings feature**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# Security_HKLM_only

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Security Zones: Use only machine settings** .

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# Security_options_edit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\CurrentVersion\Internet Settings

**Description**
Stores configuration data for the policy setting **Security Zones: Do not allow users to change policies**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Windows\Installer Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**
The Installer subkey stores the entries created when you configure a Group Policy setting for Windows Installer in Windows Server 2003. Group Policy creates and maintains these entries, and Windows Installer reads and interprets them.

This subkey stores entries that apply to all users of the computer. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the Computer Configuration folder in Group Policy.

The Installer Subkey subkey in HKEY_CURRENT_USER stores entries that are configured separately for each user. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the User Configuration folder in Group Policy.

**Change Method**
To add, remove, or change the value of entries in this subkey, use Group Policy.

**Concepts**
Installer Subkey

# AllowLockdownBrowse

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Installer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Enable user to browse for source while elevated**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Installer.

# AllowLockdownMedia

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Installer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Enable user to use media source while elevated**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Installer.

# AllowLockdownPatch

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Installer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Enable user to patch elevated products**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Installer.

# AlwaysInstallElevated

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Installer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Always install with elevated privileges**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Installer.

# DisableBrowse

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Installer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove browse dialog box for new source**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Installer.

# DisableMedia

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Installer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prevent removable media source for any install**.

Stores configuration data for the policy setting **Default cache size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NetCache\Enabled Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Allow or Disallow use of the Offline Files feature**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# GoOfflineAction

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Action on server disconnect**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NetCache\NoConfigCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit user configuration of Offline Files**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NoConfigCache Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit user configuration of Offline Files**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NetCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**
The NetCache subkey contains entries that store Group Policy settings for the Offline Files feature. Group Policy creates and maintains these entries, and the Offline Files program reads and interprets them. In Group Policy, these policy settings appear in the Computer Configuration\Administrative Templates\Network\Offline Files folder.

This subkey stores entries related to policy settings that apply to all users of this computer. The NetCache subkey in HKEY_CURRENT_USER stores policy setting related entries that are configured separately for each user.

Also, many of the policy setting related entries in this subkey take precedence over user settings while the policy setting is in effect. The affected user settings are stored in HKLM\Software\Microsoft\Windows\CurrentVersion\NetCache.

# AlwaysPinSubFolders

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Subfolders always available offline**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# EncryptCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

**Description**
Stores configuration data for the policy setting **Encrypt the Offline Files cache**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# EventLoggingLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Event logging level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NoReminders

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Turn off reminder balloons**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# PurgeAtLogoff

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **At logoff, delete local copy of userÆs offline files**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# PurgeOnlyAutoCacheAtLogoff

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

**Description**
Stores configuration data for the policy setting **At logoff, delete local copy of userÆs offline files**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# ReminderBalloonTimeoutSeconds Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Reminder balloon lifetime**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# AssignedOfflineFolders\ReminderBalloonTimeoutSeconds

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Reminder balloon lifetime**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# ReminderFreqMinutes Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Reminder balloon frequency**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# AssignedOfflineFolders\ReminderFreqMinutes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Reminder balloon frequency**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# AssignedOfflineFolders

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\NetCache

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# InitialBalloonTimeoutSeconds

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\AssignedOfflineFolders

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Initial reminder balloon lifetime**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# CustomGoOfflineActions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\NetCache

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# ExcludeExtensions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\CustomGoOfflineActions

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Files not cached**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NoCacheViewer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\CustomGoOfflineActions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prevent use of Offline Files folder**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NoMakeAvailableOffline

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\CustomGoOfflineActions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Remove 'Make Available Offline'**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# DisableFRAdminPin

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\NoMakeAvailableOfflineList

**Description**
Stores configuration data for the policy setting **Do not automatically make redirected folders available offline**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# SlowLinkSpeed

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\NetCache\NoMakeAvailableOfflineList

**Description**
Stores configuration data for the policy setting **Configure Slow link speed**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Offline Files.

# NoMakeAvailableOfflineList

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\NetCache

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# NC_AddRemoveComponents

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit adding and removing components for a LAN or remote access connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_AdvancedSettings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit access to the Advanced Settings item on the Advanced menu**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_AllowAdvancedTCPIPConfig

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit TCP/IP advanced configuration**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_AllowNetBridge_NLA

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

**Description**
Stores configuration data for the policy setting **Prohibit installation and configuration of Network Bridge on your DNS domain network**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_ChangeBindState

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit Enabling/Disabling components of a LAN connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_DeleteAllUserConnection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Ability to delete all user remote access connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_DeleteConnection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit deletion of remote access connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_DialupPrefs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit access to the Remote Access Preferences item on the Advanced menu**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_EnableAdminProhibits

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

**Description**
Stores configuration data for the policy setting **Enable Windows 2000 Network Connections settings for Administrators**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_LanChangeProperties

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit access to properties of components of a LAN connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_LanConnect

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Ability to Enable/Disable a LAN connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_LanProperties

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit access to properties of a LAN connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_NewConnectionWizard

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit access to the New Connection Wizard**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_PersonalFirewallConfig

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

**Description**
Stores configuration data for the policy setting **Prohibit use of Internet Connection Firewall on your DNS domain network**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_RasAllUserProperties

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Ability to change properties of an all user remote access connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_RasChangeProperties

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit access to properties of components of a remote access connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_RasConnect

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit connecting and disconnecting a remote access connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_RasMyProperties

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit changing properties of a private remote access connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_RenameAllUserRasConnection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections

**Description**
Stores configuration data for the policy setting **Ability to rename all user remote access connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# NC_RenameConnection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**
The Network Connections subkey contains entries that store Group Policy settings for Network and Dial-up Connections. Group Policy creates and maintains the entries in this subkey, and the Network and Dial-up Connections program reads and interprets them.

This subkey stores entries related to policy settings that apply to all users of this computer. The Software\Policies\Microsoft\Windows\Network Connections subkey in HKEY_CURRENT_USER stores policy setting related entries that are configured separately for each user.

# 8021XCARootHash

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Network Connections\8021X

**Description**
Stores configuration data for the policy setting **IEEE 802.1x Certificate Authority for Machine Authentication**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\Network Connections.

# 8021X

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\Network Connections

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# MaxOutstandingSends

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit outstanding packets**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler.

# TimerResolution

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Set timer resolution**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler.

# NonBestEffortLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit reservable bandwidth**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler.

# Psched

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**
The Psched subkey stores entries created when you configure a Group Policy setting for the Quality of Service (QoS) Packet Scheduler.

Each entry in this subkey stores a policy setting used to configure the Packet Scheduler. The Packet Scheduler reads and interprets these entries when it implements the policy setting.

# DiffservByteMappingConforming\ServiceTypeBestEffort

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingConforming

**Description**
Stores configuration data for the policy setting **Best effort service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of conforming packets.

# DiffservByteMappingConforming\ServiceTypeControlledLoad

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingConforming

**Description**
Stores configuration data for the policy setting **Controlled load service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of conforming packets.

# DiffservByteMappingConforming\ServiceTypeGuaranteed

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingConforming

**Description**
Stores configuration data for the policy setting **Guaranteed service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of conforming packets.

# DiffservByteMappingConforming\ServiceTypeNetworkControl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingConforming

**Description**
Stores configuration data for the policy setting **Network control service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of conforming packets.

# DiffservByteMappingConformingServiceTypeQualitative

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingConforming

**Description**
Stores configuration data for the policy setting **Qualitative service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of conforming packets.

# DiffServByteMappingConforming

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\Psched

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# ServiceTypeBestEffort Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingNonConforming

**Description**
Stores configuration data for the policy setting **Best effort service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of non-conforming packets.

# DiffservByteMappingNonConforming\ServiceTypeControlledLoad

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingNonConforming

**Description**
Stores configuration data for the policy setting **Controlled load service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of non-conforming packets.

# DiffservByteMappingNonConforming\ServiceTypeGuaranteed

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingNonConforming

**Description**
Stores configuration data for the policy setting **Guaranteed service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of non-conforming packets.

# DiffservByteMappingNonConforming\ServiceTypeNetworkControl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingNonConforming

**Description**
Stores configuration data for the policy setting **Network control service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of non-conforming packets.

# DiffservByteMappingNonConforming\ServiceTypeQualitative

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingNonConforming

**Description**
Stores configuration data for the policy setting **Qualitative service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\DSCP value of non-conforming packets.

# UserPriorityMapping\ServiceTypeBestEffort

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\UserPriorityMapping

**Description**
Stores configuration data for the policy setting **Best effort service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\Layer-2 priority value.

# UserPriorityMapping\ServiceTypeControlledLoad

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\UserPriorityMapping

**Description**
Stores configuration data for the policy setting **Controlled load service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\Layer-2 priority value.

# UserPriorityMapping\ServiceTypeGuaranteed

Updated: March 28, 2003

HKLM\Software\Policies\Microsoft\Windows\Psched\UserPriorityMapping

**Description**
Stores configuration data for the policy setting **Guaranteed service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\Layer-2 priority value.

# UserPriorityMapping\ServiceTypeNetworkControl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\UserPriorityMapping

**Description**
Stores configuration data for the policy setting **Network control service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\Layer-2 priority value.

# ServiceTypeNonConforming

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\UserPriorityMapping

**Description**
Stores configuration data for the policy setting **Non-conforming packets**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\Layer-2 priority value.

# UserPriorityMapping\ServiceTypeQualitative

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Psched\UserPriorityMapping

**Description**
Stores configuration data for the policy setting **Qualitative service type**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\QoS Packet Scheduler\Layer-2 priority value.

# UserPriorityMapping

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\Psched

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# AddAdminGroupToRUP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Add the Administrators security group to roaming user profiles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# AllowX-ForestPolicy-and-RUP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Allow Cross-Forest User Policy and Roaming User Profiles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# CompatibleRUPSecurity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Do not check for user ownership of Roaming Profile Folders**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# DeleteRoamingCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Delete cached copies of roaming profiles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# DenyRsopToInteractiveUser

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Disallow Interactive Users from generating Resultant Set of Policy data**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# DenyUsersFromMachGP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Remove users ability to invoke machine policy refresh**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# DisableCMD

Updated: January 6, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 0 |

**Description**

Stores configuration data for the policy setting **Prevent access to the command prompt**.

| Value | Meaning |
|---|---|
| 0 | Allows users access to the command prompt. |
| 1 | Prevents users from running the interactive command prompt, Cmd.exe. This setting also restricts batch files and logon scripts (.cmd and .bat) from running on the computer.<br>**Caution**<br>If you enable this setting and the user tries to open a command window, the system displays a message explaining that a setting prevents the action. |
| 2 | Prevents users from running the interactive command prompt, Cmd.exe, but allows batch files and logon scripts to run.<br>**Tip**<br>You should use this setting if you run logon, logoff, startup, or shutdown batch file scripts, or if users run Remote Desktop Services (Terminal Services). |

**Change Method**

To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# System\DisableInHelp

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Restrict these programs from being launched from Help**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# System\DisableInHelp Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Restrict these programs from being launched from Help**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# DLT_AllowDomainMode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Allow Distributed Link Tracking clients to use domain resources**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# ExcludeProfileDirs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Exclude directories in roaming profile**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# GroupPolicyMinTransferRate Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Group Policy slow link detection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# System\GroupPolicyMinTransferRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Group Policy slow link detection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# GroupPolicyRefreshTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Group Policy refresh interval for computers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# GroupPolicyRefreshTimeDC

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Group Policy refresh interval for domain controllers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# GroupPolicyRefreshTimeOffset

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Group Policy refresh interval for computers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# GroupPolicyRefreshTimeOffsetDC

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Group Policy refresh interval for domain controllers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# HelpQualifiedRootDir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Restrict potentially unsafe HTML Help functions to specified folders**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# LocalProfile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Only allow local user profiles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# System\ProfileDlgTimeOut

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Timeout for dialog boxes**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# ProfileErrorAction

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Log users off when roaming profile fails**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# ProfileUnloadTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Maximum retries to unload and update user profile**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# ReadOnlyProfile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Prevent Roaming Profile changes from propagating to the server**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# RSoPLogging

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

**Description**
Stores configuration data for the policy setting **Turn off Resultant Set of Policy logging**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# SlowLinkDetectEnabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Do not detect slow network connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# System\SlowLinkTimeOut

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Slow network connection timeout for user profiles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# SlowLinkUIEnabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prompt user when slow link is detected**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# UserPolicyMode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **User Group Policy loopback processing mode**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Group Policy.

# UserProfileMinTransferRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Slow network connection timeout for user profiles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# System\SlowLinkProfileDefault

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Wait for remote user profile**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\User Profiles.

# Windows\System Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# PromptPasswordOnResume

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\System\Power

**Description**
Stores configuration data for the policy setting **Prompt for password on resume from hibernate / suspend**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Power Management.

# Power

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\System

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Allow Browse

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit Browse**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# Task Scheduler5.0\Disable Advanced

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Hide Advanced Properties Checkbox in Add Scheduled Task Wizard**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# Disable Advanced Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Hide Advanced Properties Checkbox in Add Scheduled Task Wizard**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# DragAndDrop

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit Drag-and-Drop**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# Execution

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prevent Task Run or End**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# Property Pages

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Hide Property Pages**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# Task Creation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit New Task Creation**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# Task Deletion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\Task Scheduler5.0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prohibit Task Deletion**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Task Scheduler.

# Task Scheduler5.0

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

**Description**
The Task Scheduler5.0 subkey stores the entries created when you configure a Group Policy setting for the Scheduled Tasks feature of Windows Server 2003. Group Policy creates and maintains these entries, and Scheduled Tasks reads and interprets them.

This subkey stores entries that apply to all users of the computer. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the Computer Configuration folder in Group Policy.

The Task Scheduler5.0 subkey in HKEY_CURRENT_USER stores entries that are configured separately for each user. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the User Configuration folder in Group Policy.

# Windows\WindowsUpdate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# AU

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows\WindowsUpdate

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# AUOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Configure Automatic Updates**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# NoAutoRebootWithLoggedOnUsers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **No auto-restart for scheduled Automatic Updates installations**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# NoAutoUpdate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Configure Automatic Updates**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# RescheduleWaitTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Reschedule Automatic Updates scheduled installations**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# ScheduledInstallDay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Configure Automatic Updates**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# ScheduledInstallTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Configure Automatic Updates**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# UseWUServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Specify intranet Microsoft update service location**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# WUServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Specify intranet Microsoft update service location**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# WUStatusServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows\WindowsUpdate\AU

**Description**
Stores configuration data for the policy setting **Specify intranet Microsoft update service location**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Update.

# Policies\Microsoft\Windows NT Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

**Description**
The Windows NT subkey contains entries that store Group Policy settings for Windows Server 2003. Group Policy creates and maintains these entries, and the system components read and interpret them.

This subkey stores entries that apply to all users of the computer. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the Computer Configuration folder in Group Policy.

The Policies\Microsoft\Windows NT subkey in HKEY_CURRENT_USER stores policy setting-related entries that are configured separately for each user. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the User Configuration folder in Group Policy.

**Change Method**
To add, delete, or change an entry in this subkey, use Group Policy.

# Windows NT\CurrentVersion Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# MYS

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\CurrentVersion

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# DisableShowAtLogon

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\CurrentVersion\MYS

**Description**
Stores configuration data for the policy setting **Do not display Manage Your Server page at logon**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# SyncForegroundPolicy

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\CurrentVersion\Winlogon

**Description**
Stores configuration data for the policy setting **Always wait for the network at computer startup and logon**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Logon.

# CurrentVersion\Winlogon Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\CurrentVersion

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# ApplyToRemovableMedia

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Apply policy to removable media**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# Enable

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Enable disk quotas**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# Enforce

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Enforce disk quota limit**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# LimitUnits

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Default quota limit and warning level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# LogEventOverLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Log event when quota limit exceeded**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# LogEventOverThreshold

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Log event when quota warning level exceeded**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# Threshold

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Default quota limit and warning level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# ThresholdUnits

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Default quota limit and warning level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# Limit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DiskQuota

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Default quota limit and warning level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Disk Quotas.

# RegisterAdapterName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **Register DNS records with connection-specific DNS suffix**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# RegisterReverseLookup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **Register PTR Records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# RegistrationEnabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **Dynamic Update**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# RegistrationRefreshInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **Registration Refresh Interval**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# RegistrationTtl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **TTL Set in the A and PTR records**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# SearchList

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **DNS Suffix Search List**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# UpdateSecurityLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **Update Security Level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# UseDomainNameDevolution

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\DNSClient

**Description**
Stores configuration data for the policy setting **Primary DNS Suffix Devolution**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Network\DNS Client.

# Windows NT\DNSClient

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Windows NT\Driver Signing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# BehaviorOnFailedVerify

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Driver Signing

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Code signing for device drivers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System.

# PreventIISInstall

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\IIS

**Description**
Stores configuration data for the policy setting **Prevent IIS installation**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Internet Information Services.

# IIS

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Windows NT\Printers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT

**Description**
The Printers subkey contains entries that store Group Policy settings for printers. Group Policy creates and maintains these entries, and the printing functions in Windows Server 2003 read and interpret them.

This subkey stores entries that apply to all users of the computer. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the Computer Configuration folder in Group Policy.

The Policies\Microsoft\Windows NT\Printers subkey in HKEY_CURRENT_USER stores policy setting related entries that are configured separately for each user. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the User Configuration folder in Group Policy.

# DisableWebPrinting

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Web-based printing**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# Immortal

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Allow pruning of published printers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# KMPrintersAreBlocked

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

**Description**
Stores configuration data for the policy setting **Disallow installation of printers using kernel-mode drivers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PhysicalLocation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Computer location**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PhysicalLocationSupport

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Pre-populate printer search location text**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PruneDownlevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Prune printers that are not automatically republished**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PruningInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Directory pruning interval**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PruningPriority

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Directory pruning priority**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PruningRetries

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Directory pruning retry**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PruningRetryLog

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

**Description**
Stores configuration data for the policy setting **Log directory pruning retry events**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PublishPrinters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Allow printers to be published**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# RegisterSpoolerRemoteRpcEndPoint

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

**Description**
Stores configuration data for the policy setting **Allow Print Spooler to accept client connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# ServerThread

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Printer browsing**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# SupportLink

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Custom support URL in the Printers folder's left pane**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# VerifyPublishedState

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Check published state**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# PointAndPrint

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# InForest

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\PointAndPrint

**Description**
Stores configuration data for the policy setting **Point and Print Restrictions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# NoAddPrinter

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\PointAndPrint

**Description**
Stores configuration data for the policy setting **Prevent addition of printers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# NoDeletePrinter

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\PointAndPrint

**Description**
Stores configuration data for the policy setting **Prevent deletion of printers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# Restricted

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\PointAndPrint

**Description**
Stores configuration data for the policy setting **Point and Print Restrictions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# ServerList

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\PointAndPrint

**Description**
Stores configuration data for the policy setting **Point and Print Restrictions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# TrustedServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\PointAndPrint

**Description**
Stores configuration data for the policy setting **Point and Print Restrictions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# Auto Publishing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\Wizard

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Automatically publish new printers in Active Directory**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Printers.

# Default Search Scope

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\Wizard

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Default Active Directory path when searching for printers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# Downlevel Browse

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\Wizard

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Browse the network to find printers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# Printers Page URL

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Printers\Wizard

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Browse a common web site to find printers**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Control Panel\Printers.

# Wizard

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Printers

| Data type | Range | Default value |
|---|---|---|

# PublishDfsRoots

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\SharedFolders

**Description**
Stores configuration data for the policy setting **Allow DFS roots to be published**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Shared Folders.

# PublishSharedFolders

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\SharedFolders

**Description**
Stores configuration data for the policy setting **Allow shared folders to be published**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Shared Folders.

# ColorDepth

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Limit maximum color depth**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# DeleteTempDirsOnExit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not delete temp folder upon exit**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Temporary folders.

# fAllowFullControl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Solicited Remote Assistance**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Remote Assistance.

# fAllowToGetHelp

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Solicited Remote Assistance**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Remote Assistance.

# fAllowUnsolicited

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Offer Remote Assistance**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Remote Assistance.

# fAllowUnsolicitedFullControl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Offer Remote Assistance**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Remote Assistance.

# fDenyTSConnections

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Allow users to connect remotely using Terminal Services**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# fDisableAutoReconnect

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Automatic reconnection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# fDisableCam

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Allow audio redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fDisableCcm

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not allow COM port redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fDisableCdm

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not allow drive redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fDisableClip

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not allow clipboard redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fDisableCpm

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not allow client printer redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fDisableForcibleLogoff

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Deny log off of an administrator logged in to the console session**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# fDisableLPT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not allow LPT port redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fEnableSmartCard

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not allow smart card device redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fEnableTimeZoneRedirection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Allow Time Zone Redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fEncryptRPCTraffic

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Secure Server (Require Security)**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Encryption and Security\RPC Security Policy.

# fForceClientLptDef

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not set default client printer to be default printer in a session**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Client/Server data redirection.

# fInheritInitialProgram

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Start a program on connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# fNoRemoteDesktopWallpaper

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Enforce Removal of Remote Desktop Wallpaper**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# fPreventLicenseUpgrade

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Prevent License Upgrade**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Licensing.

# fPromptForPassword

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Always prompt client for password upon connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Encryption and Security.

# fReconnectSame

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Allow reconnection from original client only**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Sessions.

# fResetBroken

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Terminate session when time limits are reached**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Sessions.

# fSecureLicensing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **License Server Security Group**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Licensing.

# fSingleSessionPerUser

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Restrict Terminal Services users to a single remote session**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# fUseMailto

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Solicited Remote Assistance**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Remote Assistance.

# fWritableTSCCPermTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not allow local administrators to customize permissions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# InitialProgram

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Start a program on connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# KeepAliveEnable

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Keep-Alive Connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# Terminal Services\KeepAliveInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Keep-Alive Connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# MaxConnectionTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Sets a time limit for active Terminal Services sessions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Sessions.

# MaxDisconnectionTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Set time limit for disconnected sessions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Sessions.

# MaxInstanceCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Limit number of connections**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# MaxTicketExpiry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Solicited Remote Assistance**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Remote Assistance.

# MaxTicketExpiryUnits

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Solicited Remote Assistance**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Remote Assistance.

# MinEncryptionLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Set client connection encryption level**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Encryption and Security.

# PerSessionTempDir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Do not use temp folders per session**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Temporary folders.

# SessionDirectoryActive

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Join Session Directory**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Session Directory.

# SessionDirectoryClusterName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Session Directory Cluster Name**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Session Directory.

# SessionDirectoryExposeServerIP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Terminal Server IP Address Redirection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Session Directory.

# SessionDirectoryLocation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Session Directory Server**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Session Directory.

# Terminal Services\Shadow

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Sets rules for remote control of Terminal Services user sessions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# WFHomeDir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **TS User Home Directory**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# WFHomeDirDrive

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **TS User Home Directory**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# WFHomeDirUNC

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **TS User Home Directory**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# WFProfilePath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Set path for TS Roaming Profiles**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# WorkDirectory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Start a program on connection**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services.

# MaxIdleTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services

**Description**
Stores configuration data for the policy setting **Sets a time limit for active but idle Terminal Services sessions**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Terminal Services\Sessions.

# Terminal Services Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Windows File Protection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft\Windows NT

**Description**
The Windows File Protection subkey contains entries that store Group Policy settings for the Windows File Protection feature of Windows Server 2003. Group Policy creates and maintains the entries in this subkey, and the Windows File Protection program reads and interprets them.

# SFCDllCacheDir Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Windows File Protection

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores configuration data for the policy setting **Specify Windows File Protection cache location**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows File Protection.

# SfcQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Windows File Protection

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Limit Windows File Protection cache size**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows File Protection.

# Windows File Protection\SfcScan

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Windows File Protection

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Set Windows File Protection scanning**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows File Protection.

# Windows File Protection\SfcShowProgress

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\Windows NT\Windows File Protection

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores configuration data for the policy setting **Hide the file scan progress window**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\System\Windows File Protection.

# QuickLaunchShortcut

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Prevent Quick Launch toolbar shortcut creation**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player.

# SetAndLockSkin

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Set and Lock Skin**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\User Interface.

# DefaultSkin

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Set and Lock Skin**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\User Interface.

# DesktopShortcut

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Prevent Desktop shortcut creation**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player.

# DisableAutoUpdate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Prevent Automatic Updates**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player.

# DoNotShowAnchor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Do Not Show Anchor**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\User Interface.

# DontUseFrameInterpolation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Prevent Video Smoothing**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player.

# EnableScreenSaver

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Allow Screen Saver**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Playback.

# GroupPrivacyAcceptance

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Disable Setup First Use Configuration Dialogs**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player.

# HideNetworkTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Hide Network Tab**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# HidePrivacyTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Hide Privacy Tab**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\User Interface.

# HideSecurityTab

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Hide Security Tab**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\User Interface.

# PreventCDDVDMetadataRetrieval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Prevent CD and DVD media information retrieval**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player.

# PreventCodecDownload

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Prevent Codec Download**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Playback.

# PreventMusicFileMetadataRetrieval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer

**Description**
Stores configuration data for the policy setting **Prevent music file media information retrieval**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player.

# WindowsMediaPlayer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Policies\Microsoft

| Data type | Range | Default value |

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# HTTP Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols

**Description**
Stores configuration data for the policy setting **Streaming Media Protocols**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# TCP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols

**Description**
Stores configuration data for the policy setting **Streaming Media Protocols**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# UDP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols

**Description**
Stores configuration data for the policy setting **Streaming Media Protocols**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# UDPPorts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols

**Description**
Stores configuration data for the policy setting **Streaming Media Protocols**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# WindowsMediaStreamingProtocols

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols

**Description**
Stores configuration data for the policy setting **Streaming Media Protocols**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# Multicast

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols

**Description**
Stores configuration data for the policy setting **Streaming Media Protocols**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# HTTP\AutodetectProxy Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols\HTTP

**Description**
Stores configuration data for the policy setting **Configure HTTP Proxy**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# BypassProxyLocal Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols\HTTP

**Description**
Stores configuration data for the policy setting **Configure HTTP Proxy**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# BypassProxyLocalAddress Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols\HTTP

**Description**
Stores configuration data for the policy setting **Configure HTTP Proxy**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# ProxyAddress Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Policies\Microsoft\WindowsMediaPlayer\Protocols\HTTP

**Description**
Stores configuration data for the policy setting **Configure HTTP Proxy**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in Administrative Templates\Windows Components\Windows Media Player\Networking.

# HTTP\ProxyPolicy

Updated: March 28, 2003

HKLM\SOFTWARE

**Description**
The Program Groups subkey remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this subkey.

In Windows NT 4.0 and earlier, the Program Groups subkey stored the contents of program groups the user defined in Program Manager. In Windows 2000 and Windows Server 2003, these Program Groups appear as shortcuts in subfolders of the **Start** menu.

**Note**

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# SYSTEM

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM

**Description**
The subkeys in the HKEY_LOCAL_MACHINE\SYSTEM key store entries for the current control set and for other control sets that can be used, or have been used, to run Windows Server 2003. Windows Server 2003 maintains at least two control sets to ensure that the system always starts.

# ControlSet00n

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM

**Description**
The *ControlSet00n* subkeys represent a control set for the system.

The numbered ControlSet00n subkeys, such as ControlSet001 and ControlSet002, contain control sets that can be used to start and run Windows Server 2003. Most systems have two numbered control sets (an original and a backup copy) of a control set that has been used to start the system successfully, but the system can maintain as many as four control sets.
Windows Server 2003 maintains backup copies so that you can undo configuration changes that might otherwise prevent you from starting the system.

Windows Server 2003 identifies the control set that was last used successfully, the current control set, and the default control set. These designations are stored in the Select subkey.

Windows Server 2003 automatically maintains the control sets and selects one of them when the system starts. It bases this selection on settings in the Select subkey and on the success or failure of system startup. Users can specify the LastKnownGood control set by pressing the F8 key on the **OS Choices Menu** during system startup to display the **Advanced Startup Options** menu.

All the numbered control set subkeys, including the one that appears in the CurrentControlSet subkey, can have the same subkeys and entries. In this reference, these subkeys are entries listed in the CurrentControlSet subkey.

**Note**

- The *ControlSet00n* subkey is a variable representing the numbered control sets in the HKLM\SYSTEM key. It does not actually appear in the registry.

**See Also**
**Concepts**
Select
CurrentControlSet

# CurrentControlSet

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM

**Description**
The CurrentControlSet subkey does not actually contain a control set. The subkeys and entries that appear in the CurrentControlSet subkey are the contents of one of the numbered control sets, such as ControlSet001. The control set that appears in CurrentControlSet is selected by the system at startup and is identified by the value of the **Current** entry in the Select subkey.

For example, if the value of the **Current** entry is 1, then the contents of ControlSet001 appear in CurrentControlSet.

# Control

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet

**Description**
The Control subkey and its subkeys contain entries that control system startup, such as the subsystems to load and the size and location of paging files.

**Activation Method**
You must restart the system before any changes in the Control subkey take effect.

# RegistrySizeLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**

This entry is not used by Windows Server 2003. In older versions of Windows Server, it specified the maximum amount of memory and disk space that the registry could consume.

# BackupRestore

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The BackupRestore subkey contains subkeys that determine which files the system does not back up and which registry subkeys and entries the system does not restore.

**Caution**

- Do not change the values of these entries. Altering these values can prevent Windows Backup from successfully backing up and/or restoring data.

# FilesNotToBackup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\BackupRestore

**Description**
The FilesNotToBackup subkey contains entries that specify the files that Backup omits.

Each of the entries in this subkey has the following format:

| Entry name | Data type | Value |
|---|---|---|
| *component* | REG_MULTI_SZ | *[drive][path]\filename* **[/s]** |

- *Drive* specifies the drive and is optional. For example, c:
- *Path* specifies the path and is optional. It cannot contain wildcard characters.
- *Filename* specifies the file and is required. It can contain wildcard characters.
- **/s** specifies that the file affects all subdirectories of the specified path. Environment variables can be substituted for all or part of the above.

| Entry | Default Value |
|---|---|
| Client Side Cache | %Systemroot%\csc* /s |
| ComPlus | %Systemroot%\registration*.clb |
| Internet Explorer | %UserProfile%\index.dat /s |
| Memory Page File | \Pagefile.sys |
| MS Distributed Transaction Coordinator | %Systemroot%\WINNT\System32\DTCLog\MSDTC.LOG |
| Power Options | \hiberfil.sys |
| Single Instance Storage | \SIS Common Store*.* /s |
| Temporary Files | %TEMP%* /s |

**Change Method**
To change the value of these entries, use Backup. From the **Tools** menu, click **Options**, then click the **Exclude Files** tab. Use the **Add new**, **Edit**, and **Remove** buttons to select those files not to be backed up.

**Caution**

- Do not change the values of the entries in this subkey. Altering these values can prevent Backup from successfully backing up or restoring data.

# KeysNotToRestore

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\BackupRestore

**Description**
The KeysNotToRestore subkey specifies the names of those registry subkeys and entries that Backup will not restore.

Each of the entries has the following format:

| Entry name | Data type | Value |
|---|---|---|
| *component* | REG_MULTI_SZ | *registry path* [*registry path*] |

The paths are relative from HKEY_LOCAL_MACHINE\SYSTEM and can take one of three forms:

- A path ending with "\" indicates that neither the subkey nor any of its subkeys or entries will be restored from the backup. Instead, the current values will be preserved.
- A path ending with "*" indicates that neither the subkey nor any of its subkeys and entries will be restored from the backup, but new entries will be merged from the backup.
- A path ending with an entry name indicates that the entry will not be restored from the backup.

| Entry | Default Value |
|---|---|
| Active Directory Restore | CurrentControlSet\Services\NTDS\Restore In Progress\<br>CurrentControlSet\Services\NTDS\Parameters\New Database GUID |
| Fault Tolerance | Disk\ |
| Installed Services | CurrentControlSet\Services* |
| LDM Boot Information | CurrentControlSet\Control\Services\dmio\boot info\ |
| Mount Manager | MountedDevices\ |
| Pending Rename Operations | CurrentControlset\Control\Session Manager\PendingFileRenameOperations |
| Plug & Play | CurrentControlSet\Session Manager\PendingFileRenameOperations |
| Session Manager | CurrentControlSet\Control\SessionManager\AllowProtectedRename |
| Windows Setup | Setup\SystemPartition |

**Caution**

- Do not change the values of the entries in this subkey. Altering these values can prevent Backup from successfully backing up or restoring data.

# BootVerificationProgram

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The BootVerificationProgram subkey stores data about custom startup verification programs. Startup verification programs specify the criteria for a successful startup and notify the system that the startup is successful—two functions otherwise performed by Winlogon. You can write a custom startup verification program and use this subkey to direct the Windows Server 2003 service controller to run it.

Some custom startup verification programs notify the system that startup was not successful, causing the system to restart using the LastKnownGood control set. Other programs determine whether their criteria were satisfied, and if so, they run Bootok.exe, a program that notifies the system that startup was successful. Bootok.exe is included in Windows Server 2003.

### Notes

- To run a custom startup verification program, you must disable the standard startup verification functions in Winlogon by setting the value of the ReportBootOk entry to 0.
- You cannot run a custom startup verification program if you are also running the Bootvrfy startup verification program.

### Caution

- Do not add or change the value of the entries in the BootVerificationProgram subkey unless you need to run a custom verification program.

**See Also**
**Concepts**
ReportBootOk

# BootVerificationProgram\ImagePath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\BootVerificationProgram

| Data type | Range | Default value |
|---|---|---|
| REG_SZ \| REG_EXPAND_SZ | Filename | (None) |

**Description**
Specifies the full path and file name of a custom startup verification program. At startup, the Windows Server 2003 service controller runs the program listed here.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- To run a custom startup verification program, you must disable the standard startup verification functions in Winlogon by setting ReportBootOk to 0.

ReportBootOk

# Class

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Class subkey stores configuration data for classes of hardware devices.

Each subkey in the Class subkey represents a device class and is named by the globally unique identifier (GUID) for the class. It appears as a 16-digit alphanumeric string within curly braces. These {*Class-GUID*} subkeys store configuration data that applies to the entire class of devices, such as the class of all modems.

Within the {*Class-GUID*} subkeys are device-specific subkeys, which represent particular devices that are instances of the class.

Because the Class subkey is hardware specific, its contents vary widely. The Class subkey on your computer might look quite different from the attributes described in this reference.

**Tip**

- To determine the type of hardware device represented by a {*Class-GUID*} subkey, use the registry editor Regedit.exe. Click the name of the {*Class-GUID*} subkey (it appears as a 16-byte alphanumeric string within brackets). The device type appears in the value of the first, unnamed entry in the subkey.

- To display hidden devices, non–Plug and Play devices, and devices not attached to the computer (commonly known as "ghosted" or "phantom" devices), type `set DEVMGR_SHOW_NONPRESENT_DEVICES=1` at the command line. Then, use Device Manager to remove or reconfigure these devices. Do not edit the registry. For more information about viewing hidden devices, see *Microsoft Windows XP Professional Resource Kit Documentation*.

**Caution**

- Do not change any entries in the Class subkey or any subkey within it. These subkeys are configured by the system to comply with Plug and Play standards. Changing any data can prevent your computer devices from starting or operating properly.

# (Network adapters) {4D36E972-E325-11CE-BFC1-08002BE10318}

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# WanEndpoints

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class\(Network adapters) {4D36E972-E325-11CE-BFC1-08002BE10318}\WAN Miniport (L2TP) *Device-number (000n)*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x5 |

**Description**
Stores the number of wide area network (WAN) endpoints currently configured for use.

This entry stores the setting in the **Maximum ports** box in Routing and Remote Access.

**Change Method**
To change the value of this entry, use Routing and Remote Access. Right-click **Ports**, click **Properties**, click **WAN Miniport (L2TP)**, and then click **Configure**. This entry stores the value in the **Maximum ports** box.

### Note

- The value of this entry must be less than or equal to the value of the entry **MaxWanEndpoints**.

### Caution

- Do not change the value of this entry by editing the registry. If you do, the system cannot adjust corresponding values, and Layer Two Tunneling Protocol (L2TP) might not support the number of endpoints you request.

# {Class-GUID}

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class

**Description**
The {*Class-GUID*} subkey represents the component associated with the class-GUID.

Each {*Class-GUID*} subkey in the Class subkey represents a device class and is named by the GUID for the class. It appears as a 16-digit alphanumeric string within curly braces. These {*Class-GUID*} subkeys store configuration data that applies to the entire class of devices, such as the class of all modems.

Within the {*Class-GUID*} subkeys are 4-digit numbered subkeys, which represent particular devices that are instances of the class. These subkeys store data that apply only to that device.

Because the Class subkey is hardware specific, its contents vary widely. The Class subkey on your computer might look quite different from the attributes described in this reference.

**Change Method**
It is strongly recommended that you do not make changes to entries in the Class subkey or any subkey within it.

### Note

- The {*Class-GUID*} subkey is a variable representing the subkeys in the HKLM\SYSTEM\CurrentControlSet\Control\Class subkey. It does not actually appear in the registry. This variable subkey displays the entries and subkeys that are common to many of the subkeys in the Class subkey. The actual Class subkeys in your registry depend on the hardware installed on the computer or available to the system.

### Tip

- To determine the type of hardware device represented by a {*Class-GUID*} subkey, use the registry editor Regedit.exe. Click the name of the class-GUID subkey (it appears as a 16-byte alphanumeric string within brackets). The device type appears in the value of the first, unnamed entry in the subkey.

### Caution

- Do not change any entries in the Class subkey or any subkey within it. These subkeys are configured by the system to comply with Plug and Play standards. Changing any data can prevent your computer devices from starting or operating properly.

# Device-number (000n) Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class*{Class-GUID}*

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Linkage Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class*{Class-GUID}**Device-number (000n)*

**Description**
The Linkage subkey stores configuration data for binding network components. It exists only for net class (adapters) devices that have a class globally unique identifier (GUID) of {4D36E972-E325-11CE-BFC1-08002bE10318}. The bindings associate devices and services with the transport protocols they use.

A binding consists of three entries: **UpperBind**, **Export**, and **RootDevice**. Each of these entries can include more than one component. The entries list the components in a precise order, so the first component in one entry corresponds with the first component in the other entries, and each subsequent component corresponds with subsequent components in the other entries.

In Windows NT 4.0 and earlier, all Linkage subkeys were stored in subkeys of the Services subkey (HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services*Service-name*). In Windows Server 2003, the Linkage subkeys for services are still in the Services subkey, but Linkage subkeys for devices are stored in HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Class*{Class-GUID}*, in the numeric subkey representing the particular device.

### Notes

- A valid binding requires a value for three entries: **UpperBind**, **Export**, and **RootDevice**.
- This information is provided only for reference. Use only published application programming interfaces. Do not include the Linkage subkey in Windows programs. This subkey might not be included in future versions of Windows.

### Tip

- To determine the type of hardware device represented by a class-GUID subkey, use the registry editor Regedit.exe. Click the name of the class-GUID subkey (it appears as a 16-byte alphanumeric string within brackets). The device type appears in the value of the first, unnamed entry in the subkey.
- Many digits in the GUID are unique to your system. However, the three digits preceding the first hyphen are specific to the device class and are the same on all systems. For example, the three digits preceding the first hyphen in the DVD/CD-ROM drives class are always 965.

### Caution

- Do not change any entries in the Class subkey or any subkey within it. The system configures these subkeys to comply with Plug and Play standards. Changing any data can prevent your computer devices from starting or operating properly.
- This value is maintained by the Network Configuration subsystem. Do not specify this value in an .inf file.

# Ndi Subkeys

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class*{Class-GUID}\Device-number (000n)*

**Description**
The Ndi subkeys store data for network driver installers (NDI). They appear only in the subkey for the Class GUID {4D36E972-E325-11CE-BFC1-08002bE10318}. They store data that the Network Class Installer uses to install and configure the component.

The entries in the Ndi subkeys vary with the requirements of the component. The entries described in this subkey are common to many components.

### Note

- Windows Server 2003 does not include NetRules subkeys. In Windows NT 4.0 and earlier, the NetRules subkeys contained entries that specified bind rules for network software components. Some bind specifications are stored in the Ndi subkeys that contain configuration data for network driver installers. However, these are primary upper bind and lower bind settings only.

Linkage Subkey

# {4D36E972-E325-11CE-BFC1-08002BE10318}

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class

**Description**
The {4D36E972-E325-11CE-BFC1-08002BE10318} subkey represents the class of network adapter devices that the system supports.

This subkey contains several 4-digit numbered subkeys, which represent particular network adapters. These subkeys store data that applies only to that device.

**Caution**

- Do not change any entries in the Class subkey or any subkey within it. The system configures these subkeys to comply with Plug and Play standards. Changing any data can prevent your computer devices from starting or operating properly.

# {4D36E972-E325-11CE-BFC1-08002bE10318}\Device-number (000n)

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class\{4D36E972-E325-11CE-BFC1-08002bE10318}

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Ndi Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class\{4D36E972-E325-11CE-BFC1-08002bE10318}*Device-number (000n)*

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Device-number (000n)\Interfaces

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class\{4D36E972-E325-11CE-BFC1-08002bE10318}*Device-number (000n)*\Ndi

**Description**
The Interfaces subkey specifies the upper and lower binding interfaces for the component. It has two values:

- **Upper Range**. A REG-SZ value which is a comma-delimited string of interface names to which the compoonent can bind at its top edge.

- **Lower Range**. A REG-SZ value which is a comma-delimited string of interface names to which the component can bind at its lower edge.

# UpperRange

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Control\Class\{4D36E972-E325-11CE-BFC1-08002bE10318}*Device-number (000n)*\Ndi\Interfaces

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *List of interfaces* | (None) |

**Description**
Specifies the interfaces to which the driver can bind at the upper edge. An upper interface is a higher-level (farther from hardware) component with which the driver communicates.

### Note

- Windows Server 2003 does not include NetRules subkeys. In Windows NT 4.0 and earlier, the NetRules subkeys contained entries that specified bind rules for network software components. Some bind specifications are stored in the Ndi subkeys that contain configuration data for network driver installers. However, these are primary upper bind and lower bind settings only.

# CrashControl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CrashControl**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Crash Control subkey stores entries that specify what happens when the system locks, fails, or terminates abnormally.

**Change Method**
To change the values of entries in this subkey, use System in Control Panel. Right-click **My Computer**, click **Properties**, click the **Advanced** tab, and then click **Startup and Recovery**.

# AutoReboot

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AutoReboot**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the system restarts automatically after it fails or locks.

This entry stores the setting of the **Automatically reboot** check box in System in Control Panel.

| Value | Meaning |
|---|---|
| 0 | Do not restart automatically. |
| 1 | Restart automatically. |

**Change Method**
To change the value of this entry, use the System in Control Panel. Click the **Advanced** tab, then click the **Startup and Recovery** button. When the **Automatically reboot** box is selected, the value of this entry is 1.

**Activation Method**
To make changes to this value effective, you must restart Windows Server 2003.

### Note

- To change the value of this entry, you must be an administrator of the computer.

# CrashDumpEnabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CrashDumpEnabled**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 3 | 3 |

**Description**
Specifies whether Windows Server 2003 writes the contents of the system memory to a log file when the system stops unexpectedly. The contents of this log file can be useful in determining why the system stopped.

This entry stores the setting of the **Write debugging information** box in System in Control Panel. The name and location of the file appear in the DumpFile entry.

| Value | Meaning |
|---|---|
| 0 | Debugging information is not written to a file. |
| 1 | Complete crash dump is written to a file. |
| 2 | Kernel memory dump is written to a file. |
| 3 | Small memory dump is written to a file. |

**Change Method**
To change the value of this entry, use the System in Control Panel. Click the **Advanced** tab, then click **Startup and Recovery**. Select one of the options from the **Write Debugging Information** box.

**Activation Method**
You must restart Windows to make changes to this entry effective.

### Note

- To change the value of this entry, you must be an administrator of the computer.

**See Also**
**Concepts**
DumpFile
Overwrite

# DumpFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DumpFile**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %SystemRoot%\MEMORY.DMP |

**Description**
Specifies the location of the recovery log file. If the system stops abnormally, and the value of the **CrashDumpEnabled** entry is either 1 or 2, then Windows Server 2003 copies the contents of system memory to the recovery log file.

If you change the value of this entry, then Windows Server 2003 does not move any existing recovery log files. Instead, the next time the system stops abnormally, it creates a recovery log file in the new location.

This entry stores the value of the **Dump File** text box in **Write debugging information** in System in Control Panel.

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Advanced** tab, then click **Startup and Recovery**. Under **Write debugging information**, in the **Dump File** text box, enter the location of the log file.

**Activation Method**
You must restart Windows to make changes to this entry effective.

### Note

- To change the value of this entry, you must be an administrator of the computer.

### Tip

- For best performance, the recovery log file should be on the system drive. This prevents the crashdump engine from copying the file from the system drive, where it is created, to another drive.

# LogEvent

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**LogEvent**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the system writes an error to the System Log in Event Viewer when Windows Server 2003 terminates abnormally.

This entry stores the setting of the **Write an event to the system log** check box in System in Control Panel.

| Value | Meaning |
|---|---|
| 0 | No events are logged when the system terminates abnormally. |
| 1 | The system writes an error message to the System Log when the system terminates abnormally. |

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Advanced** tab, then click **Startup and Recovery**. When the **Write an event to the system log** box is selected, the value of this entry is 1.

**Activation Method**
You must restart Windows to make changes to this entry effective.

### Note

- To change the value of this entry, you must be an administrator of the computer.

# MinidumpDir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MinidumpDir**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %SystemRoot%\Minidump |

**Description**
Specifies the location of the minidump recovery log file. If the system stops abnormally, and the value of the **CrashDumpEnabled** entry is 1, 2, or 3, then Windows Server 2003 stores the minidump recovery log file at the location specified in the value of this entry.

**Activation Method**
You must restart Windows to make changes to this entry effective.

### Note

- To change the value of this entry, you must be an administrator of the computer.

# NMICrashDump

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NMICrashDump**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the system performs standard software error processing when a hardware error causes a nonmaskable interrupt (NMI).

This entry is used only on computers with x86 architecture, such as Intel (™) processor platforms. Other systems always perform standard software error processing when hardware interrupts are detected.

By default, an NMI interrupt stops the system and displays a hardware-malfunction message. If the value of this entry is 1, then the system also performs standard software error processing. The software error processing displays a Stop (*blue screen*) message containing information about the state of the operating system and of other programs when the NMI interrupt occurred.

If the value of the CrashDumpEnabled entry is also 1, then the standard error processing routine writes the contents of system memory to a recovery log file.

| Value | Meaning |
|---|---|
| 0 | NMI interrupts do not trigger standard software error processing. Only a hardware-malfunction message is displayed. |
| 1 | NMI interrupts display a hardware-malfunction message and also trigger standard software error processing, including a Stop (*blue screen*) message. |

This entry is designed to suppress the Stop message when a hardware error causes the system to stop. The text display associated with the Stop message might fill the screen and make it difficult to find the hardware malfunction message. Also, some processors cannot process the high volume of error messages associated with an NMI interrupt and a Stop message without error. For more information, see the Microsoft Knowledge Base link on the Web Resources page. Search the Knowledge Base for Article Q174830.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to this value effective, you must restart Windows.

### Note

- To change the value of this entry, you must be an administrator of the computer.

**Concepts**
CrashDumpEnabled

# Overwrite

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Overwrite**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the system writes over the old recovery file or creates a new recovery file each time the system stops abnormally.

When the system stops abnormally and the value of CrashDumpEnabled is either 1 or 2, Windows Server 2003 copies the contents of system memory to the recovery log file. The data in this file can help determine the cause of the failure. Note that minidumps are never overwritten, so this entry affects only Full and Kernel dumps.

This entry stores the setting of the **Overwrite any existing file** check box in System in Control Panel.

| Value | Meaning |
|---|---|
| 0 | The system creates a new recovery file for each abnormal stop. This value preserves a record of previous abnormal stops to aid your investigation into the cause of the stops. |
| 1 | The system overwrites the existing recovery file. This value prevents the system from accumulating unused recovery files. |

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Advanced** tab, then click the **Startup and Recovery** button. When the **Overwrite any existing file** check box is selected, the value of this entry is 1.

**Activation Method**
To make changes to this value effective, you must restart Windows Server 2003.

### Note

- To change the value of this entry, you must be an administrator of the computer.

**See Also**
**Concepts**

DumpFile

# SendAlert

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SendAlert**
HKLM\SYSTEM\CurrentControlSet\Control\CrashControl

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the system alerts administrators of the computer when the system stops unexpectedly.

This entry stores the value of the **Send an administrative alert** check box in System in Control Panel.

| Value | Meaning |
|---|---|
| 0 | The system does not alert administrators when the system stops. |
| 1 | The system alerts administrators when the system stops. |

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Advanced** tab, then click the **Startup and Recovery** button. When the **Send an administrative alert** check box is selected, the value of this entry is 1.

**Activation Method**
To make changes to this value effective, you must restart Windows Server 2003.

### Note

- To change the value of this entry, you must be an administrator of the computer.

# CriticalDeviceDatabase

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CriticalDeviceDatabase**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The CriticalDeviceDatabase subkey stores the critical device database. This database stores configuration data for new devices that must be installed and started before the Windows Server 2003 components that normally install devices are started.

# FileSystem

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**FileSystem**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The FileSystem subkey stores entries for file systems that Windows supports.

# NtfsAllowExtendedCharacterIn8dot3Name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NtfsAllowExtendedCharacterIn8dot3Name**
HKLM\SYSTEM\CurrentControlSet\Control\FileSystem

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the characters from the extended character set, including diacritic characters, can be used in short file names using the 8.3 naming convention on NTFS volumes.

| Value | Meaning |
|---|---|
| 0 | On NTFS volumes, file names using the 8.3 naming convention are limited to the standard ASCII character set (minus any reserved values). |
| 1 | On NTFS volumes, file names using the 8.3 naming convention may use extended characters. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# NtfsDisable8dot3NameCreation

Updated: November 6, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

**NtfsDisable8dot3NameCreation**
HKLM\SYSTEM\CurrentControlSet\Control\FileSystem

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 3 | 2 |

**Description**
Specifies whether NTFS generates a short name in the 8.3 naming convention for long file names and for file names that contain characters from the extended character set. If the value of this entry is 0, then files can have two names: the name that the user specifies and the short name that NTFS generates. If the name that the user specifies conforms to the 8.3 naming convention, then NTFS does not generate a short name.

Changing this value does not change the file, but it does change the way that NTFS displays and manages the file. Also, files are named according to whatever rule is specified by this entry at the time of their creation; changing this entry does not alter the names of existing files.

| Value | Meaning |
|---|---|
| 0 | NTFS creates short file names. This setting enables applications that cannot process long file names and computers that use differentcode pages to find the files. |
| 1 | NTFS does not create short file names. Although this setting increases file performance, applications that cannot process long file names, and computers that use different code pages, might not be able to find the files. |
| 2 | NTFS sets the 8.3 naming convention creation on a per volume basis. |
| 3 | NTFS disables 8dot3 name creation on all volumes except the system volume. |

**Modifying the 8.3 naming convention settings on your system**
To disable/enable 8.3 naming convention, users can issue the set command as follows:

```
C:\Windows\system32>fsutil 8dot3name set /?
usage : set [0 through 3] | [<Volume Path> 1 | 0]
```

When a volume is specified the operation updates the on disk flag.

| Note |
|---|
| This operation is only meaningful if the registry value is set to 2. |

**Sample commands**
The following command disables 8dot3 name creation on all volumes:

```
fsutil 8dot3name set 1
```

The following command disables 8dot3 name creation on the C drive:

```
fsutil 8dot3name set C: 1
```

**Activation Method**
If you are using Windows Server 2003 or Windows Server 2003 R2, you must restart Windows to make changes to this entry

effective. If you are using Windows Server 2008 or Windows Server 2008 R2, then you do not have to restart Windows to make the changes to this entry effective.

# NtfsDisableLastAccessUpdate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NtfsDisableLastAccessUpdate**
HKLM\SYSTEM\CurrentControlSet\Control\FileSystem

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether NTFS updates the last-accessed timestamp of a file when that file is opened.

Because updating the last-accessed timestamp requires writing data to the disk, an activity that accesses many files might be faster if this type of update is disabled. However, some applications may require that files have an accurate last-accessed timestamp.

| Value | Meaning |
|---|---|
| 0 | NTFS updates the last-accessed timestamp of a file whenever that file is opened. |
| 1 | NTFS does not update the last-access timestamp of a file when that file is opened. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# NtfsEncryptionService

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NtfsEncryptionService**
HKLM\SYSTEM\CurrentControlSet\Control\FileSystem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Efs | Efs |

**Description**
Windows Server 2003 does not use this entry. It was used in Windows 2000 to specify which encryption service the NTFS file system used. Encrypting File System (EFS) is the encryption service built into Windows Server 2003.

# Win95TruncatedExtensions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Win95TruncatedExtensions**
HKLM\SYSTEM\CurrentControlSet\Control\FileSystem

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether NTFS and FAT generate file names for new files with the 8.3 naming convention.

Setting the value of this entry to 1 does not change any existing file name extensions, nor does it change the way these extensions are displayed or managed by Find, File Manager, or Windows Explorer. However, it causes NTFS and FAT to generate short names for new files, and to truncate the third character of file name extensions.

The following table shows how "filename.html" would be truncated:

| Value | Short name generated |
|---|---|
| 0 | filena~1.ht~ |
| 1 | filena~1.htm |

The following table provides an example of how this entry changes the file system's response to commands entered in a command prompt window.

| Value | Command: del *.htm | Command: del *.html |
|---|---|---|
| 0 | Deletes only files with extension .htm. | Deletes only files with extension .html. |
| 1 | Deletes files with extensions beginning with .htm, including *.htm and *.html but not *.ht~. | Deletes only files with extension .html. |

**Activation Method**
You must restart the computer for changes to this entry to take effect.

# GraphicsDrivers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**GraphicsDrivers**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# DCI

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DCI**
HKLM\SYSTEM\CurrentControlSet\Control\GraphicsDrivers

**Description**
Stores configuration data for graphics drivers, including those implementing DirectDraw for Windows Server 2003.

# Timeout Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Timeout**
HKLM\SYSTEM\CurrentControlSet\Control\GraphicsDrivers\DCI

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Seconds* | 7 |

**Description**
Specifies how long a DirectDraw application can keep a graphics-device frame-buffer locked while a dynamic-mode or security-desktop change is pending.

When the time specified in the value of this entry expires, the system requires the DirectDraw application to release the frame buffer. Requiring the release prevents the DirectDraw application from locking and thus not releasing its resources. However, requiring the release might cause an access violation error.

| Value | Meaning |
|---|---|
| 0 | DirectDraw acceleration is disabled and direct frame-buffer access is not permitted. However, DirectDraw continues to run in emulation mode. |
| *Seconds* | The number of seconds the system waits before requiring a DirectDraw application to release a frame buffer. |

**Activation Method**
Changes made to this entry take effect when you change video modes with **Display Properties** and when you restart the computer.

# GroupOrderList

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**GroupOrderList**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
This subkey stores the order in which services in a service group are loaded when the system starts.

Services in a service group are assigned a tag. A *tag* is a numeric value that is unique within a service group. When the system loads a service group, it loads the services in the order in which their tags appear in the **GroupOrderList** entry for that service group.

Each entry in the GroupOrderList subkey represents a service group. The value of the entry contains the number of tags, followed by a series of tags in a specified order. All entries have the same format:

| | | |
|---|---|---|
| *Service group name* | REG_BINARY | *Number of tags Tag [Tag ...]* |

For example,

| | | |
|---|---|---|
| PointerPort | REG_BINARY | 03000000020000000100000003000000 |

The value in this example determines the order in which the three services in the PointerPort service group are loaded. The first significant digit (3) indicates that the value of the entry contains three tags. The remaining significant digits (2, 1, and 3) indicate that the service assigned tag 2 will load first in that group, followed by the service assigned tag 1, and then the service assigned tag 3.

**Tip**

- To find the services in any service group, use the registry editor Regedit.exe to open HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services. On the **Edit** menu, click **Find**, type the name of the service group, and select only the **Data** check box. Press F3 to find other services in the service group.

- To find the service group and tag number of any service, open the subkey representing the service in \CurrentControlSet\Services. Click **Group** to find its service group, and click **Tag** to find its tag number.

# hivelist

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**hivelist**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The hivelist subkey contains the locations of files that store the permanent keys of the registry. Permanent keys are not recreated each time the system starts. By default, the files for all permanent keys except those in HKEY_CURRENT_USER are in *Systemroot*\System32\Config. The HKEY_CURRENT_USER files are stored in the subdirectories of *System-drive*\Documents and Settings.

# \REGISTRY\MACHINE\SYSTEM

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**\REGISTRY\MACHINE\SYSTEM**
HKLM\SYSTEM\CurrentControlSet\Control\hivelist

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Path | \Device\Harddisk 0\Partition1\WINNT\System32\Config\System |

**Description**
Specifies the location of the files that store the HKEY_LOCAL_MACHINE\SYSTEM key.

# \REGISTRY\MACHINE\HARDWARE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**\REGISTRY\MACHINE\HARDWARE**
HKLM\SYSTEM\CurrentControlSet\Control\hivelist

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Path | (None) |

**Description**
This entry has no value because the HKEY_LOCAL_MACHINE\Hardware key is recreated each time the system starts. The contents of this entry are not saved in a file.

# \REGISTRY\MACHINE\SAM

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**\REGISTRY\MACHINE\SAM**
HKLM\SYSTEM\CurrentControlSet\Control\hivelist

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Path | \Device\Harddisk 0\Partition1\WINNT\System32\Config\SAM |

**Description**
Specifies the location of files that store the HKEY_LOCAL_MACHINE\SAM key.

# \REGISTRY\MACHINE\SECURITY

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**\REGISTRY\MACHINE\SECURITY**
HKLM\SYSTEM\CurrentControlSet\Control\hivelist

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Path | \Device\Harddisk 0\Partition1\WINNT\System32\Config\SECURITY |

**Description**
Specifies the location of the files that store the HKEY_LOCAL_MACHINE\Security key.

# \REGISTRY\MACHINE\SOFTWARE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**\REGISTRY\MACHINE\SOFTWARE**
HKLM\SYSTEM\CurrentControlSet\Control\hivelist

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Path | \Device\Harddisk 0\Partition1\WINNT\System32\Config\Software |

**Description**
Specifies the location of the files that store the HKEY_LOCAL_MACHINE\SOFTWARE key.

# \REGISTRY\USER\.DEFAULT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**\REGISTRY\USER\.DEFAULT**
HKLM\SYSTEM\CurrentControlSet\Control\hivelist

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Path | Device\Harddisk 0\Partition1\WINNT\System32\Config\Default |

**Description**
Specifies the location of the files that store the HKEY_USERS\.DEFAULT key.

# \REGISTRY\USER\Security ID number

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**\REGISTRY\USER\ Security ID number**
HKLM\SYSTEM\CurrentControlSet\Control\hivelist

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Path | \Device\Harddisk #\Documents and Settings*Username*\NTUSER.DAT |

**Description**
Specifies the location of the files that store the current user profile.

### Note

- The \REGISTRY\USER*Security ID number* entry is a variable representing the entries in the hivelist subkey. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the hivelist subkey.

# IDConfigDB

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IDConfigDB**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The IDConfigDB subkey stores configuration data that identifies the current hardware configuration of the system.

# CurrentConfig

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CurrentConfig**
HKLM\SYSTEM\CurrentControlSet\Control\IDConfigDB

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 1 |

**Description**
Identifies the hardware profile currently in use on the computer.

The value of this entry corresponds to the number of one of the *Profile-number* subkeys in the CurrentControlSet\Hardware Profiles subkey of HKEY_LOCAL_MACHINE. (HKLM\System\CurrentControlSet\Hardware Profiles). It indicates the *Profile-number* subkey that stores the values that make up the current profile. The content of the indicated subkey also appears in the Hardware Profiles\Current subkey in Hardware Profiles.

This value also corresponds to the number of one of the *Profile-number* subkeys in the Hardware Profiles subkey of IDConfigDB (HKLM\System\CurrentControlSet\Control\IDConfigDB\Hardware Profiles). This subkey stores information about the hardware profiles configured for use on the computer, including FriendlyName, which stores the name of the profile used in System in Control Panel.

# Hardware Profiles Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware Profiles**
HKLM\SYSTEM\CurrentControlSet\Control\IDConfigDB

**Description**
The Hardware Profiles subkey stores information about the hardware profiles configured on the system.

A *hardware profile* consists of specified changes to the original hardware profile configured in the HKLM\SOFTWARE and SYSTEM keys of HKEY_LOCAL_MACHINE. These changes are stored in the CurrentControlSet\Hardware Profiles subkey in HKEY_LOCAL_MACHINE.

The Hardware Profiles subkey in the IDConfigDB subkey stores information about the profile, but not the profile itself.

You can use System in Control Panel to create a hardware profile. Also, the system creates new hardware profiles automatically when it encounters configurations that require new profiles, such as when a portable computer is undocked or is moved from one docking station to another.

**Tip**

- To create a hardware profile, double-click System in Control Panel, click the **Hardware** tab, and then click the **Hardware Profiles** button.

# Profile-number

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Profile-number**
HKLM\SYSTEM\CurrentControlSet\Control\IDConfigDB\Hardware Profiles

**Description**
A *Profile-number* subkey stores information about a particular hardware profile on the system.

The data stored in this subkey is specific to the hardware profile.

### Notes

- The *Profile-number* subkey is a variable representing the numbered subkeys in the IDConfigDB\Hardware Profiles subkey. It does not actually appear in the registry. This subkey describes features common to all numbered Hardware Profiles subkeys in the registry.

- This subkey stores information about the hardware profile, but it does not store the hardware profile. The changes that comprise the actual hardware profile are stored in a *Profile-number* subkey in HKLM\System\CurrentControlSet\Hardware Profiles.

### Tip

- To determine which numbered subkey in Hardware Profiles represents the current hardware profile, see the CurrentConfig entry. Its value corresponds to the number of the subkey that contains the current hardware profile.

**See Also**
**Concepts**
CurrentConfig

# Profile-number\FriendlyName Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**FriendlyName**
HKLM\SYSTEM\CurrentControlSet\Control\IDConfigDB\Hardware Profiles*Profile-number*

**Description**
Stores the commonly used name for the hardware profile. This name is used to identify the hardware profile in System in Control Panel and in Device Manager.

**Tip**

- To determine which numbered subkey in Hardware Profiles represents the current hardware profile, see the CurrentConfig entry in HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\IDConfigDB. Its value corresponds to the number of the subkey that contains the current hardware profile.

# Lsa

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Lsa**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Lsa subkey stores configuration data for the Local Security Authority (LSA).

**Tip**

- For more information about Windows Server 2003 security, see the *Windows Server 2003 Technical Reference*.

# Bounds

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Bounds**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | 0x0–0x00 00 0A 00 00 00 0A 00 | 0x00 30 00 00 00 20 00 00 (Upper bound = 0x3000 (12,288); lower bound = 0x2000 (8,192)) |

**Description**
Specifies thresholds for managing the length of the kernel-mode Local Security Authority (LSA) audit queue. The audit queue stores kernel-mode events destined for the Security Log in Event Viewer.

The value of this entry is an 8-byte binary field. The value of the first four bytes specifies the maximum number of items that can be held in the audit queue (the upper bound). When the number of audits exceeds this value, LSA discards all new audits until the number of audits remaining in the queue reaches the lower bound, as specified by the value of the last four bytes.

**Tip**

- The system does not notify you when the queue is nearing, has reached, or has exceeded its upper bound. To prevent the system from running when it cannot report all security events, set the value of CrashOnAuditFail to 1.

**Concepts**
CrashOnAuditFail

# CrashOnAuditFail

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CrashOnAuditFail**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 0 |

**Description**
Directs the system to halt when it cannot record new events in the Security Log in Event Viewer. This feature prevents unauthorized activities from occurring when they cannot be recorded in the Security Log.

The system also uses this entry to indicate that this feature has been triggered (a value of 2). When the value of this entry is 2, only members of the Administrators group can log on to the computer. This restricted state lets an Administrator log on to resolve the problem and to reset the value of this entry to 1.

| Value | Meaning |
|---|---|
| 0 | The feature is off. The system does not halt, even when it cannot record events in the Security Log. |
| 1 | The feature is on. The system halts when it cannot record an event in the Security Log. |
| 2 | The feature is on and has been triggered. The system halted because it could not record an auditable event in the Security Log. Only members of the Administrators group can log on. |

Typically, the system cannot record security events because the Security Log in Event Viewer is full or because the internal queue to the log has reached the maximum established by the value of Bounds.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
You must restart the computer before changes to this entry take effect.

Bounds

# everyoneincludesanonymous

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**everyoneincludesanonymous**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the local *Everyone group* of users includes anonymous users. Specifically, this entry determines whether the Local Security Authority (LSA) includes the security identifier (SID) of the Everyone group in the security token of an anonymous user.

The *Everyone group* is a generic group of users that includes all users.

| Value | Meaning |
|---|---|
| 0 | The local Everyone group does not include anonymous users. |
| 1 | The local Everyone group includes anonymous users. |

**Change Method**
To change the value of this entry, use the **Let Everyone permissions apply to anonymous users** local security setting. In **Control Panel**, click **Performance and Maintenance**, then click **Administrative Tools**, and then click **Local Security Policy**. Double-click **Local Policies**, and then click **Security Options**. Right click **Network Access: Let Everyone permissions apply to anonymous users**, and then click **Properties**. If the local security setting is **Enabled**, then the value of this entry is 0. If the local security setting is **Disabled**, then the value of this entry is 1.

### Notes

For more information about the *LSA*, see the *Security Subsystem Architecture* section of the *Active Directory Data Storage* chapter in the *Distributed Systems Guide*.

### Tip

You can mimic the LSA behavior of Windows 2000 by setting the value of this entry to 1.

# NoLMHash

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoLMHash**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether Security Accounts Manager (SAM) stores the LAN Manager (LM) hash of the user's password. The LM hash of the user's password is necessary to authenticate downlevel clients that cannot use NTLM or NTLMv2 authentication.

| Value | Meaning |
|---|---|
| 0 | SAM stores the message digest of the user's password. |
| 1 | SAM does not store the message digest of the user's password. |

# Notification Packages

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Notification Packages**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *File name*[ *file name*...] | FPNWCLNT RASSFM KDCSVC scecli |

**Description**
Specifies the dynamic-link libraries (DLLs) that are loaded or called when passwords are set or changed. To specify more than one file, list the file names one above the other by pressing ENTER between each file name.

This entry is often used to load libraries for services such as File and Print Services for NetWare.

You can use this entry to implement custom DLLs that specify alternate criteria for valid passwords, such as complex password rules. Notification packages that implement password verification are recommended for all primary and backup domain controllers. You can also write a custom password filter to fulfill special security requirements.

**Tip**

- To audit the loading of notification packages, from the **Start** menu, point to **Programs**, point to **Administrative Tools**, and then click **Local Security Policy**. Expand **Local Policies**, and then double-click **Audit Policy**. Double-click **Audit System Events**, and then use the **Success** and **Failure** check boxes.

# RestrictAnonymous

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RestrictAnonymous**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 0 |

**Description**
Restricts anonymous users from displaying lists of users and from viewing security permissions.

| Value | Meaning |
|---|---|
| 0 | Disabled. Anonymous users are not restricted. |
| 1 | Enabled. Users who log on anonymously (also known as *null session connections*) cannot display lists of domain user names, nor share names. Also, these users cannot view security permissions, and they cannot use all of the features of Windows Explorer, Local Users and Groups, and other programs that enumerate users or shares. |
| 2 | Anonymous users have no access without explicit anonymous permissions. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Do not set the value of this entry to 2 in mixed-mode environments. Only consider setting it to 2 in environments running only Windows Server 2003, and only after verifying that appropriate service levels and program function are maintained.

### Caution

- Pre-defined "High Secure" security templates set the value of this entry to 2. Use caution when using these templates.

# Kerberos

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Kerberos**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

**Description**
The Kerberos subkey stores configuration data for the Kerberos V5 authentication protocol in Windows Server 2003. The Kerberos V5 protocol is the primary security protocol for authentication within a domain. It verifies the identity of the user and the system.

# KerberosDomains

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domains**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos

**Description**
The Domains subkey stores information about non-Windows Kerberos realms.

**Change Method**
To change the value of the entries in this subkey, use Kerberos Setup (Ksetup.exe), a tool included in Windows Support Tools. Do not use the registry editor Regedit.exe.

# Realm-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Realm-name**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Domains

**Description**
The *Realm-name* subkey stores configuration data for a non-Windows-based Kerberos realm. Non-Windows Kerberos servers use realms instead of Windows domains.

Kerberos Setup (Ksetup.exe), a tool included with the Windows Server 2003 Support Tools, adds this subkey to the registry when you use it to create a Kerberos realm. The Kerberos Security Provider in Windows Server 2003 uses the data in the subkey to locate a non-Windows Kerberos Key Distribution Center and to interoperate with the Kerberos realm.

This subkey bears the name you assign to the realm when you use the **/SetRealm** command in Ksetup.exe.

**Change Method**
To add, delete, or change the configuration of a Kerberos realm, use Ksetup.exe.

### Note

- The *Realm-name* subkey does not actually appear in the registry. It is a placeholder used to describe the elements common to realm-specific subkeys in the Domains subkey.

### Caution

If you use a domain's realm name in this configuration, the workstation treats the domain simply as a Kerberos realm.

# KdcNames

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**KdcNames**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Domains*Realm-name*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Space-separated list of the DNS names of KDC servers* | (None. You must specify at least one KDC server when you create a realm.) |

**Description**
Stores the Domain Name System (DNS) names of computers that are running the Key Distribution Center (KDC) service for an Kerberos realm.

This entry stores the values that you enter when you use the **/AddKdc** command in Kerberos Setup (Ksetup.exe), a tool included in Windows Server 2003 Support Tools.

Computers that are running Windows Server 2003 can use a non-Windows Kerberos server to administer authentication, instead of using a Windows Server 2003 domain. These systems participate in an Kerberos realm instead of a Windows domain, and the DNS names for the KDC servers are stored in this entry in the registry, instead of on a domain controller.

**Change Method**
To change the value of this entry, use Ksetup.exe. Do not edit the registry.

### Note

- If this entry is absent from the *Realm-name* subkey, then the computer uses a DNS query (for SRV records) to locate the KDC for the realm.

# KpasswdNames

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**KpasswdNames**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Domains*Realm-name*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *List of computer names* | (None. You must specify at least one password server when you create a realm.) |

**Description**
Lists the computer names of Kerberos Change Password Protocol Servers for the Kerberos realm. These servers communicate on port 464.

This entry stores the values that you enter when you use the **/AddKpasswd** command in Kerberos Setup (Ksetup.exe), a tool included in Windows Server 2003 Support Tools.

Computers running Windows Server 2003 can use a non-Windows Kerberos server to administer authentication, instead of using a Windows Server 2003 domain. These systems participate in a Kerberos realm instead of a Windows domain, and the names of the Key Distribution Center (KDC) password servers are stored in this entry in the registry, instead of on a domain controller.

**Change Method**
To change the value of this entry, use Ksetup.exe. Do not edit the registry.

### Caution

- If this entry is absent from the *Realm-name* subkey, then the computer attempts to locate the Kerberos Change Password Protocol Servers by using a DNS query for SRV records for the realm. If no servers can be located, then users are not be able to change their passwords in the realm.

# RealmFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RealmFlags**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Domains*Realm-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–7 | 0 |

**Description**
Specifies additional features of a non-Windows-based Kerberos realm.

Computers that are running Windows Server 2003 can use a non-Windows Kerberos server to administer authentication, instead of using a Windows Server 2003 domain. These systems participate in a Kerberos realm instead of a Windows domain. This entry establishes the features of the realm.

To enable a feature, set the bit representing the feature to 1, or sum the decimal or hexadecimal values representing each feature. For example, to enable all features, set the value of this entry to 7 (1 + 2 + 4).

| Value | Flag | Meaning |
|---|---|---|
| 0 | None | No additional features enabled. |
| 1 | SendAddress | Include IP numbers within tickets. Useful for solving some compatibility issues. |
| 2 | TcpSupported | Realm supports TCP rather than just UDP. |
| 4 | Delegate | Everyone in this realm is trusted for delegation. |
| 8 | NcSupported | Realm supports name canonicalization. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Kerberos\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Parameters**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos

**Description**
The Parameters subkey stores configuration options for the Kerberos V5 authentication protocol in Windows Server 2003.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# UserList

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**UserList**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos

**Description**
The UserList subkey stores entries that associate a Kerberos security principal to a local Windows Server 2003 user account.

Computers that are running Windows Server 2003 can use a non-Windows Kerberos Key Distribution Center to administer authentication, instead of using a Windows Server 2003 domain. For ease of use, the system lets you map a Kerberos security principal, such as the name of a principal or a realm, to a local Windows user account.

This subkey stores mappings that you enter when you use the **/MapUser** command in Kerberos Setup (Ksetup.exe), a tool included in *Windows Server 2003 Support Tools*. Ksetup.exe adds the entries to the registry.

All entries in this subkey have the following format, where * indicates all users:

| Entry name | Data type | Value |
|---|---|---|
| *Kerberos-name* or * | REG_SZ | *Local-name* or * |

For example, if you enter the following mapping command in Ksetup.exe:

```
ksetup /mapuser user@domain.reskit.com  Guest
```

then Ksetup.exe adds the following entry to the UserList subkey:

| Entry name | Data type | Value |
|---|---|---|
| user@domain.reskit.com | REG_SZ | *Guest* |

**Change Method**
To change the value of the entries in this subkey, use Ksetup.exe. Do not edit the registry.

### Caution

- Mapping a Kerberos principal to a local account grants access to your computer to anyone who knows the password to the Kerberos principal. Use of a wildcard entry should be used cautiously, especially if it can reference a local account with administrative rights.

# MSV1_0

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MSV1_0**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa

**Description**
The MSV1_0 subkey stores information about the computer's security settings.

# NtlmMinClientSec

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NtlmMinClientSec**
HKLM\SYSTEM\CurrentControlSet\Control\Lsa\MSV1_0

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x10 \| 0x20 \| 0x80000 \| 0x20000000 | 0x0 |

**Description**
Specifies the minimum required security setting of client-side network connections for applications using the NTLM security support provider (SSP).

| Value | Meaning |
|---|---|
| 0x0 | None. No security is used for authentication or session security. |
| 0x10 | Message integrity. If the value of either this entry or the NtlmMinServerSec entry is 0x10, then the connection will fail unless message integrity is negotiated. |
| 0x20 | Message confidentiality. If the value of either this entry or the **NtlmMinServerSec** entry is 0x20, then the connection will fail unless message confidentiality is negotiated. |
| 0x80000 | NTLMv2 session security. If the value of either this entry or the **NtlmMinServerSec** entry is 0x80000, then the connection will fail unless NTLMv2 session security is negotiated. |
| 0x20000000 | 128-bit encryption. If the value of either this entry or the **NtlmMinServerSec** entry is 0x20000000, then the connection will fail unless 128-bit encryption is negotiated. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must restart Windows to make changes to this entry effective.

### Note

- These settings do not guarantee that an application uses message integrity or confidentiality, even if they are negotiated. For more information, see *Article Q147706* in the Microsoft Knowledge Base, or search by using the keywords *LM authentication*.

# Control\Network Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Network subkey stores configuration data for networking components and connections.

# DUPTILE1_NetworkProvider

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NetworkProvider**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The NetworkProvider subkey contains information about the available network providers.

**See Also**
**Concepts**
service-name\networkprovider

# NetworkProvider\Order

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Order**
HKLM\SYSTEM\CurrentControlSet\Control\NetworkProvider

**Description**
The Order subkey contains a list of the network providers that use the Microsoft network-independent APIs.

**See Also**
**Concepts**
service-name\networkprovider

# ProviderOrder

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ProviderOrder**
HKLM\SYSTEM\CurrentControlSet\Control\NetworkProvider\Order

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Provider name*[, *Provider name*, ...] | LanmanWorkstation (when a single network is installed) |

**Description**
Contains a list of the available network providers in the order in which they are accessed.

To appear in this list, a network provider must be represented by a subkey in HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services. It must be a member of the NetworkProvider service group, and it must have a service-name\networkprovider subkey in its Services subkey. The NetworkProvider subkey stores information for the Multiple Provider Router. The service group for each service is stored in the value of the Group entry.

**Change Method**
To change the value of this entry, double-click Network in Control Panel. From the **Advanced** menu, choose **Advanced Settings** and click the **Provider Order** tab. Click on a provider and use the up and down arrows to change the order.

**Tip**

- To find all the services configured to run in the NetworkProvider service group, SC, a tool included in Windows Server 2003, and type:

```
sc queryex group= networkprovider state= all
```

**See Also**
**Concepts**

service-name\networkprovider

# Nls

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Nls**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Nls subkey stores data for the National Language Support (NLS) interface. This subkey contains information about supported locales and code pages.

The CodePage and Language subkeys of the Nls subkey associate code page and locale identification codes with the translation files required to use them.

**See Also**
**Concepts**
CodePage
Language

# CodePage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CodePage**
HKLM\SYSTEM\CurrentControlSet\Control\NIs

**Description**
Contains data that associates code page IDs with code page translation files installed on the system.

Each entry in the CodePage subkey represents one supported code page. If the code page is installed on the system, then the value of the entry is the name of the code page file. If the code page is supported but not installed, then the value of the entry is blank.

# code-page

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**code-page**
HKLM\SYSTEM\CurrentControlSet\Control\Nls\CodePage

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *NLS filename* | (*Depends on locale and language group installed.*) |

**Description**
Represents a code page.

Each entry in the CodePage subkey represents one supported code page. If the code page is installed on the system, then the value of the entry is the name of the code page file. If the code page is supported but not installed, then the value of the entry is blank.

Entries in the CodePage subkey have the following format:

| Entry name | Data type | Value |
|---|---|---|
| # *CodePageID* | REG_SZ | *Filename* \| (blank) |

For example, the following entry indicates that code page 10000 is installed on the system and is associated with code page file C_10000.nls:

| Entry name | Data type | Value |
|---|---|---|
| 10000 | REG_SZ | c_10000.nls |

As another example, the following entry indicates that code page 10006 is supported but is not installed on the system:

| Entry name | Data type | Value |
|---|---|---|
| 10006 | REG_SZ | |

**Note**

- The *code-page* entry is a variable representing the entries in the CodePage subkey. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the CodePage subkey.

# ACP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ACP**
HKLM\SYSTEM\CurrentControlSet\Control\NIs\CodePage

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *code page* | 1252 (*U.S. English*) |

**Description**
Indicates the default code page for non-Unicode Windows characters. These code pages are supported for compatibility with non-Unicode programs. For U.S. English, the value of this entry indicates that code page 1252 and its file, C_1252.nls, are used for non-Unicode Windows characters.

| Value | Character set |
|---|---|
| 874 | Thai |
| 932 | ShiftJIS—Japan |
| 936 | GBK—Chinese (China, Singapore) |
| 949 | Korean Unified Hangul |
| 950 | Big5 Extended—Chinese (Taiwan, Hong Kong SAR) |
| 1250 | Central European |
| 1251 | Cyrillic |
| 1252 | U.S. (ANSI) |
| 1253 | Greek |
| 1254 | Turkish |
| 1255 | Hebrew |
| 1256 | Arabic |
| 1257 | Baltic |
| 1258 | Vietnamese |

**Caution**

- Changing the value of this entry could prevent the computer from properly displaying characters in non-Unicode programs, and could also result in data loss.

# MACCP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MACCP**
HKLM\SYSTEM\CurrentControlSet\Control\NIs\CodePage

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *code page* | 10000 (*U.S. English*) |

**Description**
Indicates the default code page for characters in non-Unicode Macintosh programs. For U.S. English, the value of this entry indicates that code page 10000 and its file, C_10000.nls, are used for non-Unicode Macintosh programs.

| Value | Character set |
|---|---|
| 10000 | Roman |
| 10001 | Japanese |
| 10002 | Chinese (Big5) |
| 10003 | Korean |
| 10004 | Arabic |
| 10005 | Hebrew |
| 10006 | Greek I |
| 10007 | Cyrillic |
| 10010 | Romanian |
| 10017 | Ukrainian |
| 10029 | Latin 2 |
| 10079 | Icelandic |
| 10081 | Turkish |
| 10082 | Croatian |

**Caution**

- Changing the value of this entry could prevent the computer from properly displaying characters in non-Unicode programs, and could also result in data loss.

# OEMCP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**OEMCP**
HKLM\SYSTEM\CurrentControlSet\Control\NIs\CodePage

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *code page* | 437 (*U.S. English*) |

**Description**
Indicates the default code page for OEM (original equipment manufacturers) characters, used primarily in DOS programs. For U.S. English, the value of this entry indicates that code page 437 and its file, C_437.nls, are used for OEM characters.

| Value | Character set |
|---|---|
| 437 | United States |
| 708 | Arabic (ASMO 708) |
| 720 | Arabic (Transparent ASMO) |
| 737 | Greek (formerly 437G) |
| 775 | Baltic |
| 850 | Multilingual (Latin I) |

**Caution**

- Changing the value of this entry could prevent the computer from properly displaying characters in non-Unicode programs, and could also result in data loss.

# Language

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Language**
HKLM\SYSTEM\CurrentControlSet\Control\NIs

**Description**
Contains data that associates locale IDs with internal supporting files installed on the system.

Each entry in the Language subkey represents one locale. If the locale is installed on the system, then the value of the entry is the name of its internal supporting file. If the locale is supported but not installed, then there is no value for the entry.

# language-ID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**language-ID**
HKLM\SYSTEM\CurrentControlSet\Control\Nls\Language

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *.nls filename* | (*Depends on locale and language group installed.*) |

**Description**
Stores the filename of the *casing table* for a particular locale.

A *casing table* specifies the use of upper and lower case letters for a particular language. For example, the character "a" uppercases to the character "A".

Each entry in the Language subkey represents one locale supported by Windows Server 2003. If the language group for that particular locale is installed on the system, then the casing table is also installed and the value of this entry is the name of the file that contains the casing table. The filename extension is .nls. If the language group is supported but not installed, then there is no value for the entry.

Each entry has the following format:

| Entry name | Data type | Value |
|---|---|---|
| # *LanguageID* | REG_SZ | *Filename.nls* \| (no value) |

For example, the following entry indicates that the language group for the locale 0402 is installed on the system and, therefore, the casing file L_intl.nls is also installed for locale 0402:

| Entry name | Data type | Value |
|---|---|---|
| 0402 | REG_SZ | l_intl.nls |

As another example, the following entry indicates that the language group for the locale 0403 is supported by Windows Server 2003, but is not installed on the computer, and no casing file is therefore supported for this locale:

| Entry name | Data type | Value |
|---|---|---|
| 0403 | REG_SZ | |

**Note**

- The *language-ID* entry is a variable representing the entries in the Language subkey. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the Language subkey.

# Language Groups

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Language Groups**
HKLM\SYSTEM\CurrentControlSet\Control\Nls

**Description**
The Language Groups subkey contains information about the supported and installed language groups.

Each of the entries in this subkey represents a language group that is supported by Windows Server 2003.

| ***group-number*** | **Language Group** |
|---|---|
| 1 | Western Europe |
| 2 | Central Europe |
| 3 | Baltic |
| 4 | Greek |
| 5 | Cyrillic |
| 6 | Turkish |
| 7 | Japanese |
| 8 | Korean |
| 9 | Traditional Chinese |
| a | Simplified Chinese |
| b | Thai |
| c | Hebrew |
| d | Arabic |
| e | Vietnamese |
| f | Indic |
| 10 | Georgian |
| 11 | Armenian |

# group-number

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**group-number**
HKLM\SYSTEM\CurrentControlSet\Control\Nls\Language Groups

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | (Blank) \| 1 | (None) |

**Description**
Indicates which language groups are installed.

| Value | Meaning |
|---|---|
| (Blank) | The language group is supported but not installed. |
| 1 | The language group is installed. |

### Note

- This entry is a placeholder representing the type of entries in the Language Groups subkey; "group-number" does not actually appear in the registry.

# Nls\Locale

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Locale**
HKLM\SYSTEM\CurrentControlSet\Control\Nls

**Description**
The entries in this subkey list the locales that are installed on the system.

# Alternate Sorts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Alternate Sorts**
HKLM\SYSTEM\CurrentControlSet\Control\Nls\Locale

**Description**
The Alternate Sorts subkey contains data about the alternate sorts available for the installed locale. These sorting codes determine which sorting order is used for those locales that have more than one sorting order.

**Change Method**
For some locales, Windows provides multiple sorting methods. When a computer is configured for a locale with multiple sorting methods, you can change the sorting method from **Regional and Language Options**.

In **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. If the currently configured locale has multiple sorting methods, then Windows displays a **Sorting** tab. Click the **Sorting** tab, and then select a method from the **Select the sorting method to use with this language** list. Click **OK**.

# Control\Print

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Print**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Print subkey stores printer information and settings that apply to all users of the computer.

### Note

- For more information about printing with Windows Server 2003, see *Administering Microsoft Windows XP Professional*.

# BrowsePrintWorkstations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**BrowsePrintWorkstations**
HKLM\SYSTEM\CurrentControlSet\Control\Print

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0xFFFFFFFF | 2 |

**Description**
Used to calculate the number of clients in whose browse list the printer appears.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make the value of this entry effective, you must restart the Print Spooler service.

# EnableBroadcastSpoolerStatus

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**EnableBroadcastSpoolerStatus**
HKLM\SYSTEM\CurrentControlSet\Control\Print

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the system sends spooler and job status messages when the job count changes.

| Value | Meaning |
|---|---|
| 0 | Status messages are not sent. |
| 1 | Status messages are sent. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- A value of 1 can degrade the performance of your system by requiring programs that don't use spooler information to read and discard it.

# MaxRpcSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MaxRpcSize**
HKLM\SYSTEM\CurrentControlSet\Control\Print

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (in bytes) | 1048576 (1 MB) |

**Description**
Specifies the maximum size, in bytes, of incoming data blocks from a remote procedure call (RPC).

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to the value of this entry effective, you must restart the Print Spooler service.

### Caution

- This entry can help prevent malicious denial-of-service attacks. If the data block of a remote procedure call (RPC) is larger than the value of this entry, the RPC run-time library rejects the call and sends an error message to the client. However, if you set the value of this entry to 0xFFFFFFFF, the limit on the size of incoming data blocks is removed, and your system is more vulnerable to attack.

# NetPrinterDecayPeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NetPrinterDecayPeriod**
HKLM\SYSTEM\CurrentControlSet\Control\Print

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF milliseconds | 0x36EE80 (3,600,000 milliseconds = 1 hour) |

**Description**
Specifies how long a network printer remains in the browse list.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# ServerThreadTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ServerThreadTimeout**
HKLM\SYSTEM\CurrentControlSet\Control\Print

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *milliseconds* | 0x927C0 (600,000 milliseconds = 10 minutes) |

**Description**
Specifies the amount of time that the server thread is idle before it notifies other print servers of its printers.

If the value of this entry is greater than the value of NetPrinterDecayPeriod, then the printer does not appear in the printer list.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make the value of this entry effective, you must restart the Print Spooler service.

**See Also**
**Concepts**
NetPrinterDecayPeriod

# SpoolerPriority

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SpoolerPriority**
HKLM\SYSTEM\CurrentControlSet\Control\Print

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x20 \| 0x40 \| 0x80 | 0x20 |

**Description**
Specifies the priority class of the print spooler process.

The priority of the print spooler process establishes a range of priority for print spooler threads.

| Value | Meaning |
|---|---|
| 0x20 | Normal priority |
| 0x40 | Idle |
| 0x80 | High priority |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Windows environment-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows environment-name**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Environments

**Description**
The Windows *environment-name* subkey represents a platform environment, and stores entries that apply only to that environment.

### Notes

- The Windows *environment-name* subkey is a placeholder representing the types of subkeys in the Environments subkey; "environment-name" does not actually appear in the registry.

- The Windows *environment-name* subkeys contain subkeys that store configuration data for printing on different platforms on which different versions of Windows run. Each subkey representing a platform has two subkeys, Drivers and Print Processors, which store configuration data for the print drivers and processors installed on Windows.

# Drivers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Drivers**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Environments\Windows *environment-name*

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Version-number

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Version-number**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Environments\Windows *environment-name*\Drivers

**Description**
The Version-*number* subkey contains information about the drivers for a print environment. There is a different number for each version of the printer driver. Version-2 drivers are for Windows NT 4.0; Version-3 drivers are for Windows 2000 and Windows Server 2003.

### Note

- The Version-*number* subkey is a placeholder representing the subkeys in the Drivers subkey, which have a specific number in their name. "Version-*number*" does not actually appear in the registry.

# driver-name Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**driver-name**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Environments\Windows *environment-name*\Drivers\Version-*number*

**Description**
The *driver-name* subkey in the Version-*number* subkey contains information about necessary files and settings for the specified printer driver.

### Note

- The *driver-name* subkey is a placeholder representing the types of entries in the Version-*number* subkey; "driver-name" does not actually appear in the registry.

# Version

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Version**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Environments\Windows *environment-name*\Drivers\Version-*number**driver-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Version number* | (Depends on printer driver.) |

**Description**
Contains the version number of the installed print driver.

### Note

- The print spooler adds this entry to the registry when a printer driver is installed into the print subsystem.

# Monitors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitors**
HKLM\SYSTEM\CurrentControlSet\Control\Print

**Description**
The Monitors subkey stores entries for print monitors installed on Windows Server 2003. The Monitors subkey contains a subkey for each port monitor that stores configuration data for the port monitor installed on the system.

# Monitor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitor**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Monitors

**Description**
The *Monitor* subkey contains information about the status and drivers of the monitors used by the computer.

### Note

- The *Monitor* subkey is a placeholder representing the types of subkeys in the Monitors subkey; "Monitor" does not actually appear in the registry.

# Ports Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Ports**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Monitors*Monitor*

**Description**
The Ports subkey contains information about the current availability of the ports.

# StatusUpdateEnabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**StatusUpdateEnabled**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Monitors*Monitor*\Ports

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the port monitor is able to update the spooler with the port status.

| Value | Meaning |
|---|---|
| 0 | Disabled. The monitor is not able to update the spooler with the port status. |
| 1 | Enabled. The monitor is able to update the spooler with the port status. |

This entry does not appear in every *Monitors* subkey. It appears only in the Standard TCP/IP Port subkey.

**Tip**

- For pooled printers, set the value of this entry to 1, and StatusUpdateInterval to a minumum value, to allow the spooler to send print jobs to an alternate printer when one printer in the pool is offline.

**See Also**
**Concepts**
Providers\RestartJobOnPoolEnabled
RestartJobOnPoolError Entry
StatusUpdateInterval

# StatusUpdateInterval

Updated: September 2, 2014

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**StatusUpdateInterval**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Monitors*Monitor*\Ports

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *number of minutes* | 0xA (10 minutes) |

**Description**
Specifies how often the port monitor updates the spooler with port status.

This entry does not appear in every *Monitors* subkey. It appears only in the Standard TCP/IP Port subkey.

**Tip**

- For pooled printers, setting the value of StatusUpdateEnabled to 1 and **StatusUpdateInterval** to a minumum value will allow the spooler to send print jobs to an alternate printer when one printer in the pool is offline.

# Print\Providers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providers**
HKLM\SYSTEM\CurrentControlSet\Control\Print

**Description**
The Providers subkey contains information about the network printers. The printers listed in this subkey are not hosted locally, but they are printers to which the local computer is connected.

### Note

- Providers entries for LanMan Print Services are stored in the Providers Subkey subkey in the SOFTWARE key.

**See Also**
**Concepts**
Providers Subkey
server-name\Providers

# EventLog Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**EventLog**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Providers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x1F (bitmask) | Windows XP Professional: 0x1B (11011) Windows Server 2003: 0x1F (11111) |

**Description**
Specifies the level of detail of events that the print spooler logs for local print jobs.

The value of this entry is a bitmask. To direct the print spooler to log entries of the type specified, either set the bit representing that type to 1 or sum the hexadecimal values of all desired types. For example, the default value for Windows Server 2003 (11111) indicates that the print spooler logs all events. The default value for Windows XP Professional (11011) indicates that the print spooler logs all events except information.

| Value | Event type |
|---|---|
| 0x0 (0 binary) | Success |
| 0x1 (1 binary) | Error |
| 0x2 (10 binary) | Warning |
| 0x4 (100 binary) | Information |
| 0x8 (1000 binary) | Audit success |
| 0x10 (10000 binary) | Audit failure |

**Change Method**
To change the value of this entry, from the **Start** menu, point to **Settings**, and click **Printers**. From the **File** menu, click **Server Properties**, click the **Advanced** tab, and then select or clear the check boxes representing each event type.

**See Also**
**Concepts**
Providers\EventLog

# Providers\RestartJobOnPoolEnabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RestartJobOnPoolEnabled**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Providers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether a print job to a local printer can be restarted after an error.

If the value of this entry is set to 1, then a **Cancel/Retry** dialog box will appear on the user's system for the duration of the value of the RestartJobOnPoolError Entry entry.

| Value | Meaning |
|---|---|
| 0 | Print jobs cannot be restarted on error. |
| 1 | Print jobs can be restarted on error. |

### Notes

- This entry applies only to pooled printers.
- The print job cannot be restarted if it is completely sent to the printer and deleted from the print queue.

**See Also**
**Concepts**
RestartJobOnPoolEnabled Entry
RestartJobOnPoolError Entry

# RestartJobOnPoolError Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RestartJobOnPoolError**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Providers

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *number of seconds* | 0x258 (600 seconds = 10 minutes) |

**Description**
Specifies how long the print monitor waits after an error occurs before starting a print job on another port in the print pool.

### Notes

- This entry applies only to pooled printers.
- Both the print monitor and the printer must support SNMP.
- The print job cannot be restarted if it has been completely sent to the printer and deleted from the print queue.

# NetWare or Compatible Network

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NetWare or Compatible Network**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Providers

**Description**
Stores options for printing when using print resources on NetWare servers.

This subkey is used when you connect a Windows XP Professional system to a server running NetWare server software.

### Note

- This subkey is added to the registry when you install Client Service for NetWare.

**See Also**
**Concepts**
PrintOption

# DisplayName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DisplayName**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Providers\NetWare or Compatible Network

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *provider name* | NetWare or Compatible Network |

**Description**
Specifies the localized name of the print service provider displayed in the Print Manager and Printers main window.

### Note

- This entry only appears by default in the registry of a computer that has Client Services for NetWare installed.

# Name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Name**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Providers\NetWare or Compatible Network

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *file name* | nwprovau.dll |

**Description**
Specifies the dynamic-link library (DLL) for the NetWare or Compatible Print Service provider.

This DLL is stored in *Systemroot*\WINNT\system32.

### Note

- This entry only appears by default in the registry of a computer that has Client Services for NetWare installed.

# NetWare or Compatible Network\Timeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Timeout**
HKLM\SYSTEM\CurrentControlSet\Control\Print\Providers\NetWare or Compatible Network

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x2710–0xFFFFFFFE *milliseconds* \| 0xFFFFFFFF | (None) |

**Description**
Specifies how often Windows Server 2003 updates the print queue of a NetWare server. The value of this entry specifies the time interval between automatic refresh updates.

| Value | Meaning |
|---|---|
| 0x2710–0xFFFFFFFE *milliseconds* | Specifies the time between updates of the NetWare print queue. |
| 0xFFFFFFFF | Disables automatic updates. Windows Server 2003 sends new print jobs to the NetWare server, but it does not update the queue list. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# ProductOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ProductOptions**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
Stores information about the variations of Windows Server 2003 running on the computer.

**Caution**

- Do not delete this subkey or change its contents. This subkey stores protected operating system data. Editing this data violates your Windows Server 2003 licensing agreement and disqualifies you from receiving Microsoft Product Support Services. In addition, if a program tries to change the data, the system stops abnormally and displays a Stop error screen.

# ProductSuite

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ProductSuite**
HKLM\SYSTEM\CurrentControlSet\Control\ProductOptions

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Platform suite* or blank | (None) |

**Description**
Stores data that identifies a special operating system variation running on the computer. This entry lets programs identify and customize their features to the platform.

**Tip**

- To view this data, programs can use the GetVersionEx and VerifyVersionInfo application programming interfaces (APIs).

**Caution**

- Do not delete this entry or change its value. This entry stores protected operating system data. Editing this data violates your Windows Server 2003 licensing agreement and disqualifies you from receiving Microsoft Product Support Services service. If programs try to change the data, the system stops abnormally and displays a Stop error screen.

# ProductType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ProductType**
HKLM\SYSTEM\CurrentControlSet\Control\ProductOptions

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Platform identifier* | Windows XP Professional: WinNT Windows Server 2003: ServerNT or LanmanNT |

**Description**
Stores data that identifies the operating system platform running on the computer. This data lets programs identify and customize their features to the platform.

In Windows Server 2003, the following entries identify the platform options.

| Value | Meaning |
|---|---|
| WinNT | Windows XP Professional |
| ServerNT | Windows Server 2003 |
| LanmanNT | Windows Server 2003 |

**Tip**

- To view this data, programs can use the GetVersionEx and VerifyVersionInfo application programming interfaces.

**Caution**

- Do not delete this entry or change its value. This entry stores protected operating system data. Editing this data violates your Windows Server 2003 licensing agreement and disqualifies you from receiving Microsoft Product Support Services service. If a program tries to change the data, the system stops abnormally and displays a blue screen.

# SafeBoot

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SafeBoot**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The entries in the SafeBoot subkey contain information about the safe mode settings of the computer. In safe mode, Windows Server 2003 uses default settings: VGA monitor, no network, Microsoft mouse driver, and the minimum device drivers required to start Windows.

For example, if your computer does not start after you install new software, you might be able to start it in safe mode with minimal services and then either change your computer settings or remove the newly installed software.

**Change Method**
To start Windows Server 2003 in safe mode, restart the computer and press F8 when you see the message **Please select the operating system to start**.

### Caution

- Changing the values of the entries in this subkey can prevent Windows Server 2003 from starting.

# AlternateShell

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AlternateShell**
HKLM\SYSTEM\CurrentControlSet\Control\SafeBoot

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Program name* | Cmd.exe |

**Description**
Lists the name of the alternative environment used when the **Safe mode with Command Prompt** option is selected.

**Change Method**
To start Windows Server 2003 in safe mode, restart the computer, and then press F8 when you see the message **Please select the operating system to start**.

### Note

- For information about starting the computer in safe mode, see Windows Server 2003 Help or Windows XP Professional Help.

### Caution

- Changing the value of this entry can prevent Windows Server 2003 from starting.

# Minimal

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Minimal**
HKLM\SYSTEM\CurrentControlSet\Control\SafeBoot

**Description**
The Minimal subkey stores the names of basic files and drivers (mouse, keyboard, mass storage, base video, and default system services) used when the **Safe Mode** startup option is selected.

**Change Method**
To start Windows Server 2003 in safe mode, restart the computer, and then press F8 when you see the message **Please select the operating system to start**.

### Note

- For information about starting the computer in safe mode, see Windows Server 2003 Help or Windows XP Professional Help.

### Caution

- Changing the value of this entry can prevent Windows Server 2003 from starting.

# file-name or driver-name Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**file-name or driver-name**
HKLM\SYSTEM\CurrentControlSet\Control\SafeBoot\Minimal

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File name or driver name* | *File name or driver name* |

**Description**
Store the names of basic files and drivers (mouse, keyboard, mass storage, base video, and default system services) used when the **Safe Mode** startup option is selected.

**Change Method**
To start Windows Server 2003 in safe mode, restart the computer, and then press F8 when you see the message **Please select the operating system to start**.

### Note

- For information about starting the computer in safe mode, see Windows Server 2003 Help or Windows XP Professional Help.
- The ***file_name or driver_name*** subkey is a variable representing the subkeys in the HKLM\SYSTEM\CurrentControlSet\Control\SafeBoot\Minimal subkey. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the Minimal subkey.

### Caution

- Changing the value of this entry can prevent Windows Server 2003 from starting.

# Safeboot\Network Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network**
HKLM\SYSTEM\CurrentControlSet\Control\SafeBoot

**Description**
The Network subkey stores the names of basic files, drivers, and network connections (mouse, keyboard, mass storage, base video, and default system services) used when the **Safe Mode with Networking** startup option is selected.

**Change Method**
To start Windows Server 2003 in safe mode, restart the computer, and then press F8 when you see the message **Please select the operating system to start**.

### Note

- For information about starting the computer in safe mode, see Windows Server 2003 Help or Windows XP Professional Help.

### Caution

- Changing the value of this entry can prevent Windows Server 2003 from starting.

# Network\file-name or driver-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**file-name or driver-name**
HKLM\SYSTEM\CurrentControlSet\Control\SafeBoot\Network

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File name or driver name* | *File name or driver name* |

**Description**
Store the names of basic files and drivers (mouse, keyboard, mass storage, base video, and default system services) used when the **Safe Mode with Networking** startup option is selected.

**Change Method**
To start Windows Server 2003 in safe mode, restart the computer, and then press F8 when you see the message **Please select the operating system to start**.

### Note

- For information about starting the computer in safe mode, see Windows Server 2003 Help or Windows XP Professional Help.
- The *file_name or driver_name* subkey is a variable representing the subkeys in the HKLM\SYSTEM\CurrentControlSet\Control\SafeBoot\Network subkey. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the Network subkey.

### Caution

- Changing the value of this entry can prevent Windows Server 2003 from starting.

# SecurePipeServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SecurePipeServers**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The SecurePipeServers subkey contains the winreg subkey, which controls remote access to the registry. If these subkeys do not appear in the registry, then the permissions set in each registry subkey determine the remote access to the registry.

**Change Method**
To change the permissions set for the SecurePipeServers subkey, use the registry editor Regedit.exe. On the **Edit** menu, click **Permissions**.

### Note

- Remote registry security and the functions of the SecurePipeServers and winreg registry subkeys are included in Windows Server 2003 and Microsoft Windows XP Professional. However, they are only enabled by default on Windows Server 2003. If you add these subkeys to the registry of a computer running Microsoft Windows XP Professional, it will operate as described.

# winreg

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**winreg**
HKLM\SYSTEM\CurrentControlSet\Control\SecurePipeServers

**Description**
The permissions set for the winreg subkey determine who can remotely connect to a registry. If this subkey does not exist, then all users can remotely connect to the registry.

To remotely connect to a registry, a user must have at least Read Access to the winreg subkey on the target computer.

After the user is connected, the type of access that the user has to various registry keys and subkeys is determined by the permissions that have been granted to that user. Administrators have Full Control permission to winreg, and Backup Operators have read-only access to winreg.

**Change Method**
To view the permissions set for the winreg subkey, use the registry editor Regedit.exe. On the **Edit** menu, click **Permissions**.

### Note

- By default, the winreg subkey exists on both clients and servers. However, it is enabled by default only on Windows Server 2003. If you add this subkey to the registry of a computer that is running Windows XP Professional, then it will operate as described here.

# AllowedPaths

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AllowedPaths**
HKLM\SYSTEM\CurrentControlSet\Control\SecurePipeServers\winreg

**Description**
Contains a list of the registry paths that all users can access remotely, even if they do not otherwise have permission to access the winreg subkey. This subkey permits users to perform some system functions that require remote access to specific registry keys, such as checking the status of a printer, without having access to the winreg subkey.

**Change Method**
To view the permissions set for this subkey, use the registry editor Regedit.exe. On the **Edit** menu, click **Permissions**.

### Note

- The paths specified in this subkey can be accessed anonymously.

# Machine

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Machine**
HKLM\SYSTEM\CurrentControlSet\Control\SecurePipeServers\winreg\AllowedPaths

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Registry paths* | SYSTEM\CurrentControlSet\Control\ProductOptions<br>SYSTEM\CurrentControlSet\Control\Print\Printers SYSTEM\CurrentControlSet\Services\Eventlog<br>SOFTWARE\Microsoft\Windows NT\CurrentVersion |

**Description**
Lists registry paths in the HKEY_LOCAL_MACHINE subtree that all remote users can access. Remote users can access the paths listed in this subkey, and all subkeys of those paths, even if they do not otherwise have permission to access to the registry remotely.

### Note

- The paths specified can be accessed anonymously.

# ServiceGroupOrder

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ServiceGroupOrder**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The ServiceGroupOrder subkey contains a list of all service groups in the order in which the groups are loaded.

**Tip**

- To determine the service group to which a service belongs, find the value of its Group entry.
- To find all services in a service group, use the registry editor Regedit.exe. On the **Edit** menu, click **Find**, type the name of the service group, and then select only the **Data** check box.
- To specify the name of the group for a particular service, use SC, a tool included in Windows Server 2003.

**See Also**
**Concepts**
Group
GroupOrderList

# Session Manager

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Session Manager**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Session Manager subkey contains data used by many different components of the Session Manager.

# LicensedProcessors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**LicensedProcessors**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 4 |

**Description**
Indicates how many processors the system is licensed to support.

This entry is protected by the Windows licensing agreement. If you change or delete the value or any properties of this entry, the system stops abnormally and displays a STOP 0x0000009A (SYSTEM_LICENSE_VIOLATION) blue screen. The STOP code is followed by the hexadecimal parameter, 0x00000005, indicating that off-line changes were made to the number of licensed processors.

**Caution**

- Deleting or changing this value violates your Windows licensing agreement and disqualifies you from receiving Microsoft Product Support Services services.

# RegisteredProcessors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RegisteredProcessors**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 2 \| 4 | Windows Server 2003: 4 Windows XP Professional: 2 |

**Description**
This entry is for internal use only. Do not delete or change it.

# Environment Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Environment**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager

**Description**
The Environment subkey stores the values of static environment variables that the system creates. These variables are used by Winlogon and Windows Explorer in Windows NT 4.0 and later, and by Program Manager in Windows NT 3.51 and earlier.

This subkey does not store dynamic environment variables that the system creates. Also, it does not store environment variables that the user creates. User environment variables are stored in the Environment Key subkey.

**Change Method**
To change the values of entries in this subkey, in **Control Panel** double-click **System**, click the **Advanced** tab and then click **Environment Variables**. These entries appear in the **System variables** section.

### Caution

- The data type of entries in this subkey must be REG_EXPAND_SZ. If a user or application changes the data type, the system will not replace the variable with its intended value.

- Use extreme care when changing these the values of entries. If the operating system cannot find the files specified for a subsystem, you will not be able to run applications designed for other environments.

# ComSpec

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ComSpec**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | Filename | %SystemRoot%\system32\cmd.exe |

**Description**
Stores the path and file name of the Windows Server 2003 command interpreter, Cmd.exe. The command interpreter is analogous to MS-DOS Command.com.

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Advanced** tab and then click **Environment Variables**. This entry appears in the **System variables** section.

### Caution

- The data type of this entry must be REG_EXPAND_SZ. If a user or application changes the data type, then the system will not replace the variable with its intended value.

# Path Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Path**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Filename* | %SystemRoot%\system32; %SystemRoot% |

**Description**
Stores the path to system files.

**Change Method**
To change the value of this entry, double-click System in Control Panel. Click the **Advanced** tab, and then click **Environment Variables**. This entry appears in the **System variables** box.

### Caution

- The data type of this entry must be REG_EXPAND_SZ. If a user or an application changes the data type, then the system will not replace the variable with its intended value.

# PROCESSOR_ARCHITECTURE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PROCESSOR_ARCHITECTURE**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Processor type* | x86 |

**Description**
Stores the type of processors installed on the system.

For Windows Server 2003, the system always sets the value of this entry to x86. However, this entry remains in the system to anticipate future needs and to maintain compatibility with earlier systems.

# PROCESSOR_LEVEL

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PROCESSOR_LEVEL**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Model number* | (None) |

**Description**
Stores the model number of the processor installed on the computer. Programs can use this entry to adjust their configuration for different systems.

# Environment\TEMP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TEMP**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %SystemRoot%\Temp |

**Description**
Stores the path to the TEMP temporary directory for the system.

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Advanced** tab and then click **Environment Variables**. This entry appears in the **System variables** section.

### Caution

- The data type of this entry must be REG_EXPAND_SZ. If a user or application changes the data type, then the system will not replace the variable with its intended value.

# Environment\TMP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TMP**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %SystemRoot%\Temp |

**Description**
Stores the path to the TMP temporary directory for the system.

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Advanced** tab and then click **Environment Variables**. This entry appears in the **System variables** section.

### Caution

- The data type of this entry must be REG_EXPAND_SZ. If a user or application changes the data type, then the system will not replace the variable with its intended value.

# windir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**windir**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Pathname* | %SystemRoot% |

**Description**
Stores the path to the executable file for Win16 on Win32 (WOW).

### Caution

- The data type of this entry must be REG_EXPAND_SZ. If a user or application changes the data type, then the system will not replace the variable with its intended value.

# Memory Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Memory Management**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager

**Description**
The Memory Management subkey stores configuration data for paging files.

**Change Method**
To create a new paging file or to change the size of a paging file, double-click **System** in Control Panel, click the **Advanced** tab, click the **Performance Options** button, and then click the **Change button** in the Virtual Memory box.

### Note

- For more information on memory management and paging files, see Windows Server 2003 Help or Windows XP Professional Help.

### Tip

- To create a new paging file or to change the size of a paging file, double-click **System** in Control Panel, click the **Advanced** tab, click the **Performance Options** button, and then click the **Change** button in the Virtual Memory box.

### Caution

- Do not change the size of the paging file by editing the registry. To create a new paging file or to change the size of a paging file, use Control Panel.

# ClearPageFileAtShutdown

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ClearPageFileAtShutdown**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether inactive pages in the paging file are filled with zeros when the system stops. This is a Windows Server 2003 security feature that prevents the pages from being read by another process. The system cannot fill active pages with zeros because some are being used by the system or by other active processes.

| Value | Meaning |
|---|---|
| 0 | Inactive pages are not filled with zeros. |
| 1 | Inactive pages are filled with zeros. |

**Caution**

- Changing this value can degrade the performance of your computer.

# DisablePagingExecutive

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DisablePagingExecutive**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether kernel-mode drivers and kernel-mode system code can be paged to disk when not in use.

| Value | Meaning |
|---|---|
| 0 | Drivers and system code can be paged to disk as needed. |
| 1 | Drivers and system code must remain in physical memory. |

**Activation Method**
To make changes to this entry effective, you must restart the system.

**Tip**

- Setting this value to 1 is useful when debugging drivers, because all of the code and data is always memory resident. It also improves performance on machines with a lot of memory, because it prevents disk reads to get code or data.

# LargeSystemCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**LargeSystemCache**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | Windows XP Professional: 0 Windows Server 2003: 1 |

**Description**
Specifies whether the system maintains a standard size or a large size file system cache, and influences how often the system writes changed pages to disk.

Increasing the size of the file system cache generally improves server performance, but it reduces the physical memory space available to applications and services. Similarly, writing system data less frequently minimizes use of the disk subsystem, but the changed pages occupy memory that might otherwise be used by applications.

| Value | Meaning |
|---|---|
| 0 | Establishes a standard size file-system cache of approximately 8 MB. The system allows changed pages to remain in physical memory until the number of available pages drops to approximately 1,000. This setting is recommended for servers running applications that do their own memory caching, such as Microsoft SQL Server, and for applications that perform best with ample memory, such as Internet Information Services (IIS). |
| 1 | Establishes a large system cache working set that can expand to physical memory, minus 4 MB, if needed. The system allows changed pages to remain in physical memory until the number of available pages drops to approximately 250. This setting is recommended for most computers running Windows Server 2003 on large networks. |

This entry and the **Size** entry (which is in the HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters subkey) store the setting of the **Optimization** section of the **Server Optimization** tab in Network and Dial-up Connections.

| Option setting | Large System Cache value | Size value |
|---|---|---|
| Minimize memory used | 0 | 1 |
| Balance | 0 | 2 |
| Maximize data throughput for file sharing | 1 | 3 |
| Maximize data throughput for network applications | 0 | 3 |

**Change Method**
To change the value of this entry on Windows Server 2003, use the **Server Optimization** tab in Network and Dial-up Connections. Right-click My Network Places, click **Properties**, right-click **Local Area Connection**, click **Properties**, click **File and Printer Sharing for Microsoft Networks**, and then click the **Properties** button. To set the value of this entry to 0, select the **Maximize data throughput for network applications** option. To set the value to 1, select **Maximize data throughput for file sharing**.

**Note**

- Because setting the value of this entry to 1 is not recommended for computers running Windows XP Professional, you cannot use Network and Dial-up Connections in Windows XP Professional to change the value of this entry.

- The Windows Server 2003 default value (1) is designed for file servers. Because this value can degrade service performance, it is not recommended for application servers. If you are running an application server, change the value of this entry to 0 by selecting the **Maximize data throughput for network applications** option in Network and Dial-up Connections.

- The system sets the value of this entry to 1 when you install Windows Server 2003. But many applications, such as SQL Server and Microsoft Exchange, change the value of this entry to 0.

# NonPagedPoolQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NonPagedPoolQuota**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1–128 (megabytes) | 0 |

**Description**
Establishes the maximum space in the nonpaged pool that can be allocated by any process. Any attempt by a process to allocate more space in the nonpaged pool will fail.

| Value | Meaning |
|---|---|
| 0 | The system calculates an optimal value for this entry based on the amount of physical memory on the computer, and it adjusts this value if the amount of memory changes. This value is optimal for most systems. |
| 1–128 | Overrides the value calculated by the system, and prevents the system from adjusting this value dynamically. This setting can degrade performance. |

**Caution**

- Do not change the value of this entry. The system adjusts this value dynamically. Changing the value prevents the system from using its algorithms to calculate an optimal value for the system.

PagedPoolQuota

# NonPagedPoolSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NonPagedPoolSize**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| *Number of bytes* | 0 |

**Description**
Specifies the size of the nonpaged pool.

| Value | Meaning |
|---|---|
| 0 | The system calculates an optimal value for this entry based on the amount of physical memory on the computer, and it adjusts this value if the amount of memory changes. This value is optimal for most systems. |
| *Number of bytes* | Creates a nonpaged pool of the specified size. This takes precedence over the value calculated by the system, and it prevents the system from adjusting this value dynamically. This setting can degrade performance. |

**Activation Method**
You must restart the computer before a change to this value takes effect.

### Caution

- Changing the value of this entry can degrade the performance of your computer.

**See Also**
**Concepts**
NonPagedPoolQuota
NonPagedPoolSize

# PagedPoolQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PagedPoolQuota**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1–128 (megabytes) | 0 |

**Description**
Establishes the maximum space in the paged pool that can be allocated by any process. Any attempt by a process to allocate more space in the paged pool will fail.

| Value | Meaning |
|---|---|
| 0 | The system calculates an optimal value for this entry based on the amount of physical memory on the computer, and adjusts this value if the amount of memory changes. This value is optimal for most systems. |
| 1–128 | Overrides the value calculated by the system and prevents the system from adjusting this value dynamically. This setting can degrade performance. |

**Activation Method**
You must restart the computer before a change to this value takes effect.

### Caution

- Do not change the value of this entry. The system adjusts this value dynamically based on internal algorithms. Changing this value prevents the system from calculating an optimal value. This is likely to degrade the performance of your system.

NonPagedPoolSize

# PagedPoolSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PagedPoolSize**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0x20000000 *bytes* \| 0xFFFFFFFF | 0x0 |

**Description**
Specifies the size of the paged pool.

| Value | Meaning |
|---|---|
| 0x0 | The system calculates an optimal value for this entry based on the amount of physical memory in the computer, and it adjusts this value if the amount of memory changes. The system algorithm typically sets the size of the paged pool to approximately twice that of the nonpaged pool size. This value is optimal for most systems. |
| 0x1–0x20000000 *bytes* | Creates a paged pool of the specified size. This takes precedence over the value that the system calculates, and it prevents the system from adjusting this value dynamically. Limiting the size of the paged pool to 192 MB (or smaller) lets the system expand the file system (or system pages) virtual address space up to 960 MB. This setting is intended for file servers and other systems that require an expanded file system address space (meaning slightly faster access) at the expense of being able to actually cache less data. This only makes sense if you know the files your server frequently accesses already fit easily into the cache. |
| 0xFFFFFFFF | The system calculates the maximum paged pool allowed for the system in this configuration. For 32-bit systems, this is typically less than 500 MB. This setting is typically used for servers that are attempting to cache a very large number of frequently used small files, some number of very large size files, or both. In these cases, the file cache that relies on paged pool to manage its caching is able to cache more files (and for longer periods of time) if more paged pool is available. |

**Activation Method**
You must restart the computer before a change to this value takes effect.

### Note

- If the paged pool on a system is 192 MB or smaller (including 0, which means auto-size), then the system can expand the file system virtual address space or the system pages virtual address space up to 960 MB. For more information, see the SystemPages entry.

# PagingFiles

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PagingFiles**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Name Minimum(MB) Maximum(MB)* | (*Varies from system to system*) |

**Description**
Specifies the name of the paging file and the minimum and maximum size range (in megabytes) for the paging file.

**Change Method**
To change the size range of the paging file or to create new paging files, double-click **System** in Control Panel, click the **Advanced** tab, click the **Performance Options** button, and then click the **Change** button in the **Virtual Memory** box.

### Note

- For more information about memory management and paging files, see Windows Server 2003 Help or Windows XP Professional Help.

# SystemPages

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SystemPages**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFE *entries* \| 0xFFFFFFFF | 0x0 |

**Description**
Defines the number of system page table entries that are reserved for mapping I/O buffers and other information into the system address space. Each system page table entry maps one page.

| Value | Meaning |
|---|---|
| 0x0 | The system calculates an optimal number of page table entries based on the platform type and the amount of memory available to the system. The system adjusts this value if the amount of memory changes. |
| 0x1–0xFFFFFFFE | Specifies the number of reserved page table entries. This value takes precedence over the system's calculated value, and it prevents the system from adjusting the value. |
| 0xFFFFFFFF | Maximize system pages. The system creates the largest number of page table entries possible within physical memory. The system monitors and adjusts this value dynamically when the configuration changes. |

**Caution**

- Do not change the value of this entry. Changing it prevents the system from calculating an optimal value for your system and adjusting the value when your system changes.

**See Also**
**Concepts**
NonPagedPoolSize

# SecondLevelDataCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SecondLevelDataCache**
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1–*Cache size (in bytes)* | 0 (*256 KB*) |

**Description**
Specifies the number of bytes in the secondary processor cache, also known as the L2 cache. The value of this entry is used only when the Hardware Abstraction Layer (HAL) cannot detect the L2 cache.

| Value | Meaning |
|---|---|
| 0 | Sets the L2 cache size to 256 KB. |
| *Number of bytes* | Sets the L2 cache size to the value specified. |

# VirtualDeviceDrivers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VirtualDeviceDrivers**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The VirtualDeviceDrivers subkey stores configuration data for virtual device drivers.

# VDD

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VDD**
HKLM\SYSTEM\CurrentControlSet\Control\VirtualDeviceDrivers

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Filenames* | (None) |

**Description**
Specifies the Win32 dynamic-link libraries (DLLs) for virtual device drivers. The system loads the virtual device drivers in this list when a Windows Server 2003 virtual DOS machine is started. By default, this entry has no value because the Windows Server 2003 virtual device drivers are built into the system and do not need to be loaded separately.

# Control\Windows Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows**
HKLM\SYSTEM\CurrentControlSet\Control

**Description**
The Windows subkey contains configuration data for the Win32 subsystem in Windows Server 2003.

**See Also**
**Concepts**
Microsoft\Windows
Microsoft\Windows Subkey

# NoInteractiveServices

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoInteractiveServices**
HKLM\SYSTEM\CurrentControlSet\Control\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Prevents background services from interacting with users. This entry was designed to improve performance of unattended computers.

This entry cannot be used to make a service interact with a user unless the service is written to be interactive. Also, it will not prevent a service from displaying error messages.

| Value | Meaning |
|---|---|
| 0 | Interactive background services (Type 0x110) can communicate with users. |
| 1 | Background services cannot interact with users. This value takes precedence over the Control Panel setting for interactive services (as described below) and the SERVICE_INTERACTIVE_PROCESS option in the CreateService API. |

### Note

- To determine whether a service is run in interactive mode, from the **Start** menu, point to **Programs**, point to **Administrative Tools**, and then double-click **Computer Management**. Double-click **System Tools**, double-click **Services**, right-click a service to see its properties, and then select the **Log On** tab. The **Allow Service to Interact with Desktop** check box is selected if the service is interactive, and cleared if it is not. Selecting the check box will not make a service interact with the user unless it is written to do so.

# NoPopUpsOnBoot

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoPopUpsOnBoot**
HKLM\SYSTEM\CurrentControlSet\Control\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether pop-up error messages that appear when the system starts are suppressed. You can add **NoPopUpsOnBoot** to the registry to prevent Windows Server 2003 from displaying messages when no one is there to read them, such as computers that are configured to log on to Windows Server 2003 automatically.

| Value | Meaning |
|---|---|
| 0 | Pop-up error messages are displayed. |
| 1 | Pop-up error messages are suppressed. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- This entry does not suppress the message notifying the user that the domain controller cannot be contacted. To suppress that message, use ReportDC.

**See Also**
**Concepts**
ReportDC
ReportControllerMissing

# Enum Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet

**Description**
The Enum subkey contains a database representing all devices installed on the computer and recognized by the system. The database stores configuration data for hardware devices independent of the drivers they use. This subkey is critical to the configuration of Plug and Play devices in Windows.

**Change Method**
To change device settings, use Device Manager.

### Note

- Users, including administrators, cannot change the contents of the Enum subkey. These restrictions protect the integrity of the operating system and the devices on the computer.

### Caution

- Do not attempt to change the permissions on the Enum subkey. If you do, you might damage the sequence of inherited permissions in the registry. If you change the content of the Enum subkey, you can damage the Plug and Play functions of Windows Server 2003 and prevent devices from operating. If you must gain access to the Enum subkey, contact Microsoft Product Support Services.

**See Also**
**Concepts**
service-name\Enum

# Root

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# *PNP03<#>

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Device Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP03<#>\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# KeyboardDataQueueSize Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP03<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 - 0xFFFFFFFF | 0x64 (100) |

**Description**
Specifies the number of keyboard events buffered by the keyboard driver. It is also used in calculating the size of the keyboard driver's internal buffer in nonpaged memory pool. To determine the number of bytes to allocate for the buffer, the system multiplies the size of the KEYBOARD_INPUT_DATA structure (defined in NTDDKBD.H) by the value of **KeyboardDataQueueSize**.

Consider increasing this value if the driver does not initialize or operate correctly and the System Log in Event Viewer contains the following message from the source, Inport:

```
"The ring buffer that stores incoming keyboard data has overflowed (buffer size is configurable via the Registry)."Text goes here.
```

### Note

- This entry is created by copying the value of Parameters\KeyboardDataQueueSize from the i8042prt subkey. Thereafter, the system uses only the entries in this location.

**See Also**
**Concepts**
Parameters\KeyboardDataQueueSize

# Device Parameters\PollStatusIterations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP03<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 - 0xFFFFFFFF | 0x1 |

**Description**
Specifies the maximum number of times the system verifies interrupts on the i8042 controller status register. If the interrupt cannot be verified in the number of trials specified in **PollStatusIterations**, then the interrupt is ignored.

This entry is designed to minimize the effect of interrupts raised before the Output Buffer Full bit is set in the i8042 status register. This condition occurs on some computers, such as the Olivetti MIPS computer.

If the system seems to ignore keyboard interrupts, then increase the value of this entry. The system might mistakenly ignore an interrupt if the Output Buffer Full bit is not set when the interrupt is raised. However, if you increase the value of **PollStatusIterations**, then the Interrupt Service Routine will take longer to execute because there is a one microsecond delay following each check for Output Buffer Full.

### Note

- This entry is created by copying the value of PollStatusIterations Entry from the i8042prt subkey. Thereafter, the system uses only the entries in this location.

### Tip

- To determine whether the driver is processing keyboard interrupts correctly, press the NUM LOCK key. If the **Num Lock** light on the keyboard turns on or off, then this indicates that the i8042prt driver handled the keyboard interrupt correctly.

**See Also**
**Concepts**
PollStatusIterations Entry

# *PNP0F<#>

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

# EnableWheelDetection Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 1 |

**Description**
Specifies whether the driver attempts to detect and enable the wheel on the mouse device. Some devices are equipped with a mouse wheel to provide rapid scrolling and other control features when supported by an application.

| Value | Meaning |
|---|---|
| 0 | Disable mouse wheel detection. The driver does not attempt to determine whether the mouse has a wheel or to enable it. Even if the mouse has a wheel, the wheel does not function in programs. |
| 1 | Detect and enable the mouse wheel. If the driver detects a wheel on the mouse, then it enables the wheel. |
| 2 | Enable without detecting. The driver attempts to enable a mouse wheel without determining whether the mouse has a wheel. |

### Note

- This entry is created by copying the value of Parameters\EnableWheelDetection from the i8042prt subkey. Thereafter, the system uses only the entries in this location.
- For mouse devices that do not fully support all Intellimouse and PS/2 functions, including dynamic enabling, set the value of this entry to 2.

### Tip

- To view or change the value of this entry for a particular PS/2 mouse, use Device Manager. In the tree control, click **Device** and then, in the results pane, click **Mouse**, double-click the device name, and click the **Advanced Settings** tab. This value appears in the **Wheel Detection** box.

### Caution

- In rare instances, when the system tries to detect and enable the mouse wheel, the system stops responding. To recover, restart Windows. If the problem persists, restart by using the LastKnownGood control set.

# MouseDataQueueSize Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 - 0xFFFFFFFF | 0x64 (100) |

**Description**
Specifies the number of mouse events buffered by the mouse driver. It is also used in calculating the size of the mouse driver's internal buffer in nonpaged memory pool. To determine the number of bytes to allocate for the buffer, the system multiplies the size of the MOUSE_INPUT_DATA structure (defined in NTDDMOU.H) by the value of **MouseDataQueueSize**.

Consider increasing this value if the driver does not initialize or operate correctly and the System Log in Event Viewer contains the following message from the source, Inport :

```
The ring buffer that stores incoming mouse data has overflowed (buffer size is configurable via the
Registry).
```

### Note

- This entry is created by copying the value of Parameters\MouseDataQueueSize from the i8042prt subkey. Thereafter, the system uses only the entries in this location.

### Tip

- To view or change the value of this entry for a particular PS/2 mouse, use Device Manager. In the tree control, click **Device** and then, in the results pane, click **Mouse**, double-click the device name, and click the **Advanced Settings** tab. This value appears in the **Input Buffer Length** box.

**See Also**
**Concepts**
Parameters\MouseDataQueueSize

# MouseInitializePolled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies how the mouse is initialized. The default value, whereby the driver initializes the mouse in response to an interrupt, is quicker. Polling can increase the time it takes to start Windows by 5 to 15 seconds. Do not change the default unless the system does not respond to the mouse or keyboard when the **Logon Information** (CTRL+ALT+DEL) screen is displayed.

| Value | Meaning |
|---|---|
| 0 | In response to an interrupt. A hardware interrupt signals the PS/2 mouse driver to initialize the mouse. |
| 1 | By polling the hardware. The driver attempts to initialize the mouse. If it is unsuccessful, it tries at regular intervals until it succeeds. |

**Tip**

- To view or change the value of this entry for a particular PS/2 mouse, use Device Manager. In the tree control, click **Device** and then, in the results pane, click **Mouse**, double-click the device name, and click the **Advanced Settings** tab. This value is set by using the **Fast Initialization** check box. If the box is checked, the mouse is initialized in response to an interrupt; if it is cleared, it is initialized by polling.

# MouseResolution Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Mouse resolution specifier* | 0x3 |

**Description**
Specifies the resolution of the mouse port. The number of counts per millimeter of resolution is determined by raising 2 to the power of the value of **MouseResolution**.

For example, if the value of MouseResolution is 3, then the mouse resolution is 2**3, or 8, counts per millimeter.

### Note

- This entry is created by copying the value of Parameters\MouseResolution from the i8042prt subkey. Thereafter, the system uses only the entries in this location.

**See Also**
**Concepts**
Parameters\MouseResolution

# MouseSynchIn100ns Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Time in 100-nanosecond units* | 20000000 (2 seconds) |

**Description**
Specifies the length of time after which the next mouse interrupt is assumed to indicate the start of a new mouse packet (partial packets are discarded). This enables the driver to synchronize its internal notion of the mouse packet state with the hardware state when a mouse interrupt is lost.

Consider modifying this value if the system appears to be generating extra mouse events, such as when objects are selected although the mouse button has not been pressed.

### Note

- This entry is created by copying the value of Parameters\MouseSynchIn100ns from the i8042prt subkey. Thereafter, the system uses only the entries in this location.

**See Also**
**Concepts**
Parameters\MouseSynchIn100ns

# Device Parameters\NumberOfButtons

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 - 0xFFFFFFFF | 0x2 |

**Description**
Specifies the number of buttons on the mouse port mouse at startup. If the number of buttons detected at startup is incorrect, then you can override it by changing the value of this entry.

### Note

- This entry is created by copying the value of NumberOfButtons Entry from the i8042prt subkey. Thereafter, the system uses only the entries in this location.

**See Also**
**Concepts**
NumberOfButtons Entry

# Device Parameters\SampleRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 20 \| 40 \| 60 \| 80 \| 100 \| 200 | 100 Hz |

**Description**
Specifies how often, in Hertz, the PS/2 driver measures the characteristics and activities of the PS/2 mouse. The driver uses the information gathered by sampling to optimize the operation of the mouse device.

### Note

- This entry is created by copying the value of SampleRate Entry from the i8042prt subkey. Thereafter, the system uses only the entries in this location.

### Tip

- To view or change the value of this entry for a particular PS/2 mouse, use Device Manager. In the tree control, click **Device** and then, in the results pane, click **Mouse**, double-click the device name, and click the **Advanced Settings** tab. This value appears in the **Sample Rate** box.

**See Also**
**Concepts**
SampleRate Entry

# WheelDetectIDs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *ASCII identification string* | (None) |

**Description**
A list of ASCII identification strings of wheel mice enabled on the system. By storing the identities of mouse wheel devices that have already been enabled, the system avoids redetecting and reenabling the device. This entry is used only when the value of EnableWheelDetection Entry is 1.

This entry is used to associate wheel mouse devices newly detected on the system with those already registered. When the system acquires an identification string from a new wheel mouse, it converts the string from scan codes into ASCII and compares it to the values stored in this entry. If the new string matches one of the values in this entry, then the mouse wheel is enabled without further delay. If no match is found, then the system attempts to enable the mouse wheel.

### Note

- Unlike some entries in this subkey, this entry remains in the Parameters subkey and is read from this location even after a PS/2 mouse is installed.

**See Also**
**Concepts**
Parameters\EnableWheelDetection
EnableWheelDetection Entry

# WheelDetectionTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Root*PNP0F<#>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 - 0xFFFFFFFF *microseconds* | 5DC (1.5 seconds) |

**Description**
Specifies how long the mouse driver waits between attempts to detect and enable the mouse wheel. This entry is used when the mouse driver is attempting to enable the mouse wheel. It is used only when the value of EnableWheelDetection Entry is 1 or 2.

By default, this entry does not have a value. However, the default interval is 1.5 seconds in the absence of a value for this entry.

### Note

- To override the default value, you must add this entry to the registry.

# Device Parameters\NumberOfButtons Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Serenum\<*Device-name*>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 - 0xFFFFFFFF | 0x2 |

**Description**
Stores the number of buttons on the serial mouse that are detected when the system starts. If the number of buttons detected at startup is incorrect, then you can override it by changing the value of this entry.

If you have upgraded from Windows NT 4.0 or earlier, then the system copies the value of the Parameters\NumberOfButtons Subkey entry in the HKLM\SYSTEM\CurrentControlSet\Services\Sermouse\Parameters subkey to the device-specific Enum subkeys of all new serial mouse devices that are enumerated by the system.

### Note

- The precise path to this entry varies with the device.

### Tip

- To access this value programmatically, use the SetupDi API or Configuration Manager API.

# WaitEventMask

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Enum\Serenum\<*Device-name*>\Device Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1 - 0xFFFFFFFE \| 0xFFFFFFFF | 0x0 |

**Description**

Specifies whether the serial mouse driver detects when the serial mouse has been replaced on a serial port by another device.

The serial mouse alternates its use of serial ports with other serial devices, such as modems. By monitoring the state of modem lines, the driver can infer when the serial mouse has been removed dynamically from the port in favor of another device.

To monitor the modem lines, the serial mouse uses state data gathered by the serial port driver at initialization. From this data, it builds a bitmask representing the state of modem lines. A bit is set to 1 to indicate that a CTS (clear-to-send) or DSR (data-set-ready) signal is detected and that the line should be monitored for changes. It compares the bitmask to new data to detect changes in modem state and then infers when the serial mouse has been removed.

| Value | Meaning |
|---|---|
| 0x0 | Enables device removal detection. The serial driver creates a bitmask that represents all modem lines and monitors them for changes that indicate the removal of a device. |
| 0x1 - 0xFFFFFFFE | A bitmask representing the modem lines. If you enter a bitmask, the serial mouse driver uses the value you enter instead of building its own bitmask. |
| 0xFFFFFFFF | Disables serial device removal detection. The serial driver does not monitor modem lines. Instead, users must inform the system when modems can be removed. |

**Note**

- The precise path to this entry varies with the device.

**Caution**

- Do not change the value of this entry. If you enter a bitmask in this value, the serial mouse driver no longer creates a bitmask dynamically; Instead, it uses the mask you provide.

# CurrentControlSet\Hardware Profiles

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet

**Description**
The Hardware Profiles subkey stores the hardware profiles on your system.

A *hardware profile* consists of specified changes to the original hardware profile configured in the HKLM\SOFTWARE and SYSTEM keys of HKEY_LOCAL_MACHINE. To allow hardware profiles to be easily applied and removed, the original value in the SOFTWARE or SYSTEM key is not changed. Instead, the change is stored in a numbered subkey of the Hardware Profiles subkey.

You can use System in Control Panel to create a hardware profile. Also, the system creates new hardware profiles automatically when it encounters configurations that require one, such as when a portable computer is undocked or moved from one docking station to another.

Each hardware profile is stored in a *Profile-number* subkey of the Hardware Profiles subkey. The content of the numbered subkeys looks like a miniature version of the Software and System subkeys. It contains only those subkeys in the path to the entry that the hardware profile changes. When a hardware profile is applied, the values in the numbered subkeys override the corresponding values in Software and System.

The current hardware profile is stored in one of the numbered subkeys in the Hardware Profiles subkey, but it also appears in the Hardware Profiles\Current subkey of Hardware Profiles and in the HKEY_CURRENT_CONFIG subtree of the registry. Because the Current subkey and the HKEY_CURRENT_CONFIG subtree merely store pointers to the content of the numbered Hardware Profiles subkey currently in use, you can view and edit the data in any of these three locations.

### Note

- For information about the entries in a subkey of Hardware Profiles, see the description of that entry in the SOFTWARE or SYSTEM keys. For example, to find a description of the contents of Hardware Profiles*Profile-number*\Software\Fonts, see the description of HKLM\Software\Fonts.

### Tip

- To create hardware profiles, use System in Control Panel. Click the **Hardware** tab, and then click **Hardware Profiles**.

**See Also**
**Concepts**
Hardware Profiles\Current
HKEY_CURRENT_CONFIG

# Hardware Profiles\Current

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Hardware Profiles

**Description**
The Current subkey in the Hardware Profiles subkey displays configuration data for the hardware profile currently in use on the system.

The Current subkey does not actually contain any data. Instead, it contains a pointer to the *Profile-number* subkey in Hardware Profiles, which contains the current hardware profile. As such, the contents of the selected subkey appear in the Current subkey.

Also, the contents of the Current subkey appear in the HKEY_CURRENT_CONFIG subtree of the registry. Because the Current subkey and HKEY_CURRENT_CONFIG merely store pointers to the content of the numbered Hardware Profiles subkey currently in use, you can view and edit the data in any of the three locations.

The system always designates one profile as the current one.

- If the system does not have any hardware profiles that are appropriate to the current hardware configuration, then the system creates one automatically, and that profile becomes the current hardware profile.
- If the system includes only one hardware profile that is appropriate to the current hardware configuration, then that profile is automatically chosen to be the current hardware profile.
- If the system includes more than one hardware profile that is appropriate to the current hardware configuration, then when the system starts, it prompts the user to select from among the appropriate hardware profiles. The chosen profile becomes the current profile.

The current hardware profile remains current until the system stops or the hardware configuration changes, such as when an ACPI-capable (Advanced Configuration and Power Interface) portable computer docks or undocks.

**Tip**

- To determine which numbered subkey in Hardware Profiles represents the current hardware profile, see the CurrentConfig entry in HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\IDConfigDB. The value of **CurrentConfig** corresponds to the number of the subkey that contains the current hardware profile.

# Services Subkeys

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet

**Description**
The Services subkeys contain entries for standard and optional Windows Server 2003 services, such as device drivers, file system drivers, and Win32 service drivers. Although the values of the entries differ for each service, most Services subkeys have the same subkeys and entries.

Each Services subkey bears the name of the service that uses it. Often, this is also the name of the file from which the service is loaded.

Some of the services and devices represented by subkeys in the Services subkey are installed on the computer, but some of the subkeys represent services that are not installed or not enabled. To determine which services are installed on the computer, click **Services** in Computer Management. To determine which devices are installed on the computer, use Device Manager.

**Note**

- Adding a subkey to the Services subkey does not install a service. Windows Server 2003 does not recognize a service unless it is properly installed using standard installation methods, such as the CreateService API or the SC CREATE command.

# service-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
Represents a service for Windows Server 2003.

Entries and subkeys common to Services subkeys appear in the *service-name* subkey. Entries and subkeys that are specific to a service are described in the subkey bearing the service name.

**Note**

- The *service-name* subkey is a variable representing the subkeys in the HKLM\SYSTEM\CurrentControlSet\Services subkey. It does not actually appear in the registry. This variable subkey displays the entries and subkeys that are common to many of the Services subkeys. The actual Services subkeys in the registry depend on the services installed on the computer or available to the system.

# ErrorControl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–3 | 1 |

**Description**
Specifies how to proceed if the driver for the service or device fails to load or initialize properly. By default, the value of this entry for all Windows Server 2003 services and drivers is 1.

| Value | Meaning |
|---|---|
| 0 | Ignore. Startup proceeds with no warning messages. |
| 1 | Normal. Startup proceeds, but a warning message appears. |
| 2 | Severe. The system declares that the startup has failed, and it restarts by using the LastKnownGood control set. If startup is already using the LastKnownGood control set, then it continues. |
| 3 | Critical. The system declares that the startup has failed, and it restarts by using the LastKnownGood control set. If startup is already using the LastKnownGood control set, then the system stops the startup procedures and runs a debugging program. |

**Change Method**
To change the value of this entry, you can use the Services snap-in. You can also use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- This information is presented for reference only. You cannot change the load configuration of a service by editing this entry.

# Group

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Service group name* | (None) |

**Description**
Specifies the name of the service group to which the service belongs. If this entry does not appear in the registry, then the service does not belong to a service group. As a result, it will be loaded after all services in service groups are loaded.

**Change Method**
To change the value of this entry, you can use the Services snap-in. You can also use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- This information is presented for reference only. You cannot change the service group of a service by editing this entry.

# service-name\ImagePath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path and file name* | *Systemroot*\System32\Drivers*Driver-name*.sys (Drivers) *Systemroot*\System32*Service-name*.exe (Services) |

**Description**

Specifies the location of the executable file for the driver or service. This entry is not used for network adapters.

**Caution**

Do not change the value of this entry.

# ObjectName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Object name* | Drivers: *Systemroot*\System32\Drivers*Driver-name*.sys Services: *Systemroot*\System32*Service-name*.exe |

**Description**
Specifies the name of the Windows Server 2003 driver object that I/O Manager uses to load the device driver, if the service represented by the subkey is either a kernel-mode driver or a file system driver.

If the service represented by the subkey is a Win32 service, then this entry specifies the account name that the service uses to log on to Windows Server 2003.

**Change Method**
To change the value of this entry, you can use the Services snap-in. You can also use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- This information is presented for reference only. You cannot edit this entry to change the driver object or account name that Windows Server 2003 uses to start a service.

### Tip

- To determine what type of service the subkey represents, see the Type Entry entry.

# Start Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–4 | (None) |

**Description**
Specifies how the service is loaded or started. If the service is a Win32 service, then the value of this entry must be 2, 3, or 4. This entry is not used for network adapters.

| Value | Meaning |
|---|---|
| 0 | Boot (loaded by kernel loader). Components of the driver stack for the boot (startup) volume must be loaded by the kernel loader. |
| 1 | System (loaded by I/O subsystem). Specifies that the driver is loaded at kernel initialization. |
| 2 | Automatic (loaded by Service Control Manager). Specifies that the service is loaded or started automatically. |
| 3 | Manual. Specifies that the service does not start until the user starts it manually, such as by using Device Manager. |
| 4 | Disabled. Specifies that the service should not be started. |

**Change Method**
To change the value of this entry, you can use the Services snap-in. You can also use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- This information is presented for reference only. You cannot change the starting rules for a service by editing this entry.

### Tip

- To determine what type of service is represented by the subkey, see Type Entry.

# Type Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 \| 4 \| 8 \| 16 \| 32 \| 272 \| 288 | (None) |

**Description**
Identifies the type of service represented by the subkey.

| Value | Meaning |
|---|---|
| 1or 0x1 | A kernel-mode device driver. |
| 2 or 0x2 | A file system driver. |
| 4 or 0x4 | A set of arguments for an adapter. |
| 8 or 0x8 | A file system driver service, such as a file system recognizer. |
| 16 or 0x10 | A Win32 program that runs in a process by itself. This type of Win32 service can be started by the service controller. |
| 32 or 0x20 | A Win32 program that shares a process. This type of Win32 service can be started by the service controller. |
| 272 or 0x110 | A Win32 program that runs in a process by itself (like Type16) and that can interact with users. |
| 288 or 0x120 | A Win32 program that shares a process and that can interact with users. |

**Change Method**
To change the value of this entry, you can use the Services snap-in. You can also use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- This information is presented for reference only. You cannot edit this entry to change the view of a service by Windows Server 2003.

# DependOnGroup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Service group name* [*service group name*] | (None) |

**Description**
Specifies the service group(s) that must be loaded before this service is loaded. This entry ensures that prerequisite services are loaded successfully.

**Change Method**
To change the prerequisite services for a service, use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- This information is presented for reference only. You cannot change the prerequisite services for a service by editing this entry.

# DependOnService

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Service group name* [*service name*] | (None) |

**Description**
Specifies the service(s) that must be loaded before this service is loaded. This entry ensures that prerequisite services are loaded successfully.

**Change Method**
To change the value of this entry, you can use the Services snap-in. You can also use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- This information is presented for reference only. You cannot change the prerequisite services for a service by editing this entry.

# service-name\Enum

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

**Description**
The Enum subkey in each Services subkey stores information about the hardware associated with that service. The values in the Enum subkey associate the service with the instance of the device it controls.

The Enum subkey appears in subkeys that are in the Services subkey and that store values for drivers and other services controlling or interacting with devices.

**Note**

- Values of entries in this subkey are rewritten each time the system starts. Do not change the values of entries in this subkey.

**See Also**
**Concepts**
Enum Subkey

# service-name\Linkage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

**Description**
The Linkage subkey stores configuration data for binding network components. The bindings associate network services with protocols and with devices that support them.

The Linkage subkey appears in the Services subkeys for network services and protocols.

Hardware devices, such as network adapters, and network services, such as File and Print Services for Microsoft, also have Linkage subkeys. These Linkage subkeys store data about bindings from the perspective of the device. They associate devices and services with the transport protocols they use. In Windows Server 2003, the Linkage Subkey are stored in HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Class*{Class-GUID}*, in the numeric subkey representing the particular device.

Windows Server 2003 creates the bindings from data stored in the Linkage subkeys in both locations.

A binding consists of three entries, Bind, Export, and Route Entry. Each of these entries can include more than one component. The components are listed in the entries in a precise order, so that the first component in one entry corresponds with the first component in the other entries, and each subsequent component corresponds with subsequent components in the other entries.

### Note

- Windows Server 2003 does not include NetRules subkeys. In Windows NT 4.0 and earlier, the NetRules subkeys contained entries that specified bind rules for network software components. Some bind specifications are stored in the Ndi subkeys that contain configuration data for network driver installers. However, these are primary upper bind and lower bind settings only.

### Caution

- Do not change the values of these entries. Bindings are created by the system.

**See Also**
**Concepts**
Linkage Subkey
Ndi Subkeys

# Bind

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Linkage

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *ObjectName ObjectName* ... | (None) |

**Description**
Specifies the services, protocols, and devices to which this service is associated in a binding. The system builds the bind from the values in this entry and in the **Bind** entries of the associated protocols and devices.

More than one component of the same type can be listed in this value. For example, if the computer has two networks, then the value of **Bind** for a network adapter type contains two object names.

### Note

- A valid binding requires a value for three entries: **Bind**, Export, and Route Entry.

### Caution

- Bindings are created by the system. Do not change the values of these entries.

**See Also**
**Concepts**
Linkage Subkey

# Export

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Linkage

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *ObjectName ObjectName* ... | (None) |

**Description**
Specifies objects that the service creates to enable other services to access it. Objects named in the value of this entry must be installed on the system and available to the service or device.

### Note

- A valid binding requires a value for three entries: Bind, **Export**, and Route Entry.

### Caution

- Bindings are created by the system. Do not change the values of these entries.

**See Also**
**Concepts**
Linkage Subkey

# OtherDependencies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Linkage

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *ServiceName ServiceName* ... | (None) |

**Description**
Specifies services that the network component requires, in addition to those specified in the binding. This entry and its value are retained when bindings are reconfigured, even when the other entries in the Linkage subkey are deleted and recreated.

For example, in the NetBT\Linkage subkey, the value of the **OtherDependencies** entry is **Tcpip**. This value indicates that NetBIOS over TCP/IP (NetBT) requires TCP/IP, regardless of its current binding configuration.

### Notes

- A valid binding requires a value for three entries: Bind, Export, and Route Entry.
- Windows Server 2003 adds this entry to the subkey only if the network component requires it. This entry does not appear in all Linkage subkeys.

### Caution

- Bindings are created by the system. Do not change the values of these entries.

**See Also**
**Concepts**
Linkage Subkey

# Route Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Linkage

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *SubkeyName SubkeyName* ... | (None) |

**Description**
Specifies the Linkage subkeys from which data was collected to create the binding. Each name in the value of this entry indicates a path through the binding protocol.

The Linkage subkeys that appear in the value of this entry can represent services or devices.

- Linkage subkeys for services bear the name of the service (such as Tcpip) and appear in HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services.

- Linkage subkeys for devices are named by the globally unique identifier (GUID) of the device class and appear in HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Class.

### Note

- A valid binding requires a value for three entries: Bind, Export, and Route Entry.

### Caution

- Bindings are created by the system. Do not change the values of these entries.

**Concepts**
Linkage Subkey

# service-name\networkprovider

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

**Description**
The networkprovider subkey stores the name of the device and the provider path. It can appear in the Services subkeys for a network service. If a network service has a networkprovider subkey, the value of the Group entry in the *service-name* subkey must be **NetworkProvider**.

**See Also**
**Concepts**
DUPTILE1_NetworkProvider

# service-name\Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

**Description**
The Parameters subkeys contain entries specific to each service, such as a registry entry to enable an optional component of the service. Many entries in the Parameters subkeys are not added to the registry when you install the service. You must add them by editing the registry or by using a snap-in or administrative program that adds the entries to the registry.

# Performance Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

**Description**
The Performance subkey contains entries for the performance counter dynamic-link library (DLL) for the service. The performance library uses these values to collect data for the performance counters that monitor the service. These entries are maintained by the system and should not be changed.

**Activation Method**
To make changes to entries in this subkey effective, restart the Remote Registry Service or restart Windows Server 2003.

### Tip

- If particular performance counters do not appear in your performance monitoring tool, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib detects disabling errors in a counter DLL, it records an event in the log and sets the value of Disable Performance Counters to 1 to disable the counters.

# Collect Timeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Performance

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xEE6B2800 *milliseconds* | (The value of OpenProcedureWaitTime.) |

**Description**
Defines a slow Collect procedure call for these counters.

This entry tells the Performance Library (Perflib) how long the Collect procedure call for these counters is expected to run. If the time specified in the value of this entry expires before the call completes, then Perfib considers the call to be abnormally slow, and it records an error in the Application Log in Event Viewer. Also, if the value of the Configuration Flags entry requires it, then Perflib disables the counters and does not display them again until you manually re-enable them.

Perflib times the procedure calls of non-trusted counters to identify counters that can delay or lock performance tools during initialization. While the Collect procedure call proceeds, you cannot use the performance tools, and remote users cannot log on to the local computer.

**Activation Method**
To make changes to this entry effective, restart the Remote Registry Service or restart Windows.

### Notes

- Timing procedure calls is one of several tests Perflib performs to maintain the integrity of the counters. To configure the Perflib test feature, use the Configuration Flags entry.
- Perflib does not time the procedure calls of trusted performance counter dynamic-link libraries (DLLs). This entry applies only to non-trusted DLLs.
- Perflib disables counters because of slow procedure calls only when the 0x8 (1000) bit is set and the 0x2 (10) bit is not set in the Configuration Flags entry.
- Perflib does not time procedure calls when the 0x4 (100) bit is set in the Configuration Flags entry.
- Perflib disables counters by setting the value of the Disable Performance Counters entry for that service to 1. After you have repaired or replaced the counter DLLs, you must re-enable them manually by changing the value of **Disable Performance Counters** to 0.
- Some performance counters DLLs add this entry to the registry. If this entry does not appear, you can add it to the registry to override the default value.

### Tip

- If you suspect problems with procedure calls, check the Application Log in Event Viewer. Perflib records an error in the log whenever a procedure call exceeds its limit.

**See Also**
**Concepts**
OpenProcedureWaitTime
Open Timeout

# Disable Performance Counters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*Service-name*\Performance

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Enables and disables registry-based performance counters for this service.

If the value of this entry is 1, then the Performance Library (Perflib) does not retrieve performance data about these counters from the registry. As a result, System Monitor and other tools that use the data cannot display it. Instead, the tools display a value of 0 or 100 percent, depending on the counter.

Perflib uses this entry to disable counters that cause serious errors. The disabling prevents those counters from jeopardizing the display of all performance counters on the system. You can use this entry to re-enable the counters for a service after the counter dynamic-link library (DLL) has been repaired or replaced.

| Value | Meaning |
|---|---|
| 1 | Disables performance counters for this service. |
| 2 | The Win32 version is disabled on computers running a Win64 version of the operating system. |
| 4 | The Win64 version of the service is disabled. |

**Change Method**
To change the value of this entry, use *Extensible Performance Counter List* (Exctrlst.exe) available with *Windows Server 2003 Resource Kit Tools*.

**Activation Method**
To make changes to this entry effective, restart Windows Server 2003.

### Note

- This entry affects only the performance counters for a particular service. To enable or disable all registry-based performance counters on the system, add the Disable Performance Counters Entry entry to the Perflib subkey.
- To prevent Perflib from disabling counters, set the 0x2 (10) bit in the value of the Configuration Flags entry.

### Tip

- If particular performance counters do not appear in your performance monitoring tool, then check the Application Log in Event Viewer for events recorded by Perflib. When Perflib detects disabling errors in a counter DLL, it records an event in the log and sets the value of Disable Performance Counters to 1 to disable the counters.

### Caution

- If you set the value of this entry to 1, then the performance objects and counters for this service do not appear in any performance tool. You will not be able to use System Monitor, nor any tool that uses Performance Library data, to monitor these counters.
- Do not use the registry editor Regedit.exe or Exctrlst.exe to enable counters that Perflib has disabled, unless the counter DLL has been repaired or replaced. If you do, then Perflib will detect the errors and disable the counters again. In addition, the troublesome counters can prevent you from monitoring any performance counters on your system.

# Library Validation Code

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*Service-name*\Performance

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *Unique code signature* | (None) |

**Description**
Identifies a trusted performance counter dynamic-link library (DLL).

This entry stores data identifying a particular version of a performance counter DLL as one that has been certified to be free of disabling errors. When the data for a DLL matches the value of this entry, the Performance Library (Perflib) considers the DLL to be trusted.

This entry is added to the registry by the script that installs the DLL in Windows Server 2003.

**Activation Method**
To make changes to this entry effective, restart the Remote Registry Service or restart Windows.

### Note

- By default, trusted counter DLLs are exempt from Perflib's extensive run-time testing, but you can use ExtCounterTestLevel to require some tests. **ExtCounterTestLevel** applies to all trusted counters on the system, not just those of a particular service.

### Tip

- If particular performance counters do not appear in your performance monitoring tool, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib detects disabling errors in a counter DLL, it records an event in the log and sets the value of Disable Performance Counters to 1 to disable the counters.

### Caution

- Do not change the value of this entry by editing the registry. If you do, the performance counters for this service will not operate properly.

Disable Performance Counters

# Open Timeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Performance

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xEE6B2800 *milliseconds* | The value of OpenProcedureWaitTime |

**Description**
Defines a slow Open procedure call for these counters.

This entry tells the Performance Library (Perflib) how long the Open procedure call for these counters is expected to run. If the time specified in the value of this entry expires before the call completes, then Perfib considers the call to be abnormally slow, and it records an error in the Application Log in Event Viewer. Also, if the Configuration Flags entry requires it, then Perflib disables the counters and does not display the counters again until you manually re-enable them.

Perflib times the procedure calls of non-trusted counters to identify counters that can delay or lock performance tools during initialization. While the Collect procedure call proceeds, you cannot use the performance tools, and remote users cannot log on to the local computer.

**Activation Method**
To make changes to this entry effective, restart the Remote Registry Service or restart Windows.

### Note

- Timing procedure calls is one of several tests Perflib performs to maintain the integrity of the counters. To configure the Perflib test feature, use the Configuration Flags entry.
- Perflib does not time the procedure calls of trusted performance counter dynamic-link libraries (DLLs). This entry applies only to non-trusted DLLs.
- Perflib disables counters because of slow procedure calls only when, the 0x8 (1000) bit is set and the 0x2 (10) bit is not set in the value of Configuration Flags.
- Perflib does not time procedure calls when the 0x4 (100) bit is set in the value of Configuration Flags.
- Perflib disables counter by setting the value of Disable Performance Counters for that service to 1. After you have repaired or replaced the counter DLLs, you must re-enable them manually by changing the value of **Disable Performance Counters** to 0.
- Some performance counters DLLs add the **Collect Timeout** entry to the registry. If it does not appear, you can add this entry to the registry to override the default value.
- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Tip

- If you suspect problems with procedure calls, check the Application Log in Event Viewer. Perflib records an error in the log whenever a procedure call exceeds its limit.

# service-name\Security Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*

**Description**
The Security subkey stores information about the permissions set for a driver or a Win32 service.

# Security\Security Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Security

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *Security descriptor* | (None) |

**Description**
Stores the security descriptor for the service. A security descriptor specifies the security attributes of the service, including the security identifier (SID) and access control lists associated with the service.

Applications view and edit this entry by using the QueryServiceObjectSecurity() and SetServiceObjectSecurity() Win32 APIs.

**Change Method**
To change the value of this entry, you can use the Services snap-in. You can also use the ChangeServiceConfig API or use SC, a tool included in Windows Server 2003.

### Note

- Not all services have this entry. In its absence, the Security Configuration Manager uses a default security descriptor.

# AtmUni

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The AtmUni subkey stores configuration data for the Asynchronous Transfer Mode (ATM) user-to-network interface (UNI) Call Manager. The ATM UNI Call Manager is a Windows Server 2003 component that creates switched and permanent virtual circuits for ATM signaling and communication.

The AtmUni\Parameters subkey stores entries that apply to all ATM network adapters. Entries that configure a particular adapter are stored in the subkey named by the globally unique identifier (GUID) of the adapter in the AtmUni\Parameters\Adapters subkey.

The AtmUni subkey and its subkeys appear in the registry only after you install an ATM network adapter. The system detects the adapter and installs the Windows ATM Services and their registry elements.

By default, the AtmUni subkey contains only the standard entries associated with a Windows service. However, Windows ATM Services adds entries to these subkeys when you use Network and Dial-up Connections to change the default properties of an ATM connection, the ATM Call Manager, or an ATM network adapter. You can also add the entries to configure your ATM adapters.

# AtmUni\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AtmUni

**Description**
The AtmUni subkey stores configuration data for the asynchronous transfer mode (ATM) user-to-network interface (UNI) Call Manager. The ATM UNI Call Manager is a Windows Server 2003 service that creates switched and permanent virtual circuits for ATM signaling and communication.

The Parameters subkey stores entries that apply to all ATM network adapters.

In addition to these entries, the Parameters subkey contains an Adapters subkey, which contains a subkey for each ATM network adapter installed on the system. The subkeys within AtmUni\Parameters\Adapters are named by the globally unique identifier (GUID) of a particular network adapter, and they store entries that apply only to that adapter.

# LogFileName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AtmUni\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Fully-qualified path to a text file (.txt)* | (None) |

**Description**
Specifies the location of the ATMUNI event log file. If you do not add this entry to the registry, then the AtmUni Call Manager does not create a log.

By adding this entry to the registry, you direct the AtmUni Call Manager to create an event log file at the specified location. To specify the types of events to record in the log, use the LogFlags entry. By default, no events are recorded in the log.

The AtmUni Call Manager creates a new log file at the specified location each time the service starts, and it records events in that file until the service stops. There is no limit on the log file size. To prevent a particular log file from being overwritten when the service starts again, you must rename the file or change the value of this entry.

This entry does not exist in the regitry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- The ATMUNI log file records events generated by activity on all asynchronous transfer mode (ATM) network adapters. You cannot configure a log file for a particular ATM adapter.

**See Also**
**Concepts**
LogFlags

# LogFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AtmUni\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xF *bitmask value* | 0x0 |

**Description**
Specifies which types of events are recorded in the ATMUNI log file. The ATMUNI log file is created only when the value of this entry is greater than 0x0 and you have added a LogFileName entry to the AtmUni\Parameters subkey.

The value of this entry is a bitmask. To add an event type to the log, set the bit representing that event type to 1. To remove an event type from the log, set the bit representing that event type to 0. You can also determine the necessary value for this entry by summing the hexadecimal values of the event types that you want to appear in the log.

For example, to indicate that all event types should appear in the log, enter 0xF (1 + 2 + 4 + 8).

| Value | Meaning |
|---|---|
| 0x0 (0) | Do not write any events to the log. No log is created. |
| 0x1 (01) | Failed calls. |
| 0x2 (10) | Successful calls. |
| 0x4 (100) | Abnormal call terminations. |
| 0x8 (1000) | Normal call terminations. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- The ATMUNI log records events generated by the activity of all asynchronous transfer mode (ATM) network adapters. You cannot configure a log file for a particular ATM adapter.

**See Also**
**Concepts**
LogFileName

# Parameters\Adapters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AtmUni\Parameters

**Description**
The Adapters subkey stores asynchronous transfer mode (ATM) configuration data that applies only to a particular adapter. (Entries that apply to all adapters appear in the AtmUni\Parameters subkey.) This subkey enables you to configure individual adapters independently.

The Adapters subkey contains one or more subkeys. Each of these subkeys represents a particular ATM network adapter, and each is named by the globally unique identifier (GUID) of that adapter. Each of the *Adapter-GUID* subkeys stores entries that apply only to the adapter represented by the subkey.

Some entries can appear in the AtmUni\Parameters subkey and in an *Adapter-GUID* subkey. If the entry appears in both locations, then the value in the *Adapter-GUID* subkey takes precedence over the value in the AtmUni\Parameters subkey when configuring that particular adapter.

# Adapter-GUID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AtmUni\Parameters\Adapters

**Description**
Each *Adapter-GUID* subkey in the Adapters subkey represents a particular asynchronous transfer mode (ATM) network adapter, and each is named by the globally unique identifier (GUID) of the adapter. The actual *Adapter-GUID* subkeys in your registry depend on the ATM adapters that are installed on the computer or that are available to the system.

Some entries can appear in the AtmUni\Parameters subkey and in an *Adapter-GUID* subkey. If the entry appears in both locations, then the value in the *Adapter-GUID* subkey takes precedence over the value in the AtmUni\Parameters subkey when configuring that particular adapter.

### Note

- The *Adapter-GUID* subkey is a variable representing the subkeys in the HKLM\System\CurrentControlSet\Services\AtmUni\Parameters\Adapters subkey. It does not actually appear in the registry. This variable subkey displays the entries and subkeys that are common to many of the subkeys in Adapters.

# Adapter-GUID\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AtmUni\Parameters\Adapters*Adapter-GUID*

**Description**
The Parameters subkey stores configuration data that applies only to the asynchronous transfer mode (ATM) network adapter represented by the subkey.

Some entries can appear in the AtmUni\Parameters subkey and in an *Adapter-GUID* subkey. If the entry appears in both locations, then the value in the *Adapter-GUID* subkey takes precedence over the value in the AtmUni\Parameters subkey when configuring that particular adapter.

# IlmiRegisterAddresses

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AtmUni\Parameters\Adapters*Adapter-GUID*\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**

Specifies whether Integrated local management interface (ILMI) is enabled on the adapter.

By default, ILMI address registration is enabled on all ATM network adapters. To disable ILMI on a particular adapter, set the value of this entry to 0 in the *Adapter-GUID* subkey representing the target adapter.

| Value | Meaning |
|---|---|
| 0 | ILMI is disabled. |
| 1 | ILMI is enabled. |

# AuthSrv

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The AuthSrv subkey stores configuration data shared by the Internet Authentication Service (IAS) and Routing and Remote Access.

# AuthSrv\Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\AuthSrv

**Description**
The Parameters subkey stores configuration data shared by the Internet Authentication Service (IAS) and Routing and Remote Access.

# BootVerification

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The BootVerification subkey stores entries for Bootvrfy.exe, a program included in Windows Server 2003 that notifies the system that startup was successful. Bootvrfy.exe can be run on a local or remote computer.

By default, Winlogon determines whether a startup is successful, and it notifies the system of the success or failure. However, you can use Bootvrfy.exe to declare the logon successful instead. Typically, users place Bootvrfy.exe in a service group so that it runs after mission-critical applications have been loaded successfully. This ensures that startup is declared successful only after these applications have been loaded.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Notes

- To run a custom startup verification program, you must disable the standard startup verification functions in Winlogon by setting the value of the ReportBootOk entry to 0.

- You cannot run Bootvrfy.exe if you are also running a custom startup verification program. Custom boot verification programs are listed in the value of the BootVerificationProgram\ImagePath entry in the BootVerificationProgram subkey.

### Tip

- To run Bootvrfy.exe, use Regedit.exe to add the BootVerification subkey to the registry. Then, add the following entries to the subkey with the values specified:

| Entry name | Data type | Value |
|---|---|---|
| ErrorControl | REG_DWORD | 1 |
| service-name\ImagePath | REG_EXPAND_SZ | Bootvrfy.exe |
| ObjectName | REG_SZ | LocalSystem |
| Start Entry | REG_DWORD | 3 |
| Type Entry | REG_DWORD | 2 |

**Concepts**
BootVerificationProgram
BootVerificationProgram\ImagePath
ReportBootOk

# Cdrom

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The Cdrom subkey stores configuration data for CD-ROM drivers and devices.

**Activation Method**
You can activate changes to the values of entries in this subkey by restarting the computer.

You can also activate changes without restarting the computer. From Device Manager, in Computer Management, first disable all CD-ROM drives and then enable all CD-ROM drives.

**Caution**

Invalid configuration of entries in this subkey can prevent the computer from starting.

# Cdrom\AutoRun

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Cdrom

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the CD-ROM driver sends a Media Change Notification (MCN) message to clients, including the Windows interface, when it detects a change in media. The MCN message triggers media-related features, such as autoplay when a CD-ROM is inserted into the CD-ROM drive.

If the MCN message is disabled, then the media features that use it do not operate.

| Value | Meaning |
|---|---|
| 0 | Does not send an MCN message. |
| 1 | Sends an MCN message. |

**Activation Method**
You can activate changes to the value of this entry by restarting the computer. Or, in Computer Management, in Device Manager, disable all CD-ROM drives and then enable all CD-ROM drives.

### Note

- If the value of this entry is 0, then Autoplay does not operate, regardless of the value of the **NoDriveAutoRun** entry (in HKLM and HKCU) and the **NoDriveTypeAutoRun** entry (in HKLM and HKCU).

### Tip

- To disable Autoplay on particular drives, use **NoDriveAutoRun** (in HKLM or HKCU) or **NoDriveTypeAutoRun** (in HKLM or HKCU). Do not disable the MCN message unless you have no alternative.

### Caution

Disabling MCN may cause other system components, such as NT Media Services, to not work properly with the CD-ROMs in the system. Consider disabling only Autoplay, as described in Tips.

**See Also**
**Concepts**
AutoRunAlwaysDisable

# AutoRunAlwaysDisable

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Cdrom

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Vendor or product identfiers* | (List of identified products and product groups.) |

**Description**
Suppresses the Media Change Notification (MCN) message for particular CD-ROM drives.

By default, the system sends an MCN message when a CD-ROM is inserted in a CD-ROM drive. The MCN message triggers media features, such as Autoplay. When the MCN message is suppressed, these media features do not operate.

This entry identifies devices that do not support media features. Typically, this list consists of CD-ROM changers that do not support Autoplay because they must attempt to physically load the media to verify that the media is present.

The entries in this list do not need to be complete device identifiers. The system suppresses the MCN message for all devices that begin with the characters of an entry in the list. This method makes it easier to disable media features for all products of a certain vendor or product line.

### Notes

- If the value of this entry is not blank, then it takes precedence over a value of 1 in Cdrom\AutoRun for the particular devices identified.
- If a device is identified in this list, then Autoplay does not operate on the device, regardless of the value of the **NoDriveAutoRun** entry (in HKLM and HKCU) and the **NoDriveTypeAutoRun** entry (in HKLM and HKCU).
- The identifiers listed in this value are those reported to the system by the device. These identifiers might differ from those listed on the drive housing.
- The default value for this entry consists of products and product groups that have been identified through testing as being unable to support Autoplay. This list might change as testing progresses and products are updated.

### Tip

- To disable Autoplay on particular drives, use the **NoDriveAutoRun** entry (HKLM or HKCU) or the **NoDriveTypeAutoRun** entry (HKLM or HKCU). Do not disable the MCN message unless you have no alternative.

### Caution

- If you add or remove items from the list stored in this entry, then your CD-ROM drives might not operate properly.

Cdrom\AutoRun

# DHCP Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Dhcp\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Dhcp

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Options

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Dhcp\Parameters

**Description**
The Options subkey stores configuration data for options that the client can request from the Dynamic Host Configuration Protocol (DHCP) service by using DHCP Manager.

The Options subkey does not contain entries. Instead, it contains numbered subkeys, each of which represents a DHCP option. The entries in each Option# subkey apply only to the option represented by the subkey.

**Caution**

- Do not directly modify the values of entries in the subkeys of this subkey by, for example, using the Registry Editor (regedit.exe). Values in this subkey should only by modified by using the standard interface.

# Option#

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Dhcp\Parameters\Options

**Description**
The Parameters subkey contains *Option#* subkeys, which store configuration data for options that the client can request from the Dynamic Host Configuration Protocol (DHCP) service by using DHCP Manager.

Most of the entries described in this reference as being stored in the *Option#* subkey can appear in any of the subkeys in the Options subkey.

**Note**

- "*Option#*" subkey is a placeholder representing the subkeys in the subkey DHCP\Parameters\Options "Option#" does not actually appear in the registry.

**Caution**

- Do not edit the value of these types of entries by using the Registry Editor (regedit.exe). Values in this subkey should only by modified by using the standard interface.

# KeyType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Dhcp\Parameters\Options*Option#*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–7 | 7 |

**Description**
Specifies the data type of the registry entry that stores configuration data for the option that the client can request from the Dynamic Host Configuration Protocol (DHCP) service. The data type defines the length and format of data that the entry can store.

| Value | Meaning |
|---|---|
| 1 | REG_SZ |
| 2 | REG_EXPAND_SZ |
| 3 | REG_BINARY |
| 4 | REG_DWORD or REG_DWORD_LITTLE_ENDIAN |
| 5 | REG_DWORD_BIG_ENDIAN |
| 6 | REG_LINK |
| 7 | REG_MULTI_SZ |

**Note**

- The name of the entry that stores configuration data appears in the value of the RegLocation entry.

**Tip**

- For more information about data types, see Data Types in the Registry.

**See Also**
**Concepts**
RegLocation

# RegLocation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Dhcp\Parameters\Options*Option#*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Registry path* | (Varies with the option.) |

**Description**
Specifies the path to the registry entry that stores configuration data for the option that the client can request from the Dynamic Host Configuration Protocol (DHCP) service. This data is obtained from the Dynamic Host Configuration Protocol (DHCP) service.

The path to the entry can include a variable (*?*) that represents the Services subkey for the network adapter. For example, if the value of **RegLocation** is System\CurrentControlSet\Services\?\Parameters\Tcpip\DhcpSubnetMaskOpt, it indicates that data for the option is stored in the value of the **DhcpSubnetMaskOpt** entry in HKLM\System\CurrentControlSet\Control\Services\AdapterName#\Parameters\Tcpip.

**Tip**

- The data type of the registry entry that stores configuration data appears in the value of the KeyType entry.

# DHCPServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The DHCPServer subkey stores configuration data for the Dynamic Host Configuration Protocol (DHCP) service. A DHCP server is a server that is running a Windows Server 2003 operating system, Microsoft TCP/IP, and the DHCP-compatible server software.

DHCP servers maintain a database of TCP/IP configuration information and provide that information to clients upon request.

# DHCPServer\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DHCPServer

**Description**
The Parameters subkey stores configuration options for the Dynamic Host Configuration Protocol (DHCP) service database on this server. DHCP servers maintain a database of TCP/IP configuration information and provide that information to clients upon request.

# ActivityLogFlag

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether Dynamic Host Configuration Protocol (DHCP) activity is audited and recorded in a log.

| Value | Meaning |
|---|---|
| 0 | DHCP activity is not audited or logged. |
| 1 | DHCP activity is audited and logged. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use the DHCP Manager snap-in. Right-click the name of the server, click **Properties**, and then click the **General** tab. This entry stores the setting of the **Enable Audit Log** check box.

# APIProtocolSupport

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 \| 0x2 \| 0x4 \| 0x5 \| 0x7 | 0x5 (5) |

**Description**

Specifies the supported protocols for the Dynamic Host Configuration Protocol (DHCP) server, and ensures that different computers running different protocols can access the DHCP server.

To enable support for a protocol, set the corresponding bit to 1, or add the hexadecimal value to the value of APIProtocolSupport. For example, to enable support for all protocols, set the value of this entry to 0x7 (111 binary).

| Binary value | Hexadecimal value | Meaning |
|---|---|---|
| 1 | 0x1 | Supports TCP/IP protocol |
| 10 | 0x2 | Supports named pipes protocols |
| 100 | 0x4 | Supports local procedure call (LPC) protocols |

# BackupDatabasePath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | *Systemroot*\System32\dhcp\backup |

**Description**
Specifies the directory where the backup copy of the Dynamic Host Configuration Protocol (DHCP) client information database is stored. If you change the value of this entry, then DHCP saves new backup copies in the new location, but it does not move existing backup copies of the database.

**Change Method**
To change the value of this entry, use the DHCPmgmt.msc snap-in or the netsh dhcp server commands.

**Activation Method**
To make changes to the value of this entry effective, you must restart DHCP server using the DHCPmgmt.msc snap-in, netsh, or services.msc

### Tip

- Store the backup file on a hard drive other than the one on which the database resides. This lets you recover the database even when the system drive fails. However, because DHCP Manager cannot access a network drive for database backup and recovery, you cannot store the backup file on a network drive.

**Concepts**
DatabasePath
BackupInterval

# BackupInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–71582 *minutes* | 60 |

**Description**
Specifies how often the Dynamic Host Configuration Protocol (DHCP) client information database is backed up.

### Note

- Because DHCP stores this value internally in milliseconds, this entry is limited to values less than 71583. When converted to milliseconds, higher values are too large to store in a DWORD field.

**See Also**
**Concepts**
BackupDatabasePath

# DatabaseCleanupInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *minutes* | 0x5A0 |

**Description**

Specifies how often the Dynamic Host Configuration Protocol (DHCP) Service deletes expired (*doomed*) records from the DHCP client information database. By default, records expire after four hours. Deleting expired records releases space for new IP addresses.

# DatabaseName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Filename* | dhcp.mdb |

**Description**
Specifies the name of the file that contains the Dynamic Host Configuration Protocol (DHCP) client information database.

**Change Method**
To change the value of this entry, use DHCP Manager.

**See Also**
**Concepts**
DatabasePath

# DatabasePath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | *Systemroot*\System32\dhcp |

**Description**
Specifies the directory where the Dynamic Host Configuration Protocol (DHCP) client information database files and audit log files are stored. If you change the value of this entry, DHCP stores new database files in this location, but it does not move existing database files to the new location.

By default, database files and audit log files are stored in the same directory. The location of log files is determined by the value of the DhcpLogFilePath entry.

**Change Method**
To change the value of this entry, use the DHCP Manager snap-in. Right-click the name of the server, click **Properties**, click the **Advanced** tab, and enter a new path in the **Database path** field.

**See Also**
**Concepts**
DatabaseName
DhcpLogFilePath

# DetectConflictRetries

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–5 *retries* | 0 |

**Description**
Specifies how many times the Dynamic Host Configuration Protocol (DHCP) service issues Internet Control Message Protocol (ICMP) Ping messages if the messages are not successful. When the number of unsuccessful messages reaches the value of this entry, the DHCP service offers a new IP address.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the DHCP Manager snap-in. Right-click the name of the server, click **Properties**, and then click the **Advanced** tab. This entry stores the value in the **Conflict detection attempts** box.

### Note

- The maximum valid value for this entry is 5. If you enter a value greater than 5, then the DHCP service interprets it as 5.

# DhcpLogDiskSpaceCheckInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *number of audit log entries* | 0x32 (50) |

**Description**
Specifies how often Dynamic Host Configuration Protocol (DHCP) verifies that disk space and file size are adequate for its audit log. The value of this entry represents the number of audit log records entered between each verification check.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
DhcpLogMinSpaceOnDisk

# DhcpLogFilePath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Path name* | Same as DatabasePath |

**Description**
Specifies the directory where Dynamic Host Configuration Protocol (DHCP) audit logs are stored. If you change the value of this entry, then DHCP moves the audit log files to the new location.

By default, the audit logs are stored in the same directory as the DHCP client information database. The location of the database is specified in the value of the DatabasePath entry.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the DHCP Manager snap-in. Right-click the name of the server, click **Properties**, click the **Advanced** tab, and enter a new path in the **Log file path** box.

**See Also**
**Concepts**
DatabasePath

# DhcpLogFilesMaxSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *MB* | 0x7 (7 MB) |

**Description**
Specifies the maximum combined size of one week's worth of Dynamic Host Configuration Protocol (DHCP) audit logs. If the audit logs exceed the size specified by this value, then DHCP stops writing to the audit log until sufficient space becomes available.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# DhcpLogMinSpaceOnDisk

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *MB* | 0x14 (20 MB) |

**Description**
Specifies the minimum amount of free disk space required for audit logging.

The Dynamic Host Configuration Protocol (DHCP) periodically verifies that it has sufficient disk space to proceed with audit logging (the interval is specified in the value of the DhcpLogDiskSpaceCheckInterval entry). This entry specifies the minimum value that DHCP requires. If the amount of free disk space is less than the value of this entry, then the DHCP service does not write to the audit log. Logging is suspended until sufficient disk space is available.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
DhcpLogDiskSpaceCheckInterval

# IgnoreBroadcastFlag

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the Dynamic Host Configuration Protocol (DHCP) server complies with or ignores the value of the broadcast bit (broadcast flag) in a client DHCP Discover message.

By default, Windows Server 2003 DHCP servers ignore the broadcast bit on the client requests. Instead, they send all DHCP responses as IP broadcasts to the limited broadcast address (255.255.255.255). However, a DHCP server can be configured to send responses as unicast responses if the client request specifies that a broadcast response is not required.

On Microsoft DHCP clients, the broadcast bit is not set, that is, it is set to request initial Dhcpoffer and Dhcpack packets in unicast messages.

| Value | Meaning |
|---|---|
| 0 | Comply with broadcast flag in client request. |
| 1 | Ignore broadcast flag in client requests, and broadcast all DHCP packets |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must restart the system before a change to this value takes effect.

**Caution**

- Setting the value of this entry to 0 reduces broadcast traffic. However, clients cannot receive unicast Dhcpoffer and Dhcpack packets unless the Microsoft DHCP server and DHCP client are on a homogeneous Ethernet network or the same subnet of a Token Ring network. Do not change the default broadcast behavior of a Microsoft DHCP server if the server and client are on different Token Ring subnets or are separated by a router or bridge that does media access control (MAC) level address translation, for example, Ethernet to or from Token Ring.

# MaxActiveThreads

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–20 | 1 |

**Description**
Used to calculate the maximum number of Dynamic Host Configuration Protocol (DHCP) message processing threads that can be active at any given time. The DHCP service will activate no more threads than the value of this entry, plus one thread for each processor on the server computer.

The value of this entry must be no more than the value of the MaxProcessingThreads entry. If you enter a higher value, then the system uses the value of **MaxProcessingThreads**.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
MaxProcessingThreads

# MaxProcessingThreads

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DhcpServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x11 |

**Description**
Used to calculate the maximum number of message processing threads that the Dynamic Host Configuration Protocol (DHCP) service can create. The DHCP service creates no more threads than the value of this entry, plus one thread for each processor on the server computer. Although you can set the value of this entry higher than 20, DHCP creates no more than 20 threads.

This value must be greater than or equal to the value of the MaxActiveThreads entry.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
MaxActiveThreads

# DNS Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The DNS subkey stores configuration information for the Domain Name System (DNS) server.

DNS associates IP addresses and other data identifying a computer with the computer's display name, for example host.reskit.com.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, the changes are not effective until you restart the DNS server.

**Tip**

- This subkey stores data for the DNS server. To configure DNS dynamic update on the DNS client, see the following entries in the Tcpip subkey: **DefaultRegistrationTTLEnableAdapterDomainNameRegistrationDisableDynamicUpdateDisableReplaceAddressesInConflicts**DisableReverseAddressRegistrations**UpdateSecurityLevel**

# DNS\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS

**Description**
The Parameters subkey stores Domain Name System (DNS) configuration data that applies to all zones in the network. Settings that apply to a specific zone are stored in a subkey representing that zone in the Zones subkey.

# AddressAnswerLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 5–28 *records* | 0 |

**Description**

Specifies the maximum number of A (host IP address) resource records that the Domain Name System (DNS) server can insert in the answer section of a response to an A record query (a query for an IP address). The value of this entry also influences the setting of the truncation bit. If the value of this entry is from 5 through 28, then the truncation bit is not set on the response, even when the packet space is exceeded.

The value of **AddressAnswerLimit** is imposed upon A record queries only; it does not affect other types of queries.

| Value | Meaning |
|---|---|
| 0 | There is no limit on the number of A records in a response. If the response, including all A records, does not fit in a UDP DNS packet, then the truncation bit is set. |
| 5 - 28 | The maximum permissible number of A records in a response. The truncation bit is not set, regardless of the size of the response. |

**Change Method**

To change the value of this entry, use Dnscmd.exe, a tool included in Windows Support Tools. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**

DNS reads its registry entries only when it starts. You can modify entries while the DNS server is running by using the DNS console. If you modify entries by editing the registry, the changes are not effective until you restart the DNS server.

### Note

- This entry was designed to resolve a problem in DNS for Windows 95 (without service packs) in which DNS fails when it receives more than 28 A records in a response to an A query. This occurs infrequently and only when numerous servers are supporting a Web site. However, because the truncation bit is not set, limiting A records has the added benefit of preventing remote DNS servers from using TCP to retry these queries. DNS servers often use TCP to retry queries when they receive a response with the truncation bit set.

- DNS does not add this entry to the registry. You can add it by using Dnscmd.exe, or by using the registry editor Regedit.exe.

# AutoCacheUpdate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the DNS server attempts to update its cache file, Cache.dns, at startup. The cache file contains a list of NS records and A records for root servers. The cache file is updated with information that it obtains by querying root DNS servers for root NS type records .

| Value | Meaning |
|---|---|
| 0 | The DNS server does not update the cache file automatically. An administrator must update the cache file by using the DNS console or by editing the Cache.dns file manually. If you edit Cache.dns, you must restart the DNS server to make changes effective. |
| 1 | The DNS server attempts to update the cache file automatically with information that it obtains by querying root DNS servers. It queries the root servers the first time it does a recursive query. |

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in *Windows Server 2003 Support Tools*. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Notes

- This entry does not affect NS and A records that are added or changed by using the DNS snap-in or the New Server Wizard. Records added or changed in this manner are always written to the cache file.
- Some Internet root servers do not maintain an accurate set of root server data. As a result, even when updated, the cache file might not be complete.

### Tip

- To force an immediate update, in the DNS snap-in, right-click the name of the DNS server, and then click **Update Server Data Files**.

# AutoConfigFileZones

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 3 | 1 |

**Description**
Specifies whether the Domain Name System (DNS) server updates the resource records of standard primary zones when the fully qualified domain name (that is, the name or the primary DNS suffix) of the local computer changes.

This entry establishes criteria for zone updates. If a zone meets the criteria, and the fully qualified domain name of the local computer changes, then the DNS server updates the host name on resource records that include the local computer name, such as SOA (Start of Authority), NS (name server), and A (address) records. Otherwise, the records are not updated when the computer name changes.

| Value | Meaning |
|---|---|
| 0 | No zones. The DNS server does not update resource records when the local computer name changes. |
| 1 | Dynamic update zones. The DNS server updates only the resource records of standard primary zones that permit dynamic updates. |
| 2 | No dynamic update zones. The DNS server updates only the resource records of standard primary zones that do not permit dynamic updates. |
| 3 | All zones. The DNS server updates the resource records of all standard primary zones. |

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in *Windows Server 2003 Support Tools*. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can modify entries while the DNS server is running by using the DNS console. If you modify entries by editing the registry, then the changes are not effective until you restart the DNS server.

**Tip**

- To find other registry entries related to DNS dynamic update, type "dynamic update" on the Search tab in this file.

**See Also**
**Concepts**
PreviousLocalHostname

# BindSecondaries

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Enables the Domain Name System (DNS) server to communicate with non-Microsoft DNS servers that use an earlier, slower version of the DNS BIND service.

| Value | Meaning |
|---|---|
| 0 | The Microsoft DNS server places as many resource records as possible in each message to achieve maximum compression and speed of transfer. Microsoft DNS servers and non-Microsoft DNS servers that use BIND version 4.9.4 or higher can receive transfers in this format. |
| 1 | The Microsoft DNS server sends zone transfers to non-Microsoft DNS secondaries with one resource record in each message. Non-Microsoft DNS servers using BIND versions prior to 4.9.4 can receive the transfer only in this format. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the DNS console. Right-click the server name, click **Properties**, and then click the **Advanced** tab. This entry corresponds to the **Bind Secondaries** option in the Advanced server options list.

**Activation Method**
DNS reads its registry entries only when it starts. You can modify entries while the DNS server is running by using the DNS console. If you modify entries by editing the registry, then the changes are not effective until you restart the DNS server.

## Notes

- Transfers between Microsoft DNS servers always use the faster, high-compression method, regardless of the value of this entry.

- The default value of this entry is appropriate for most DNS servers. Change the value of this entry to 0 only if you have NEW BIND servers (or non-BIND,non-Windows servers) that are secondaries to a Microsoft DNS server and if transfer performance is a high priority.

# DatabaseDirectory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Directory path* | *Systemroot*\System32\Dns |

**Description**
Specifies the directory that contains the Domain Name System (DNS) database.

By default, the DNS database is located in *Systemroot*\System32\Dns, but you can add this entry to the registry to change the default location. If you do, then the DNS server loads from and writes new zone records to the new location. If you already have a DNS database in *Systemroot*\System32\Dns, then you must manually move it to the new location. DNS will not move or maintain the original database.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in Windows Support Tools. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. To make changes to this entry effective, you must restart DNS.

# DisableAutoReverseZones

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Enables and disables automatic reverse zones, an optimizing feature of the Domain Name System (DNS). When this feature is enabled, DNS automatically creates three reverse lookup zones.

Reverse lookup zones enable the DNS server to be authoritative, that is, to know the answer in advance and to respond immediately to the most common name queries, thus eliminating unnecessary recursive queries. In accordance with pertinent Requests for Comments (RFCs), by default, the DNS server is authoritative for three reverse lookup zones:

- 0.in-addr.arpa (0.0.0.0)
- 127.in-addr.arpa (127.0.0.1 - loopback)
- 255.in-addr.arpa (255. 255. 255. 255 - broadcast)

| Value | Meaning |
|---|---|
| 0 | The automatic reverse zones feature is enabled. The DNS server automatically creates three reverse lookup zones. |
| 1 | The automatic reverse zones feature is disabled. The DNS server does not automatically create reverse lookup zones. |

**Change Method**
If Microsoft Product Support Services instructs you to change the value of this entry, use Dnscmd.exe, a tool included in the Windows Support Tools, and then restart the DNS server.

**Activation Method**
Because the DNS server creates zones only when it starts, you must restart the DNS server to make changes to this entry effective, even if you use Dnscmd.exe to make the change.

### Note

- DNS does not add this entry to the registry. You can add it by using the registry editor Regedit.exe, or by using a program that stores changes in the registry, such as Dnscmd.exe.

### Caution

- Do not change the value of this entry unless instructed to by Microsoft Product Support Services. Using automatic reverse zones improves the performance of the DNS server. The default value is optimal for almost all DNS server configurations.

# DoNotRoundRobinTypes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Contains a list of types of DNS resource records to exclude from round-robin name resolution. If the value of the **RoundRobin** entry is 1 (which configures the DNS service to use round-robin name resolution), then the types of resource records listed in this registry entry are excluded from round-robin name resolution.

Valid values for this registry entry are any standard DNS record type, including SOA, NS, A, PTR, CNAME, MX, and SRV. In addition, three types of resource records that are not part of standard DNS are also supported: WINS, WINS-R, and ATMA. For more information about resource records, see the *Networking Collection* of the *Windows Server 2003 Technical Reference* (or see the Networking Collection on the Web at http://www.microsoft.com/reskit).

### Notes

- To exlude all types of DNS records from round-robin name resolution, set the value of **RoundRobin** to zero.
- The default configuration of Windows Server 2003 DNS is for round-robin name resolution. This entry adds flexibility to Windows Server 2003 DNS, by allowing you to choose partial round-robin name resolution without requiring you to turn it off completely.

LocalNetPriority

# Parameters\EventLogLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 4 | 4 |

**Description**
Specifies which events Domain Name System (DNS) records in the DNS server log in Event Viewer.

| Value | Meaning |
|---|---|
| 0 | None. |
| 1 | Errors only. |
| 2 | Errors and warnings. |
| 4 | All events: errors, warnings, and informational events. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in the Windows Support Tools. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using Dnscmd.exe. If you change entries by using the registry editor Regedit.exe, the changes are not effective until you restart the DNS server.

# ForwardDelegations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the Domain Name System (DNS) server forwards queries about delegated subzones to servers outside of its authoritative zone. This entry is used only if the delegated subzone is within the DNS server's authoritative zone, even though the primary server for the subzone is in another zone.

By default, when the DNS server receives a query for a name outside its authoritative zone, it forwards the query to a similarly-named server in another zone. However, when it receives a query for a delegated subzone, and the subzone is within the DNS server's zone (even when the primary server for the site is in another zone), it sends the query directly to the subzone and does not forward it. When the value of this entry is 1, the DNS server forwards queries for delegated subzones to other servers, just as it does for names in other zones.

Consider adding this entry and setting the value to 1 if the delegation is at a remote site that a remote server can reach more easily.

| Value | Meaning |
|---|---|
| 0 | The DNS server sends queries about delegated subzones that are within its authoritative zone directly to the subzone. It does not forward them. |
| 1 | The DNS server forwards all name queries about delegated subzones to servers in other zones. |

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in the Windows Support Tools. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using Dnscmd.exe. If you change entries by using the registry editor Regedit.exe, then the changes are not effective until you restart the DNS server.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe, or by using a program that edits the registry, such as Dnscmd.exe.
- This entry is used only when forwarding is enabled. If the value of the **Forwarders** entry does not contain at least one valid IP address, then this entry is ignored.

**See Also**
**Concepts**
IsSlave
NoRecursion

# IsSlave

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies how the Domain Name System (DNS) server responds when it does not receive a response to a query that it has forwarded.

| Value | Meaning |
|---|---|
| 0 | If the forwarder servers do not respond, the DNS server issues standard iterative queries to try to resolve the remote name. |
| 1 | If the forwarder servers do not respond, the DNS server terminates the search and sends a SERVER_FAILURE response to the query. |

**Change Method**
To change the value of this entry, select or clear the **Do not use recursion** check box on the **Forwarders** tab in the DNS console. You can also use Dnscmd.exe, a tool included with the Windows Support Tools. Your changes are effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console or Dnscmd.exe. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Note

- If you start DNS by using a standard BIND file, the value of Slave in the BIND file takes precedence over the value of this registry entry. This entry might be deleted, or the value in the BIND file might replace the value of this entry.
- This entry is used only when forwarding is enabled, that is, when the value of the **Forwarders** entry includes at least one valid IP address.
- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Tip

- In general, a single forwarder is more efficient than multiple forwarders, because query results are concentrated in one forwarder's cache. To indicate that a forwarder should be queried more than once if an initial query is unsuccessful, list the IP address of the forwarder more than once on the **Forwarders** tab.

### Caution

- Do not change the value of this entry by editing the registry. If the **Forwarders** entry contains valid IP addresses and this entry is deleted, then the DNS server might not start or might not operate properly.

# ListenAddresses

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *IP address[, IP address] ... (dotted decimal form)* | (None) |

**Description**
Lists the IP addresses bound to the Domain Name System (DNS) server. If this entry does not appear in the registry or its value contains no addresses, the DNS server attempts to bind to all IP addresses on the computer.

**Change Method**
To change the value of this entry, use the **Interfaces** dialog in the DNS console or Dnscmd.exe, a tool included with the Windows Support Tools. Your changes are effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Note

- This feature does not usually improve the performance of DNS servers that are running Windows Server 2003.
- The default value is optimal for most servers. However, you might need to exclude certain interfaces, especially if you are running Windows NT 4.0 prior to Service Pack 2, which cannot bind to more than 15 IP addresses. Windows Server 2003 is not limited. Also, in Windows NT 4.0 and earlier, the DNS server does not detect and bind to more than 35 interfaces properly.
- The DNS server must bind to individual IP addresses because many resolvers require that the DNS response comes from the IP address to which the query was sent. The responses may not appear to come from the same IP address for multi-IP servers, depending on TCP/IP stack's routing table.
- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# LocalNetPriority

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies the order in which the Domain Name System (DNS) server returns A (address) records when it has multiple A records for the same name.

| Value | Meaning |
|---|---|
| 0 | The DNS server returns the A records in the order in which they were added to the database. It does not sort the records. If the value of the **RoundRobin** entry is 1, then the server rotates among the records it returns. |
| 1 | The DNS server returns records in order of their similarity to the IP address of the querying client. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the DNS console. Right-click the server name, click **Properties**, and then click the **Advanced** tab. This entry corresponds to the **Enable Netmask Ordering** option. You can also use Dnscmd.exe, a tool included in Windows Support Tools.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console or Dnscmd.exe. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Note

- The order in which A records are returned depends on the value of this entry and of the **RoundRobin** entry, as follows:
- If both entries are set to 1 (or neither entry appears in the registry), then the DNS server rotates among the A records it returns in local net priority order, that is, in order of their similarity to the IP address of the querying client.
- If the value of **RoundRobin** is 0 and the value of **LocalNetPriority** is 1, then the DNS server returns the records in local net priority order. It does not rotate among available addresses.
- If the value of **RoundRobin** is 1 and the value of **LocalNetPriority** is 0, then the DNS server rotates among the available records in the order in which the records were added to the database.
- If the values of **RoundRobin** and **LocalNetPriority** are both 0, then the DNS server returns the records in the order in which they were added to the database. It does not attempt to sort them or to rotate among them.

# LogLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1 \| 0x10 \| 0x20 \| 0xFE\| 0x100 \| 0x200 \| 0x1000 \| 0x2000 \| 0x4000 \| 0x8000 \| 0xFFFF \| 0x10000 \| 0x20000 \| 0x1000000 \| 0x80000000 | 0x0 |

**Description**

Specifies which events the Domain Name System (DNS) server records in its transaction log, Dns.log.

This entry is a 32-bit binary value. To direct DNS to log a type of event, the DNS console sets the value of this entry to that event type, as listed below. To direct DNS to log more than one type of event, the DNS console sets the value to the sum of the values representing each event type you want to include in the log.

To get a complete log, set the value to 0x8100F331.

| Value | Meaning |
|---|---|
| 0x0 | None. The DNS Service does not create Dns.log. |
| 0x1 | Queries. |
| 0x10 | Notifications. |
| 0x20 | Updates. |
| 0xFE | Non-query transactions. |
| 0x100 | Questions. |
| 0x200 | Answers. |
| 0x1000 | Send packets. |
| 0x2000 | Receive packets. |
| 0x4000 | UDP (User Datagram Protocol) packets. |
| 0x8000 | TCP packets. |
| 0xFFFF | All packets. |
| 0x10000 | Active Directory write transaction. |
| 0x20000 | Active Directory update transaction. |
| 0x1000000 | Full packets. |
| 0x80000000 | Write-through transactions. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use the DNS console. Right-click the server name, click **Properties**, and then click the **Logging** tab. This bitmask corresponds to the check boxes in the **Debug logging options** section.

**Activation Method**

DNS reads its registry entries only when it starts. You can modify entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, the changes are not effective until you restart the DNS server.

**See Also**
**Concepts**
Parameters\EventLogLevel

# MaxCacheTtl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFF *seconds* | 0x15180 (86,400 seconds = 1 day) |

**Description**
Specifies how long the Domain Name System (DNS) server can save a record of a recursive name query.

If the value of this entry is 0x0, then the DNS server does not save any records.

The DNS server saves the records of recursive name queries in a memory cache so that it can respond quickly to new queries for the same name. Records are deleted from the cache periodically to keep the cache content current. The interval during which the records remain in the cache usually is determined by the value of the Time to Live (TTL) field in the record. This entry establishes the maximum time that records can remain in the cache. The DNS server deletes records from the cache when the value of this entry expires, even if the value of the TTL field in the record is greater.

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in Windows Support Tools. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. If you change the value of this entry by editing the registry, then the changes are not effective until you restart the DNS server.

### Notes

- This entry does not affect Windows Internet Name Service (WINS) data saved in the DNS memory cache. WINS data is saved until the Cache Timeout Value on the WINS record expires. To view or change the Cache Timeout Value on the WINS record, use the DNS snap-in. Right-click a zone name, click **Properties**, click the **WINS** tab, and then click the **Advanced** button.

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# NoRecursion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the Domain Name System (DNS) server performs recursive resolution in accordance with the RecursionDesired bit in the DNS name query packet header. Recursion occurs only when the value of this entry is 0 and the RecursionDesired bit is set.

| Value | Meaning |
|---|---|
| 0 | The DNS server acts in accordance with the RecursionDesired bit set in the DNS query packet header. |
| 1 | The DNS server does not perform recursive resolution regardless of the setting of the RecursionDesired bit in the DNS query packet header. |

You might consider changing the value of this entry if clients are limited to the names on a server, such as within an intranet, or if the server cannot resolve external names.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the DNS console. Right-click the server name, click **Properties**, and then click the **Advanced** tab. This entry corresponds to the **Disable Recursion** option. Or use Dnscmd.exe, a tool included in Windows Support Tools. Using either method, the changes are effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console or Dnscmd.exe. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Note

- If you start DNS by using a standard BIND file, then the value of the RecursionDesired bit in the BIND file takes precedence over the value of this registry entry. The entry might be deleted or its value replaced by the value in the BIND file.

# PreviousLocalHostname

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Fully qualified domain name* | (Fully qualified domain name of the local computer) |

**Description**
Stores the fully qualified domain name of the local computer. When the computer name or the primary Domain Name System (DNS) suffix changes, the DNS server uses the previous name to update resource records on primary, Active Directory–integrated zones.

The DNS server copies the name of the local computer (stored in the **Hostname** entry) and the primary DNS suffix (stored in the **PrimaryDnsSuffix** entry) to the value of this entry. If the computer name or primary DNS suffix changes, then the DNS server searches SOA (Start of Authority), NS (name server), and A (address) resource records for the value of this entry, and it replaces each instance with the new computer name. Then, it copies the new value of **Hostname** and **PrimaryDnsSuffix** to the value of this entry for future changes.

### Note

- The DNS server updates resource records according to the standards set for the zone and stored in the AutoConfigFileZones entry.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

**See Also**
**Concepts**
AutoConfigFileZones

# PublishAutonet

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the Domain Name System (DNS) server builds A (address) records for temporary IP addresses produced by Automatic Private IP Addressing (APIPA). This entry applies only when the DNS server is building A records for the computer on which it is running.

APIPA is designed for computers on single-subnet networks that do not include a Dynamic Host Configuration Protocol (DHCP) server. APIPA automatically assigns an IP address from its reserved range, 169.254.0.0 through 169.254.255.255. These APIPA IP addresses, commonly known as *autonet* addresses, are used only until the system finds a DHCP server. APIPA addresses cannot be used on the Internet.

| Value | Meaning |
|---|---|
| 0 | Exclude APIPA addresses. |
| 1 | Include APIPA addresses. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in Windows Support Tools. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. If you change entries by using the registry, then the changes are not effective until you restart the DNS server.

# RecursionRetry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF *seconds* | 0x3 |

**Description**

Specifies how often Domain Name System (DNS) repeats recursive client queries when it does not receive a response from a remote server. If the DNS server does not receive a response before the time specified by the value of this entry expires, then the DNS server repeats the query to the same server or to other DNS servers.

The default value is appropriate for most servers. However, if this value is less than the time that a remote server requires to respond over a slow link, then increase this value so that it is slightly longer than the observed response time.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use Dnscmd.exe, a tool included in Windows Support Tools.

**Activation Method**

Changes made by using Dnscmd.exe are effective immediately; you do not have to restart the DNS server. If you change the value of this entry by editing the registry, then the changes are not effective until you restart the DNS server.

# RpcProtocol

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x7 \| 0xFFFFFFFF | 0xFFFFFFFF |

**Description**
Specifies the protocols that administrative remote procedure calls (RPCs) use. Although these flags are not specific to Domain Name System (DNS), the DNS server establishes endpoints to allow connections using these protocols.

The value of this entry is a bitmap. You can set multiple bits by adding the bits together and setting the value of this entry to that sum:

| Bit | Meaning |
|---|---|
| 0x0 | No protocols (disables RPC for DNS) |
| 0x1 (001 binary) | TCP/IP |
| 0x2 (010 binary) | Named pipes |
| 0x4 (100 binary) | LPC |
| 0xFFFFFFFF | All protocols |

**Change Method**
To change the value of this entry, use the DNS console.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

# SecureResponses

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether the Domain Name System (DNS) server tries to eliminate illegitimate records by filtering the records that it saves in its memory cache.

The DNS server saves the records of recursive name queries in a memory cache so that it can respond quickly to new queries for the same name. By default, it saves all records. However, if the value of this entry is 1, then DNS saves only those query records for names that are in the same subtree as the server that provided them. For example, the DNS server would save an NS (name server) record for ns.reskit.com from the reskit.com server, but it would not save the NS record for ns.contoso.com from the reskit.com server. This filtering is designed to minimize the effect of malicious attacks on an Internet server, but it might generate additional network traffic.

| Value | Meaning |
|---|---|
| 0 | The DNS server saves all name query records in its memory cache. It does not attempt to filter out illegitimate records. |
| 1 | The DNS server saves only those records of names that are in the same subtree as the name in the original query. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use the DNS console. Right-click the name of a DNS server, and then click the **Advanced** tab. This entry stores the setting of the **Secure cache against pollution** check box.

**Activation Method**

DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

# StrictFileParsing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies how the Domain Name System (DNS) server responds when it receives zone files whose records contain errors that violate standards specified by Requests for Comments (RFCs). These include records for names outside of the zone, and CNAME (canonical name) records that contain other records.

| Value | Meaning |
|---|---|
| 0 | When the DNS server encounters an erroneous record, it writes an error to the DNS log in Event Viewer and continues to load. |
| 1 | When the DNS server encounters erroneous records, it writes an error to the DNS log in Event Viewer and stops without loading. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the DNS console. Right-click the server name, click **Properties**, and then click the **Advanced** tab. This entry corresponds to the **Fail On Load If Bad Zone Data** option. Or, use Dnscmd.exe, a tool included in Windows Support Tools.

**Activation Method**
Changes made by using either the DNS console or Dnscmd.exe are effective immediately; you do not have to restart the DNS server. If you change the value of this entry by editing the registry, then the changes are not effective until you restart the DNS server.

### Note

- The default behavior of DNS changed in Windows NT 4.0 with Service Pack 4. In Windows NT 4.0 (previous to Service Pack 4) and earlier, the DNS server does not start if it encounters incorrect zone records. Check the System Log in Event Viewer for errors.

# UpdateOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x80000000 | 0x30F |

**Description**

Prohibits Domain Name System (DNS) dynamic update of certain types of records.

This entry is a bitmask. To disable DNS dynamic update on a record type, set the bit for that record type to 1, or sum the hexadecimal values of the record types.

For non-secure zones:

| Value | Meaning |
|---|---|
| 0x1 | SOA (Start of Authority) records. |
| 0x2 | NS (name server) records. |
| 0x4 | Delegation NS records. |
| 0x8 | A (address) records in the DNS server's own host record. |

For secure zones:

| Value | Meaning |
|---|---|
| 0x100 | SOA records. |
| 0x200 | NS records. |
| 0x400 | Delegation NS records. |
| 0x800 | A (address) records in the DNS server's own host record. |

Other possible values:

| Value | Meaning |
|---|---|
| 0x0 | Allows DNS dynamic update on all record types. |
| 0x30F | Prevents all of the update policy options for unsecure zones, and allows only SOA and zone root NS updates for secure zones. |
| 0x1000000 | Prevents the relay to a DNS server's peers of the server's A record updates. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use Dnscmd.exe, a tool included in Windows Support Tools. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**

DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

- To find other registry entries related to DNS dynamic update, type "dynamic update" on the Search tab in this file.

# WriteAuthorityNs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies when the Domain Name System (DNS) server writes NS (name server) records in the Authority section of a response. This entry prevents the DNS server from writing unnecessary NS records in the Authority section, and it ensures that the DNS server complies with relevant Requests for Comments (RFCs).

| Value | Meaning |
|---|---|
| 0 | The DNS server writes NS records in the Authority section of referrals only. This setting complies with RFC 1034, Domain names—concepts and facilities, and with RFC 2181, Clarifications to the DNS Specification. |
| 1 | The DNS server writes NS records in the Authority section of all successful authoritative responses. These NS records are neither required nor useful. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use Dnscmd.exe, a tool included in Windows Support Tools.

**Activation Method**

Changes made by using Dnscmd.exe are effective immediately; you do not have to restart the DNS server. If you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

### Note

- The default value is optimal for most DNS servers. Providing NS records in the Authority section consumes processor time and network bandwidth, and it is not recommended unless a network application or service requires it.

# XfrConnectTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\DNS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 1E (30 seconds) |

**Description**
Specifies how long the Domain Name System (DNS) server waits for the secondary server to connect to a primary server. If the connection is not established when the value of this entry expires, then the DNS server drops the connection.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use Dnscmd.exe, a tool included in *Windows Server 2003 Support Tools*. The change is effective immediately; you do not have to restart the DNS server.

**Activation Method**
DNS reads its registry entries only when it starts. You can change entries while the DNS server is running by using the DNS console. However, if you change entries by editing the registry, then the changes are not effective until you restart the DNS server.

# Services\EventLog

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The EventLog subkey stores configuration data that Event Viewer uses to manage the event logs.

This subkey contains the standard entries that appear in all Services subkeys. It also contains subkeys, called *Log-name*, representing each of the logs.

Windows Server 2003 creates subkeys for the three standard logs that appear in Event Viewer: Application, Security, and System. Windows services, such as the Domain Name System (DNS), also create subkeys for their own logs. Programmers can create additional log-specific subkeys for custom logs that they create.

# Log-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog

**Description**
The *Log-name* subkeys store configuration data for logs that are kept by Event Viewer. Each *Log-name* subkey is named for the log it configures. Logs include those created by Windows and its services, as well as those created by administrators. This reference documents entries and subkeys that are common to all of the logs.

**Note**

- "Log-name" does not actually appear in the registry. "*Log-name*" is a placeholder for the subkeys of this type in the Services\EventLog subkey.

# DisplayNameFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *File name* | *Systemroot*\system32\els.dll |

**Description**
Identifies the file that stores the localized name of the event log.

The name stored in the specified file appears as the log name in Event Viewer.

If this entry does not appear in the registry for an event log, then Event Viewer displays the name of the *Log-name* subkey as the log name.

**Caution**

- Do not change the value of this entry. If you do, Event Viewer cannot locate the file containing the log name.

**See Also**
**Concepts**
DisplayNameID

# DisplayNameID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | (None) |

**Description**
Stores the message identification number of the log name string.

This number indicates the message in which the localized display name appears. The message is stored in the file specified by the value of the DisplayNameFile entry.

For example, if the value of **DisplayNameID** is 0x5, then the localized display name for the log appears in Message ID 5.

If this entry does not appear in the registry for an event log, then Event Viewer displays the name of the *Log-name* subkey as the log name.

### Caution

- Do not change the value of this entry. If you do, Event Viewer cannot locate the correct display name for an event log.

DisplayNameFile

# File

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path and file name* | %SystemRoot%\System32\Config\AppEvent.evt |

**Description**
Specifies the fully qualified path to the file where each event log is stored. This entry enables Event Viewer and other log processing programs to find the log files.

The value of this entry is displayed in **Log name** in the Properties dialog box for a log in Event Viewer.

**Note**

- If you must move the event log files, do not use variables other than %Systemroot% in the file paths. Event Viewer cannot resolve variables other than %Systemroot% on remote computers.

# MaxSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x10000–0xFFFF0000 (*bytes, in 64 KB increments*) (64 KB–4 GB) | 0x80000 (*512 KB*) |

**Description**
Specifies the maximum size of the log file.

This entry corresponds to the **Maximum log size** option on the Properties page for a log in Event Viewer.

**Change Method**
To change the value of this entry, use Event Viewer.

### Note

- You cannot resolve a full log by increasing the value of this entry. You must clear the log file manually by clicking **Clear all Events** on the Properties page for any log in Event Viewer.

# PrimaryModule

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Subkey name* | (None) |

**Description**
Stores the name of the subkey in Services\Eventlog*Log-name* that contains default values for the entries in the Services\Eventlog*Log-name**Source-name* subkey.

These default values are used to display events in Event Viewer when the source program has not specified values in a *Source-name* subkey, or when files specified as the value of an entry cannot be opened or do not contain the required data.

For example, in the Services\Eventlog\Security subkey, the default value of **PrimaryModule** is Security. This value indicates that the Services\Eventlog\Security\Security subkey contains default values for entries that appear in the Services\Eventlog\Security*SourceName* subkey. These values are used to display events in the security log when the source program does not specify valid values for the entries.

**Change Method**
You can change this entry only by editing the registry.

**Concepts**
Log-name
Source-name

# Retention

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFE \| 0xFFFFFFFF (*seconds*) | 0x93A80 (*604,800 seconds = 7 days*) |

**Description**

Specifies the time, in seconds, that records of events are protected from being overwritten. When the age of an event reaches or exceeds the value of this entry, it can be overwritten.

| Value | Meaning |
|---|---|
| 0x0 | Event Viewer overwrites events only when the log reaches the maximum size, as defined by the value of the MaxSize entry. This value corresponds to the **Overwrite events as needed** option on the **Properties** dialog box for a log in Event Viewer. |
| 0x1–0xFFFFFFFE | Specifies how long records are protected. |
| 0xFFFFFFFF | Records are never overwritten. When the log file reaches its maximum size, as defined by the MaxSize entry, you must clear the log manually by clicking **Clear all Events**. Otherwise, the file discards new events. The log file must be cleared before any change to its size can take effect. This value corresponds to the **Do not overwrite events** option in Event Viewer. You can also activate a security feature that prevents a machine from being used if it cannot generate audit events. To activate this feature, set the value of the CrashOnAuditFail entry to a value other than 0. |

**Change Method**

To change the value of this entry, use Event Viewer. This entry corresponds to the options in the **Event log wrapping** section of the Properties page for any log.

### Note

- Event Viewer requires that you enter retention values in days, not seconds, and it enforces a range of one day (86,400 seconds) to 365 days (31,536,000 seconds). If you change the value of this entry by editing the registry, the value you enter is effective. However, if you change any values in the **Event Log Settings** Properties dialog box for any log in Event Viewer, then Event Viewer converts the value of this entry to the nearest day and replaces the value in the registry.

# Sources

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Names of programs* | (None) |

**Description**
Specifies the applications, services, or groups of applications that write events to this log. Each program listed in the value of this entry is represented by a subkey in the *Log-Name* subkey.

# Source-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name*

**Description**
The *Source-name* subkeys store configuration information for Event Viewer about the log sources specifed by *Source-name* in the registry path. The configuration information tells Event Viewer where to find the events for that source and how to display them. Event Viewer displays those events as part of the log specified by Log-name in the registry path.

A log source is a program, service, or operating system component that writes to an event log. For each log source, Event Viewer maintains a *Source-name* subkey that is named for the log source. "Source-name" does not actually appear in the registry; *Source-name* is a placeholder for this type of subkey.

For example, the Dr. Watson for Windows service records its events in the Application Log in Event Viewer. Therefore, the source, DrWatson, has a subkey in the EventLog\Application subkey.

### Note

- If a log source for which there is no *Source-name* subkey writes an event to an event log, then Event Viewer uses the configuration information in the subkey specified by the registry entry PrimaryModule to display the event.

### Caution

- Do not change the values of these entries by editing the registry. Log sources should use the standard Win32 application programming interfaces (APIs) to register a source program and to write events to the event log.

**Concepts**
Log-name

# CategoryCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name**Source-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | (None) |

**Description**
Specifies the number of event categories defined by the source program.

This entry is required if the source uses categories and registers a category message file (as specified in the value of the CategoryMessageFile entry).

### Notes

If the **CategoryMessageFile** entry appears in the registry for a source, then a **CategoryCount** entry is also required for that source.

**See Also**
**Concepts**
CategoryMessageFile

# CategoryMessageFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name**Source-name*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | Path and file name [; Path and file name] | (None) |

**Description**
Stores the location of the file containing categories for the events generated by the source program. Typically, event categories are included in the dynamic-link library (DLL) or executable file for the source program.

The data in the category message file associates events with categories. The category classifies the event, usually by identifying the component or function that generated the event. Each source program can define its own categories and associate them with events. The category of an event is displayed in the **Category** column in Event Viewer.

### Notes

- The same file can be used as the value of the EventMessageFile, **CategoryMessageFile**, and ParameterMessageFile entries.
- If **CategoryMessageFile** appears in the registry, the CategoryCount entry is required.

ParameterMessageFile

# EventMessageFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name**Source-name*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | Path and file name [; Path and file name] | (None) |

**Description**
Stores the location of the file that contains event identifiers for the events generated by the source program, and text describing each event. Typically, event identifiers are included in the dynamic-link library (DLL) or executable file for the source program.

A program can enter more than one file name in this value. Because Event Viewer opens the files in the order in which they are listed, you should list files in the order in which event identifiers are most likely to be found.

Also, when displaying the event log of a remote computer, Event Viewer first tries to locate the event identifiers in the first event message file listed for the source on the remote computer. If Event Viewer cannot open the event message file or cannot find the event identifier, it searches in the first event message file listed for the source on the local computer before searching other event message files on the remote or local computers.

### Note

- The same file can be used as the value of the **EventMessageFile**, CategoryMessageFile, and ParameterMessageFile entries.

**See Also**
**Concepts**
CategoryMessageFile
ParameterMessageFile

# ParameterMessageFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name**Source-name*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | Path and file name [; Path and file name] | (None) |

**Description**
Stores the location of the file that contains values for variables in the event description. This file is optional.

The descriptive text in the event message file can contain variables. The variables indicated by %n are resolved by substituting data from the event record. The variables indicated by %%n are resolved by substituting text from a parameter message file (stored in the ParameterMessageFile entry). The Event Log service locates the correct values and replaces the variables before displaying the text in the Description field in Event Viewer.

**Change Method**
You can change this entry only by editing the registry.

### Note

- The same file can be used as the value of the EventMessageFile, CategoryMessageFile, and **ParameterMessageFile** entries.

# TypesSupported

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\EventLog*Log-name**Source-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x1F (*bitmask*) | (None) |

**Description**

Indicates the types of events generated by the source program.

The value of this entry stores the settings of the **Types** check boxes in Event Viewer. (To view the **Types** check boxes, from the **View** menu in Event Viewer, click **Filter**.)

Each bit in the mask represents an event type. To indicate that the source program generates events of a certain type, set the bit for that type to 1. To indicate that the source program supports more than one type of event, set multiple bits, or sum the hexadecimal values for each event type.

| Bitmask value | Meaning |
|---|---|
| 0 | Success |
| 1 | Error |
| 10 binary (2) | Warning |
| 100 binary (4) | Information |
| 1000 binary (8) | Success audit |
| 10000 binary (16) | Failure audit |

**Caution**

- Do not change the value of this entry by editing the registry. Changing this value does not change the types of events generated by a source program. Source programs that add events of a new type should use the standard Win32 application programming interfaces (APIs) to change this value.

# i8042prt

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The i8042prt subkey stores data for the i8042prt driver. The i8042prt driver controls the keyboard and PS/2-compatible mouse for the Intel 8042 controller.

### Note

- For Windows Server 2003, many of the entries in the i8042prt\Parameters subkey are used only when a device is installed. When the system recognizes a new device, it copies these entries from Parameters to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum. For more information, see the entries in the Parameters subkey.

# i8042prt\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt

**Description**
The Parameters subkey stores data for the i8042prt driver. The i8042prt driver controls the keyboard and PS/2-compatible mouse for the Intel 8042 controller.

For Windows Server 2003, many of the entries in the Parameters subkey are used only when a device is installed. When the system recognizes a new device, it copies these entries from Parameters to a device-specific subkey in the Enum Subkey. Thereafter, it uses only the entries in Enum. For more information, see the entries in the Parameters subkey.

**Caution**

- Do not edit the Enum or Parameters subkeys. To change the value of entries in Enum or Parameters, use Device Manager.

# Parameters\EnableWheelDetection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 1 |

**Description**
Specifies whether the driver attempts to detect and enable the wheel on the mouse device. Some devices are equipped with a mouse wheel to provide rapid scrolling and other control features if supported by an application.

| Value | Meaning |
|---|---|
| 0 | Disable mouse wheel detection. The driver does not attempt to determine whether the mouse has a wheel or to enable it. Even if the mouse has a wheel, the wheel does not function in programs. |
| 1 | Detect and enable the mouse wheel. If the driver detects a wheel on the mouse, then it enables the wheel. |
| 2 | Enable without detecting. The driver attempts to enable a mouse wheel without determining whether the mouse has a wheel. |

**Note**

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.
- For mouse devices that do not fully support all Intellimouse and PS/2 functions, including dynamic enabling, set the value of this entry to 2.

**Tip**

- To view or change the value of this entry for a particular PS/2 mouse, use Device Manager. In the tree control, click **Device** and then, in the results pane, click **Mouse**, double-click the device name, and click the **Advanced Settings** tab. This value appears in the **Wheel Detection** box.

**Caution**

- In rare instances, when the system tries to detect and enable the mouse wheel, the system stops responding. To recover, restart Windows Server 2003. If the problem persists, restart by using the LastKnownGood control set.

# Parameters\KeyboardDataQueueSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x64 (*100*) |

**Description**

Specifies the number of keyboard events that the keyboard driver buffers. This entry is also used in calculating the size of the keyboard driver's internal buffer in nonpaged memory pool. To determine the number of bytes to allocate for the buffer, the system multiplies the size of the KEYBOARD_INPUT_DATA structure (defined in NTDDKBD.H) by the value of **KeyboardDataQueueSize**.

Consider increasing this value if the driver does not initialize or operate correctly and the System Log in Event Viewer contains the following message from the source, i8042prt:

```
The ring buffer that stores incoming keyboard data has overflowed (buffer size is configurable via the registry).
```

### Note

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.

# KeyboardDeviceBaseName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Base keyboard port device name* | KeyboardPort |

**Description**

This entry is added to the registry, but it is not used. In Windows NT 4.0 and earlier, the keyboard class driver uses this entry to locate keyboard port device objects. In Windows Server 2003, the keyboard class driver locates non–Plug and Play keyboards by using entries in the DEVICEMAP subkey (HKEY_LOCAL_MACHINE\Hardware\Devicemap\KeyboardClass).

# Parameters\MouseDataQueueSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x64 (*100*) |

**Description**

Specifies the number of mouse events that the mouse driver buffers. This entry is also used in calculating the size of the mouse driver's internal buffer in nonpaged memory pool. To determine the number of bytes to allocate for the buffer, the system multiplies the size of the MOUSE_INPUT_DATA structure (defined in NTDDMOU.H) by the value of **MouseDataQueueSize**.

You might consider increasing this value if the driver does not initialize or operate correctly and the System Log in Event Viewer contains the following message from the source, Inport:

```
The ring buffer that stores incoming mouse data has overflowed (buffer size is configurable via the
Registry).
```

### Note

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.

### Tip

- To view or change the value of this entry for a particular PS/2 mouse, use Device Manager. In the tree control, click **Device** and then, in the results pane, click **Mouse**, double-click the device name, and click the **Advanced Settings** tab. This value appears in the **Input Buffer Length** box.

# MouseResendStallTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*microseconds*) | 3E8 (*1,000 microseconds = 1 millisecond*) |

**Description**
Specifies how long the mouse driver waits for an acknowledgement (ACK) of a reset if a RESEND message is returned without an ACK. This entry is used when the mouse driver interrupt service routine includes a reset.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Unlike some entries in this subkey, this entry remains in the Parameters subkey and is read from this location even after a keyboard is installed.

# Parameters\MouseResolution

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Mouse resolution specifier* | 0x3 |

**Description**
Specifies the resolution of the mouse port. The number of counts per millimeter of resolution is determined by raising 2 to the power of the value of **MouseResolution**.

For example, if the value of MouseResolution is 3, then the mouse resolution is 2**3, or 8 counts per millimeter.

### Note

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.

# Parameters\MouseSynchIn100ns

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Time in 100-nanosecond units* | 20000000 (2 seconds) |

**Description**
Specifies the length of time after which the next mouse interrupt is assumed to indicate the start of a new mouse packet (partial packets are discarded). This enables the driver to synchronize its internal record of the mouse packet state with the hardware state when a mouse interrupt is lost.

Consider modifying this value if the system appears to be generating extra mouse events, such as when objects are selected although the mouse button has not been pressed.

**Note**

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.

# NumberOfButtons Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x2 |

**Description**
Specifies the number of buttons on the mouse-port mouse at startup. If the number of buttons detected at startup is incorrect, then you can override it by changing the value of this entry.

### Note

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.

# OverrideKeyboardSubtype

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x0 |

**Description**
Specifies the OEM-dependent keyboard subtype. You can add this entry to the registry to correct an error in the keyboard subtype detected at startup.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Unlike some entries in this subkey, this entry remains in the Parameters subkey and is read from this location even after a keyboard is installed.

# OverrideKeyboardType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | (None) |

**Description**

Specifies the keyboard type. You can add this entry to the registry to correct an error in the keyboard type detected at startup.

The following table shows some commonly used values for this entry. This is not a complete list.

| Value | Meaning |
|---|---|
| 0x2 | Enhanced 101-key keyboard or compatible |
| 0x4 | Enhanced 102-key keyboard or compatible |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- Unlike some entries in this subkey, this entry remains in the Parameters subkey and is read from this location even after a keyboard is installed.

# PointerDeviceBaseName Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Base mouse port device name | PointerPort |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 and earlier.

In Windows NT 4.0 and earlier, the mouse port driver used this entry to locate pointer port device objects. In Windows Server 2003, the mouse port driver locates non–Plug and Play pointing devices by using entries in the DEVICEMAP subkey (HKEY_LOCAL_MACHINE\Hardware\Devicemap\PointerClass).

**Caution**

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

**See Also**
**Concepts**
DEVICEMAP

# PollingIterations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x400–0xFFFFFFFF (*attempts*) | 0x2EE0 (*12,000 attempts*) |

**Description**
Specifies the maximum number of times Windows Server 2003 polls the hardware. If the number of trials specified in this entry is exceeded, then Windows Server 2003 stops polling. This entry is used on keyboards other than old-style AT keyboards.

Consider increasing this value if the driver does not initialize or operate correctly and the System Log in Event Viewer contains the following message from the source, i8042prt:

```
The operation on <driver name> timed out (time out is configurable via the registry).
```

### Note

- Unlike some entries in this subkey, this entry remains in the Parameters subkey and is read from this location even after a keyboard is installed.

**See Also**
**Concepts**
PollingIterationsMaximum

# PollingIterationsMaximum

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x400–0xFFFFFFFF (*attempts*) | 0x2EE0 (*12,000 attempts*) |

**Description**
Specifies the maximum number of times Windows Server 2003 polls the hardware on older-style AT keyboards. If the number of trials specified in this entry is exceeded, then Windows Server 2003 stops polling.

You might consider increasing this value if the driver does not initialize or operate correctly and the System Log in Event Viewer contains the following message from the source, i8042prt:

```
The operation on <driver name> timed out (time out is configurable via the Registry).
```

### Note

- Unlike some entries in this subkey, this entry remains in the Parameters subkey and is read from this location even after a keyboard is installed.

**See Also**
**Concepts**
PollingIterations

# PollStatusIterations Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x1 |

**Description**
Specifies the maximum number of times the system verifies interrupts on the i8042 controller status register. If the interrupt cannot be verified in the number of trials specified in the value of this entry, then the interrupt is ignored.

This entry is designed to minimize the effect of interrupts raised before the Output Buffer Full bit is set in the i8042 status register. This condition occurs on some computers, such as the Olivetti MIPS computer.

If the system seems to ignore keyboard interrupts, then increase the value of this entry. The system might mistakenly ignore an interrupt if the Output Buffer Full bit is not set when the interrupt is raised. However, if you increase the value of this entry, then the Interrupt Service Routine will take longer to execute, because there is a one-microsecond delay following each check of the Output Buffer Full bit.

### Note

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.

### Tip

- To determine whether the driver is processing keyboard interrupts correctly, press the NUM LOCK key. If the **Num Lock** light on the keyboard turns on or off, this indicates that the i8042prt driver handled the keyboard interrupt correctly.

# ResendIterations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x3 |

**Description**
Specifies the maximum number of times a hardware operation is attempted. If the number of trials exceeds the value of this entry, then Windows Server 2003 considers the operation to have failed.

You might consider increasing this value if the driver does not initialize or operate correctly and the System Log in Event Viewer contains the following message from the source, i8042prt:

```
Exceeded the allowable number of retries (configurable via the Registry) on device <device-name>.
```

### Note

- Unlike some entries in this subkey, this entry remains in the Parameters subkey and is read from this location even after a keyboard is installed.

# SampleRate Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\i8042prt\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 20 \| 40 \| 60 \| 80 \| 100 \| 200 | 100 Hz |

**Description**
Specifies how often, in Hertz, the PS/2 driver measures the characteristics and activities of the PS/2 mouse. The driver uses the information gathered through sampling to optimize the operation of the mouse device.

### Note

- This entry is used only when a device is installed. When the system recognizes a new device, it copies this entry to a device-specific subkey in the Enum Subkey subkey. Thereafter, it uses only the entries in Enum.

### Tip

- To view or change the value of this entry for a particular PS/2 mouse, use Device Manager. In the tree control, click **Device** and then, in the results pane, click **Mouse**, double-click the device name, and click the **Advanced Settings** tab. This value appears in the **Sample Rate** box.

# IAS

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
Stores configuration data for the Internet Authentication Service (IAS) in Windows Server 2003.

IAS performs centralized authentication, authorization, auditing, and accounting of users who connect to a network by using the virtual private network (VPN) and dial-up functions.

# IAS\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\IAS

**Description**
The Parameters subkey stores configuration data for the Internet Authentication Service (IAS) in Windows Server 2003.

IAS performs centralized authentication, authorization, auditing, and accounting of users who connect to a network by using the virtual private network (VPN) and dial-up functions.

# Allow SNMP Set

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\IAS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether Internet Authentication Service (IAS) accepts incoming Simple Network Management Protocol (SNMP) *Set* messages. This entry applies only when SNMP is being used to monitor IAS.

*Set* messages change or update values in an SNMP management information database (MIB). IAS accepts these messages only when an agent has permission to write to the MIB.

Set messages are prohibited by default, but you can add this entry to the registry to permit the to accept Set messages.

| Value | Meaning |
|---|---|
| 0 | IAS rejects Set messages. |
| 1 | IAS accepts Set messages. |

# Ping User-Name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\IAS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *User name* | (None) |

**Description**
Specifies a user name (or user name pattern with variables) that the Internet Authentication Service (IAS) recognizes as a fictitious name. As a result, IAS rejects authentication requests, and it responds to all accounting requests from the network access server (NAS). Also, IAS does not record transactions involving this user in any log files.

Proxy servers implementing the Remote Authentication Dial-In User Service (RADIUS) protocol and network access servers periodically send authentication and accounting requests (known as *ping requests*) to verify that the server is responsive. These ping requests include fictional user names.

This entry helps IAS recognize the fictitious name or naming scheme used in ping requests. This method is likely to improve IAS performance and to make the event log easier to interpret.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Tip**

- To indicate more than one user name, enter a name pattern, such as a Domain Name System (DNS) name including wildcard characters. For more information about pattern-matching, see Help and Support Center for Windows Server 2003.

# LanmanServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The LanmanServer subkey stores configuration data for the LAN Manager 2.*x* Server service.

# LanmanServer\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer

**Description**
The Parameters subkey stores configuration data that is specific to the LAN Manager 2.*x* Server service.

# AlertSchedule

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFF (*1–65,535 minutes*) | 0x5 |

**Description**

Specifies how often the Server service checks alert conditions and sends alert messages. This entry also defines the time interval used in calculating the general error rate (**ErrorThreshold**) and the rate of network errors (**NetworkErrorThreshold**).

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# ConnectionNoSessionsTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF (*minutes*) | 0x2 |

**Description**

Specifies how long the Server service maintains an unused virtual circuit. If the time specified in value of this entry expires, and the client has not established a session, then the Server service closes the virtual circuit.

Decreasing this value can conserve server resources, but it might impair performance by requiring more virtual circuits to be re-established.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# DiskSpaceThreshold

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–99 (*percent*) | 10 |

**Description**
Specifies the percentage of disk space that must remain free for use. If the percentage of free space falls below the value of this entry, then the Server service records the following event in the System Log in Event Viewer:

```
"The <disk-letter> disk is at or near capacity. You might need to delete some files." (Srv Event ID 2013)
```

If the value of this entry is zero, then the system does not check the percentage of free space on the disk; it also does not check for free space in megabytes as specified by LowDiskSpaceMinimum.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
LowDiskSpaceMinimum

# EnableWFW311DirectIpx

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**

Specifies whether older, direct-hosted Internetwork Packet Exchange (IPX) clients can connect to this server.

Clients running earlier versions of Windows for Workgroups provide inadequate support for named pipes when running over direct-hosted IPX, causing named-pipe applications to stop responding. You can prevent these clients from connecting to the server by setting the value of this entry to 0.

| Value | Meaning |
|---|---|
| 0 | Direct-hosted IPX clients cannot connect to the server. |
| 1 | Direct-hosted IPX clients can connect to the server. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# hidden

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | 0 \| 1 | 0 |

**Description**
Specifies whether the server's computer name is displayed to other computers in the domain.

If the value of this entry is 0, or if this entry is absent from the registry, then users can see the server's computer name in the following displays:

- In the Network Connection Wizard.
- In the **Browse for Network Connections** dialog box (In the **Map Network Drive** dialog box, click **Browse**, or in My Network Places, click **Add Network Place**).
- In My Network Places, by clicking **Entire Network** or **Computers Near Me**.

To omit this computer's name from the display, add this entry to the registry and change its value to 1.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# IRPStackSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 11–50 (*stack locations*) | 15 |

**Description**

Specifies how many stack locations the Server service establishes for I/O Request Packets (IRPs).

It might be necessary to increase this number for certain transports, or if you have many file system drivers installed on the system. Each stack uses 36 bytes of memory for each receive buffer (also known as a *work item*).

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- Some older applications may incorrectly set the value of this entry to a value that is outside (below) the valid range. By deleting the invalid value, you can restore this entry to its default value. You can also set the value yourself.

# LowDiskSpaceMinimum

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF MB | 400 MB |

**Description**

Specifies the amount of disk space that must remain free for use. If the amount of free space falls below the value of this entry and below the percentage specified by the value of the DiskSpaceThreshold entry, then the Server service records the following event in the System Log in Event Viewer:

```
"The <disk-letter> disk is at or near capacity. You might need to delete some files." (Srv Event ID 2013)
```

If the value of this entry is 0, then the system does not check whether free disk space has decreased below a specific number of megabytes. However, unlike DiskSpaceThreshold (which when equal to zero prevents both checks of free space), the value of this entry has no effect on the check specified by DiskSpaceThreshold.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# RestrictNullSessAccess

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the Server service limits access to the system by clients that are logged on to the system account without user name and password authentication.

| Value | Meaning |
|---|---|
| 0 | Null session access is not restricted. Unauthenticated users access all shared resources. |
| 1 | Null session access is restricted. Unauthenticated users can access only the server pipes listed in the value of the **NullSessionPipes** entry and the shared directories listed in the value of the **NullSessionShares** entry. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SessConns

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–2,048 (*connections*) | 2048 |

**Description**
Specifies the maximum number of connections to network shares (tree connects) that are permitted for a single network connection. If the client requests more connections, then the Server service returns an error message.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SessOpens

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–16,384 (*files*) | 16,384 |

**Description**
Specifies the maximum number of open files permitted for each connection. It is possible to have multiple sessions on a single connection.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SessUsers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–2,048 (*users*) | 2,048 |

**Description**
Specifies the maximum number of users that can be logged on to each virtual circuit.

**Note**

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SharingViolationDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–1,000 (*milliseconds*) | 200 |

**Description**
Specifies how often the Server service repeats a file operation when the initial request resulted in a sharing violation error. The value of this entry specifies the minimum time that must elapse between repeated attempts to open, rename, or delete a file.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
SharingViolationRetries

# SharingViolationRetries

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–1,000 (*attempts*) | 5 |

**Description**
Specifies the maximum number of times the Server service repeats an attempted file operation when the request results in a sharing violation error.

The Server service repeats the operation, at a rate determined by the value of the SharingViolationDelay entry, until either the operation is successful or the value of this entry is reached. If a client requests more attempts than the value of this entry permits, then the Server service returns an error. This entry applies to open, rename, and delete file operations.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
SharingViolationDelay

# SizReqBuf

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 512–65,536 (*bytes*) | |

**Description**

Specifies the size of the request buffers that the Server service uses.

Small buffers use less memory, but large buffers can improve performance.

### Notes

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.
- For computers running Windows Server 2003 and with 512 MB or more of physical memory, the default size of the request buffers is 16,644 bytes; for servers with less physical memory, the default size is 4,356 bytes. If this entry is present in the registry, its value overrides the default value.

# srvcomment

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Text string* | (None) |

**Description**
Specifies the text that appears in the **Comment** field next to the name of this computer in My Network Places.

To view the comment text, in My Network Places, double-click **Entire Network** or **Computers Near Me**. From the **View** menu, either click **Details** or double click the name of any computer. Or, in My Network Places, double-click **Add Network Place,** and view the comment text in the **Browse for Network Resource** dialog box.

**Change Method**
To enter a computer description, right click **My Computer**, select **Properties**, and in the **Computer Name** tab, type the text you want to use in the **Computer description** text box, and then click **Apply**.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# ThreadPriority

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 15 | 1 |

**Description**

Specifies the priority of all Server service threads in relation to the base priority of the Server service process.

| Value | Meaning |
|---|---|
| 0 | Run at the same priority as the process. |
| 1 | Run at one priority level higher than the process. This is equivalent to a process running in the foreground, where it interacts with users. |
| 2 | Run at two priority levels higher than the process. |
| 15 | Run at real-time priority. Threads running in real time can exclude all other threads, including essential system threads and threads that process mouse and keyboard commands. |

**Note**

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Users

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFE \| 0xFFFFFFFF (*users*) | 0xFFFFFFFF |

**Description**
Specifies whether a limit exists for the number of users that can be logged on to the Server service simultaneously, and if so, specifies what the limit is.

| Value | Meaning |
|---|---|
| 0x1–0xFFFFFFFE | Specifies the maximum number of users who can be logged on simultaneously. |
| 0xFFFFFFFF | There is no limit to the number of users who can be logged on simultaneously. |

**Change Method**
You can change this entry only by editing the registry.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# LanmanWorkstation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The LanmanWorkstation subkey stores configuration data for the Workstation service. The Workstation service provides network connections and communications on computers running Windows XP Professional and Windows Server 2003.

# LanmanWorkstation\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation

**Description**
The Parameters subkey stores configuration data for the Workstation service. The Workstation service provides network connections and communications on computers running Windows XP Professional and Windows Server 2003.

# BufNamedPipes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**

Specifies whether the redirector caches character-mode named pipes. If named pipes are not stored in the cache, then they are flushed to the server immediately, and read-ahead is disabled on these named pipes.

| Value | Meaning |
|---|---|
| 0 | Character-mode named pipes are not cached. |
| 1 | Permits the Workstation service to cache character-mode named pipes. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# KeepConn

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–65,535 (*seconds*) | 600 (*10 minutes*) |

**Description**

Specifies the maximum amount of time that an idle connection can remain open. If the idle time for a connection reaches the value of this entry, then the connection is closed.

Increase the value of this entry if your application closes and opens Universal Naming Convention (UNC) files on a server less frequently than every 10 minutes. This decreases the number of reconnections to a server.

# LockIncrement

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*milliseconds*) | 0xA (*10*) |

**Description**
Specifies how long an OS/2–based application can wait when a request for a lock fails. If the lock request cannot be granted before the time specified in the value of this entry expires, then the redirector rejects the lock request. This entry is used either if OS/2–based applications running on servers (except servers using LAN Manager version 2.0 and later) request that a lock operation wait indefinitely or if the lock cannot be granted immediately.

**Note**

- Do not change this value unless you are running an OS/2-based application that requests lock operations that might fail. This entry does not affect Windows 32-bit applications.

# LockMaximum

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*milliseconds*) | 0x1F4 (*500*) |

**Description**
Used to configure the lock backoff package. This entry prevents an application from consuming server time by issuing nonblocking requests when no data is available for the application.

# LockQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*bytes*) | 0x1800 (*6 KB*) |

**Description**

Specifies the maximum amount of data that can be read from a file when the value of the UseLockReadUnlock entry is 1.

Consider increasing the value of this entry if your application performs a significant number of lock-and-read operations. These are operations in which an application locks data and then immediately reads the data.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Increasing the value of this entry to more than 2 MB and using an application that locks megabtyes of data can cause the system to deplete its paged pool.

# MaxCmds

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 50–65535 (*network control blocks*) | 50 |

**Description**

Specifies the maximum number of network control blocks that the redirector can reserve. The value of this entry coincides with the number of execution threads that can be outstanding simultaneously.

Increase this value to improve network throughput, especially if you are running applications that perform more than 15 operations simultaneously. However, because this entry also limits the number of outstanding execution threads, your network performance might not improve. Each additional execution thread uses a margin of 1 KB of nonpaged pool when the network is at capacity. However, these resources are not consumed until the user references data in the network control block.

# MaxCollectionCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFF (*0–65,535 bytes*) | 0x10 (*16*) |

**Description**
Specifies the amount of data that must be present in the character-mode buffer of a named pipe to trigger a write operation. If the amount of data in the buffer meets or exceeds this value, then it is written immediately. Otherwise, it is retained in the buffer until either more data is added or the value of the **CollectionTime** entry expires.

Increasing the value of this entry can improve the performance of named-pipe applications, but it does not affect applications that do their own buffering, such as SQL Server applications.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
SizCharBuf

# SizCharBuf

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 64–4,096 (*bytes*) | 512 |

**Description**

Specifies the size of the character buffers for a named pipe. The redirector maintains a read-ahead buffer and a write-behind buffer for each pipe. This entry establishes the size of both buffers.

The buffer size determines the amount of data the redirector reads and writes.

When reading, the redirector attempts to read enough data to fill the read buffer. If the data it is reading is smaller than the buffer, then the redirector reads ahead until the buffer is full. If the data is larger than the buffer, then the redirector bypasses the character-mode buffer and reads the data directly into the user buffer.

When writing, the redirector collects data in the character-mode buffer until it meets or exceeds the size specified by the value of the MaxCollectionCount entry, or until the time specified by the value of the **CollectionTime** entry expires.

Increasing the value of this entry can improve the performance of named-pipe applications, but it does not affect applications that do their own buffering, such as SQL Server applications.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# UseLockReadUnlock

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the lock-and-read and write-and-unlock performance enhancements are enabled. These features improve performance when an application locks data and then immediately reads the data, or writes data and then immediately unlocks it.

| Value | Meaning |
|---|---|
| 0 | Lock-and-read and write-and-unlock features are not enabled. |
| 1 | Lock-and-read and write-and-unlock features are enabled. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Setting this value to 1 usually improves performance significantly. However, it degrades the performance of database applications that lock a range of data and do not allow data within that range to be read.

**See Also**
**Concepts**
LockQuota

# UseOpportunisticLocking

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the opportunistic-locking (oplock) performance enhancement is enabled. If enabled, the redirector requests an opportunistic lock on any file opened in "Deny None" mode. As a result, the server performs automatic read-ahead and write-behind caching on behalf of the redirector.

| Value | Meaning |
|---|---|
| 0 | Disables opportunistic locking |
| 1 | Enables opportunistic locking |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- Opportunistic locks improve performance significantly. Do not change the value of this entry unless you are testing the system.

# UseUnlockBehind

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\LanmanWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the unlock-behind optimization feature is enabled. If enabled, the redirector unlocks data immediately in response to an unlock request. It does not wait for confirmation from the server that the unlock operation is complete.

| Value | Meaning |
|---|---|
| 0 | Disables the unlock-behind optimization feature |
| 1 | Enables the unlock-behind optimization feature |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- Unlock-behind optimization improves performance significantly. Do not change the value of this entry unless you are testing the system.

# Mouclass

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
Stores configuration data for the Mouseclass device driver. The Mouseclass device driver handles hardware-independent operations on a specific class of devices—in this case, the mouse and other pointing devices. The port drivers manage the hardware-specific operations.

# Mouclass\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Mouclass

**Description**
The Parameters subkey in the Mouclass subkey stores configuration data for the Mouseclass device driver. The Mouseclass device driver handles hardware-independent operations on a specific class of devices—in this case, the mouse and other pointing devices. The port drivers manage the hardware-specific operations.

# ConnectMultiplePorts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Mouclass\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether there is one or more than one port device object for each class device object. This entry is used primarily by device drivers.

| Value | Meaning |
|---|---|
| 0 | 1:1. Indicates that the class device object created by the driver is connected to one port device object. |
| 1 | 1:Many. Indicates that the class device object created by the driver is connected to multiple port device objects. As a result, the events generated by all pointing devices on the system are fed to the Windows subsystem in a single input stream. |

The mouse class driver can route all information from all the declared mouse ports in the system to a single class device object. By doing this, the class driver can work with older raw input threads that cannot open multiple, independent mouse devices. Windows Server 2003 reads all mouse devices independently, so this value is set to 0 by default.

**See Also**
**Concepts**
MaximumPortsServiced

# MaximumPortsServiced

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Mouclass\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x3 |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# Parameters\PointerDeviceBaseName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Mouclass\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Base port device name* | PointerClass |

**Description**
Specifies the base name for the device objects created by the mouse class device driver.

### Note

- The device driver stores information about the device in a subkey of DEVICEMAP (HKEY_LOCAL_MACHINE\HARDWARE\DEVICEMAP) that has the same name as the value of this entry. The pointer class driver uses the information in the DEVICEMAP subkey to locate all non–Plug and Play pointer port device objects. (The Plug and Play subsystem passes all instances of Plug and Play port device objects to the class driver's AddDevice routine, which negates the need for the class driver to search for devices.)

# MRxSmb

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The MRxSmb subkey stores configuration data for the Browser Server service. The Browser Server service provides the list of participating browser servers on the network.

# Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\MRxSmb

**Description**
The Parameters subkey stores configuration data for the Browser Server service. The Browser Server service provides the list of participating browser servers on the network.

# MailslotDatagramThreshold

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\MRxSmb\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFE \| 0xFFFFFFFF | 0xFFFFFFFF |

**Description**
Establishes the maximum number of mailslot requests that can be missed in one hour without generating an event. If more requests are missed, then the browser service writes an event to the System Log in Event Viewer.

| Value | Meaning |
|---|---|
| 0x0–0xFFFFFFFE | The number of requests that triggers an Event Log message. |
| 0xFFFFFFFF | No events are generated when requests are missed. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe. In Windows NT 3.1 and earlier, add this entry to the DGRcvr\Parameters subkey.

# NDIS

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
Stores configuration data for the Network Driver Interface Specification (NDIS) interface in Windows Server 2003, Ndis.sys.

Ndis.sys supports communication between protocol drivers, network interface drivers, and network adapters. It acts as an intermediary between protocol drivers and network adapters, so that they can remain independent. This allows a network adapter to support multiple network protocols, such as TCP/IP and Internetwork Packet Exchange (IPX). It also allows multiple network interface drivers and multiple network adapters to co-exist within a system.

# NDIS/Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NDIS

**Description**
The Parameters subkey stores configuration data for the Network Driver Interface Specification (NDIS) 5.0 interface in Windows Server 2003, Ndis.sys.

Ndis.sys supports communication between protocol drivers, network interface drivers, and network adapters. Ndis.sys acts as an intermediary between protocol drivers and network adapters, so that they can remain independent. This allows a network adapter to support multiple network protocols, such as TCP/IP and IPX. It also allows multiple network interface drivers and multiple network adapters to co-exist within a system.

# ProcessorAffinityMask

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NDIS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFE \| 0xFFFFFFFF | 0xFFFFFFFF (*-1*) |

**Description**

Specifies which processors can be associated with a network adapter and can service the delayed procedure calls (DPCs) generated by that network adapter. This entry is designed for multiprocessor computers, specifically those with more than one network adapter.

Each of the 32 bits in the value of this entry represents one processor. The high bit represents processor 32, and the low bit represents processor 0.

If a bit is set to 1, then the processor represented by the bit can be associated with a network adapter and service all of the DPCs it generates.

If a bit is set to 0, then the processor represented by the bit cannot be associated with any particular network adapter. When a network adapter is not associated with a processor, its DPCs are serviced by the same processor that serviced the interrupt from which the DPC evolved.

| Value | Meaning |
|---|---|
| 0x0 \| 0xFFFFFFFF | If all of the bits are set to either 0 or 1, then none of the processors are associated with network adapters. DPCs are serviced by the same processor that serviced the interrupt. This setting is useful for platforms that distribute interrupts among all processors. These values are treated the same to skip the affinity association and thus avoid DPC redirecting. |
| 0x1–0xFFFFFFFE | If some of the bits are set to 0 and others are set to 1, then the system skips processors associated with bits set to 0, and it assigns network adapters to processors whose bits are set to 1. |

**Note**

- Windows Server 2003 sets this entry to the optimum value for your system. Do not modify the value of this entry.

# NdisWan

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The NdisWan subkey stores configuration data for NDISWAN drivers supporting remote access service. This subkey appears in the registry only when remote access is installed on the computer.

### Note

- NDISWAN is an intermediate-level Network Device Interface Specification (NDIS) driver that lies between an 802.3 miniport and a WAN miniport, converting NDIS packets to WAN packets. NDISWAN supports Point-to-Point Protocol (PPP) protocol/link framing, compression, and encryption.

# NdisWan\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NdisWan

**Description**
The Parameters subkey stores configuration data for NDISWAN drivers supporting remote access service. The NdisWan subkey appears in the registry only when remote access service is installed on the computer.

NDISWAN is an intermediate-level Network Device Interface Specification (NDIS) driver that lies between an 802.3 miniport and a WAN miniport, converting NDIS packets to WAN packets. NDISWAN supports Point-to-Point Protocol (PPP) protocol/link framing, compression, and encryption.

# IGMPIdle

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NdisWan\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether NdisWan drivers consider Internet Group Management Protocol (IGMP) packets to be valid communications traffic.

Many servers send IGMP packets periodically to prevent a silent, but active, line from being mistaken for an idle line. These packets can be misinterpreted as communication. They can also prevent a truly idle line from being disconnected.

| Value | Meaning |
|---|---|
| 0 | IGMP packets are considered to be valid communications traffic, which keeps a line active. |
| 1 | IGMP packets are filtered out and not counted as valid communications traffic. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# NetBT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# NetBT\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# BcastNameQueryCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 - 0xFFFF | 3 |

**Description**
Specifies the number of times that NetBIOS over TCP/IP (NetBT) broadcasts a query for a unique name without receiving a response.

**Activation Method**
If this interface is configured by Dynamic Host Configuration Protocol (DHCP), then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

### Note

- This entry is installed with its default value during installation of the TCP/IP components.

**See Also**
**Concepts**
BcastQueryTimeout
NameSrvQueryCount

# BcastQueryTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 100 to 0xFFFFFFFF | 750 (0x2EE) |

**Description**
Specifies the interval, in milliseconds, between successive broadcast queries for a single name. This entry is installed with its default value during installation of the TCP/IP components.

**Activation Method**
If this interface is configured by DHCP, then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

**See Also**
**Concepts**
BcastNameQueryCount
NameSrvQueryTimeout

# BroadcastAddress

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 - 0xFFFFFFFF | |

**Description**
Specifies whether NetBIOS over TCP/IP (NetBT) uses a specific address for all name-related broadcasts. This entry does not exist by default, and you must add it to the registry to change the default broadcast address. Also, this entry sets the broadcast address to which NetBT sends name-related packets for all the subnets to which NetBT is bound.

**Activation Method**
If this interface is configured by DHCP, then enter the command **ipconfig /renew** at the command line for a change in parameters to take effect. Otherwise, you must restart the computer for a change to take effect.

### Note

- By default, NetBT uses the ones broadcast address appropriate for each net. For example, for a network of 11.101.0.0 with a subnet mask of 255.255.0.0, the subnet broadcast address is 11.101.255.255. If the network uses the zeroes broadcast address (which is configured by setting **UseZeroBroadcast**), then create this entry and set it to zero. In this example, the appropriate subnet broadcast address is 11.101.0.0, and the value of this entry is set to 0x0b650000.

# CacheTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 60000 to 0xFFFFFFFF | 600000 milliseconds (10 minutes) |

**Description**
Specifies the interval, in milliseconds, that NetBIOS names are cached by NetBIOS over TCP/IP (NetBT).

**Activation Method**
If this interface is configured by DHCP, then enter the command **ipconfig /renew** at the command line for a change in parameters to take effect. Otherwise, you must restart the computer for a change to take effect.

### Note

- This entry is installed with its default value during installation of the TCP/IP components.

# ConnectOnRequestedInterfaceOnly

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether NetBIOS connections to this computer are restricted to a particular adapter. When the redirector on a multihomed computer calls another computer name, it places calls on all NetBIOS over TCP/IP (NetBT) *transports* (protocol-adapter combinations) to which it is bound. Each transport independently attempts to reach the target name. Setting the value of this entry to 1 limits each transport to connecting to other computers that are reachable via its own adapter, preventing crossover traffic.

This entry is ignored if **CachePerAdapterEnabled** is absent from the registry or if it is present and its value is zero.

**Activation Method**
You must restart the computer for changes to take effect.

### Note

- This entry does not exist by default, and you must add it to the registry and set the value to 1 if you want to restrict NetBIOS connections to a specific interface. You can add this entry to the registry and set its value by using the registry editor Regedit.exe.

**See Also**
**Concepts**
RandomAdapter

# DhcpNodeType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 8 |

**Description**
This parameter specifies the NetBIOS over TCP/IP (NetBT) node type. The node type specified by the entry NodeType, if valid, overrides the value of this entry. If neither this entry nor **NodeType** exist in the registry, and there are no WINS servers configured on the network, then NetBT uses B-node name resolution. If there is at least one WINS server available, NetBT uses H-node name resolution.

| Value | Meaning |
|---|---|
| 1 | B-node. NetBT uses IP broadcast messages to register and resolve IP addresses from NetBIOS names. |
| 2 | P-node. NetBT uses point-to-point communication with a NetBIOS name server (in Windows Server 2003–based networks, this is the WINS server) to register and resolve IP addresses from NetBIOS names. |
| 4 | M-node. NetBT uses a mix of B-node and P-node to register and resolve NetBIOS names. M-node first uses broadcast resolution (B-node), then if necessary, uses a server query (P-node). |
| 8 | H-node. NetBT uses a hybrid of B-node and P-node. An H-node client always directly queries a name server first and then uses broadcasts only if the direct query fails. |

**Note**

- For more information on configuring WINS, see the *Networking Collection* of the *Windows Server 2003 Technical Reference* (or see the Networking Collection on the Web at http://www.microsoft.com/reskit).

**Caution**

This entry is created and maintained by the DHCP client service, if enabled, and you should not modify it. It is included here only for reference.

**See Also**
**Concepts**
NodeType

# DhcpScopeID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores the scope identifier that this computer received from the Dynamic Host Configuration Protocol (DHCP) server. The scope identifier, a dot-separated string (for example, microsoft.com) is appended to the NetBIOS over TCP/IP (NetBT) name, and should not be confused with DHCP scope (which specifies a range of addresses available for assignment by the DHCP server).

### Caution

This entry is created and maintained by the DHCP client service, if enabled, and you should not modify it. It is included here only for reference.

# EnableLMHOSTS

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether NetBIOS over TCP/IP (NetBT) searches the Lmhosts file for names that it has not been able to resolve with name queries to a WINS server and broadcast name queries to the network. Though use of the Lmhosts file is enabled by default, there is no default Lmhosts file. When the value of this entry is 1 and there is no Lmhosts file, no action takes place.

| Value | Meaning |
|---|---|
| 0 | NetBT does not search the Lmhosts file. |
| 1 | NetBT searches the Lmhosts file, if it exists, for names that cannot be resolved by WINS or broadcast name queries. |

**Change Method**
To change the value of this entry, use **Network Connections** in Control Panel. Right-click **Local Area Connection** (or the name of another connection, if appropriate), click **Properties**, click **Internet Protocol (TCP/IP)** , and then click the **Properties** button. On the **Internet Protocol (TCP/IP) Properties** page, click the **Advanced** button, and click the **WINS** tab. This entry is associated with **Enable LMHOSTS lookup**, which you can check to enable and clear to disable.

**Activation Method**
Changes made to this entry through the **Properties** page for the interface take effect immediately.

### Note

- The path to the Lmhosts file is specified in the **DatabasePath** entry.

# InitialRefreshT.O.

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 960000 to 0xFFFFFFF | 960000 (16 minutes) |

**Description**
Specifies the initial refresh timeout, in milliseconds, used by NetBIOS over TCP/IP (NetBT) during name registration. NetBT tries to contact the WINS servers at 1/8th of this time interval when it is first registering names. When it receives a successful registration response, it uses the refresh interval specified in the response for subsequent registration attempts.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
If this interface is configured by DHCP, then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

# LmhostsTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1000 to 0xFFFFFFFF | 6000 milliseconds (6 seconds) |

**Description**

Specifies the timeout interval, in milliseconds, for NetBIOS over TCP/IP (NetBT) name queries to Lmhosts and DNS. The units used by the timer are equal in length to the value of this entry, so the actual timeout can be as much as twice the value of this entry.

**Activation Method**

If this interface is configured by DHCP, then enter the command **ipconfig /renew** at the command line for a change in parameters to take effect. Otherwise, you must restart the computer for a change to take effect.

# MaxDgramBuffering

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 to 0xFFFFFFFF | 0x20000 (128 Kb) |

**Description**
Specifies the maximum amount of memory that NetBIOS over TCP/IP (NetBT) dynamically allocates for all outstanding sent datagrams. Once this limit is reached, attempting to send additional datagrams would fail due to insufficient resources.

**Activation Method**
If this interface is configured by DHCP, then enter the command **ipconfig /renew** at the command line for a change in parameters to take effect. Otherwise, you must restart the computer for a change to take effect.

# NameServerPort

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 to 65535 | 137 |

**Description**
Specifies the IP port number to which NetBIOS over TCP/IP (NetBT) sends packets related to name service, such as name queries and registrations. The Windows Internet Name Service (WINS), which provides name service for NetBIOS names, listens on port 137, the default for this entry. NetBIOS name servers from other vendors may listen on different ports. This entry is installed with its default value during installation of the TCP/IP components.

**Activation Method**
If this interface is configured by DHCP, then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

# NameSrvQueryCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 to 0xFFFF | 3 |

**Description**
Specifies the number of times that NetBIOS over TCP/IP (NetBT) sends a query to a Windows Internet Name Service (WINS) server for a given name without receiving a response. This entry is installed with its default value during installation of the TCP/IP components.

**Activation Method**
If this interface is configured by Dynamic Host Configuration Protocol (DHCP), then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

**See Also**
**Concepts**
BcastNameQueryCount
NameSrvQueryTimeout

# NameSrvQueryTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 100 - 0xFFFFFFFF | 1500 (1.5 seconds) |

**Description**
Specifies the interval, in milliseconds, between successive name queries to a Windows Internet Name Service (WINS) server for a given name. This entry is installed with its default value during installation of the TCP/IP components.

**Activation Method**
If this interface is configured by Dynamic Host Configuration Protocol (DHCP), then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

**See Also**
**Concepts**
NameSrvQueryCount
BcastQueryTimeout

# NodeType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 \| 4 \| 8 | 1 or 8, depending on how WINS is configured |

**Description**
Specifies what methods NetBIOS over TCP/IP (NetBT) uses to register and resolve names. Resolution via Lmhosts and/or DNS, if enabled, use these methods.

| Value | Meaning |
|---|---|
| 1 | B-node. NetBT uses IP broadcast messages to register and resolve IP addresses from NetBIOS names. |
| 2 | P-node. NetBT uses point-to-point communication with a NetBIOS name server (in Windows Server 2003–based networks, this is the WINS server) to register and resolve IP addresses from NetBIOS names. |
| 4 | M-node. NetBT uses a mix of B-node and P-node to register and resolve NetBIOS names. M-node first uses broadcast resolution (B-node), then if necessary, uses a server query (P-node). |
| 8 | H-node. NetBT uses a hybrid of B-node and P-node. An H-node client always directly queries a name server first and then uses broadcasts only if the direct query fails. |

This entry does not exist by default, and if you create it, its setting overrides the configuration specified by DhcpNodeType. If neither this entry nor **DhcpNodeType** exist in the registry, and there are no WINS servers configured on the network, then NetBT uses B-node name resolution. If there is at least one WINS server available, then NetBT uses H-node name resolution.

**Activation Method**
If this interface is configured by DHCP, then enter the command **ipconfig /renew** at the command line for a change in parameters to take effect. Otherwise, you must restart the computer for a change to take effect.

### Note

- For more information on configuring WINS, see the *Networking Collection* of the *Windows Server 2003 Technical Reference* (or see the Networking Collection on the Web at http://www.microsoft.com/reskit).

DhcpNodeType

# NoNameReleaseOnDemand

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the computer releases its NetBIOS name when it receives a name-release request. If the value of this entry is 0 (the default), then the computer releases its NetBIOS name upon request; if the value of this entry is 1, then the computer does not release its NetBIOS name. Configuring the computer to refuse release of its NetBIOS name can protect against malicious requests for name release.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must restart the computer for changes to take effect.

# RandomAdapter

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies how NetBIOS over TCP/IP (NetBT) chooses the IP address to put in a name query. If the value of this entry is 1, then NetBT randomly chooses an IP address from all of its bound interfaces. If this entry is 0 or is absent from the registry, then NetBT uses the address of the interface on which the query arrived.

This entry is applicable only to multihomed computers. This feature is used by servers with multiple interfaces on the same network for load balancing. This entry does not exist in the registry by default, and you must add it if you want to configure NetBT to randomly choose an IP address from its available interfaces.

**Activation Method**
If this interface is configured by Dynamic Host Configuration Protocol (DHCP), then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

**See Also**
**Concepts**
ConnectOnRequestedInterfaceOnly

# RefreshOpCode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 8 \| 9 | 8 |

**Description**
Specifies the operation code that NetBIOS over TCP/IP (NetBT) uses in name refresh packets.

The Microsoft implementation of NetBT uses a default of 8; however, other implementations, such as Ungermann-Bass, use a default of 9. Interoperation of clients and servers depends on them using the same operation code. If the default operation code (8) is incompatible with other systems on your network, then add this entry and set the value to 9.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
If this interface is configured by DHCP, then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

# SessionKeepAlive

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 60000 to 0xFFFFFFFF | 3600000 milliseconds (1 hour) |

**Description**
Specifies the interval, in milliseconds, between keep-alive transmissions on a session. NetBIOS over TCP/IP (NetBT) sends keep-alive transmissions to verify that idle connections are still active. This prevents NetBT from inadvertently disconnecting active lines. Setting the value of this entry to 0xFFFFFFF disables keep-alive transmissions. This entry is installed with its default value during installation of the TCP/IP components.

**Activation Method**
If this interface is configured by DHCP, then a change in parameters will take effect if you enter the command **ipconfig /renew** at the command line. Otherwise, you must restart the computer for a change to take effect.

**See Also**
**Concepts**
Parameters\KeepAliveInterval

# TryAllIPAddrs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether, as a WINS client, this computer attempts to connect to all addresses it receives in response to a name query, or whether it attempts to connect to only the first address and stops if that fails. The default action is for the computer to try all addresses.

| Value | Meaning |
|---|---|
| 0 | Computer tries to connect only to the first address, and does not try another address in the event of failure. |
| 1 | Computer tries to connect to each address in the response to a name query, in order, from first to last. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must restart the computer for changes to take effect.

### Note

- When a WINS server answers a name query, it returns a list of IP addresses that are sorted into a preference order according to whether any of them are on the same subnet as an interface belonging to the client that sent the name query.

# TryAllNameServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the client continues to query additional WINS servers from its list of WINS servers when a request to one of them for a NetBIOS session fails.

| Value | Meaning |
|---|---|
| 0 | Computer stops trying to query a WINS server after its first attempt fails. |
| 1 | Computer attempts to query all WINS servers in its list. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must restart the computer for changes to take effect.

# UseDnsOnlyForNameResolutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether the computer should use only DNS for name resolution; that is, the computer does not attempt to resolve computer names through NetBIOS. The computer still registers and refreshes its NetBIOS names, and NetBIOS sessions are still allowed.

| Value | Meaning |
|---|---|
| 0 | Computer uses all available methods for name resolution. |
| 1 | Computer uses only DNS for name resolution. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**

You must restart the computer for changes to take effect.

**Tip**

To completely disable NetBIOS on an interface, see the regsitry entryNetbiosOptions.

# WinsDownTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1000 – 0xFFFFFFFF | 15,000 (15 seconds) |

**Description**
Specifies the amount of time that NetBIOS over TCP/IP (NetBT) waits before trying to use WINS again after it fails to contact any WINS server. This timeout is primarily for allowing computers that are temporarily disconnected from the network, such as portable devices, to proceed through their startup process without waiting for each name registration or query attempt to time out and fail individually.

**Activation Method**
You must restart the computer for changes to take effect.

### Note

- This entry does not exist in the registry by default. To configure a timeout of a length other than 15 seconds, add this entry by using the registry editor Regedit.exe.

### Tip

For more information about WINS name resolution, see "WINS Technical Reference" in the *Networking Collection* of the *Windows Server 2003 Technical Reference*.

# DHCPNameServerList

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | | |

**Description**
Stores a list of IP addresses of Windows Internet Name Service (WINS) servers, as provided by the Dynamic Host Configuration Protocol (DHCP) service. The IP addresses are stored as dotted decimals (for example, 192.168.0.1) and are separated by spaces. If the entry NameServerList exists and contains one or more valid IP addresses, then this entry is ignored.

**Change Method**
Do not edit this entry. It is created and maintained by the DHCP client service for its own use.

### Note

- This entry replaces the entries **DHCPNameServer** and **DHCPNameServerBackup**, which were used in Windows NT 4.0.

**See Also**
**Concepts**
NameServerList

# DHCPNetbiosOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 | 1 |

**Description**
Specifies whether NetBIOS is enabled on the interface named in the registry path, as configured by Dynamic Host Configuration Protocol (DHCP). If the entry NetbiosOptions exists in the registry, then this entry is ignored.

| Value | Meaning |
|---|---|
| 1 | NetBIOS is enabled on the interface named in the registry path of this entry. |
| 2 | NetBIOS is disabled on the interface named in the registry path of this entry. |

**Change Method**
This entry is created and maintained by the DHCP client service, if enabled, and you should not modify it. It is included here only for reference.

**See Also**
**Concepts**
NetbiosOptions

# NameServerList

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | | |

**Description**
Stores a list of IP addresses of Windows Internet Name Service (WINS) servers. The addresses are specified with dotted decimals (for example, 192.168.0.1), are separated by spaces, and are ordered according to preference.

**Change Method**
To change the value of this entry, use **Network Connections** in Control Panel. Right-click **Local Area Connection** (or the name of another connection, if appropriate), click **Properties**, click **Internet Protocol (TCP/IP)**, and then click the **Properties** button. On the **Internet Protocol (TCP/IP) Properties** page, click the **Advanced** button, then click the **WINS** tab. This entry is associated with the addresses shown under **WINS addresses, in order of use**. To modify the list, use the **Add**, **Edit**, or **Remove** buttons. Select an address and click the up or down arrow button to the right of the text box to move the address up or down in the list.

**Activation Method**
Changes made to this entry through the **Properties** page for the interface take effect immediately.

## Notes

- If this entry contains one or more valid addresses, then this entry overrides any and all addresses specified in the entry DHCPNameServerList.
- This entry replaces the registry entries **NameServer** and **NameServerBackup** that were used in Windows NT 4.0.

**See Also**
**Concepts**
DHCPNameServerList

# NetbiosOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NetBT\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 | 1 |

**Description**
Specifies whether NetBIOS over TCP/IP (NetBT) is enabled on the interface named in the registry path.

| Value | Meaning |
|---|---|
| 1 | NetBT is enabled on the interface named in the registry path of this entry. |
| 2 | NetBT is disabled on the interface named in the registry path of this entry. |

**Change Method**
To change the value of this entry, use **Network Connections** in Control Panel. Right-click **Local Area Connection** (or the name of another connection, if appropriate), click **Properties**, click **Internet Protocol (TCP/IP)**, and then click the **Properties** button. On the **Internet Protocol (TCP/IP) Properties** page, click the **Advanced** button, and click the **WINS** tab. Select one of the following options by clicking on it: **Default**, **Enable NetBIOS over TCP/IP**, or **Disable NetBIOS over TCP/IP**.

The default option specifies that this computer use the NetBIOS setting specified by the Dynamic Host Configuration Protocol (DHCP) server. If this computer uses a static IP address rather than an address provided by a DHCP server, or if the DHCP server does not provide a NetBIOS setting, then NetBT is enabled.

**Activation Method**
Changes made to this entry through the **Properties** page for the interface take effect immediately.

### Note

- This entry overrides the state specified by the entry DHCPNetbiosOptions if they are both in the same registry path (that is, if they are configuring the same network interface).

**See Also**
**Concepts**
DHCPNetbiosOptions

# Services\Netlogon

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The Netlogon subkey stores information for the Net Logon service.

The Net Logon service verifies NTLM logon requests, and it registers, authenticates, and locates domain controllers. Also, to maintain backward compatibility, Net Logon manages replication of the user account database to back up domain controllers running Windows NT 4.0 and earlier.

**Note**

- For Windows Server 2003, Net Logon manages replication only when replication involves servers running Windows NT 4.0 and earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# Netlogon\Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon

**Description**
The Parameters subkey stores configuration data specific to the Net Logon service.

The Net Logon service verifies logon requests, and it registers, authenticates, and locates domain controllers. Also, to maintain backward compatibility, Net Logon manages replication of the user account database to backup domain controllers running Windows NT 4.0 and earlier.

**Note**

- For Windows Server 2003, Net Logon manages replication only when replication involves servers running Windows NT 4.0 and earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# Parameters\AutoSiteCoverage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the system can add sites to the coverage area of this domain controller.

Domain controllers *cover*, that is, provide services to, the site in which they reside and to other sites listed in the value of the entry**SiteCoverage**. In addition, when the value of **AutoSiteCoverage** is 1, the system can add sites that do not have domain controllers to this domain controller's coverage area.

| Value | Meaning |
|---|---|
| 0 | The system cannot add sites to the coverage area of this domain controller. |
| 1 | The system can add sites to the coverage area of this domain controller. |

The sites added to the domain controller's coverage are stored in memory, and a new list is assembled each time the Net Logon service starts or when Netlogon is notified of the site object changes. While Net Logon runs, it updates this list at an interval specified by the value of the entry **DnsRefreshInterval**.

To determine this extended site coverage, the Net Logon service uses information from Active Directory. It applies the criteria listed below to determine which domain controller can provide the best service to a non-covered site. By default, all domain controllers are candidates for a non-covered site. However, if you use this entry to exclude domain controllers from the selection pool, the system might not be able to select the best domain controller for the site.

The criteria are applied in the order shown, and each subsequent criterion is applied only if the candidate domain controllers are equal on all previous criteria.

- Connection cost: The connection to the domain controller is less costly than connections to other domain controllers in the domain.
- Most domain controllers: The site in which the domain controller resides has more domain controllers than other sites.
- Alphabetical order (tie breaker): The name of the site in which the domain controller resides is earlier in the alphabet than the site names of other domain controllers.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- This entry is used only when it appears in the registry of a domain controller.

**Tip**

- The list of additional sites computed for each domain controller is recorded in Netlogon.log when the value of the entry**DBFlag** entry is at least 0x20. To direct Net Logon to record the process it uses to compute site coverage, set the value of the entry **DBFlag** to 0x2800FFFF.

**See Also**
**Concepts**
Parameters\GcSiteCoverage

# AvoidPdcOnWan Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Prevents the backup domain controller (BDC) from sending new password information to a remote primary domain controller (PDC). Also, if a client password fails to authenticate on the BDC, the BDC does not attempt to authenticate that password on the remote PDC. Instead of Net Logon, the PDC and BDC use Active Directory replication to update password information.

This entry does not affect password sharing between BDCs and PDCs residing on the same site. If the BDC and PDC are on the same site, then the BDC sends password information regardless of the value of this entry.

Setting this value to 1 can reduce wide area network (WAN) traffic between domain controllers at remote locations, but PDCs might not always have the most current password data. As a result, legitimate users might not be authenticated.

| Value | Meaning |
|---|---|
| 0 | BDC sends password information to PDC in different site. |
| 1 | BDC does not send password information to PDC in different site. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# ChangeLogSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x10000–0x400000 (*64 KB–4 MB*) | 0x10000 (*64 KB*) |

**Description**
Specifies the maximum size of the Net Logon transaction log, Netlogon.chg. This limit applies to space allocated for the transaction log in physical memory and on disk in *Systemroot*\Netlogon.chg. The typical size of an entry is 32 bytes, so a 64 KB log holds approximately 2,000 entries.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Notes

- The value of this entry should be the same on all backup domain controllers. This consistency ensures that if a backup domain controller is promoted to a primary domain controller, it has the same value in this entry as the other backup domain controllers.

- Increasing the value of this entry to 4 MB does not degrade system performance. The 4 MB setting ensures that only those segments of the domain's database that changed are replicated.

- For Windows Server 2003, the Net Logon transaction log records only those replication-related changes involving servers running Windows NT 4.0 and earlier. Net Logon for Windows Server 2003 does not manage replication between servers running Windows Server 2003.

# CloseSiteTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x3C–0x418937 (*seconds*) (*1 minute–49.7 days*)49.7 days) | 0x384 (*15 minutes*) |

**Description**
Specifies how often the Net Logon service attempts to find a nearby domain controller. The value of this entry specifies the minimum time that must elapse between attempts. The value is used when Net Logon is using the secure channel to communicate with a domain controller (which it does, for example, when processing an interactive or network logon) in a site that is not nearby. In such a case, if the time elapsed since the last attempt to discover a close domain controller is greater than the time specified by this entry, Net Logon reattempts discovery of a nearby domain controller before sending the request to the remote domain controller.

This value does not apply when Net Logon is finding a domain controller to authenticate an interactive logon that is using pass-through authentication on a secure channel. These transactions do not need time between attempts.

This value helps separate attempts to locate domain controllers when a secure channel is used for other communications, such as pass-through authentication of a network logon.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Use caution when changing the value of this entry. If the value is too high, then the requesting client might be delayed significantly. If the value is too low, then repeated attempts to find the domain controller can create excessive network traffic.

# Parameters\DnsTtl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0x7FFFFFFF (*seconds*) | 0x258 (*600 seconds = 10 minutes*) |

**Description**
Specifies how long a memory cache in the client computer saves Domain Name System (DNS) records that the Net Logon service registers.

| Value | Meaning |
|---|---|
| 0x0 | DNS records registered by Net Logon are not cached. |
| 0x1–0x7FFFFFFF seconds | Specifies the maximum time that DNS records registered by Net Logon are saved in the client cache. |

This value applies to all records, regardless of how frequently or how recently the records might be referenced. This entry is relevant only on domain controllers.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Tip**

- Increasing the value of this entry might improve performance. However, if this value is too large, then the DNS records might not be refreshed on the client often enough.

# DuplicateEventlogTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x418937 (*seconds*) (*Up to 49.7 days*) | 0x3840 (*4 hours*) |

**Description**

Specifies the minimum time that must elapse between the recording of identical events in order for the Net Logon service to write both to the System Log in Event Viewer. If the time between recording is less than the value of this entry, Net Logon regards the second event as a continuation of the first event, and it does not write the second event to the System Log.

This entry minimizes the number of repeated entries in the System Log. To direct Net Logon to record all events, set the value of this entry to 0.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Parameters\ExpectedDialupDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–600 (*seconds*) | 0 |

**Description**
Specifies the additional time that the Net Logon service waits for a response from a domain controller. If the domain controller does not respond before the total time allowed elapses, then Net Logon assumes that the domain controller is not available, and it proceeds accordingly.

This entry is designed to allow extra time for a response if the domain controller is connected by a slow dialup link.

This entry extends time limits for the following conditions:

- When locating a domain controller in a trusted domain, such as when authenticating a user's logon credentials.

  Net Logon allows 15 seconds plus the value of this entry for the domain controller to respond. The time begins when the first of three datagrams is sent to the domain controller.

  ```
  Timeout = 15 seconds + ExpectedDialupDelay seconds
  ```

- When an application programming interface (API) call is issued over a secure channel to a domain controller that has already been located.

  Net Logon allows 45 seconds plus the value of this entry for the domain controller to respond.

  ```
  Timeout = 45 seconds + ExpectedDialupDelay seconds
  ```

To give remote domain controllers more time to respond, you can add this entry to the registry and increase its value.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Parameters\GcSiteCoverage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | *Site names* | (None) |

**Description**

Specifies a list of sites in which this domain controller registers itself as a global catalog resource. These sites are in addition to those that Net Logon assumes to be closely related to the site based on their physical proximity, network topology, or bandwidth. As such, this list does not include the site in which the domain controller resides.

You can add this entry to the registry to add sites to the list. This list lets you associate sites that might be logically connected, but physically disparate.

The domain controller considers itself to be closely related to the sites in this list. Therefore, it replicates to the site and, when pinged by a client in the site, indicates that it is close by turning on the *closest site* bit.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- This entry is used only when it appears in the registry of a domain controller.

# Parameters\MaximumLogFileSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*bytes*) | 0x1312D00 (*20,000,000 bytes*) |

**Description**
Specifies the maximum size of the Net Logon debugging file, Netlogon.log. When the file reaches this size, any existing Netlogon.bak file is deleted, the current Netlogon.log file is renamed to Netlogon.bak, and a new Netlogon.log file is created. Logging is not interrupted.

The Netlogon.log file is created when the value of the **DBFlag** entry is greater than 0.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# MaximumMailslotMessages

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF (*messages*) | 0x1F4 (*500 messages*) |

**Description**

Specifies the maximum number of mailslot messages queued to the Net Logon service.

The Net Logon service is designed to process incoming mailslot messages immediately, but messages can accumulate when the server is processing many requests. Each mailslot message consumes about 1,500 bytes in the nonpaged memory pool until it is processed.

Reducing the value of this entry limits the amount of the nonpaged memory pool that Net Logon consumes. However, if this value is set too low, then Net Logon might reject important incoming mailslot messages.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# MaximumPasswordAge

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–1,000,000 (*days*) | 30 |

**Description**

Specifies how often the system changes the computer account password of the local computer. This entry is used only when the system is configured to change the computer password automatically at regular intervals, that is, when the value of the **DisablePasswordChange** entry is 0.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Pulse

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 60–172,800 (*seconds, up to 48 hours*) | 300 (*5 minutes*) |

**Description**
Specifies how often a primary domain controller (PDC) notifies backup domain controllers (BDCs) that changes have been made to the Security Accounts Manager (SAM) and Local Security Authority (LSA) databases. When the time specified by the value of this entry expires, the PDC sends notices only to the BDCs whose databases are not current.

The value of this entry does not affect database changes that trigger immediate updates. These include:

- Changing an account lockout policy.
- Changing a domain password policy.
- Changing a computer account password.
- Locking out an account.
- Changing the password for a trust account.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- In Windows Server 2003, the Net Logon service manages replication only if the replication involves servers running Windows NT 4.0 or earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# PulseConcurrency

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–500 (*pulses*) | 10 |

**Description**
Defines the maximum number of simultaneous pulses that the primary domain controller (PDC) sends to backup domain controllers (BDCs).

This entry limits the workload that sending and responding to pulses places on the PDC. The PDC must be able to support the number of concurrent replication remote procedure calls stored in the value of this entry.

Increasing the value of this entry increases the load on the PDC. Decreasing the value increases the time that a domain with a large number of BDCs requires to replicate a change in the Security Accounts Manager (SAM) or Local Security Authority (LSA) databases to all of the backup controllers.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- In Windows Server 2003, the Net Logon service manages replication only if the replication involves servers running Windows NT 4.0 or earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# PulseMaximum

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 60–172,800 (*seconds, up to 48 hours*) | 7200 (*2 hours*) |

**Description**
Defines the maximum time interval between pulses. If the time specified in the value of this entry expires, then the primary domain controller (PDC) sends at least one pulse, even if all backup domain controller (BDC) databases are current.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- In Windows Server 2003, the Net Logon service manages replication only if the replication involves servers running Windows NT 4.0 or earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# PulseTimeout1

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–120 (*seconds*) | 10 |

**Description**
Defines how long the primary domain controller (PDC) waits for a response from a backup domain controller (BDC) before it considers the BDC to be unresponsive. An unresponsive BDC is not counted against the limit specified in the PulseConcurrency entry, allowing the PDC to send a pulse to another BDC in the domain.

If this value is too high, then a domain with a large number of unresponsive BDCs takes a long time to complete a partial replication. But if this number is too low, then a slow BDC might mistakenly be treated as unresponsive. When the BDC finally does respond, it will partially replicate from the PDC, increasing the load on the PDC.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- In Windows Server 2003, the Net Logon service manages replication only if the replication involves servers running Windows NT 4.0 or earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# PulseTimeout2

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 60–3,600 (*seconds*) | 300 (*5 minutes*) |

**Description**
Defines how long a primary domain controller (PDC) waits for a backup domain controller (BDC) to complete each step in the replication process. If the value of this entry is exceeded, then the PDC regards the BDC as unresponsive and can send a pulse to another BDC in the domain.

This entry applies only to PDCs, and it is used only if a BDC cannot retrieve all the changes to the Security Accounts Manager (SAM) or Local Security Authority (LSA) databases in a single remote procedure call (RPC).

To be considered responsive, the BDC must respond to a pulse and must continue reporting its progress on the replication. If the interval between progress reports exceeds the value of this entry, then the BDC is considered to be unresponsive. An unresponsive BDC is not counted against the limit specified by the PulseConcurrency entry, allowing the PDC to send a pulse to another BDC in the domain.

If the value of this entry is set too high, then a slow BDC, or one whose replication rate is too slow, consumes one of the PulseConcurrency slots. But if the value of this entry is too low, then the PDC's workload increases because of the large number of BDCs doing a partial replication.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- In Windows Server 2003, the Net Logon service manages replication only if the replication involves servers running Windows NT 4.0 or earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# Randomize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–120 (*seconds*) | 1 |

**Description**
Specifies how long a backup domain controller (BDC) waits after receiving a pulse before it responds to the primary domain controller (PDC).

The value of this entry must be smaller than the value of the PulseTimeout1 entry, otherwise the PDC will consider the BDC to be unresponsive.

When calculating an optimal value for this entry, remember that the time required to replicate a change to the Security Accounts Manager (SAM) or Local Security Authority (LSA) databases to all the BDCs in a domain will be greater than:

`[(Randomize/2) * NumberOfBDCsInDomain] /` PulseConcurrency

If this entry does not appear in the registry, then Net Logon determines optimal values for the server based on the domain controller's workload.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- In Windows Server 2003, the Net Logon service manages replication only if the replication involves servers running Windows NT 4.0 or earlier. Net Logon for Windows Server 2003 does not manage replication between two servers running Windows Server 2003.

# RefusePasswordChange

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Prevents a domain controller from accepting requests from workstations to change their computer account passwords.

By default, Windows XP Professional systems automatically request a change to their computer account passwords at regular intervals (as specified in the value of the MaximumPasswordAge entry). To direct the system to reject these changes each time they arrive, set the value of **RefusePasswordChange** to 1.

| Value | Meaning |
|---|---|
| 0 | Accept changes to workstation computer account passwords. |
| 1 | Reject changes to workstation computer account passwords. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Tip**

- To prevent a workstation from sending a password change to the domain controller, set the value of the **DisablePasswordChange** entry to 1.

**Caution**

- Disabling automatic password changes can make the system more vulnerable to malicious access. Frequent password changes can be a significant safeguard for your system.

**See Also**
**Concepts**
MaximumPasswordAge

# RegisterDnsARecords

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the domain controller registers Domain Name System (DNS) A (address) records for the domain. If the domain controller is a global catalog resource, then this entry also determines whether the domain controller registers DNS A records for the global catalog.

| Value | Meaning |
|---|---|
| 0 | Does not register DNS A records. Lightweight Directory Access Protocol (LDAP) implementations that do not support SRV records will not be able to locate the LDAP server on this domain controller. |
| 1 | Registers DNS A records. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Notes**

- This entry is used only when it appears in the registry of a domain controller.
- You might consider setting this value to 0 if DNS fails to complete its dynamic updates because it cannot update A records. DNS stops updating when an update attempt fails.

# RequireSignOrSeal

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether the system requires that all secure channel communications be either signed or sealed.

The security specifications for secure channel traffic are determined jointly by the value of this entry and the values of the RequireStrongKey, SignSecureChanneland SealSecureChannel entries.

| Value | Meaning |
|---|---|
| 0 | Channel traffic need not be signed or sealed. Instead, the security of channel traffic is negotiated with the domain controller. System preferences in the negotiation of traffic security are determined by the values of SignSecureChanneland SealSecureChannel. |
| 1 | Outgoing traffic on a secure channel must be either signed or sealed. If the domain controller on the other side of the channel does not support signing or sealing, the system refuses to establish a channel. If the value of SealSecureChannel is 1, traffic must be encrypted; otherwise, it must be signed. |

**Notes**

- The value of this entry should be set to 1 only when all of the trusted domains support signed and sealed communications.
- Windows Server 2003 adds this entry to the registry when you install the system for the first time or when you change the default value. This entry might not appear in the registry, for example, if you upgrade to Windows Server 2003 from a system running Windows NT 4.0 that does not define this entry. If this entry does not appear in the registry, the system behaves as though the value is 0

SignSecureChannel

SealSecureChannel

# RequireStrongKey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the system requires that all secure channel keys be computed using a strong key. If it does, then the trusted domain controller on the other side of the channel must be able to compute strong keys. For public, non-exportable keys, a strong key is one that is 128 bytes or longer.

All secure channels have keys. The keys are used for authentication, signing, or encryption, depending on the capability and requirements of the systems.

| Value | Meaning |
|---|---|
| 0 | The system does not require that the trusted domain controller be able to compute a strong key. |
| 1 | The system requires that the trusted domain controller be able to compute a strong key. If the domain controller on the other side of the channel does not support strong key encryption, this system refuses to establish a channel. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- This entry should be set to 1 only when all of the trusted domains are able to compute strong keys.

# Parameters\ScavengeInterval Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 60–172,800 (*seconds*) (*1 minute–2 days*) | 900 (*15 minutes*) |

**Description**

Specifies how often the Net Logon service performs scavenging activities, such as the following:

- Checks for password expirations on secure channels.
- Checks for idle secure channels.
- Discovers domain controllers for all trusted domains in which a domain controller has not yet been discovered. (Domain controllers only.)
- Attempts to add the domain's NetBIOS <1B> name. (Primary domain controllers only.)
- Cleans up sundry system resources that are no longer needed.

The default value is optimal for most systems. However, in some cases, such as when a trusted domain is connected by an expensive connection, you might add this entry to increase the time between operations.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SealSecureChannel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether outgoing secure channel traffic is encrypted (sealed). This entry is used when negotiating the conditions of a secure channel with a domain controller. If the value of this entry is 1, and the domain controller supports this functionality, the secure channel traffic is signed.

Channel traffic security is determined jointly by the value of this entry and the values of the registry entries RequireStrongKey, RequireSignOrSeal, and SignSecureChannel.

Because encryption is more secure than signing, when the value of this entry is 1, it takes precedence over the value of SignSecureChannel.

| Value | Meaning |
|---|---|
| 0 | Outgoing traffic on a secure channel should not be encrypted. |
| 1 | Outgoing traffic on a secure channel should be encrypted if the domain controller supports this functionality. |

**Note**

- Windows Server 2003 and Windows 2000 add this entry to the registry when you install the system for the first time or when you change the default value. If you upgrade from Windows NT 4.0 or earlier, the entry does not appear in the registry, but it is still in effect on your system.

# SignSecureChannel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether outgoing secure channel traffic is signed. This entry is used when negotiating the conditions of a secure channel with a domain controller. If this value of this entry is 1 and the domain controller supports signing, the secure channel traffic is signed.

Channel traffic security is determined jointly by the value of this entry and the values of the entries RequireStrongKey, RequireSignOrSeal, and SealSecureChannel. Because encryption is more secure than signing, the system behaves as if the value of this entry is 1, even if it is zero, when the value of **sealsecurechannel** is 1.

| Value | Meaning |
|---|---|
| 0 | Outgoing traffic on a secure channel should not be signed. |
| 1 | Outgoing traffic on a secure channel should be signed if the domain controller supports signing. |

**Note**

- Windows Server 2003 and Windows 2000 add this entry to the registry when you install the system for the first time or when you change the default value. If you upgrade from Windows NT 4.0 or earlier, the entry does not appear in the registry, but it is still in effect on your system.

# NTDS

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
Stores configuration data for Active Directory.

In particular, Active Directory stores domain controller information in this subkey that it uses to restart Active Directory independently and to configure the Active Directory database.

# NTDS\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NTDS

**Description**
The Parameters subkey stores configuration data for Active Directory. In particular, Active Directory saves the location of log files and replication information in this subkey.

# Repl topology update delay (secs)

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NTDS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x14–0xFFFFFFFF (*seconds*) | 0x12C (*300 seconds = 5 minutes*) |

**Description**
Specifies the amount of time after Active Directory starts that the Knowledge Consistency Checker (KCC) first evaluates the replication topology.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
Repl topology update period (secs)

# Repl topology update period (secs)

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NTDS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x14–0xFFFFFFFF (*seconds*) | 0x384 (*900 seconds = 15 minutes*) |

**Description**

Specifies how often the Knowledge Consistency Checker (KCC) reevaluates the replication topology. KCC repeatedly evaluates the topology at the specified rate whenever Active Directory is running.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Replicator async inter site packet size (bytes)

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NTDS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x400 - 0xFFFFFFFF | (sized dynamically) |

**Description**

Stores the maximum size of a packet that transports replication data between sites that are not directory partitions. The default value is sized dynamically, based on the amount of memory. This value is sent on a replication request to the source computer. The source computer uses the value it receives in the replication request or its own setting for this value, whichever is smaller.

For replication between sites that are not directory partitions, Active Directory uses the Simple Mail Transfer Protocol (SMTP). This replication is asynchronous.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Notes

- If the value of this entry is not set, then the system limits the packet size to 1/100th of the size of RAM, with a minimum of 17nbsp;MB and a maximum of 10 MB.

- For the system to function correctly, the value of this entry must be at least 0x400 (1 MB), and it must not be unreasonably high.

# Replicator inter site packet size (bytes)

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NTDS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x400 - 0xFFFFFFFF | (sized dynamically) |

**Description**
Stores the maximum size of a packet that transports replication data between sites that are directory partitions. The default value is sized dynamically, based on the amount of memory. This value is sent on a replication request to the source computer. The source computer uses the value it receives in the replication request or its own setting for this value, whichever is smaller.

For replication between sites that are directory partitions, Active Directory uses the Remote Procedure Call (RPC) transport protocol, with compression. This replication is synchronous.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
You can change this entry only by editing the registry.

### Notes

- If the value of this entry is not set, the system limits the packet size to 1/100th of the size of RAM, with a minimum of 1 MB and a maximum of 10 MB.

- For the system to function correctly, the value of this entry must be at least 0x400 (1 MB), and it must not be unreasonably high.

# Replicator intra site packet size (bytes)

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NTDS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x400 - 0xFFFFFFFF | (sized dynamically) |

**Description**

Stores the maximum size of a packet that transports replication data within a site. The default value is sized dynamically, based on the amount of memory. This value is sent on a replication request to the source computer. The source computer uses the value it receives in the replication request, or its own setting for this value, whichever is smaller.

For replication within a site, Active Directory uses the Remote Procedure Call (RPC) transport protocol, without compression. This replication is synchronous.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Notes

- If the value of this entry is not set, then the system limits the packet size to 1/100th of the size of RAM, with a minimum of 1 MB and a maximum of 10 MB.

- For the system to function correctly, the value of this entry must be at least 0x400 (1 MB), and it must not be unreasonably high.

# TCP/IP Port

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NTDS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–65,535 (*port number*) | (None) |

**Description**

Specifies the port used for Active Directory replication on this server. The remote procedure call (RPC) locator always returns this port number when queried for the Active Directory replication port for this server.

By default, Active Directory uses a dynamically assigned port to transport replication updates within sites. However, you can use this entry to create a fixed port assignment. This setting is designed for routed environments and those using port filtering.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# NtFrs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
Stores configuration data for the File Replication service (FRS). FRS automatically updates and synchronizes the contents of replicated files.

# NtFrs\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NtFrs

**Description**
The Parameters subkey stores configuration data for the File Replication service (FRS). FRS automatically updates and synchronizes the contents of folders managed by Distributed File System (DFS).

The data in this subkey typically specifies settings that are configurable by the administrator; for example, the severity setting for events logged by FRS.

# Debug Disable

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Ntfrs\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Disables the File Replication service (FRS) trace log.

By default, FRS records its actions in trace log files. These log files are named Ntfrs_000*x* and are located in the *Systemroot*\debug directory. These files are typically used to investigate FRS replication problems. You can disable the logs to reduce disk use.

| Value | Meaning |
|---|---|
| 0 | Enables the trace log. |
| 1 | Disables the trace log. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
Debug Log File
Debug Log Files
Debug Log Severity
Debug Maximum Log Messages

# Debug Log File

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Ntfrs\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Path* | *Systemroot*\debug |

**Description**
Specifies where the File Replication service (FRS) stores its trace log files.

If you change the value of this entry, then FRS creates new trace log files in the directory specified, but it does not move existing trace log files to the new location. Also, FRS does not delete or maintain log files in the original location.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to the value of this entry effective, you must stop and restart FRS.

**Tip**

- If you have more than one hard drive, you can improve disk performance by storing the FRS trace log files on a different hard drive than the one that stores the FRS database and replica tree.

**See Also**
**Concepts**
Debug Disable
Debug Log Files
Debug Log Severity
Debug Maximum Log Messages

# Debug Log Files

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Ntfrs\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 5 |

**Description**
Specifies how many File Replication service (FRS) trace log files can be active simultaneously.

FRS creates a set of sequential log files named Ntfrs_000*x*.log. The files are numbered, beginning with 0001, so that the log with the highest number contains the most recently logged entries. The log files are retained until the number of files reaches the value of this entry, then FRS deletes Ntfrs_0001 and renumbers all remaining logs accordingly.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
Debug Log File
Debug Disable
Debug Log Severity
Debug Maximum Log Messages

# Debug Log Severity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Ntfrs\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–5 | 2 |

**Description**
Specifies the level of detail that the File Replication service (FRS) records in its trace log files (Ntfrs_000*n*.log).

FRS assigns severity levels to different log print statements in the FRS code. The value of this entry determines which severity levels are written to the log. The higher the value of this entry, the more detail the log records.

If the value of this entry is 0, then only the most severe events are recorded in the log. If the value of this entry is 5, then all events are recorded in the log. The default value is set to 2 so that tracking records are displayed, as well as warning and error messages.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
Debug Log File
Debug Disable
Debug Log Files
Debug Maximum Log Messages

# Debug Maximum Log Messages

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Ntfrs\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x4E20 (20,000) |

**Description**
Specifies how many entries can be stored in each File Replication service (FRS) trace log file (Ntfrs_000*x*.log).

When the number of event entries reaches the value of **Debug Maximum Log Messages,** the system closes the current log file and starts a new one. The log files are numbered sequentially, so when the FRS closes Ntfrs_0001.log, it begins Ntfrs_0002.log.

The default value of 10,000 entries (0x2710) uses approximately 1 MB of disk space.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Staging Space Limit in KB

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Ntfrs\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*KB*) | 0xA1220 (*660,000 KB = 660 MB*) |

**Description**
Specifies the maximum amount of disk space that the File Replication service (FRS) can use to store staging files.

FRS uses staging files to encapsulate the data streams and attributes associated with each replicated file or directory object. The staging file is transferred among replica members, which use it to replicate the object.

When the space consumed by staging files reaches the value of this entry, inbound replication is suspended. FRS tries to release space by replicating staging files to all outbound partners.

Typically, staging files reach this limit because FRS cannot offload files to an outbound partner that connects infrequently.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You can add this entry or change its value while FRS is running. You do not need to restart FRS to make the change effective.

# NWCWorkstation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
Stores configuration data for Client Service for NetWare. This service enables a Windows XP Professional workstation to gain access to file and print services on Novell NetWare servers, even if it is not running NetWare client software.

### Note

- This subkey appears in the registry when you install Client Service for NetWare.

# NWCWorkstation\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation

**Description**
Stores configuration data specific to Client Service for NetWare. This service enables a Windows XP Professional workstation to gain access to file and print services on Novell NetWare servers, even if it is not running NetWare client software.

### Note

- This subkey appears in the registry when you install Client Service for NetWare.

# DefaultLocation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Server-name* or **Tree\Context* | (None) |

**Description**

Specifies the Netware 3.*x* server or NDS tree/context for all new users. This entry applies to users the first time they log on.

Once a user has logged on, administrators can use Client Service for Netware in Control Panel to change the preferred server, or tree and context.

The **DefaultLocation** and DefaultScriptOptions entries let you set default values for the preferred server and logon script client options. When both of these entries appear in the registry with valid values, the system supresses the **Select NetWare Logon** dialog box that requests this information from the user. Otherwise, the dialog box appears each time a user logs on until they select a preferred server.

**Note**

- This entry is used only when the DefaultScriptOptions entry appears in the registry with a valid value. Otherwise, the entry is ignored and the system requires a user to select a server from the **Select NetWare Logon** dialog box.

# DefaultScriptOptions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x3 \| 0x800 | 0x0 |

**Description**

Specifies whether logon scripts are enabled or disabled by default. This entry applies to users the first time they log on.

Once a user has logged on, administrators can use Client Service for NetWare in Control Panel to enable or disable logon scripts.

| Value | Meaning |
|---|---|
| 0x0 | Logon scripts are disabled. |
| 0x1 | Logon scripts are enabled only on bindery servers. |
| 0x2 | Logon scripts are enabled only on Novell Directory Services (NDS) directories. |
| 0x3 | Logon scripts are enabled on both bindery servers and NDS directories. |
| 0x800 | Logon scripts enabled and are in debugging mode. |

This entry is a bitmask. Bit 1 enables logon scripts on bindery servers. Bit 2 (10 binary) enables logon scripts on NDS servers. To enable logon scripts on a type of server, set the bit for that server type to 1. To turn debugging mode on, set bit 12 (100000000000, or 0x800) to 1.

The DefaultScriptOptions and **DefaultScriptOptions** entries let you set default values for the preferred server and logon script client options. When both of these entries appear in the registry with valid values, the system supresses the **Select NetWare Logon** dialog box that requests this information from the user. Otherwise, the dialog box appears each time a user logs on, until the user selects a preferred server.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Logon

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters

**Description**
Stores data about the current user for the Client Service for NetWare, which uses the data internally.

This subkey contains subkeys that represent users who have logged on to the system. These subkeys are named for the (security identifiers (SIDs)) of the users. The data in each SID Subkey subkey applies only to the user that the SID represents.

### Note

- This subkey appears in the registry when you install Client Service for NetWare.

### Caution

- Do not change the content of this subkey. If you do, Client Service for NetWare might not operate properly, and users might not be able to gain access to resources on NetWare servers.

**See Also**
**Concepts**
SID Subkey

# SID Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Logon

**Description**
The *SID* subkey represents particular users.

The *SID* subkey is named for the security identifier (SID) of the user. It stores data about a specific user for the Client Service for NetWare, which uses the data internally. The data in each *SID* subkey applies only to the user that the SID represents.

**Note**

- The *SID* subkey is a placeholder representing the subkeys named for the SIDs in the subkey HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Logon. "SID" does not actually appear in the registry. The actual SID subkeys in your registry are specific to your system and its users.

- This subkey appears in the registry when you install Client Service for NetWare.

**Caution**

- Do not change the contents of the Logon subkey. If you do, Client Service for NetWare might not operate properly, and users might not be able to gain access to resources on NetWare servers.

# Option

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters

**Description**
Stores the value of optional settings for users of this computer for the Client Service for NetWare, which uses the data internally.

This subkey contains subkeys that represent users who have logged on to the system. These subkeys are named for the (security identifiers (SIDs)) of the users. The data in each SID Subkey subkey applies only to the user that the SID represents.

# Option\SID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Option

**Description**
The *SID* subkeys represent particular users.

The *SID* subkey is named for the security identifier (SID) of the user. It stores data about a specific user for the Client Service for NetWare, which uses the data internally. The data in each SID subkey applies only to the user that the SID represents.

**Note**

- The *SID* subkey is a variable representing the subkeys names for the SIDs in the HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Option subkey. It does not actually appear in the registry. This variable subkey displays the subkeys and entries that are common to many of the subkeys in Logon. The actual SID subkeys in your registry are specific to your system and its users.

- This subkey appears in the registry when you install Client Service for NetWare.

# LogonScript

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Option*SID*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–3 | (See below.) |

**Description**
Specifies whether a logon script runs if the user represented by the security identifier (SID) connects directly to a NetWare server.

This entry stores the values of the **Run Login Script** check box in CSNW in Control Panel and the **Run Login Script** check box on the **Select NetWare Logon** dialog box. The **Select NetWare Logon** dialog box appears the first time a user logs on after installing Client Service for NetWare.

| Value | Meaning |
|---|---|
| 0 | Do not run NetWare login scripts. |
| 1 | Run login scripts when connecting to NetWare bindery servers. |
| 2 | Run login scripts when connecting to Novell Directory Services (NDS) servers. |
| 3 | Run login scripts when connecting to any NetWare servers. |

**Change Method**
To change the value of this entry, select or clear the **Run Login Script** check box in CSNW in Control Panel.

### Note

- This subkey appears in the registry when you install Client Service for NetWare.

# NDSPreferredServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Option*SID*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Server-name* | (None) |

**Description**
Specifies the Novell Directory Services (NDS) server that the system tries first when it logs the user on to an NDS tree.

If this entry is not in the registry or the specified server is not available, then the system logs the user on the first server in the user's tree and context that responds to the logon request. (The tree and context are stored in the value of the PreferredServer entry.)

Specifying a particular server assures that, when users log on through an NDS tree containing more than one NetWare server, they are authenticated by the same NetWare server that provides the access to NetWare resources. This provides administrators with better control over the use of NetWare connection licenses.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- This entry is used only when the client connects to a network that uses Novell Directory Services.

**See Also**
**Concepts**
PreferredServer

# PreferredServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Option*SID*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | ***** *Tree* **** *Context* or *Server-name* | (None) |

**Description**
Specifies the NetWare server or Novell Directory Services (NDS) tree and context to which this user logs on. If the specified server is not available, then the system notifies the user and lets the user select from a list of other available servers. If the value of this entry is blank, then the system does not log the user on to a NetWare server.

An asterisk (*) preceding the string indicates that the value is an NDS tree and context. Otherwise, the value indicates a NetWare 3.*x* server.

This entry stores the values of the **Select Preferred Server**, **Tree**, and **Context** text boxes in CSNW in Control Panel and in the **Select NetWare Logon** dialog box. The **Select NetWare Logon** dialog box appears the first time a user logs on after installing Client Service for NetWare.

Client Services for NetWare adds this entry to the registry with the value that the user enters in the dialog box options. If the user leaves the dialog box options blank, then the value of this entry is blank. If this entry is not in the registry, then Client Service for NetWare assumes that the user has logged on before.

Users can change the value of this entry by using CSNW in Control Panel. If this value is blank when the user logs on again, then the system displays a dialog box offering users a list of available servers. If the user selects a server, then the name of that server is written to the value of this entry. If the user does not select a server, then the user cannot log on to a NetWare server.

**Change Method**
Do not edit this entry in the registry. To change the value of this entry, use CSNW in Control Panel.

### Note

- When this entry stores an NDS tree and context, then by default, the system logs the user on to the first server in that tree and context that responds to a logon request. To indicate a preferred server within the specified NDS tree and context, use the NDSPreferredServer entry.

**See Also**
**Concepts**
NDSPreferredServer

# PrintOption

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\NWCWorkstation\Parameters\Option*SID*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x08 \| 0x10 \| 0x18 \| 0x80 \| 0x88 \| 0x90 \| 0x98 | 0x98 |

**Description**
Specifies options set by the user for printing to NetWare resources.

The value of this entry is a 4-bit value in which three of the bits represent printing options. The remaining bit is not used. A printing option is enabled when its corresponding bit is 1; the option is disabled when its corresponding bit is 0. The follow table shows the significant bits and their meaning.

| Bit | Meaning |
|---|---|
| 0x08 | Suppress form feed. |
| 0x10 | Send print notification message. |
| 0x80 | Print in banner style. |

**Change Method**
To change the value of this entry, use CSNW in Control Panel.

### Note

- This subkey appears in the registry when you install Client Service for NetWare.

NetWare or Compatible Network

# PerfDisk

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The PerfDisk subkey stores configuration data for Perfdisk.dll, the Windows Server 2003 disk performance driver. Perfdisk.dll collects performance-related data about logical and physical disk drives for display by System Monitor and other display tools.

**Caution**

- Do not modify or delete the contents of this subkey. Doing so might intefere with the collection of data.

# PerfDisk\Performance

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\PerfDisk

**Description**
The Performance subkey stores configuration data for Perfdisk.dll, the Windows Server 2003 disk performance driver. Perfdisk.dll collects performance-related data about logical and physical disk drives for display by System Monitor and other display tools.

**Activation Method**
To make changes to entries in this subkey effective, restart the Remote Registry Service or restart the system.

### Tip

- If particular performance counters do not appear in your monitoring tool, check the Application Log in Event Viewer for events recorded by Perflib. When Perflib detects disabling errors in a counter dynamic-link library (DLL), it records an event in the log, and it disables the counters by setting the value of the Disable Performance Counters entry to 1.

# NT4 Instance Names

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\PerfDisk\Performance

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether instances of the PhysicalDisk performance object displayed in performance tools, such as System Monitor, include the names of logical drives residing on the physical drive.

| Value | Meaning |
|---|---|
| 0 | Instances of the PhysicalDisk performance object display the drive number and logical drive letters. |
| 1 | Instances of the PhysicalDisk performance object display only the drive number. (Same as Windows NT 4.0 and earlier.) |

For example, suppose a physical drive, Disk 0, includes three logical disks, C, D, and E. If the value of this entry is 0, then the physical disk instance is represented as 0: C, D, E. If the value of this entry is 1, then the same instance is represented as 0.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
To make changes to this entry effective, restart the Remote Registry Service or restart Windows.

**Tip**

- To test this entry on your computer, in System Monitor, click the **+** button and, in the **Performance object** box, click **PhysicalDisk**. View the names of instances in the **Select instances from list** box. Then, add this entry to the registry, set its value to 1, and view the names again.

# PerfProc

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# PerfProc\Performance

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\PerfProc

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# ThreadNameFormat

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\PerfProc\Performance

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 | (None) |

**Description**
Specifies whether System Monitor or the Performance Logs and Alerts service displays and logs thread counter instances with the ID of the associated thread appended.

If the value of this entry is 1, or if this entry is absent from the registry, then Performance Logs and Alerts appends a unique integer to each instance of a thread name to distinguish the multiple instances from each other. If the value of this entry is 2, then Performance Logs and Alerts appends the thread ID for each instance of the thread name.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
The value of this entry is read each time the ReqQueryValueEx API is called. For Performance Logs and Alerts, you must stop and restart the service for changes to this entry to be effective.

# Rasl2tp

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The Rasl2tp subkey stores configuration data for the Layer Two Tunneling Protocol (L2TP) support in Routing and Remote Access.

L2TP is an industry standard tunneling protocol. Unlike Point-to-Point Tunneling Protocol (PPTP), which is based on Transmission Control Protocol (TCP), L2TP is based on User Datagram Protocol (UDP).

**Concepts**
ProhibitIpSec

# RasMan

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The RasMan subkey stores configuration data for Routing and Remote Access. The subkeys in the RasMan subkey vary, according to which services are installed.

# RasMan\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan

**Description**
The Parameters subkey stores configuration data for Routing and Remote Access.

# DisableSavePassword

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the passwords associated with Network Connections phone book entries are saved. If the user has many phone book entries, accumulated saved passwords can cause a slight delay after the user's credentials are typed in the **Connecting To** dialog box.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# IpOutHighWatermark

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x5 |

**Description**
Specifies the maximum number of unused IP outgoing dial-up adapters that Routing and Remote Access can maintain. If the number of these unused adapters exceeds the value of this entry, then Routing and Remote Access deletes the excess adapters.

Routing and Remote Access dynamically creates IP outgoing dial-up adapters as needed, and it deletes the adapters when they are no longer needed. Routing and Remote Access creates reserve adapters in advance to prevent call delays. However, because adapters consume system resources, you should reserve only as many adapters as you will use.

If the value of this entry is too high, then resources are wasted maintaining excess adapters. But if the value of this entry is too low, then users will experience perceptible delays while adapters are being created.

**See Also**
**Concepts**
IpOutLowWatermark

# IpOutLowWatermark

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x1 |

**Description**
Specifies the minimum number of unused IP outgoing dial-up adapters that Routing and Remote Access can maintain. If the number of these unused adapters falls below the value specified in this entry, then Routing and Remote Access creates more adapters.

Routing and Remote Access dynamically creates IP outgoing dial-up adapters as needed, and it deletes the adapters when they are no longer needed. Routing and Remote Access creates reserve adapters in advance to prevent call delays. However, because adapters consume system resources, you should reserve only as many adapters as you will use.

If the value of this entry is too high, then resources are wasted maintaining excess adapters. But if the value of this entry is too low, then users will experience perceptible delays while adapters are being created.

# Parameters\Logging

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

**Caution**

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# ProhibitIpSec

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | |

**Description**

Prevents Routing and Remote Access from conducting IP security (IPSec) negotiation on calls using Layer Two Tunneling Protocol (L2TP).

By default, Routing and Remote Access combines L2TP and IPSec to provide secure remote communication. If the value of this entry is 1, then L2TP calls are not secure.

| Value | Meaning |
|---|---|
| 0 | Routing and Remote Access conducts IPSec negotiation on L2TP calls. |
| 1 | Routing and Remote Access does not conduct IPSec negotiation on L2TP calls. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# PPP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan

**Description**
The PPP subkey contains entries for the Point-to-Point Protocol (PPP) service for Routing and Remote Access.

# BapListenTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*seconds*) | 0x2D (*45 seconds*) |

**Description**

Specifies how long the client waits for a response to a Bandwidth Allocation Protocol (BAP) callback request. While waiting, the port that the client is using is not available for any other use. When the value of this entry expires, the port is released.

This entry is used only when client computers are configured to use BAP. BAP dynamically adds and drops links as they are needed to support the network traffic. Clients send callback requests to ask the server to connect an additional link.

### Notes

- The default value is optimal for most installations. However, you might consider increasing this value if the client is not answering the server's callback. This might indicate that the client stops waiting for a response before the server calls. Increase this value by approximately 15 seconds and test the callback again.

- The remote access client implements any value you enter in this entry, even if the value is impractical. Be sure to test the effect of changes to these values before you go online.

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# DefaultCallbackDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–255 (*seconds*) | 12 |

**Description**
Specifies how long the remote access server's modem waits before calling back. You can add this entry to the registry of the remote access client to change the default value calculated by the remote access server.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# DefaultIdleTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFF (*seconds*) | 0x0 |

**Description**

Specifies how long an idle port remains active after its last transmission before it is closed.

| Value | Meaning |
|---|---|
| 0x0 | Idle ports do not time out. An idle port can remain active indefinitely. |
| 0x1–0xFFFFFFFF *seconds* | The number of seconds an idle port can remain active. |

**Note**

- The "Disconnect if Idle for" Routing and Remote Access policy takes precedence over the value of this entry.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# DefaultPortLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFE (*ports*) \| 0xFFFFFFFF | 0xFFFFFFFF |

**Description**

Specifies the maximum number of ports that can be grouped into a multi-link bundle.

| Value | Meaning |
|---|---|
| 0x0–0xFFFFFFFE | The maximum number of ports in a bundle. |
| 0xFFFFFFFF | There is no limit on the number of ports in a bundle. |

**Note**

- The "Limit Maximum ports" policy on the **Multilink** tab in Routing and Remote Access takes precedence over the value of this entry.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# DefaultSessionTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFF (*seconds*) | 0x0 |

**Description**

Specifies how long a port can remain active before it is closed.

| Value | Meaning |
|---|---|
| 0x0 | Ports do not time out. A port can remain active indefinitely. |
| 0x1–0xFFFFFFFF *seconds* | The number of seconds the port remains active. |

**Note**

- The "Restrict maximum session to" policy in Routing and Remote Access takes precedence over the value of this entry.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# LowerBandwidthThreshold

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1–100 (*percent*) | 50 |

**Description**
Specifies the minimum bandwidth used for the Bandwidth Allocation Protocol (BAP). If the percentage of bandwidth used falls below this minimum for more than the value specified in the TimeBelowThreshold entry, then Routing and Remote Access closes the connection.

If the value of this entry is 0, then no minimum bandwidth is enforced.

### Note

- This setting can be overridden by a remote access policy. If you have set the **Capacity** option on the **Multilink** tab in Routing and Remote Access to a value other than 50%, then that setting takes precedence over the value of this registry entry.
- This entry is used only when BAP is enabled on the computer.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

TimeBelowThreshold

# MaxConfigure

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–255 (*packets*) | 10 |

**Description**

Indicates how many Configure-Request packets Routing and Remote Access can send without receiving a valid Configure-ACK,Configure-NAK, or Configure-Reject response. If Routing and Remote Access does not receive a valid response after sending the number of packets indicated by the value of this entry, then it assumes that the peer cannot respond.

# MaxFailure

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–255 (*packets*) | 5 |

**Description**

Specifies how many Config-Nak packets Routing and Remote Access can send while negotiating a Point-to-Point Protocol (PPP) connection. If the negotiation does not succeed after the specified number of Config-Nak packets are sent, then Routing and Remote Access terminates the PPP negotiation and considers it to have failed.

# MaxReject

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–255 (*packets*) | 5 |

**Description**

Indicates how many Config-Reject packets Routing and Remote Access can send while negotiating a Point-to-Point Protocol (PPP) connection. If the negotiation does not succeed after the specific number of rejections are sent, then Routing and Remote Access terminates the PPP negotiation and considers it to have failed.

# MaxTerminate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–255 (*packets*) | 2 |

**Description**
Specifies how many Terminate-Request packets Routing and Remote Access can send. If Routing and Remote Access does not receive a Terminate-ACK response after sending the number of packets indicated by the value of this entry, it assumes that the peer cannot respond.

**Change Method**
You can change this entry only by editing the registry.

# NegotiateTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFF (*seconds*) | 0x96 (*150 seconds*) |

**Description**

Specifies how long Point-to-Point Protocol (PPP) negotiation can continue. If the negotiation does not result in a successful convergence in the time indicated by the value of this entry, then the server disconnects the line.

| Value | Meaning |
|---|---|
| 0x0 | There is no time limit for PPP negotiation. The line will not be disconnected for exceeding a negotiation time limit. |
| 0x1–0xFFFFFFFF seconds | The time limit for PPP negotiation. |

**Change Method**

You can change this entry only by editing the registry.

# RestartTimer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFF (*seconds*) | 0x3 |

**Description**
Specifies how long Routing and Remote Access waits for a peer to respond to the transmission of Configure-Request and Terminate-Request packets before retransmitting the packets.

**Change Method**
You can make changes to this subkey only by using registry editor.

# TimeBelowThreshold

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*seconds*) | 0x78 (*2 minutes*) |

**Description**
Specifies how long a connection using Bandwidth Allocation Protocol (BAP) can remain below the minimum bandwidth use (as specified by the value of the LowerBandwidthThreshold entry) before it is disconnected.

**Note**

- This setting can be overridden by a remote access policy. If you have set the **Capacity...for a period of** option on the **Multilink** tab in Routing and Remote Access to a value other than 120 seconds, then that setting takes precedence over the value of this entry.

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# ControlProtocols

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

**Description**
The ControlProtocols subkey stores configuration data for Point-to-Point Protocol (PPP) control and authentication protocols, such as IPCP, IPXCP, PAP, and EAP.

# BuiltIn

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols

**Description**
The BuiltIn subkey stores configuration data for Point-to-Point Protocol (PPP) control and authentication protocols that are included in Windows Server 2003.

# AcceptVJCompression

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Internet Protocol Control Protocol (IPCP) accepts IPCP standard option 0x2, Van Jacobson (VJ) header compression.

| Value | Meaning |
|---|---|
| 0 | IPCP does not accept VJ compression. |
| 1 | IPCP accepts VJ compression. |

**Note**

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# DefaultDomain

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Domain name or computer name* | *Domain name or computer name* |

**Description**

Specifies the domain used to validate a logon attempt when no domain is specified. This entry applies only to networked computers that are running Windows Server 2003. If the computer is not a member of a domain, then this entry specifies the name of the computer.

By default, the system uses the name of the primary domain of the local computer. However, you can add this entry to the registry to override the default value and to force the system to use the specified domain.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# BuiltIn\Path

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path and file name* | %SystemRoot%\System32\rasppp.dll |

**Description**

Stores the path to the dynamic-link library (DLL) for the Routing and Remote Access control protocols. A single DLL supports all control protocols.

# RegisterRoutersWithNameServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Directs Routing and Remote Access to register all outgoing dial-up routers with the Domain Name System (DNS) and Windows Internet Name Service (WINS) servers of the server router.

| Value | Meaning |
|---|---|
| 0 | Routers dialing out of the network do not register with the server router's DNS and WINS servers. |
| 1 | Routers dialing out of the network register with the server router's DNS and WINS servers. |

**Activation Method**
Changes to this entry take effect the next time a router dials out of the network.

### Note

- This entry affects routers only when they dial out of the network. It does not affect registration of routers under any other conditions.
- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# RequestNameServerAddresses

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Internet Protocol Control Protocol (IPCP) on remote access clients request Microsoft extension options 0x81, 0x82, 0x83, and 0x84 for Windows Internet Name Service (WINS) and Domain Name System (DNS) server address negotiation.

| Value | Meaning |
|---|---|
| 0 | Prevents IPCP from requesting the Microsoft extension options for WINS and DNS server address negotiation. |
| 1 | IPCP on remote access clients request the Microsoft extension options for WINS and DNS server address negotiation. |

**Note**

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.
- In Windows NT 4.0 and earlier, this entry appeared in the HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Rasman\PPP\IPCP subkey.

# RequestVJCompression

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Internet Protocol Control Protocol (IPCP) on remote access clients request IPCP standard option 0x2, Van Jacobson (VJ) header compression.

| Value | Meaning |
|---|---|
| 0 | Prevents remote access clients from requesting VJ compression. |
| 1 | Remote access clients request VJ compression. |

**Note**

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.
- In Windows NT 4.0 and earlier, this entry appeared in the HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Rasman\PPP\IPCP subkey.

# EAP Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP

**Description**
The EAP subkey stores configuration data for the Extensible Authentication Protocol (EAP) service of the Point-to-Point Protocol (PPP). EAP provides high-level security for virtual private network (VPN) and wireless (IEEE 802.1x) connections.

# 13

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\EAP

**Description**
The 13 subkey stores configuration data for the Extensible Authentication Protocol–Transport Level Security (EAP-TLS). EAP-TLS provides highly secure authentication for smart cards.

# IgnoreNoRevocationCheck

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\EAP\13

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Lets Extensible Authentication Protocol–Transport Level Security (EAP-TLS) clients connect even if the server does not perform or cannot complete a revocation check of the client's certificate chain (excluding the root certificate). Typically, revocation checks fail because the certificate does not include revocation information.

By default, an EAP-TLS client cannot connect unless the server completes a revocation check of the client's certificate chain (including the root certificate) and verifies that none of the certificates has been revoked. However, you can use this entry to override the default behavior.

This entry does not interfere with the revocation check. Also, it does not permit clients to connect if the revocation check reveals that a certificate in the chain has been revoked.

| Value | Meaning |
|---|---|
| 0 | Clients cannot connect unless a revocation check completes successfully. |
| 1 | Clients can connect even if the revocation check cannot be completed. |

You can use this entry to authenticate clients whose certificate does not include certificate revocation list distribution points (CRPs), such as those from third parties and from the Microsoft Certificate Authority prior to Windows 2000.

**Note**

- This entry is effective only when it appears in the registry of a Routing and Remote Access server.
- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# IgnoreRevocationOffline

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\EAP\13

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Lets Extensible Authentication Protocol–Transport Level Security (EAP-TLS) clients connect even if a server that stores a relevant revocation list is not available on the network.

By default, EAP-TLS does not permit a client to connect unless it can complete a revocation check of the client's certificate chain and verify that none of the certificates has been revoked. If EAP-TLS cannot connect to a server that stores a revocation list, then it considers the certificate to have failed the revocation check. However, you can add this entry to the registry to direct EAP-TLS to ignore errors related to unavailable servers.

This entry prevents a client from being denied permission to connect because poor network conditions prevented the revocation check from completing successfully.

| Value | Meaning |
|---|---|
| 0 | If the server cannot connect to a server that stores a revocation list, then it considers a certificate to have failed the revocation check. |
| 1 | If the server cannot connect to a server that stores a revocation list, then it ignores the error and permits the client to connect. |

**Note**

- This entry is effective only when it appears in the registry of a Routing and Remote Access server.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# MaxTLSMessageLength

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\EAP\13

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x5DC–0xFFFFFFFF (*bytes*) | 0x4000 (*16,384 bytes*) |

**Description**
Specifies the maximum length of a Transport Layer Security (TLS) message or a set of fragmented TLS messages. If the client or server encounters a longer message, then it ignores the message.

This entry is designed to prevent malicious users from harming the service by sending excessively long TLS messages.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# NoRevocationCheck

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\EAP\13

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Prevents Extensible Authentication Protocol–Transport Level Security (EAP-TLS) from performing a revocation check of the EAP-TLS client's public key certificate.

The revocation check verifies that the public key certificate (and the certificates in its certificate chain) have not been revoked.

| Value | Meaning |
|---|---|
| 0 | Enables the revocation check |
| 1 | Disables the revocation check |

**Note**

- This entry is effective only if it appears in the registry of a Routing and Remote Access server.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

**Tip**

- This entry disables the revocation check of the client's complete certificate chain. To disable the revocation check of the client's root certificate only, use the IgnoreNoRevocationCheck entry.

# NoRootRevocationCheck

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RasMan\PPP\EAP\13

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Prevents Extensible Authentication Protocol–Transport Level Security (EAP-TLS) from performing a revocation check of the EAP client's root public key certificate.

The revocation check verifies that the public key certificate (and the certificates in its certificate chain) have not been revoked.

This entry prevents only the revocation check of the client's root certificate. A revocation check is still performed on the remainder of the client's certificate chain.

| Value | Meaning |
|---|---|
| 0 | EAP-TLS performs a revocation check on the client's entire certificate chain, including the root certificate. |
| 1 | EAP-TLS does not perform a revocation check on the root certificate. |

You can use this entry to authenticate clients whose certificate does not include certificate revocation list distribution points (CDPs), such as those from third parties and from the Microsoft Certificate Authority prior to Windows 2000. Also, this entry can prevent certification-related delays that occur when a certificate revocation list is offline or is expired.

**Note**

- This entry is effective only when it appears in the registry of a Routing and Remote Access server.
- Windows Server 2003 does not add this entry to the registry. You can add it by editing the registry or by using a program that edits the registry.

**Tip**

- This entry only disables the revocation check of the client's root certificate. To disable the revocation check of the entire certificate chain, use the IgnoreNoRevocationCheck entry.

# RemoteAccess

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The RemoteAccess subkey stores configuration data for Routing and Remote Access.

Several other subkeys, such as RasMan, RasAuto, and RasAcd, also store entries for secondary services that support dial-in connections. The RemoteAccess subkey stores data that applies to the entire service.

**Change Method**
Some entries in this subkey can be changed using the Routing and Remote Access Manager. For details, see the description of each entry.

# Accounting

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess

**Description**
The Accounting subkey stores configuration data for Routing and Remote Access accounting providers, such as Windows and Remote Authentication Dial-In User Service (RADIUS). Accounting providers record connection information in log files.

This subkey does not contain any entries. It only contains a Accounting\Providers Subkey subkey, which contains entries that apply to all dial-up accounting providers and subkeys that represent each provider and that store provider-specific entries.

# Accounting\Providers Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Accounting

**Description**
The Providers subkey stores configuration data for Routing and Remote Access authentication providers, such as Windows and Remote Authentication Dial-In User Service (RADIUS).

This subkey contains entries that apply to all dial-up accounting providers. It also contains subkeys that represent each provider, which are named by the globally unique identifier (GUID) of the provider and which store entries that apply only to that provider.

Windows Server 2003 includes the following accounting providers:

- {1AA7F840-C7F5-11D0-A376-00C04FC9DA04} represents the RADIUS accounting provider.
- {1AA7F846-C7F5-11D0-A376-00C04FC9DA04} represents the Windows accounting provider.

# ActiveProvider Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Accounting\Providers

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Accounting or authentication provider GUID* | {1AA7F846-C7F5-11D0-A376-00C04FC9DA04} (*GUID of Windows Authentication*) |

**Description**

Specifies the accounting provider used to record dial-up connection data in a log file. This entry stores the globally unique identifier (GUID) of the accounting provider you select by using the Routing and Remote Access snap-in.

Windows is the default accounting provider, but you can use the Routing and Remote Access snap-in to select an alternate accounting provider. You cannot select a third-party authentication or accounting provider.

Windows Server 2003 includes the following accounting providers:

- {1AA7F840-C7F5-11D0-A376-00C04FC9DA04} represents the RADIUS accounting provider.
- {1AA7F846-C7F5-11D0-A376-00C04FC9DA04} represents the Windows accounting provider.

Entries specific to these providers are stored in the following subkeys in the RemoteAccess\Accounting\Providers subkey:

- {1AA7F840-C7F5-11D0-A376-00C04FC9DA04} (RADIUS accounting provider subkey)
- {1AA7F846-C7F5-11D0-A376-00C04FC9DA04} (Windows accounting provider subkey)

**Change Method**

To change the value of this entry, use Routing and Remote Access. Right-click the name of the server, click **Properties**, click the **Security** tab, and then select a provider from the **Accounting provider** drop-down box.

**Caution**

- To change the value of this entry, use Routing and Remote Access. Do not edit the registry.

# {1AA7F840-C7F5-11D0-A376-00C04FC9DA04}

Updated: March 28, 2003

# {1AA7F840-C7F5-11D0-A376-00C04FC9DA04}\Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Accounting\Providers\{1AA7F840-C7F5-11D0-A376-00C04FC9DA04}

**Description**
The Servers subkey stores server-specific configuration data for the Remote Authentication Dial-In User Service (RADIUS) accounting provider.

This subkey does not contain any entries. It contains subkeys representing each RADIUS server used for RADIUS accounting. The server-specific subkeys store entries that are configured separately for each server and that apply only to the named server.

### Note

- Routing and Remote Access adds this subkey to the registry when you add a server to the list in the **RADIUS Accounting** dialog box in Routing and Remote Access.

### Tip

- To configure a Routing and Remote Access server to use RADIUS accounting, use the **Accounting Provider** box on the **Security** tab in the Routing and Remote Access snap-in.

# {1AA7F840-C7F5-11D0-A376-00C04FC9DA04}\Server-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Accounting\Providers\{1AA7F840-C7F5-11D0-A376-00C04FC9DA04}\Servers

**Description**

The *Server-name* subkey stores server-specific configuration data for the Remote Authentication Dial-In User Service (RADIUS) accounting provider.

This subkey is a variable representing the subkeys in the RemoteAccess\Accounting\{1AA7F840-C7F5-11D0-A376-00C04FC9DA04}\Servers subkey. It does not actually appear in the registry. This variable subkey is used to display the entries and subkeys that are common to the subkeys in the {1AA7F840-C7F5-11D0-A376-00C04FC9DA04}\Servers subkey.

The *Server-name* subkeys in your registry represent RADIUS servers used for RADIUS accounting. Each subkey represents a particular server and stores configuration data that applies only to that server.

**Note**

- Routing and Remote Access adds a *Server-name* subkey to the registry when you add a server to the list in the **RADIUS Accounting** dialog box in Routing and Remote Access.

**Tip**

- To configure a Routing and Remote Access server to use RADIUS accounting, use the **Accounting Provider** box on the **Security** tab in the Routing and Remote Access snap-in.

# Server-name\NASIpAddress Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Accounting\Providers\{1AA7F840-C7F5-11D0-A376-00C04FC9DA04}\Servers*Server-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *IP address* | (None) |

**Description**
Identifies the network access server (NAS) to use with Remote Authentication Dial-In User Service (RADIUS) accounting.

The Routing and Remote Access server binds to this address. Also, it uses this address as the value of the NAS_IP_Address RADIUS attribute (Attribute 4).

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
You can change this entry only by editing the registry.

**Tip**

- To configure a Routing and Remote Access server to use RADIUS accounting, use the **Accounting Provider** box on the **Security** tab in the Routing and Remote Access snap-in.

# SendSignature

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Authentication\Providers\{1AA7F83F-C7F5-11D0-A376-00C04FC9DA04}\Servers*Server-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether Routing and Remote Access includes a digital signature in all Access-Request messages to this Remote Authentication Dial-In User Service (RADIUS) server.

| Value | Meaning |
|---|---|
| 0 | Routing and Remote Access includes a digital signature only in Extensible Authentication Protocol (EAP) Access-Request messages. |
| 1 | Routing and Remote Access includes a digital signature in all Access-Request messages. |

**Change Method**

To change the value of this entry, use the Routing and Remote Access snap-in. Right-click the name of the server, click **Properties**, and then click the **Security** tab. From the **Authentication Provider** drop-down list, select **RADIUS Authentication**, click **Configure**, click **Edit** and select the **Always use digital signatures** check box.

**Tip**

- To configure a Routing and Remote Access server to use RADIUS authentication, use the **Authentication Provider** box on the **Security** tab in the Routing and Remote Access snap-in.

# {1AA7F841-C7F5-11D0-A376-00C04FC9DA04}

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Authentication\Providers

**Description**
The {1AA7F841-C7F5-11D0-A376-00C04FC9DA04} subkey stores configuration data for the Windows authentication provider.

**Tip**

- To configure a Routing and Remote Access server to use Windows authentication, use the **Authentication Provider** box on the **Security** tab in the Routing and Remote Access snap-in.

# RemoteAccess\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess

**Description**
The Parameters subkey stores configuration data for Routing and Remote Access. The data in this subkey specifies the value of variables that apply to the entire service.

**Activation Method**
To make changes to the values of the entries in this subkey effective, you must stop and restart the remote access service.

# LanOnlyMode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# LoggingFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–3 | 3 |

**Description**
Specifies which events Routing and Remote Access records in the System Log in Event Viewer. This entry affects logging by Routing and Remote Access only. It does not affect logging by routing components or by transports, such as IP and IPX.

| Value | Meaning |
|---|---|
| 0 | No log. Routing and Remote Access does not record any events in the System Log. |
| 1 | Records errors only. |
| 2 | Records errors and warnings only. |
| 3 | Records all events (errors, warnings, and information). |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use Routing and Remote Access Manager. Right-click the server name, click **Properties**, and then click the **RAS Event Logging** tab. Do not change the value of this entry by editing the registry directly.

**Activation Method**
You must stop and restart the remote access service before changes to the value of this entry take effect.

# RouterType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–7 | 1 |

**Description**
Specifies the functions of the remote access router.

To enable more than one function, sum the value for each function. For example, to enable a router for remote access clients (value = 1) and for inter-LAN (local area network) communication (value = 2), set the value of this entry to 3.

| Value | Meaning |
|---|---|
| 1 | Remote access server |
| 2 | LAN-to-LAN router |
| 4 | LAN-to-WAN-to-LAN or Demand Dial router |

**Change Method**
To change the value of this entry, use Routing and Remote Access Manager. Right-click the name of the remote access server, click **Properties**, and click the **General** tab. Do not edit the registry.

**Activation Method**
You must stop and restart the remote access service before changes to the value of this entry take effect.

### Note

- This value appears in the registry when you use the Routing and Remote Access Manager snap-in to configure the router.

# SecurityHostTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 20–600 (*seconds*) | 120 |

**Description**
Specifies how long Routing and Remote Access waits for clients to complete third party authentication. If authentication is not complete before the value of this entry expires, then Routing and Remote Access considers authentication to have failed.

The time limit specified in this entry applies only to the third party authentication that occurs before Routing and Remote Access authentication. The time limit for Routing and Remote Access authentication is specified in the value of the AuthenticateTime entry.

**Activation Method**
You must stop and restart the remote access service before changes to the value of this entry take effect.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
AuthenticateTime

# ServerFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x3A740 |

**Description**
Determines whether important features of the remote access service are enabled.

The value of this entry is a bitmask. To enable a feature, set the bit associated with the feature to 1, or add the hexadecimal value associated with the feature to the value of this entry. To disable a feature, set the bit associated with the feature to 0, or subtract the hexadecimal value associated with the feature from the value of this entry.

To view the valid values for this entry, see Values for Remote Access ServerFlags.

The default value, 0x3A740, enables the following features for dial-in clients and routers:

- PPPCFG_UseSwCompression (0x00000002)
- PPPCFG_NegotiateSPAP (0x00000040)
- PPPCFG_NegotiateMSCHAP (0x00000100)
- PPPCFG_UseLcpExtensions (0x00000200)
- PPPCFG_NegotiateMultilink (0x00000400)
- PPPCFG_NegotiateBacp (0x00002000)
- PPPCFG_NegotiateEAP (0x00008000)
- PPPCFG_NegotiatePAP (0x00010000)
- PPPCFG_NegotiateMD5CHAP(0x00020000)

**Change Method**
To change the value of this entry, use Routing and Remote Access Manager.

**Activation Method**
You must stop and restart the remote access service before changes to the value of this entry take effect.

# ServiceDll

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %SystemRoot%\System32\mprdim.dll |

**Description**
Specifies the location of the dynamic-link library (DLL) for the remote access service.

**Caution**

- Do not change the value of this entry. If you change this value or move the DLL file, you can prevent the Routing and Remote Access service from starting.

# Stamp

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 | 0 |

**Description**
Ensures that the time stamp in the Parameters subkey is accurate even if the registry entries are copied to and changed within an internal memory cache. Routing and Remote Access uses this entry internally.

**Activation Method**
You must stop and restart the remote access service before changes to the value of this entry take effect.

### Caution

- Do not change the value of this entry. The Routing and Remote Access service uses this entry internally.

# AuthenticateRetries

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–10 | 2 |

**Description**
Specifies the maximum number of times the remote access service attempts to authenticate a client.

This entry differs from the CallbackRetries entry, which specifies the maximum number of times the remote access service tries to call the client back for the purpose of authentication.

**Change Method**
To change the value of this entry, use the **Max number of unsuccessful authentication retries** Group Policy setting (Computer Settings\Software Policies\Windows NT Remote Access).

**Activation Method**
You must stop and restart Routing and Remote Access before changes to the value of this entry take effect.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
AuthenticateTime
CallbackRetries

# AuthenticateTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 20–600 (*seconds*) | 120 |

**Description**
Specifies the time within which a user must be successfully authenticated. If the client does not complete the authentication process within this time, then the user is disconnected.

**Change Method**
To change the value of this entry, use the **Max time limit for authentication** Group Policy setting (Computer Settings\Software Policies\Windows NT Remote Access).

**Activation Method**
You must stop and restart Routing and Remote Access before changes to the value of this entry take effect.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
AuthenticateRetries

# AutoDisconnect

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFFFFFFFF (*seconds*) | 0x0 |

**Description**
Specified how long an inactive connection can remain open. If a connection remains inactive longer than the value of this entry specifies, then the connection is closed. Connections are considered to be inactive if they are not transferring NetBIOS session data, such as copying files, accessing network resources, or sending and receiving e-mail.

| Value | Meaning |
|---|---|
| 0x0 | Inactive connections never disconnect automatically. This setting might be appropriate when clients are running NetBIOS datagram applications. |
| 0x1–0xFFFFFFFF *seconds* | The maximum time the system permits an inactive connection to remain open. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the value of this entry, use the **Auto Disconnect** Group Policy setting (Computer Settings\Software Policies\Windows NT Remote Access).

**Activation Method**
You must stop and restart Routing and Remote Access before changes to the value of this entry take effect.

# CallbackRetries

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x0 |

**Description**
Specifies how many times the server attempts to call the client back if the initial callback fails. This entry is used only if the callback security feature is enabled.

If the value of this entry is 0x0 and the initial callback fails, then the system does not attempt any further callbacks.

This entry is designed for environments where telephone systems are not always reliable and multiple calls are often required to establish a connection.

This entry differs from the AuthenticateRetries entry, which specifies the maximum number of times the remote access service attempts to authenticate the client, not just to contact the client by calling back.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
DefaultCallbackDelay
AuthenticateRetries
CallbackTime

# CallbackTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 2–12 (*seconds*) | 2 |

**Description**
Specifies how long the server waits before calling back the client for authentication. The value of this entry is a default that is used only if the client does not specify an interval between callbacks, and only if the callback feature is enabled.

This entry differs from the AuthenticateTime entry, which specifies the time within which a user must be successfully authenticated, not just the time to call back the client.

**Change Method**
To change the value of this entry, use the **Wait interval for callback** Group Policy setting (Computer Settings\Software Policies\Windows NT Remote Access).

**Activation Method**
You must stop and restart Routing and Remote Access before changes to these values take effect.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# AccountLockout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

**Description**
Stores the database for the *Account Lockout* feature of Routing and Remote Access and of Internet Authentication Service (IAS).

*Account Lockout* prohibits dial-in access to a server after repeated authentication attempts fail. By default, Account Lockout is disabled.

This subkey stores entries that specify the operating criteria for the Account Lockout feature. It also includes domain:user-namesubkeys, which represent user accounts that the feature affects. Each of the domain:user-name subkeys represents one user, and each tracks the number of failed attempts to authenticate that user.

**Note**

- Account Lockout prevents dial-in access to a locked user account, not just to the computer that submitted the failed authentication.

**Tip**

- To disable Account Lockout or to reset all user denial counts to 0 while the server is running, set the value of the MaxDenials entry to 0. If you delete the AccountLockout subkey or the domain:user-name subkey for a user, then the service does not detect the change until the system is restarted.

# MaxDenials

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x0 |

**Description**
Specifies how many attempts to authenticate a user account can fail before the user is denied dial-in access to the server. Authentication fails when a user enters an incorrect password for a valid user name.

This entry also enables and disables the Account Lockout feature of the Routing and Remote Access service. If the value of this entry is greater than 0, then the Account Lockout feature is enabled on this computer. Otherwise, it is disabled.

When the value of the Denials entry reaches the value of this entry within the time specified by the ResetTime (mins) entry, the user account is locked. The system does not process any more dial-in authentication attempts until one of the following occurs:

- The value of the **ResetTime (mins)** entry expires.
- An administrator deletes the user's domain:user-name subkey.
- An administrator sets the value of the **Denials** entry for that account either to 0 or to a value less than that stored in the **MaxDenials** entry.

### Note

- Authentication fails when a user enters an incorrect password for a valid user name.

### Tip

- To disable Account Lockout or to reset all user denial counts to 0 while the server is running, set the value of this entry to 0. If you delete the AccountLockout subkey or the domain:user-name subkey for a user, the service does not detect the change until the system is restarted.

ResetTime (mins)

# ResetTime (mins)

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 2880 (*48 hours*) |

**Description**
Specifies the time interval for the Account Lockout feature of Routing and Remote Access.

When the value of the Denials entry reaches the value of the MaxDenials entry within the time specified by the value of the ResetTime (mins) entry, the user account is locked. The system does not process any more dial-in authentication attempts until one of the following occurs:

- The value of the **ResetTime (mins)** entry expires.
- An administrator deletes the user's domain:user-name subkey.
- An administrator sets the value of this entry either to 0 or to a value less than that stored in the **MaxDenials** entry.

### Note

- Authentication fails when a user enters an incorrect password for a valid user name.

### Tip

- The denial counter for each user is stored in the Denials entry. The denial threshold for the computer is stored in the MaxDenials entry.

# domain:user-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout

**Description**
The *domain:user-name* subkey stores the *Account Lockout* record for a user.

*Account Lockout* prohibits dial-in access to a server after repeated authentication attempts fail. By default, Account Lockout is disabled.

The system adds this subkey to the registry when a dial-in authentication attempt for the user account fails, that is, when the value of the Denials entry for a user account is 1. The system deletes this subkey when the value of the ResetTime (mins) entry expires.

The *domain:user-name* subkey is a variable representing the subkeys in the AccountLockout subkey. It does not actually appear in the registry. This variable subkey is used to display the entries that can appear in any AccountLockout user subkey.

**Note**

- Authentication fails when a user enters an incorrect password for a valid user name.

**Tip**

- To disable Account Lockout or to reset all user denial counts to 0 while the server is running, set the value of the MaxDenials entry to 0. If you delete the AccountLockout subkey or the *domain:user-name* subkey for a user, the service does not detect the change until the system is restarted.

# Denials

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout*domain:user-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | (None) |

**Description**
Stores the current number of failed attempts to authenticate a user account for dial-up access.

This entry stores a counter that increments on each failed attempt to authenticate the account. Authentication fails when a user enters an incorrect password for a valid user name. This entry and the user subkey that contains it are created the first time an authentication attempt fails during the interval specified by the value of the ResetTime (mins) entry. They are deleted when the value of the **ResetTime (mins)** entry expires or when the user account is successfully authenticated.

When the value of this entry reaches the value of the MaxDenials entry within the time specified by the ResetTime (mins) entry, the user account is locked. The system does not process any more dial-in authentication attempts until one of the following occurs:

- The value of the **ResetTime (mins)** entry expires.
- An administrator deletes the user's domain:user-name subkey.
- An administrator sets the value of this entry either to 0 or to a value less than that stored in the **MaxDenials** entry.

**Note**

- Authentication fails when a user enters an incorect password for a valid user name.

# Ip

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

**Description**
The Ip subkey stores entries that use IP for the Routing and Remote Access service.

# AllowClientIpAddresses

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether dial-up clients can request a connection to a particular Routing and Remote Access server by specifying the server's IP7 address.

| Value | Meaning |
|---|---|
| 0 | Clients cannot request a particular server. |
| 1 | Clients can request a particular server. |

**Note**

- In Windows NT 4.0 and earlier, this entry appeared in the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Rasman\PPP\IPCP subkey.
- The "Client may request an IP address" Routing and Remote Access policy takes precedence over the value of this entry.

# DNSNameServers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip

| Data type | Range | Default value |
|---|---|---|
| REG_MULTI_SZ | IP address [IP address] | (IP address of DNS server) |

**Description**
Specifies which Domain Name System (DNS) servers the Routing and Remote Access client uses.

You can add this entry to the registry of a Routing and Remote Access server to override the automatic assignment of the remote access server's DNS servers to the remote access client.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

WINSNameServerBackup

# InitialAddressPoolSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*addresses*) | 0xA (*10 addresses*) |

**Description**

Limits the number of addresses that the Routing and Remote Access server gets from the Dynamic Host Configuration Protocol (DHCP) server at one time.

The number of addresses in each batch cannot exceed the value of this entry. By default, the number of addresses in each batch equals the number of available Routing and Remote Access ports, plus one. But if the value of this entry is less than the number of ports plus one, then Routing and Remote Access sets the batch size to the value of this entry.

The Routing and Remote Access server gets a batch of addresses when the service starts, and it gets the same number of addresses each time it uses up the previous batch.

# WINSNameServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *IP address* | ( IP address of WINS server) |

**Description**
Specifies which Windows Internet Name Service (WINS) server the remote access client uses.

You can add this entry to the registry of a remote access server to override the automatic assignment of the remote access server's WINS server to the remote access client.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# StaticAddressPool

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip

| Data type | Range | Default value |
|---|---|---|
| | | 0 |

**Description**
The StaticAddressPool subkey stores a range of static IP addresses for use on a Routing and Remote Access server.

This subkey contains numbered subkeys, each of which represents a particular static IP address pool. The entries in the numbered subkeys define the range of IP addresses in the pool.

**Change Method**
To create a static IP address pool, use Routing and Remote Access. Right-click a server name, click **Properties**, click the **IP** tab, select **Static address pool**, and then click **Add**.

### Note

- Routing and Remote Access adds this subkey to the registry when you use Routing and Remote Access to add and configure a static address pool.

### Caution

- To create a static IP address pool, use the **IP** tab in Routing and Remote Access. Do not edit the registry.

# Pool-number

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip\StaticAddressPool

**Description**
The *Pool-number* subkey represents a particular pool of static IP addresses for Routing and Remote Access servers. These subkeys are numbered, beginning with 0, in the order that the pools are created. The entries in the *Pool-number* subkeys define the range of IP addresses in the pool.

The *Pool-number* subkey is a variable representing the subkeys in the RemoteAccess\Parameters\Ip\StaticAddressPool subkey. It does not actually appear in the registry. This variable subkey is used to display the entries and subkeys that are common to the subkeys in the StaticAddressPool subkey.

### Note

- Routing and Remote Access adds a *Pool-number* subkey to the registry when you add a static IP address pool by defining a range in the **New Address Range** dialog box in Routing and Remote Access.

### Tip

- For more information about static address pools, see Windows Server 2003 Help and Support Center or Windows XP Professional Help and Support Center.

### Caution

- To create a static IP address pool, use the **IP** tab in Routing and Remote Access. Do not edit the registry.

# Pool-number\From

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip\StaticAddressPool*Pool-number*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *IP address (in integers, not in dotted decimal format)* | (None) |

**Description**
Specifies the first IP address in the pool range.

This entry stores the value in the **Start IP address** box on the **New Address Range** dialog box in Routing and Remote Access.

This entry stores the IP address as four contiguous hexadecimal values. For example, the IP address 1.2.3.4 would appear in this entry as 0x1020304, and 255.255.255.255 would appear as 0xFFFFFFFF (255 = 0xFF).

**Change Method**
To create a static IP address pool, use Routing and Remote Access. Right-click a server name, click **Properties**, click the **IP** tab, select **Static address pool**, and then click **Add**.

### Note

- Routing and Remote Access adds the **From** entry to the registry when you add a static IP address pool by defining a range in the **New Address Range** dialog box in Routing and Remote Access.

### Tip

- For more information about static address pools, see Windows Server 2003 Help and Support Center or Windows XP Professional Help and Support Center.

### Caution

- To create a static IP address pool, use the **IP** tab in Routing and Remote Access. Do not edit the registry.

# To

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ip\StaticAddressPool*Pool-number*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *IP address (in integers, not in dotted decimal format)* | (None) |

**Description**
Specifies the last IP address in the pool range.

This entry stores the value in the **End IP address** box on the **New Address Range** dialog box in Routing and Remote Access.

This entry stores the IP address as four contiguous hexadecimal values. For example, the IP address 1.2.3.4 would appear in this entry as 0x1020304 and 255.255.255.255 would appear as 0xFFFFFFFF (255 = 0xFF).

**Change Method**
To create a static IP address pool, use Routing and Remote Access. Right-click a server name, click **Properties**, click the **IP** tab, select **Static address pool**, and then click **Add**.

### Note

- Routing and Remote Access adds the **From** entry to the registry when you add a static IP address pool by defining a range in the **New Address Range** dialog box in Routing and Remote Access.

### Tip

- For more information about static address pools, see Windows Server 2003 Help and Support Center or Windows XP Professional Help and Support Center.

### Caution

- To create a static IP address pool, use the **IP** tab in Routing and Remote Access. Do not edit the registry.

# IPX Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters

**Description**
Stores entries for remote access when it is implemented by using Internetwork Packet Exchange (IPX).

# FirstWanNode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\Ipx

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *12-digit hexadecimal value representing the node* | (None) |

**Description**

Identifies the base node number assigned to callers.

If callers are using different network numbers, then the system assigns the base node number to all callers. However, if callers are using the same network number, then the system assigns the base node number to the first caller, and then increments the node number by one for each subsequent caller.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- You must enter the node number in the registry editor Regedit.exe in hexadecimal format. Regedit.exe does not convert text values to a different radix.

# RemoteAccess\Policy

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\RemoteAccess

**Description**
Stores policy settings shared by Internet Authentication Service (IAS) and Routing and Remote Access. Remote access policies determine permissions and connection settings.

The entries in this subkey also determine which attributes are used to authenticate users and how they are evaluated.

# Sermouse

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The Sermouse subkey stores configuration data for the Microsoft serial mouse driver in Windows NT 4.0 and earlier. In Windows Server 2003, this data appears in the device-specific subkeys of the Enum Subkey subkey. However, if you upgrade an installation of Windows NT 4.0, some of the values in the Sermouse subkey are copied to the device-specific keys. For details, see the descriptions of the entries in this subkey.

# Sermouse\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Sermouse

**Description**

The Parameters subkey stores configuration data for the Microsoft serial mouse driver in Windows NT 4.0 and earlier. In Windows Server 2003, this data appears in the device-specific subkeys of the Enum Subkey subkey. However, if you upgrade from Windows NT 4.0, some of the values in this subkey are copied to the device-specific keys. For details, see the descriptions of the entries in this subkey.

# Parameters\MouseDataQueueSize Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Sermouse\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x64 (*100*) |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

In the Windows Server 2003 serial mouse driver, the queue size is equal to one packet, and it is not configurable.

**Caution**

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# Parameters\NumberOfButtons Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Sermouse\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF | 0x2 |

**Description**
Stores the number of buttons on the serial mouse that were detected at startup in Windows NT 4.0 and earlier. In Windows Server 2003, the number of mouse buttons is stored in the device-specific subkeys of the Enum Subkey subkey. However, the system uses the value of this entry as source data.

If you have a serial mouse and have upgraded from Windows NT 4.0, the system copies the value of this entry to the device-specific Enum subkeys of all serial mouse devices, and it uses the values of the entries in those subkeys.

**Caution**

- The value of this entry is copied to the device-specific Enum subkeys of all serial mouse devices recognized by the system. If you change the value of this entry, then the new value is used for all new serial mouse devices that the system recognizes.

# Parameters\PointerDeviceBaseName Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Sermouse\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Base port device name* | PointerPort |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# Parameters\SampleRate Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Sermouse\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Mouse sampling rate in Hz* | 0x28 (40 Hz) |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier. In Windows Server 2003, the serial mouse driver does not sample mouse activity.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# Services\SNMP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The SNMP subkey stores configuration data for the Simple Network Management Protocol (SNMP) service.

The SNMP service implements SNMP network standards. This service allows incoming SNMP requests to be serviced by the local computer. It includes agents that monitor activity in network devices and report to the network console workstation.

# SNMP\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\SNMP

**Description**
The Parameters subkey contains subkeys that function like standard registry entries and contain configuration information for the Simple Network Management Protocol (SNMP) service. The SNMP service implements SNMP network standards. This service allows incoming SNMP requests to be serviced by the local computer. It includes agents that monitor activity in network devices and report to the network console workstation.

# EnableAuthenticationTraps

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\SNMP\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Enables and disables authentication traps.

When authentication traps are enabled, Simple Network Management Protocol (SNMP) sends a trap when it receives a request that does not match any community name or host filter in its lists.

| Value | Meaning |
|---|---|
| 0 | The SNMP service does not send authentication traps. |
| 1 | The SNMP service sends an authentication trap when it receives a request that does not match any community name or host filter in its lists. |

**Change Method**
To change the value of this entry, use Computer Management. In the console tree, click **Services and Applications**, click **Services**, and then click **SNMP Service**. From the **Action** menu, click **Properties**, click the **Security** tab, and then select or clear the **Send authentication trap** check box.

### Note

- In Windows NT 4.0, this data was stored in the **Switch** entry in the EnableAuthenticationTraps subkey.

# ExtensionAgents

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\SNMP\Parameters

**Description**
The ExtensionAgents subkey contains entries that indicate where the registry stores the configuration data for Simple Network Management Protocol (SNMP) extension agents.

The names of the entries in this subkey are decimal integers, beginning with 0. The value of each entry is the registry path to the data that is loaded by the dynamic-link library (DLL) for the extension agent. All entries in this subkey have the REG_SZ data type.

For example, the following entry indicates that the configuration data for the WWW service is located in the HKEY_LOCAL_MACHINE\Software\Microsoft\W3SVC\CurrentVersion subkey:

| Entry name | Data type | Value |
|---|---|---|
| 0 | REG_SZ | HKLM\Software\Microsoft\W3SVC\CurrentVersion |

# Parameters\PermittedManagers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\SNMP\Parameters

**Description**
The PermittedManagers subkey stores the computer names of hosts that can send requests to a Simple Network Management Protocol (SNMP) agent.

Each entry in this subkey represents a host that is a permitted manager. The name of the entry is an ordinal number that reflects the order in which you entered the host when you configured SNMP. The value of the entry is the host name. The data type of all entries in this subkey is REG_SZ.

In the following example, the host (Host01) can send requests to an agent:

| Entry name | Data type | Value |
|---|---|---|
| 1 | REG_SZ | Host01 |

**Change Method**
To change the value of this entry, use the Services snap-in. Right-click **SNMP Service**, then click **Properties**.

### Notes

- The default configuration has no entry under this subkey. The SNMP agent accepts SNMP packets from any host.
- Only users who belong to the local Administrators group are able to access this subkey.

# Parameters\TrapConfiguration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\SNMP\Parameters

**Description**
The TrapConfiguration subkey stores names of hosts that receive trap messages for communities. Trap messages are alerts that Simple Network Management Protocol (SNMP) agents initiate.

This subkey contains a series of subkeys that each represent one community. The entries in each community subkey identify the hosts to which the SNMP agent sends traps for that community. The name of each entry is an ordinal number, beginning with 1. The value of each entry can be a host name, an IP address, or an Internetwork Packet Exchange (IPX) address. The data type of all entries in the TrapConfiguration subkey is REG_SZ.

For example, the TrapConfiguration subkey contains a subkey representing a valid community, Community01. The Community01 subkey contains one or more entries with the following format:

| Entry name | Data type | Value |
|---|---|---|
| 2 | REG_SZ | 138.10.12.86 |

In this example, the SNMP agent sends traps for Community01 to the host at the specified IP address.

**Change Method**
To view, add, or delete hosts from a community subkey, use Services in Computer Management.

# Parameters\ValidCommunities

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\SNMP\Parameters

**Description**
The ValidCommunities subkey stores a list of the communities defined to the Simple Network Management Protocol (SNMP) service.

In SNMP, a community is a group of hosts (servers, workstations, hubs, and routers) that SNMP administers together. An SNMP agent accepts requests only from management systems within the communities it recognizes and only if the permissions established for the community allow the requested operation.

Each entry in this subkey represents one community that you identify to SNMP. The name of the entry is the community name. (A community name is a network password that the hosts in the community share.) The value is a bitmask specifying the permissions of the community. The data type is REG_DWORD.

For example, the entries in this subkey could store the following list of communities:

| Entry Name | Data Type | Value |
|---|---|---|
| ROCommunity | REG_DWORD | 0x4 |
| RWCommunity | REG_DWORD | 0x8 |

**Change Method**
To change the value of this entry, use the Services snap-in. Right-click **SNMP Service**, then click **Properties**.

### Note

- Only users who belong to the local Administrators group are able to access this subkey.

# SysmonLog

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Replace Blanks

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\SysmonLog

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *any single character* | (None) |

**Description**
Specifies a single character that is used to replace blanks in the names of collections and file names created by the Performance console (Perfmon.msc) of the Microsoft Management Console.

**Change Method**
This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must stop and restart the Performance console for changes to take effect.

### Note

- In Windows 2000, the Performance console (Perfmon.msc) created log files without spaces in their names. In Windows XP and Windows Server 2003, spaces are allowed in the names of log files. However, you can add this entry to the registry to emulate the behavior of the Performance console for Windows 2000.

# Tcpip

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The Tcpip subkey stores configuration data for the Microsoft implementation of TCP/IP (Transmission Control Protocol/Internet Protocol). TCP/IP is a set of networking protocols that enable communication over diverse, interconnected networks.

This subkey stores some of the configuration data for TCP/IP, primarily the settings for the TCP/IP service. Other subkeys also store entries that affect the operation of the TCP/IP implementation on your computer. These other subkeys include those for network components and for services related to TCP/IP, such as Dynamic Host Configuration Protocol (DHCP), NetBIOS over TCP/IP (NetBT), and Windows Sockets (Winsock).

**Change Method**
To change the values of many of the entries in the Tcpip subkey and its subkeys, use Network and Dial-up Connections. Right-click **Local Area Connection**, click **Properties**, click **Internet Protocol (TCP/IP)**, and then click the **Properties** button.

# Tcpip\Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip

**Description**

The Parameters subkey stores configuration data that applies to the TCP/IP service as a whole. This data can be overridden by settings specific to a network component using TCP/IP, such as a network adapter driver, or by settings specific to a service using TCP/IP, such as Dynamic Host Configuration Protocol (DHCP) or Windows Sockets (Winsock). These component-specific entries reside in subkeys representing the component.

# Parameters\KeepAliveInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF (*milliseconds*) | 0x3E8 (*1,000 milliseconds = 1 second*) |

**Description**
Specifies how often TCP repeats keep-alive transmissions when no response is received. TCP sends keep-alive transmissions to verify that idle connections are still active. This prevents TCP from inadvertently disconnecting active lines.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
TcpMaxDataRetransmissions
KeepAliveTime

# KeepAliveTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF (*milliseconds*) | 0x6DDD00 (*7,200,000 milliseconds = 2 hours*) |

**Description**
Specifies how often TCP sends keep-alive transmissions. TCP sends keep-alive transmissions to verify that an idle connection is still active.

This entry is used when the remote system is responding to TCP. Otherwise, the interval between transmissions is determined by the value of the Parameters\KeepAliveInterval entry.

By default, keep-alive transmissions are not sent. The TCP keep-alive feature must be enabled by a program (such as Telnet), or by an Internet browser (such as Internet Explorer).

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
Parameters\KeepAliveInterval

# MaxUserPort

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 5,000–65,534 (*port number*) | 5000 |

**Description**
Specifies the highest port number that TCP can assign when an application requests an available user port from the system. Typically, *ephemeral* ports (those used briefly) are allocated to port numbers 1024 through 5000.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# NumTcbTablePartitions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFF (*TCB table partitions*) | 0x1 |

**Description**

Specifies the number of partitions in the Transport Control Block table.

Partitioning the Transport Control Block table minimizes contention for table access. This is especially useful on multiprocessor systems.

### Note

- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Caution

- Do not change the value of this entry before carefully studying the effect of different values in a test environment. When testing, do not enter a value greater than two times the number of processors on the computer.

# PPTPTcpMaxDataRetransmissions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFF (*retransmissions*) | 0x5 |

**Description**
Specifies how many times an unacknowledged Point-to-Point Tunneling Protocol (PPTP) packet is retransmitted before the connection is dropped.

This entry lets you configure a limit on PPTP retransmissions separately from the limit for regular TCP retransmissions, which is stored in the value of the TcpMaxDataRetransmissions entry. You can then adjust the TCP setting to prevent denial-of-service attacks (also known as SYN flooding) without affecting PPTP traffic.

**Tip**

- To prevent the TCP dead gateway detection feature from inadvertently disconnecting a congested Internet link, set this value higher than the default value of the TcpMaxDataRetransmissions entry.

**See Also**
**Concepts**
TcpMaxDataRetransmissions

# PrioritizeRecordData

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the DNS client, upon receiving an answer to a DNS query, looks for the address most similar to its own, when there are multiple addresses in the answer to its query. By choosing the address most like its own, the client connects to the server nearest to it on the network, which reduces network traffic. When the value of this entry is 1, the client prioritizes for the nearest address; when the value is zero, the client attempts to connect to the first address in the answer.

### Note

- This scheme attempts to reduce network traffic by connecting clients with local IP addresses. This registry entry controls whether the client prioritizes addresses, but Windows Server 2003 DNS server can also be configured to prioritize the addresses in its answers according to their similiarity to the address of the requesting client. This behavior by Whister DNS server is controlled by the value of LocalNetPriority.

- Subnet prioritization, whether configured on the client or the server, nullifies the load-balancing benefits of *round-robin name resolution*. Round-robin name resolution is a scheme by which the server rotates the order of the addresses in its answers to spread connection loads across all applicable servers. By default, Windows Server 2003 DNS service uses round-robin name resolution. For more information about subnet prioritization and round-robin name resolution, see the *TCP/IP Core Networking Guide* of the *Microsoft Windows Server 2003 Technical Reference* .

**Concepts**
LocalNetPriority

# SackOpts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Enables and disables the Selective Acknowledgment (SACK) feature of Windows Server 2003 TCP/IP. SACK is specified in RFC 2018, TCP Selective Acknowledgement Options.

SACK is an optimizing feature that lets you acknowledge receipt of individual blocks of data in a continuous sequence, rather than just the last sequence number. The recipient can tell the sender that one or more data blocks are missing from the middle of a sequence, and the sender can retransmit only the missing data.

| Value | Meaning |
|---|---|
| 0 | Disables SACK. |
| 1 | Enables SACK. |

# SynAttackProtect

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SynAttackProtect**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the SYN flooding attack protection feature of TCP/IP is enabled. SYN flooding attack protection is enabled when the value of this entry is 1 and the value of the **TcpMaxConnectResponseRetransmissions** entry is at least 2 (see note below).

The SYN flooding attack protection feature of TCP detects symptoms of denial-of-service attacks (also known as SYN flooding), and it responds by reducing the time that the server spends on connection requests that it cannot acknowledge.

| Value | Meaning |
|---|---|
| 0 | SYN flooding attack protection is not enabled. |
| 1 | SYN flooding attack protection is enabled. |

**Notes**

- This value is used only when the number of SYN-ACK retransmissions is likely to impair the server, that is, when the value of the **TcpMaxConnectResponseRetransmissions** entry is at least 2.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# Tcp1323Opts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tcp1323Opts**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 3 | 3 |

**Description**
Specifies whether TCP uses the timestamping and window scaling features described in RFC 1323, TCP Extensions for High Performance.

Window scaling permits TCP to negotiate a scaling factor for the TCP receive window size, allowing for a very large TCP receive window of up to 1 GB. The TCP receive window is the amount of data that the sending host can send at one time on a connection.

Timestamps help TCP measure round trip time (RTT) accurately in order to adjust retransmission timeouts. The Timestamps option provides two timestamp fields of 4 bytes each in the TCP header, one to record the time the initial transmission is sent and one to record the time on the remote host.

This entry is a 2-bit bitmask. The lower bit determines whether scaling is enabled; the higher bit determines whether timestamps are enabled. To enable a feature, set the bit representing the feature to 1. To disable a feature, set its bit to 0.

| Value | Meaning |
|---|---|
| 0 (00) | Timestamps and window scaling are disabled. |
| 1 (01) | Window scaling is enabled. |
| 2 (10) | Timestamps are enabled. |
| 3 (11) | Timestamps and window scaling are enabled. |

**Note**

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

**Tip**

- For more information about RFC 1323, see the *Request for Comments (RFC)* link on the Web Resources page.

# TcpMaxConnectRetransmissions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpMaxConnectRetransmissions**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–255 (*retransmission attempts*) | 2 |

**Description**
Specifies how many times TCP retransmits an unanswered request for a new connection. TCP retransmits new connection requests until they are answered or until this value expires.

TCP/IP adjusts the frequency of retransmissions over time. The delay between the original transmission and the first retransmission for each interface is determined by the value of the **TcpInitialRTT** entry. By default, it is three seconds. This delay doubles after each attempt. After the final attempt, TCP/IP waits for an interval equal to double the last delay, and then it abandons the connection request.

### Notes

- This entry determines how many times TCP retransmits requests for new connections. When sending data on existing connections, the maximum number of retransmissions is determined by the value of the TcpMaxDataRetransmissions entry.

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
TcpMaxDataRetransmissions

# TcpMaxDataRetransmissions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpMaxDataRetransmissions**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*retransmission attempts*) | 0x5 |

**Description**
Specifies how many times TCP retransmits an unacknowledged data segment on an existing connection. TCP retransmits data segments until they are acknowledged or until this value expires.

TCP/IP adjusts the frequency of retransmissions over time. TCP establishes an initial retransmission interval by measuring the round trip time on the connection. The interval doubles with each successive retransmission on a connection, and it is reset to the initial value when responses resume.

This entry is also used in the Windows algorithm for defining non-operational (*dead*) gateways.

A given connection defines a gateway as dead (and switches to the next gateway in the list in stored in the value of the **DefaultGateway** or **DhcpDefaultGateway** entries) when a packet sent to the gateway must be retransmitted more than half of the number of times specified in the value of this entry. The system defines a gateway as dead when more than 25 percent of its connections have switched to the next default gateway in the list.

### Notes

- This entry determines how many times TCP retransmits data segments. The maximum number of retransmissions of requests for new connections is determined by the value of the TcpMaxConnectRetransmissions entry.

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

**See Also**

TcpMaxConnectRetransmissions

# TcpMaxDupAcks

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpMaxDupAcks**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–3 | 2 |

**Description**
Specifies how many duplicate ACKs (ACKs for the same sequence numbers) constitute a signal to retransmit a segment. If you set the value of this entry to 1, then the system retransmits a segment when it receives an ACK for a segment with a sequence number that is less than the number of the segment currently being sent.

When data arrives with a sequence number that is greater than expected, the receiver assumes that data with the expected number was dropped, and it immediately sends an ACK with the ACK number set to the expected sequence number. The receiver sends ACKs set to the same missing number each time it receives a TCP segment that has a sequence number greater than expected. The sender recognizes the duplicate ACKs and sends the missing segment.

**Note**

- This entry is used only when the receiver supports the fast retransmit feature. Fast retransmit lets TCP retransmit data before the retransmission timer (as set by the value of the **TcpInitialRtt** entry) expires.

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# TcpMaxHalfOpen

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpMaxHalfOpen**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0xFFFFFFFF (*connections*) | Windows Server 2003: 0x1F4 (*500*) Windows XP Professional: 0x64 (*100*) |

**Description**
Specifies how many connections the server can maintain in the half-open(SYN-RCVD) state before TCP/IP initiates SYN flooding attack protection. This entry is used only when SYN flooding attack protection is enabled on this server, that is, when the value of the SynAttackProtect entry is 1 and the value of the **TcpMaxConnectResponseRetransmissions**entry is at least 2.

This entry establishes one of three configurable thresholds that, if exceeded, trigger TCP's SYN attack flooding protection feature. Because SYN flooding often results in many half-open connections, TCP interprets an elevated number of half-open connections to be a symptom of SYN flooding.

The other two thresholds are:

- The number of connections that remain in the half-open(SYN-RCVD) state even after a connection request has been retransmitted exceeds the value of the TcpMaxHalfOpenRetried entry.

- The number of connection requests that the system refuses exceeds the value of the **TcpMaxPortsExhausted** entry. The system must refuse all connection requests when its reserve of open connection ports runs out.

## Notes

- The value of this entry should be greater than the value of the TcpMaxHalfOpenRetried entry.

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**

TcpMaxHalfOpenRetried

# TcpMaxHalfOpenRetried

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpMaxHalfOpenRetried**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x50 (*80*)–0xFFFFFFFF | Windows Server 2003: 0x190 (*400*) Windows XP Professional: 0x50 (*80*) |

**Description**
Specifies how many connections the server can maintain in the half-open(SYN-RCVD) state even after a connection request has been retransmitted. If the number of connections exceeds the value of this entry, then TCP/IP initiates SYN flooding attack protection. This entry is used only when SYN flooding attack protection is enabled on this server, that is, when the value of the SynAttackProtect entry is 1 and the value of the **TcpMaxConnectResponseRetransmissions** entry is at least 2.

This entry establishes one of three configurable thresholds that, if exceeded, trigger TCP's SYN attack flooding protection feature. Because SYN flooding often results in many half-open connections, TCP interprets an elevated number of half-open connections to be a symptom of SYN flooding.

The other two thresholds are:

- The total number of connections in the half-open(SYN-RCVD) state exceeds the value of the TcpMaxHalfOpen entry.
- The number of connection requests that the system refuses exceeds the value of the **TcpMaxPortsExhausted** entry. The system must refuse all connection requests when its reserve of open connection ports runs out.

**Notes**

- The value of this entry should be less than the value of the TcpMaxHalfOpen entry.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# TcpMaxSendFree

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpMaxSendFree**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 - 65535 | 5000 |

**Description**
Sets the size limit of the TCP header resource. On computers with ample RAM, increasing this limit can improve responsiveness during a SYN flood denial-of-service attack.

**Activation Method**
You must restart the computer for changes to this entry to take effect.

**See Also**
**Concepts**
TcpMaxHalfOpen
SynAttackProtect

# TcpNumConnections

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpNumConnections**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x40000–0xFFFFFE | 0xFFFFFE |

**Description**
Specifies the maximum number of connections that TCP can have open simultaneously.

If the value of this entry is 0, then you cannot establish any connections.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# TcpTimedWaitDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpTimedWaitDelay**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 0x12C (*0–300 seconds*) | 0x78 (*120 seconds = 2 minutes*) |

**Description**
Specifies the time that must elapse before TCP can release a closed connection and reuse its resources. This interval between closure and release is known as the TIME_WAIT state or 2MSL state. During this time, the connection can be reopened at much less cost to the client and server than establishing a new connection.

RFC 793 requires that TCP maintains a closed connection for an interval at least equal to twice the maximum segment lifetime (2MSL) of the network. When a connection is released, its socket pair and TCP control block can be used to support another connection. By default, the maximum segment lifetime is defined to be 120 seconds, and the value of this entry is equal twice that, or 4 minutes. However, you can use this entry to customize the interval.

Reducing the value of this entry allows TCP to release closed connections faster, providing more resources for new connections. However, if the value is too low, then TCP might release connection resources before the connection is complete, requiring the server to use additional resources to reestablish the connection.

### Notes

- Normally, TCP does not release closed connections until the value of this entry expires. However, TCP can release connections before this value expires if it is running out of TCP control blocks. The number of TCP control blocks that the system creates is specified by the value of the **MaxFreeTcbs** entry.

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# TcpUseRFC1122UrgentPointer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpUseRFC1122UrgentPointer**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies which mode TCP uses for urgent data. The two modes interpret the urgent pointer in the TCP header and the length of the urgent data differently. The two modes do not interoperate.

| Value | Meaning |
|---|---|
| 0 | TCP uses the mode used by systems derived from Berkeley Software Distribution (BSD). |
| 1 | TCP uses the specification in RFC 1122, Requirements for Internet hosts—communication layers, for urgent data. |

**Note**

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# TcpWindowSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TcpWindowSize**
HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–0x3FFFFFFF (1073741823 decimal) bytes | see description |

**Description**
Sets the maximum size of the TCP receive window. The receive window specifies the number of bytes that a sender can transmit without receiving an acknowledgment. In general, larger receive windows improve performance over high-latency, high-bandwidth networks. For greatest efficiency, the receive window should be an even multiple of the TCP Maximum Segment Size.

The TCP/IP stack of Windows Server 2003 was designed to tune itself in most environments. Instead of using a fixed size for the receive window, TCP negotiates for and adjusts to an even increment of the maximum segment size. Matching the receive window to even increments of the maximum segment size increases the percentage of full-sized TCP segments used during bulk data transmission. (Sizes larger than 64 KB can be achieved only when connecting to other systems that support RFC 1323 *Window Scaling*.)

The default value is the smaller of the following numbers:

- 65535
- Value of registry entry **GlobalMaxTcpWindowSize**
- Four times the MSS on the network
- Even multiple of the MSS larger than 16384

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must restart the computer for changes to this entry to take effect.

### Notes

- The default window size can start at 17520 for Ethernet, but may shrink slightly when a connection to another computer is established that supports extended TCP options (such as SACK and TIMESTAMPS) because these options increase the TCP header beyond the usual 20 bytes, which decreases room for data.
- When an entry with the name of this entry is in HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters, it sets the receive window size globally for all TCP interfaces. However, an entry with this name is in HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name* has precedence for the interface named in its registry path, and its value, rather than whatever value might be set globally, is used for that interface.

# DisableDynamicUpdate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Disables the Domain Name System (DNS) dynamic update registration for all interfaces on the system. The default value is zero.

With *dynamic update*, DNS client computers automatically register and update their resource records whenever address changes occur.

| Value | Meaning |
|---|---|
| 0 | Enables dynamic update registration. |
| 1 | Disables dynamic update registration. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
You can also disable dynamic update registration by using Group Policy.

**Activation Method**
To make changes to the value of this entry effective, you must restart the computer.

### Note

- For dynamic update to operate on any interface, it must be enabled at both the system and interface levels. To disable it for a particular interface, add the entry **DisableDynamicUpdate** to an *Interface-name* subkey, and set its value to 1. To disable it on all interfaces of a system, add the **DisableDynamicUpdate** entry to the Tcpip\Parameters subkey and set its value to 1.

# DisableReplaceAddressesInConflicts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Prevents the Domain Name System (DNS) client from overwriting an existing resource record when it discovers an address conflict during dynamic update.

An address conflict occurs when the DNS client discovers that an existing A (address) record associates its DNS name with the IP address of a different computer.

By default, the DNS client tries to replace the original registration with a record associating the DNS name to its own IP address. However, you can use this entry to direct DNS to back out of the registration process and to record an error in the Event Viewer log instead.

This entry is designed for zones that do not use secure dynamic update. It prevents unauthorized users from changing the IP address registration of a client computer.

| Value | Meaning |
|---|---|
| 0 | The DNS client overwrites the existing A record with an A record for its own IP address. |
| 1 | The DNS client backs out of the registration process and writes an error to the Event Viewer log. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

- To find other registry entries related to DNS dynamic update, type "dynamic update" on the Search tab in this file.

**See Also**
**Concepts**
DisableReverseAddressRegistrations

# DisableReverseAddressRegistrations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Disables the Domain Name System (DNS) dynamic update registration of PTR (pointer) records by this DNS client. PTR records associate an IP address with a computer name.

This entry is designed for enterprises in which the primary DNS server that is authoritative for the reverse lookup zone cannot or is configured not to perform dynamic updates. It reduces unnecessary network traffic and eliminates event log errors that record failed attempts to register PTR records.

| Value | Meaning |
|---|---|
| 0 | Register PTR records. |
| 1 | Do not register PTR records. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

- To find other registry entries related to DNS dynamic update, type "dynamic update" on the Search tab in this file.

**See Also**
**Concepts**
DisableReplaceAddressesInConflicts

# DisableUserTOSSetting

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether individual applications can alter the type of service (TOS) bits in the header of outgoing IP packets. In general, individual applications should not be allowed to manipulate TOS bits, because this can defeat system policy mechanisms.

**Activation Method**
You must restart the computer for changes to this entry to take effect.

### Note

- Every IP datagram has an octet commonly known as the *TOS byte*. The first three bits specify a level of priority. The next four bits, interpreted as a number, specify a type of service. The last bit is currently unused. For more information about the TOS byte, see IETF RFC 1349: *Type of Service in the Internet Protocol Suite*.

# EnableICMPRedirect

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
This parameter controls whether Windows Server 2003 alters its routing table in response to Internet Control Message Protocol (ICMP) messages that instruct it to direct datagrams for the recipient along a different route.

**Activation Method**
You must restart the computer for changes to this entry to take effect.

### Notes

- ICMP provides a means by which a host sending IP datagrams can be informed about delivery issues. ICMP does not guarantee delivery of IP datagrams (that kind of error correction is left to higher level protocols, like TCP), but rather, it allows network devices, like a router, to tell a sending computer about delivery errors, to suggest shorter routes to a destination, and to assist in probing the network. For more information about ICMP, see RFC 792 *Internet Control Message Protocol*, and RFC 1122 *Requirements for Internet Hosts—Communication Layers*.

- Windows Server 2003 accepts redirection messages from any host in the route between this computer and the destination computer, and not just first-hop routers. Accepting redirection from only first-hop routers causes problems in some scenarios involving Routing & Remote Access Service (RAS).

# IGMPLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 2 |

**Description**

Specifies the extent to which the system supports IP multicasting, and participates in the Internet Group Management Protocol.

| Value | Meaning |
|---|---|
| 0 | Only send IP multicast packets. Treated the same as a value of 1. |
| 1 | Only send IP multicast packets. |
| 2 | Send and receive IP multicast packets (participate in IGMP). |

**Note**

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

# Adapters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

**Description**
The Adapters subkey stores TCP/IP configuration data that can be configured differently for each network adapter on the computer.

This subkey contains one or more *adapter-name* subkeys. The *adapter-name* subkeys each represent one network adapter, and they are named by their network identifiers. The entries in the *adapter-name* subkeys apply only to the network adapter that the subkey represents, and the values in those entries override any conflicting settings in the Tcpip\Parameters Subkey subkey.

# Adapters\interface-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Adapters

**Description**
The *interface-name* subkeys represent network adapters or network adapter drivers, and they are named for the network identifiers. Each subkey represents a particular adapter, and it stores configuration data that applies only to that adapter.

Most of the entries described here as being stored in the *interface-name* subkey can appear in any of the subkeys in the Adapters subkey.

Some entries can appear in both the Tcpip\Parameters Subkey subkey and the *interface-name* subkeys. If an entry appears in the Parameters subkey, then its value applies to all adapters by default. If the entry appears in an *interface-name* subkey, then its value applies only to the adapter that the subkey represents, and it takes precedence over the value in the Parameters subkey when configuring this particular adapter.

**Note**

- The *interface-name* subkey is a placeholder representing the types of subkeys in the HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Adapters subkey; "interface-name" does not actually appear in the registry.

# LLInterface

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Adapters*interface-name*\

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | Any valid device name. | |

**Description**
Specifies the name of a device to which IP should bind on the interface named in the subkey. If this value contains the name of a link-layer protocol, then IP binds to that protocol. If this value is empty, then IP binds to the built-in ARP module. This entry is always present for all adapters.

**Caution**

- This entry is created and maintained by the TCP/IP Notify object, and you should not modify it. It is included here only for reference.

# Interfaces Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

**Description**
The Interfaces subkey stores configuration data specific to aTCP/IP communications interface.

This subkey stores TCP/IP configuration data that can be configured differently for each interface that the system uses. It contains one or more subkeys, called *interface-name*, each of which represents one interface. The entries in the *interface-name* subkeys apply only to the interface that the subkey represents, and they take precedence over any conflicting settings in the Tcpip\Parameters Subkey subkey.

# Interfaces\interface-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces

**Description**
The *interface-name* subkeys representTCP\IP communication interfaces, and they are named for the network name of the interface. Each subkey represents a particular interface, and it stores configuration data that applies only to that interface.

Most of the entries in the *interface-name* subkey described here can appear in any of the subkeys in the Interfaces subkey.

Some entries can appear in the Tcpip\Parameters Subkey subkey, in an *interface-name* subkey, or in both. If an entry appears in the Parameters subkey, then it applies to all interfaces by default. If it appears in an *interfaces-name* subkey, then it applies only to the interface that the subkey represents, and it takes precedence over the entry in the Parameters subkey when configuring that interface.

**Note**

- The *interface-name* subkey is a placeholder representing the types of subkeys in the subkey Tcpip\Parameters\Interfaces; "interface-name" does not actually appear in the registry.

# EnableDHCP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Determines whether the Dynamic Host Configuration Protocol service (DHCP) is enabled. If the value of this entry is 1, then the DHCP client service is used to configure this interface.

| Value | Meaning |
|---|---|
| 0 | Disables DHCP for this interface. |
| 1 | Enables DHCP for this interface. |

**Change Method**
To change the value of this entry, use Network and Dial-up Connections. Right-click **Local Area Connection**, click **Properties**, and click **Internet Protocol (TCP/IP)**. This entry is associated with the **Obtain an IP address automatically** option.

### Notes

- This entry is added to the registry when you use Network Connections in Control Panel to configure TCP/IP.
- When DHCP is enabled, the phrase **DHCP Enabled** appears in the IP address box in place of a static IP address. To view this setting, in Control Panel double-click Network Connections, right-click **Local Area Connection**, click **Properties**, click **Internet Protocol (TCP/IP)**, click **Advanced**, and then click the **IP Settings** tab.

# IPAutoconfigurationAddress

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *IP address, in dotted decimal format* | 0.0.0.0 |

**Description**

Stores the IP address that the IP autoconfiguration feature assigns to this interface.

Autoconfiguration allows TCP/IP to configure an interface even when it cannot locate a Dynamic Host Configuration Protocol (DHCP) server. If TCP/IP cannot locate DCHP server, then it configures the interface by using IP addresses from the Microsoft reserved Class B network (169.254.0.0), subnet mask 255.255.0.0. During autoconfiguration, TCP/IP continues trying to locate a DHCP server, and it abandons autoconfiguration if it finds one.

**Note**

- This entry is used only when IP autoconfiguration is enabled, that is, when the value of the IPAutoconfigurationEnabled entry is 1.

**Caution**

- Do not change the value of this entry. If you do, the IP address assigned to the interface might not be reliable.

# IPAutoconfigurationEnabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | (None) |

**Description**
Specifies whether the IP autoconfiguration feature is enabled for this interface. If the value of this entry is 1, then autoconfiguration is enabled; if the value of this entry is 0, or if this entry is absent from the registry, then autoconfiguration is not enabled.

Autoconfiguration allows TCP/IP to configure an interface even when it cannot locate a Dynamic Host Configuration Protocol (DHCP) server. If TCP/IP cannot locate a DCHP server, then it configures the interface by using IP addresses from the Microsoft reserved Class B network (169.254.0.0), subnet mask 255.255.0.0. During autoconfiguration, TCP/IP continues trying to locate a DHCP server, and it abandons autoconfiguration if it finds one.

**IPAutoconfigurationEnabled** also appears in the Parameters subkey, and its value applies, by default, to all interfaces. However, if this entry appears in any subkey of the Interfaces subkey, then it takes precedence over the entry in the Parameters subkey when configuring the interface.

### Note

- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe.

### Caution

- Autoconfiguration, if enabled, could interfere with configuration of IP addresses by other methods.

# SubnetMask

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | (A space-delimited list of dotted decimal subnet masks.) | 0.0.0.0 |

**Description**

Specifies the subnet mask for the IP address specified in the value of the **IPAddress** entry or the **DhcpIPAddress** entry. This entry, which can be changed by the user, overrides the DHCP-configured values for the subnet mask.

The subnet mask is determined by two entries, **DhcpSubnetMask** (which is configured by DHCP), and **SubnetMask** (which you can configure). If the value of **SubnetMask** is not 0.0.0.0, then it overrides the value of **DhcpSubnetMask**.

**Change Method**

To change the value of this entry, use **Network Connections**. Right-click **Local Area Connection** (or the name of another interface, if appropriate), click **Properties**, click **Internet Protocol (TCP/IP)** , and then click **Properties**. At the bottom right corner of the page, click the **Advanced** button. Under **IP addresses** click the **Add** button, and enter the IP address and corresponding subnet mask.

**Activation Method**

You must restart the computer for changes to take effect.

# Atmarpc

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name*

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# AddressResolutionTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name*\Atmarpc

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 - 60 | 3 seconds |

**Description**
Specifies the time, in seconds, that the address resolution protocol (ARP) client of the Asynchronous Transfer Mode (ATM) transport waits for a response after sending an ARP request for a unicast IP address or a multicast address resolution service (MARS) request for a multicast or broadcast IP address. After the time specified by this entry has elapsed, the ARP client retransmits the request a maximum number of times equal to one fewer than the number specified in the registry entry **MaxResolutionAttempts**.

**Activation Method**
You must restart the computer for changes to take effect.

### Note

- This entry is installed with its default value during installation of the TCP/IP components.

### Tip

- For more information about configuring ATM under Windows Server 2003, see "ATM Technical Reference" in the *Networking Collection* of the *Windows Server 2003 Technical Reference*.

# ARPEntryAgingTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces*interface-name*\Atmarpc

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 90 - 1800 | 900 seconds (15 minutes) |

**Description**

Specifies the length of time, in seconds, that the address resolution protocol (ARP) client of the Asynchronous Transfer Mode (ATM) transport retains address resolution information for a unicast IP address before it is invalidated. When the time specified by this entry has elapsed, the ARP client does one of the following things:

- If there are no virtual circuits (VCs) associated with the IP address, it deletes the ARP entry for this IP address.
- If there is at least one permanent virtual circuit (PVC) associated with the IP address, then it uses Inverse ARP on the PVC to revalidate the ARP entry.
- If there is at least one switched virtual circuit (SVC) associated with the IP address, then it sends an ARP request to the ARP server to revalidate the ARP entry.

# Tcpip/Performance Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip

**Description**
See the description for HKLM\SYSTEM\CurrentControlSet\Services*service-name*\Performance Subkey.

**See Also**
**Concepts**
Performance Subkey

# FriendlyNetworkInterfaceNames

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Performance

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether network adapters are listed by name or by number in performance monitoring tools, such as System Monitor.

Network adapters are represented by instances of the Network Interface performance object. By default, System Monitor displays the display name provided by the network adapter driver as the name of the instance.

This entry does not exist in the registry by default. To direct System Monitor to display numbers instead of names for the network adapters, use the registry editor Regedit.exe to add this entry to the registry and set its value to 0.

| Value | Meaning |
|---|---|
| 0 | Numbers. System Monitor displays numbers to represent network adapters. |
| 1 | Names. System Monitor displays the names of network adapters. |

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
To make changes to this entry effective, restart Windows.

# Parameters\W32Time

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The W32Time subkey stores configuration settings for the Windows Time service. The Windows Time service maintains date and time synchronization for all computers running on a network.

# Config Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\

| Data type | Range | Default value |
|---|---|---|
| NULL | | |

**Description**

The Config subkey stores configuration information for the Windows Time service.

### Notes

The Windows Time service maintains date and time synchronization for all computers that are running on a network, and assigns a current clock value or timestamp for network validation and resource access requests.

# Config\AnnounceFlags Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 10 |

**Description**
Specifies whether this computer is a time server or a reliable time server. A computer will not be classified as reliable unless it is also classified as a time server.

This entry is only used by domain controllers that are running the Windows time service. The flag determines how the service is advertised by Netlogon.

| Value | Meaning |
|---|---|
| 0 | Timeserv_Announce_No, Reliable_Timeserv_Announce_No. The domain controller does not advertise time service. |
| 1 | Timeserv_Announce_Yes. The domain controller always advertises time service. |
| 2 | Timeserv_Announce_Auto. The domain controller automatically determines whether it should advertise time service. |
| 4 | Reliable_Timeserv_Announce_Yes. The domain contoller will always advertise reliable time service. |
| 8 | Reliable_Timeserv_Announce_Auto. The domain controller automatically determines whether it should advertise reliable time service. |

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Note**

- This value combines flags using the *bitwise OR* operator. For each position in the binary value, if any flag has the value of 1 in the corresponding position, the combined value does as well. For example, the flags 1 and 8, which are 0001 and 1000 in binary, are 1001 when combined with bitwise OR.

**Tip**

- W32Time has robust failover mechanisms, and manually configuring additional time services as reliable is generally unnecessary. However, there are two exceptions:

  1. You might want to configure a reliable time service in each site in your enterprise to minimize out-of-site traffic. Each service should be running on a domain controller in the root domain of each site. If the root domain of the site is also the root of the domain hierarchy, then the reliable time services should be configured manually to synchronize from external sources that are known to be highly accurate.

  2. You might want to configure a time service as reliable if it is configured to synchronize with a hardware clock.

  The optimal configuration varies with the enterprise. For more information about configuring time services, see "Windows Time Service Technical Reference" in the *Networking Collection* of the *Microsoft Windows Server 2003 Technical Reference*.

# Config\EventLogFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 \| 3 | 2 |

**Description**
Specifies the events that the time service logs.

| Value | Meaning |
|---|---|
| 1 | EvtLog_TimeJump. Time service must make a discontinuous change to the clock. |
| 2 | EvtLog_SourceChange. Time service chooses a new source of time information. |
| 3 | EvtLog_SourceNone. Time service has not acquired time samples for a period that is 1.5 times the maximum poll interval specified by Config\MaxPollInterval, and no longer trusts the local clock to be accurate. |

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**See Also**
**Concepts**
FileLogEntries

# FileLogEntries

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**

Contains a list of flags, specified by number and seperated by commas, that specify the types of information that should be written to the log file specified by **FileLogName**. A range of numbers is valid, in addition to single numbers. For example, **0-100,103,106** is a valid entry for this value. The following table shows common values and the type of data they specify.

| Value | Meaning |
|---|---|
| 2 | Errors associated with polling a time source. |
| 3 | Errors associated with establishing a session with an NTP peer. |
| 4 | Errors associated with domain hierarchy peers. |
| 5 | Errors associated with manual peers. |
| 6 | Errors associated with sending an NTP response. |
| 7 | Errors associated with NTP authentication. |
| 9 | Errors associated with provider failures. |
| 10 | Errors associated with processing NTP time samples. |
| 11 | Errors associated with configuration information. |
| 12 | Errors associated with stopping and starting the service. |
| 14 | Errors associated with NTP packet validation. |
| 52, 111 | Information relevent to automatic detection of a time source within a domain. |
| 65 | Configuration change information. |
| 67 | Configuration change made to network (for example, when a new network adapter is installed). |
| 105, 106 | Network time protocol (NTP) packets. |

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

# FrequencyCorrectRate Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 4 |

**Description**
Affects the rate at which the time service corrects the clock. This value, in units equal to the reciprocal of the rate at which the clock is corrected, is multiplied by the number of clock ticks in 64 seconds, to produce the base gain in the phase-locked loop (PLL) of the clock correction algorithm.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Note**

- A smaller value makes the time service more responsive to time changes, but if this value is too small, then the clock time is erratic. A larger value makes the system time more stable, but if the value is too large, then the time service waits a long time before synchronizing the clock.

# Config\HoldPeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 5 |

**Description**
Specifies the period of time for which spike detection is disabled in order to bring the local clock into synchronization quickly. A spike is a time sample indicating that time is off by a number of seconds, usually received after good time samples have been returned consistently.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Note**

- In this period, phase-locked loop (PLL) synchronization and spike detection are disabled to allow faster convergence.

# Config\LargePhaseOffset

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 50000000 |

**Description**

Specifies the time offset, in $10^{-7}$ seconds, by which times greater than or equal to this value are to be considered suspicious and possibly erroneous.

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Tip**

- Setting this value higher makes it less likely that the system clock will be set directly, and makes clock correction less frequent. This can be useful if you want to avoid discontinuities in system time (for example, while logging important transactions). However, the time service is more likely to regard bad time samples as good, which can lead to less accurate time.

# LastClockRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**

Stores the clock rate (in $10^{-7}$ seconds) of the CPU when the service was last stopped. The default value depends on the computer.

**Caution**

This entry is maintained automatically, and you should not modify it.

# LocalClockDispersion Entry

Updated: January 28, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008 R2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 10 |

**Description**
This setting, expressed in seconds, is applicable only when the Network Time Protocol (NTP) server is using the time of the local CMOS clock. The LocalClockDispersion value indicates the maximum error in seconds that is reported by the NTP server to clients that are requesting a time sample. The default value is 10 seconds.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Note**

- This entry is used when the local clock acts as a source of time for other computers, but is not synchronized with another network source. When the clock is synchronized from a network source, the dispersion is calculated relative to the source from which it synchronizes.

# MaxClockRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**

Specifies the largest base clock rate (in $10^{-7}$ seconds) that the clock discipline allows. The default value is 100288 plus the time interval of the system clock interrupt, which varies by computer.

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Caution**

- Increasing this value increases the rate at which time convergence is accomplished, but also increases the potential for instability.

**See Also**

**Concepts**

MinClockRate

# Config\MaxNegPhaseCorrection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*seconds*) | 54000 seconds (15 hours) for a client or member server; 0xFFFFFFFF for a domain controller |

**Description**
Specifies the time, in seconds, of the largest negative time correction that the Windows Time service is allowed to make. If the service determines that a change larger than this is required, then the service logs an event instead.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Tip**

- The smaller the value of this entry, the smaller the impact of erroneous time data. Since erroneous time data could be supplied maliciously, there is greater security in having a smaller value. However, a smaller value might also prevent the Windows Time service from making a larger but legitimate correction to the time.

# Config\MaxPollInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 15 |

**Description**

Specifies the longest interval (in units of $2^n$ seconds, where *n* is the value of this entry) that is allowed for system polling. While the system does not request samples less frequently than this, a provider may refuse to produce samples when requested to do so.

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

### Note

- The time service itself is considered unsynchronized after 1.5 times the number of seconds specified by this entry have elapsed. The Network Time Protocol specifies that the maximum clock age is 86,400 seconds, so if the value of this entry is greater than 15, then peers will eventually ignore this server.

### Caution

- The default time providers installed in Windows Server 2003 do not synchronize at an interval greater than 1024 seconds.

**See Also**

**Concepts**

Config\MinPollInterval

# Config\MaxPosPhaseCorrection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 54000 seconds (15 hours) for a client or member server; 0xFFFFFFFF for a domain controller |

**Description**
Specifies the largest positive time correction, in seconds, that the Windows Time service is allowed to make. If the service determines that a change larger than this is required, then the service logs an event instead.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Tip**

- The smaller the value of this entry, the smaller the impact of erroneous time data. Since erroneous time data could be supplied maliciously, there is greater security in having a smaller value. However, a smaller value might also prevent the Windows Time service from making a larger but legitimate correction to the time.

# MinClockRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**

Specifies the smallest base clock rate (in $10^{-7}$ seconds) that the clock discipline allows. The default value is 100288 plus the time interval of the system clock interrupt, which varies by computer.

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Caution**

- Increasing this value increases the rate at which time convergence is accomplished, but also increases the potential for instability.

**See Also**

**Concepts**

MaxClockRate

# Config\MinPollInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 6 (*domain controllers*) 10 (*member servers and standalone computers*) |

**Description**

Specifies the shortest interval (in units of $2^n$ seconds, where *n* is the value of this entry) that is allowed for system polling. While the system does not request samples more frequently than this, a provider may produce samples whenever it wants.

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

### Note

- The lower this value, the more network accesses the computer must make. This value should be lower on domain controllers, where clock accuracy is more important than efficiency.

### Caution

- The default providers installed with Windows Server 2003 do not synchronize more quickly than every 16 seconds, regardless of the value of this entry.

**See Also**
**Concepts**
Config\MaxPollInterval

# Config\PollAdjustFactor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 5 |

**Description**
Controls the decision to increase or decrease the system-recommended poll interval. Larger values mean that a smaller amount of error will cause the poll interval to be decreased.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

### Note

- The time service increases the poll interval when the computer clock proves stable for several polls.

### Tip

- Consider increasing the value of this entry if the time service is synchronizing under poor network conditions. Under such conditions, the time service might never achieve great enough stability to increase the poll interval, and the service will continue to poll at the minimum poll interval. Shorter poll intervals create more network traffic.

# Config\SpikeWatchPeriod

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 900 |

**Description**
Specifies the amount of time, in seconds, that a suspicious offset must persist before it is accepted as correct.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Tip**

- Decreasing this value causes the time service to respond to time slips more quickly. However, the time service is more likely to regard bad time samples as good, which can lead to less accurate time.

# Config\UpdateInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Config

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 100 (*domain controllers*) 30000(*member servers*) 360000(*standalone computers*) |

**Description**
Specifies the number of intervals, .01 seconds in length, between phase correction adjustments.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

### Note

- Increasing the value of this entry increases the efficiency of the time service, but makes the time service less able to account for clock drift. The value should be set low on domain controllers, which must maintain time as accurately as possible, and increased on computers for which efficiency is a higher priority.

# W32Time\Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Parameters\NtpServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *DNS name or IP address*[,0x1 \| 0x2 \| 0x3] | time.windows.com,0x1 |

**Description**

Stores a list of time sources that this computer uses to synchronize its time. The time sources appear either as a DNS name or an IP address of the time source server. The list is space-delimited, with one address per line.

Each time source may also be followed by a comma and a DWORD containing flags for special handling of that time source. If the flags are not specified, they default to 0x0. The available flags are:

| Value | Meaning |
|---|---|
| 0x1 | Instead of following the NTP specification, wait for the interval specified in the **SpecialPollInterval** entry before attempting to recontact this time source. Setting this flag decreases network usage, but it also decreases accuracy. |
| 0x2 | Use this time source only as a fallback. If all time sources that are not fallbacks have failed, then the system selects one fallback time source at random and uses it. |
| 0x4 | Set the local computer to operate in symmetric active mode in the association with this source. |
| 0x8 | Set the local computer to operate in client mode in the association with this source. |

**Change Method**

You can change the value of this entry by using the **/setsntp** parameter of the **net time** command at the command line. For more information about **net time**, see Help and Support Center for Windows Server 2003.

# Parameters\Type Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | NoSync \| NTP \| Nt5DS \| AllSync | Nt5DS for computers joined to a domain; NTP for others |

**Description**

Specifies the type of time sources, if any, to which the computer synchronizes its time.

| Value | Meaning |
|---|---|
| NoSync | Does not synchronize time. |
| NTP | Synchronizes time to the time sources specified in the Parameters\NtpServer entry. |
| Nt5DS | Synchronizes time to the domain hierarchy. |
| AllSync | Uses all synchronization mechanisms available. |

**Change Method**

To change the value of this entry, use the command-line tool w32tm.exe (specifically, the command **w32tm /config /syncfromflags**). For more information about w32tm.exe, see Windows Server 2003 Help and Support Center.

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

# W32Time\TimeProviders

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# TimeProviders\NtpClient

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# AllowNonstandardModeCombinations Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the system responds to Network Time Protocol (NTP) mode combinations that the NTP specification can understand, even if the combinations are not standard.

| Value | Meaning |
|---|---|
| 0 | The system does not respond to non-standard mode combinations. |
| 1 | The system responds to non-standard mode combinations, if the NTP specification can understand them. |

**Activation Method**
To make changes to the value of this entry effective, from the command prompt, type:

w32tm /config /update

### Note

- If this entry contains a value other than 0 or 1, the system behaves as though the value is 1.

**See Also**
**Concepts**
NtpServer\AllowNonstandardModeCombinations

# CompatibilityFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 \| 0x2 \| 0x40000000 \| 0x80000000 | 0x80000000 |

**Description**

Controls flags for behaviors that are needed for compatibility.

| Value | Meaning |
|---|---|
| 0x1 | The system ignores maximum error bounds (dispersion values), with the result that it cannot determine which of several time sources is the most accurate. |
| 0x2 | The system accepts a time stamp even if the time at which it was transmitted is earlier than the time stamp. |
| 0x40000000 | Reserved. Do not set this flag. |
| 0x80000000 | The system automatically detects Windows 2000 time sources and sets the compatibility flags appropriately. |

**Activation Method**

To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

# NtpClient\CrossSiteSyncFlags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 2 |

**Description**
Specifies whether the time service can synchronize with a partner that is outside the machine's site.

| Value | Meaning |
|---|---|
| 0 | The time service cannot synchronize with a partner that is outside the computer's site. |
| 1 | The time service can synchronize only with the primary domain controller. |
| 2 | The time service can synchronize with a partner that is outside the computer's site. |

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

# DllName Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Full path of a DLL file* | C:\WINDOWS\System32\w32time.dll |

**Description**
Specifies the dynamic-link library (DLL) file that contains the time-service provider.

**Change Method**
Changing the file name or file path of the DLL, or changing the value of this entry, is not recommended.

**Activation Method**
You must restart the computer for changes to the value of this entry to take effect.

**See Also**
**Concepts**
NtpServer\DllName

# NtpClient\Enabled Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the time-service provider should be started.

| Value | Meaning |
|---|---|
| 0 | The time-service provider should not be started. |
| 1 | The time-service provider should be started. |

**Activation Method**
To make changes to the value of this entry effective, from the command prompt type:

w32tm /config /update

### Note

- You might change the value of this entry if you install a third-party time provider to provide time samples, and you need to prevent the Windows time provider from supplying time samples that might interfere.

**See Also**
**Concepts**
NtpServer\Enabled Subkey

# NtpClient\EventLogFlags Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the time service client logs an event when its ability to reach the peer computer changes. The *peer computer* is the computer to which the client is synchronizing its time.

| Value | Meaning |
|---|---|
| 0 | Do not log an event if the reachability of the peer computer changes. |
| 1 | Log an event if the reachability of the peer computer changes. |

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Note**

- Configuring the Windows Time service to create a log entry each time it cannot reach a peer might be useful for troubleshooting. However, entries would also be added to the log for transient failures, which you might find undesirable, since they are not likely to represent a meaningful failure.

# InputProvider Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the provider is an *input provider*.

An *input provider* acquires time samples and provides them to the time service so that it can synchronize the local clock.

| Value | Meaning |
|---|---|
| 0 | The provider is not an input provider. |
| 1 | The provider is an input provider. |

**Change Method**
Changing the value of this entry is not recommended, though you can change it by editing the registry.

**Activation Method**
You must stop and restart the time service for changes to this entry to take effect.

**See Also**
**Concepts**
NtpServer\InputProvider

# NtpClient\ResolvePeerBackoffMaxTimes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 7 |

**Description**
Specifies the number of times that the time service doubles the length of the interval between attempts to find a peer computer. If contact with a particular peer continues to fail, then the time service continues to reattempt contact, but it stops doubling the wait interval if the number of reattempted contacts exceeds the value of this entry.

The initial wait interval is stored in the NtpClient\ResolvePeerBackoffMinutes entry.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Note**

- Consider setting this entry to a lower value if you want to discover failures more quickly, though doing so will increase network traffic and the number of entries in the event log.

# NtpClient\ResolvePeerBackoffMinutes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *minutes* | 15 *(15 minutes)* |

**Description**
Specifies the initial length of the interval that the time service waits between failing to receive a response from a peer computer and reattempting to contact that peer.

If contact with a particular peer continues to fail, then the time service continues to reattempt contact; for each reattempt, it doubles the length of the previous interval, until the number of reattempts matches the value specified by the NtpClient\ResolvePeerBackoffMaxTimes entry. If the number of reattempts to contact a peer exceeds the value of **ResolvePeerBackoffMaxTimes**, then the time service continues to reattempt contacting that peer on an interval equal to the last of the intervals that it was allowed to double.

**Activation Method**
To make changes to this entry effective, at the command line, type:

**w32tm /config /update**

**Note**

- Consider setting this entry to a lower value if you want to discover failures more quickly, though doing so will increase network traffic and the number of entries in the event log.

# TimeProviders\NtpServer Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# NtpServer\AllowNonstandardModeCombinations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the system responds to Network Time Protocol (NTP) mode combinations that the NTP specification can understand, even if the combinations are not standard.

| Value | Meaning |
|---|---|
| 0 | The system does not respond to non-standard mode combinations. |
| 1 | The system responds to non-standard mode combinations, if the NTP specification can understand them. |

**Activation Method**
To make changes to the value of this entry effective, from the command prompt type:

w32tm /config /update

### Note

- If this entry contains a value other than 0 or 1, the system behaves as though the value is 1.

**See Also**
**Concepts**
AllowNonstandardModeCombinations Entry

# NtpServer\DllName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Full path of a DLL file* | C:\WINDOWS\System32\w32time.dll |

**Description**
Specifies the dynamic-link library (DLL) file that contains the time-service provider.

**Change Method**
Changing the file name or file path of the DLL, or changing the value of this entry, is not recommended.

**Activation Method**
You must restart the computer for changes to the value of this entry to take effect.

**See Also**

# WINS Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services

**Description**
The WINS subkey stores configuration data for the Windows Internet Name Service (WINS).

WINS associates IP addresses to more familiar DNS and NetBios computer names. WINS enables users to find computer resources by their familiar names, instead of requiring them to use IP addresses.

# WINS\Parameters Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS

**Description**
The Parameters subkey stores general configuration data for the Windows Internet Name Service (WINS), that is, configuration data that is not related to replicating the WINS database.

WINS associates IP addresses to more familiar DNS and NetBios computer names. WINS enables users to find computer resources by their familiar names, instead of requiring them to use IP addresses.

# BackupDirPath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Path* | (None) |

**Description**
Specifies the directory where the backup of the Windows Internet Name Service (WINS) database is performed.

This entry appears in the registry only when you use the WINS console or the WINS netshell extension to establish a database backup path.

**Change Method**
To change the value of this entry, use the WINS console.

### Caution

- If you administer Windows NT 3.51 servers from a computer running a later version of Windows, the data type of this entry might be set incorrectly to REG_EXPAND_SZ. Contact Microsoft Product Support Services for assistance.

# BurstHandling

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether the Windows Internet Name Service (WINS) server uses burst handling. When using burst handling, the WINS server sends success responses to the clients whose requests are dropped.

If burst handling is enabled, then by default the WINS server stores 500 name registration and refresh queries in its queue before dropping queries.

| Value | Meaning |
|---|---|
| 0 | Disables burst handling. The WINS server does not send success responses to clients whose requests are dropped. |
| 1 | Enables burst handling. The WINS server sends success responses to clients whose requests are dropped. |

Burst handling attains temporary steady state on the WINS server when the WINS server is started with an empty database or when many WINS clients log on for the first time. The resulting name registration and name refresh operations cause a large amount of traffic.

Because success responses have small Time to Live values (TTLs), they slow the refresh rate of new WINS clients and regulate the burst of WINS client traffic. As a result, a steady state is reached much more quickly.

**Change Method**

To change the value of this entry, use the WINS console. In WINS server properties, click the **Advanced** tab. This entry corresponds to the **Enable burst handling** check box.

# DbFileNm

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %SystemRoot%\System32\Wins\wins.mdb |

**Description**
Stores the full path to the Windows Internet Name Service (WINS) database file.

**Change Method**
To change the value of this entry, use the WINS console. In WINS server properties, click the **Advanced** tab. This entry corresponds to the **Database path** box.

### Note

- This entry can also have the REG_SZ data type.

# DoBackupOnTerm

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the Windows Internet Name Service (WINS) database is backed up automatically when the WINS service stops.

| Value | Meaning |
|---|---|
| 0 | The WINS database is not backed up automatically when the WINS service stops. |
| 1 | The WINS database is backed up automatically when the WINS service stops. |

**Change Method**
To change the value of this entry, use the WINS console. In WINS server properties, click the **General** tab. This entry corresponds to the **Back up database during server shutdown** option.

# DoStaticDataInit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether the Windows Internet Name Service (WINS) server initializes its database.

| Value | Meaning |
|---|---|
| 0 | The WINS server does not initialize its database. |
| 1 | The WINS server initializes its database. |

If the value of this entry is 1, the WINS server initializes its database when the WINS process starts and when an entry in the WINS\Parameters Subkey or Parameters\DataFiles subkeys changes value (unless the change sets the value of this entry to 0). The database is initialized using records specified in the Datafiles subkey.

# LogDetailedEvents

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies the level of detail of events that the Windows Internet Name Service (WINS) server writes to the System Log in Event Viewer.

| Value | Meaning |
|---|---|
| 0 | Errors only. |
| 1 | Errors, warnings, and informational messages. |

**Change Method**
To change the value of this entry, use the WINS console. On the **Action** menu, click **Properties**, and then click the **Advanced** tab. This entry corresponds to the **Log detailed events to the Windows event log** option.

# Parameters\LogFilePath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %SystemRoot%\System32\Wins |

**Description**
Specifies whether Windows Internet Name Service (WINS) automatically backs up its database, and specifies the location where the backups are stored.

If you enter a path in the value of this entry, then WINS automatically backs up its database every three hours and stores the backup in the file named Jet.log in the specified path. If you delete this entry or its value, then WINS does not back up the database.

**Change Method**
To change the value of this entry, use the WINS console. On the **Action** menu, click **Properties**, and then click the **Advanced** tab. This entry corresponds to the **Log detailed events to Windows event log** box.

### Note

- This entry can have a data type of REG_SZ or REG_EXPAND_SZ.

# LoggingOn

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**

Specifies whether database changes are recorded in a log file.

| Value | Meaning |
|---|---|
| 0 | Database changes are not logged. |
| 1 | Database changes are logged in Jet.log. |

# McastIntvl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x960–0xFFFFFFFE (*seconds*) \| 0xFFFFFFFF | 0x960 (*2,400 seconds = 40 minutes*) |

**Description**
Specifies how often the Windows Internet Name Service (WINS) server sends a multicast message to announce its presence to other WINS servers.

| Value | Meaning |
|---|---|
| 0x960–0xFFFFFFFE seconds | WINS sends multicast messages at this interval. |
| 0xFFFFFFFF | WINS does not send multicast messages. |

**Concepts**
McastTtl
UseSelfFndPnrs

# McastTtl

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1–32 (*hops*) | 2 |

**Description**
Specifies the maximum number of *hops* (steps between subnets) that a Windows Internet Name Service (WINS) multicast announcement can perform. If the multicast announcement attempts to perform more hops than are permitted by the value of this entry, then WINS returns an Internet Control Message Protocol (ICMP) Time Exceeded error.

**Change Method**
To change the value of this entry, use the WINS console. Right-click the **Replication Partners** node, click **Properties**, and then click the **Advanced** tab. This entry corresponds to the **Multicast Time to Live (TTL)** box.

**See Also**
**Concepts**
McastIntvl
UseSelfFndPnrs

# MigrateOn

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies how the Windows Internet Name Service (WINS) server regards static database records that conflict with a new registration or replica.

| Value | Meaning |
|---|---|
| 0 | If unique and multihomed static records conflict with a new registration or replica, then they are still regarded as static records. |
| 1 | If unique and multihomed static records conflict with a new registration or replica, then they are treated as dynamic records. |

**Change Method**
To change the value of this entry, use the WINS console. Right-click the **Replication Partners** node, click **Properties**, and then, from the **General** tab, select the **Overwrite unique static mappings at this server (migrate on)** box.

# PriorityClassHigh

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies the priority class of the Windows Internet Name Service (WINS) server process. Setting the value of this entry to 1 ensures that other processes, such as electronic mail and other applications, do not preempt WINS.

| Value | Meaning |
|---|---|
| 0 | The WINS server runs in a normal priority class. |
| 1 | WINS runs in high-priority class. |

# UseSelfFndPnrs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the Windows Internet Name Service (WINS) server detects or ignores multicasts from other WINS servers on the network.

| Value | Meaning |
|---|---|
| 0 | The WINS server ignores multicasts from other WINS servers. |
| 1 | The WINS server detects multicasts from other WINS servers. |

If network routers support multicasting, then the WINS server automatically finds other WINS servers on the network by listening for their multicasts (as defined by RFC 1112, Host extensions for IP multicasting) to the IP address 224.0.1.24. Any WINS servers found by accepting WINS multicasts are automatically configured as push and pull replication partners, with pull replication set to occur every two hours.

If network routers do not support multicasting, then even if the value of this entry is 1, the WINS server finds WINS servers only on its subnet.

By default, WINS maintains partnership data that is discovered through multicasting. A WINS server that is discovered through multicasting is automatically removed as a replication partner when the WINS server shuts down successfully. However, if the WINS console has been used to change or view the found WINS server information, then the partnership data is not removed.

**Tip**

- To disable WINS multicasting, set the value of the McastIntvl entry to 0xFFFFFFFF.

# VerifyInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1FA400–0x7FFFFFFF (*seconds*) | 0x1FA400 (*576 hours = 24 days*), or 3 times the value of the entry **TombstoneInterval**, whichever is greater. |

**Description**

Specifies how long the Windows Internet Name Service (WINS) server can retain a name that it does not own before it must verify that the name is still active.

**Change Method**

To change the value of this entry, use the **Intervals** tab on the WINS ***Server-name*** **Properties** dialog box. This entry corresponds to the **Verification interval** field.

# VersCounterStartVal_HighWord

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–7FFFFFFF | 0x0 |

**Description**
Stores the highest numbered *version identifier* used in the Windows Internet Name Service (WINS) database. Each record in the database has a *version identifier*, which is a counter used to determine which WINS database entries must be updated during replication.

### Note

- The *version identifier* is a number that identifies a unique WINS record; it does not refer to the version number of the WINS database program.

**See Also**

VersCounterStartVal_LowWord

# VersCounterStartVal_LowWord

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

| Data type | Range | Default value |
|---|---|---|
| | 0x0–0x7FFFFFFF | 0x0 |

**Description**
Stores the lowest *version identifier* used in the Windows Internet Name Service (WINS) database. Each record in the WINS database has a *version identifier*, which is a counter used to determine which WINS database entries must be updated during replication. WINS uses this entry to determine the starting record in the WINS database.

### Note

- The *version identifier* is a number that identifies a unique WINS record; it does not refer to the version number of the WINS database program.

# ConsistencyCheck

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

**Description**
The ConsistencyCheck subkey is an optional subkey that you can add to the registry to direct the Windows Internet Name Service (WINS) to perform periodic database consistency checks. Typically, consistency checks are not performed because they consume substantial resources on both the WINS server and the network.

If you add this subkey, then you should set the values of its entries to minimize the load on the network due to consistency checking. To determine optimal values for these entries, consider the network topology and the number of WINS servers, WINS clients, and wide area network (WAN)/local area network (LAN) links between WINS servers.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To enable periodic automated consistency checking, use the WINS console. In WINS server properties, click the **Database Verification** tab, click the **Verify database consistency check** box, and use the options to configure consistency checking.

**Caution**

- Consistency checking uses significant network resources, and it can consume substantial processor time on WINS servers.

# MaxRecsAtATime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters\ConsistencyCheck

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1,000–*Total number of records* | 30,000 |

**Description**
Specifies the maximum number of records replicated in each consistency check cycle.

Windows Internet Name Service (WINS) performs consistency checks on the records of one *owner WINS server* at a time. (The *owner WINS server* is the WINS server from which the record was replicated.) After checking the owner WINS server, the local WINS server checks the value of this entry. If the number of records meets or exceeds this value, then the WINS server stops checking records.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To enable periodic automated consistency checking, use the WINS console. In the WINS ***Server-name*** **Properties** dialog box, click the **Database Verification** tab, select the **Verify database consistency** check box, and use the options to configure consistency checking.

### Caution

- Consistency checking uses significant network resources, and it can consume substantial processor time on WINS servers.

# SpTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters\ConsistencyCheck

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Time in hh:mm:ss format* | 2:00:00 (2:00 a.m.) |

**Description**

Specifies the time of day when the first Windows Internet Name Service (WINS) server database consistency check occurs. Thereafter, the WINS database is checked for consistency at the frequency specified in the value of the TimeInterval entry.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use the WINS console. In the WINS ***Server-name*** **Properties** dialog box, click the **Database Verification** tab. This entry corresponds to the option **Begin verifying at**.

# TimeInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters\ConsistencyCheck

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x5460–0xFFFFFFFF (*seconds*) (*6 hours or more*) | 0x15180 (*86,400 seconds = 1 day*) |

**Description**
Specifies how often the Windows Internet Name Service (WINS) server performs database consistency checks.

**Change Method**
To change the value of this entry, use the WINS console. In the WINS ***Server-name*** **Properties** dialog box, click the **Database Verification** tab. This entry corresponds to the **Verify database consistency every [ n ] hours** option.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# UseRplPnrs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters\ConsistencyCheck

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether the Windows Internet Name Service (WINS) contacts only its replication partners when performing consistency checks. Limiting the scope of a consistency check to replication partners is recommended for networks with a large number of WINS servers.

| Value | Meaning |
|---|---|
| 0 | WINS contacts the *owner WINS server* (the WINS server from which the record was replicated). |
| 1 | WINS contacts only its replication partners. If the owner of a record is a WINS replication partner, then WINS contacts the owner WINS server. If the owner is not a replication partner, then WINS contacts a WINS server selected randomly from its list of pull partners. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**

To change the value of this entry, use the WINS console. In the WINS ***Server-name*** **Properties** dialog box, click the **Database Verification** tab. This entry corresponds to the **Owner servers** or **Randomly selected partners** options in the **Verify against** section.

# DataFiles

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Parameters

**Description**
The DataFiles subkey contains entries representing the files that the Windows Internet Name Service (WINS) server uses to initialize and reinitialize its local database. These files contain static records.

By default, this subkey does not appear in the registry. However, you can add it and its entries to the registry to direct WINS to add static records in the specified data files to its database.

The entries in this subkey have the following format:

| Entry name | Data type | Value |
|---|---|---|
| [Path\] File name | REG_SZ \| REG_EXPAND_SZ | (Blank) |

The path is optional. If you do not enter a path, then WINS assumes the files are located in the directory from which the WINS service runs. The file can have any name and file name extension.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Partners

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS

**Description**
The Partners subkey contains entries that specify the properties of the Windows Internet Name Service (WINS) server and its replication partners.

This subkey contains two subkeys, Pull and Push, which store entries for pull and push operations of the WINS server.

**Change Method**
To display and change these values, use the WINS console whenever possible. Changes to these values are effective immediately; you do not have to restart WINS or Windows Server 2003.

**Tip**

To see the changes reflected in your registry editor, refresh the display.

Pull

# Pull

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Partners

**Description**
The Pull subkey contains entries that specify how and when replicas are pulled from pull partners of the Windows Internet Name Service (WINS) server. These entries are stored at the root level of the Pull subkey and apply to all pull operations.

In addition to these entries, this subkey contains subkeys representing each pull partner from which the WINS server can pull replicas. These subkeys, which are named by the IP address of the pull partner, store data that applies only to that pull partner. (See the IP address of pull partner subkey.)

**Change Method**
To display and change these values, use the WINS console. In the console tree, click **Replication Partners**, on the **Action** menu, click **Properties**, and then click the **Pull Replication** tab.

**Activation Method**
Changes to the entries in this subkey are effective immediately; you do not have to restart WINS or Windows. To see the changes reflected in your registry editor, refresh the display.

**Tip**

To see the changes reflected in your registry editor, refresh the display.

IP address of pull partner

# IP address of pull partner

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Partners\Pull

**Description**

The *IP address of pull partner* subkey is a variable representing the IP address subkeys in the WINS\Partners\Pull subkey. It does not actually appear in the registry. This variable subkey displays the entries and subkeys that are common to subkeys in the Adapters Subkey subkey.

The Pull subkey contains one subkey for each pull partner from which the Windows Internet Name Service (WINS) server can pull replicas. The subkeys are named for the IP address of the pull partner. They contain data that is configured separately for each pull partner and that applies only to that pull partner.

**Change Method**

To display and change these values, use the WINS console whenever possible. Changes to these values are effective immediately; you do not have to restart WINS or Windows Server 2003. To see the changes reflected in your registry editor, refresh the display.

# Push

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM\CurrentControlSet\Services\WINS\Partners

**Description**
The Push subkey contains entries that specify how and when the Windows Internet Name Service (WINS) server sends update notification messages to its push partners. These entries are stored at the root level of the Push subkey and apply to all push operations.

In addition to these entries, this subkey contains subkeys representing each push partner to which the WINS server sends update notification messages. These subkeys, which are named by the IP address of the push partner, store data that applies only to that push partner. (See the IP address of push partner subkey.)

**Change Method**
To display and change these values, use the WINS console. In the console tree, click **Replication Partners**, on the **Action** menu, click **Properties**, and then click the **Push Replication** tab.

**Activation Method**
Changes to the entries in this subkey are effective immediately; you do not have to restart WINS or Windows Server 2003. To see the changes reflected in your registry editor, refresh the display.

**See Also**
**Concepts**

# Disk

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 and earlier.

In Windows NT 4.0 and earlier, this subkey contained information about all physical disk drives, logical partitions of disk drives, CD-ROM drives, and network drive mappings on the computer. Windows Server 2003 eliminates this subkey and stores similar information in the MountedDevices subkey.

**Caution**

- Do not delete this subkey or its entries from the registry, and do not change the values in the entries. These changes can cause serious, unexpected results.

# MountedDevices

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM

**Description**
The MountedDevices subkey stores the database of mounted devices for the NTFS file system. This database associates persistent volume names with unique internal indentifiers for volumes. The internal identifiers often include the disk signatures of the volumes. This pairing enables NTFS to maintain the identity and persistent name of a volume, even when its variable device name changes.

NTFS uses this subkey to support mounted drives on all types of volumes, including removable drives and CD-ROM drives.

**Note**

- This subkey replaces the Disk subkey in Windows NT 4.0 and earlier. However, its contents and use are changed for Windows Server 2003.

# Select

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SYSTEM

**Description**
The Select subkey contains entries that specify which control set is used to start the system. The entries in this subkey record which control set was used to start the system this time, which control set will be used to start it next time, and which control sets have failed to start the system in the past.

**Caution**

- Do not change the values of the entries in this subkey. This subkey is maintained by Windows Server 2003 and should not be changed by users.

# Deployment Kit Compact Disc

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following contents are included on the *Windows Server 2003 Deployment Kit* companion CD:

- **Windows Server 2003 Deployment Kit.** A searchable online version of the *Windows Server 2003 Deployment Kit*.
- **Resource Kit Tools for Windows Server 2003.** A collection of tools included with the Windows Deployment and Resource Kits that can help you deploy, configure, maintain, and troubleshoot Windows Server 2003.
- **Resource Kit Registry Reference for Windows Server 2003.** A searchable online reference providing detailed descriptions of the Windows Server 2003 registry, including many entries that cannot be edited by using Windows Server 2003 tools or programming interfaces.
- **Resource Kit Performance Counters Reference for Windows Server 2003.** A searchable online reference describing what each performance counter monitors. You can use performance counters to diagnose problems or detect bottlenecks in your system.
- **Deploying Internet Information Services (IIS) 6.0 & Migration Tools.** A searchable online version of *Deploying Internet Information Services (IIS) 6.0* and tools that you can use to migrate to IIS 6.0.
- **Job Aids for the Windows Server 2003 Deployment Kit.** Worksheets and resources that can help you create your deployment plan for Windows Server 2003.
- **Windows Server 2003 Help.** The searchable Help file included with the Windows Server 2003 operating system containing technical content for the IT professional, which can be installed on Microsoft® Windows® XP Professional.
- **Microsoft Office Viewers.** Viewers you can install on your computer if you do not have Microsoft® Office, which allow you to see worksheets and resources on the *Windows Server 2003 Deployment Kit* companion CD.
- **CD-ROM Release Notes.** Late breaking information about the contents of the *Windows Server 2003 Deployment Kit* companion CD.
- **Links to Microsoft Press.** Links to the Microsoft Press Support site, which you can search for Knowledge Base articles, and to the Microsoft Press product registration site, which you can use to register this book online.

# Deployment Guide Document Conventions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following art symbols and text conventions are used throughout this book.

**Flowchart Symbols**
Use the following table of symbols as a resource for understanding the flowcharts included in this guide.

| Symbol | Meaning | Symbol | Meaning |
|---|---|---|---|
| | Step or component process | | Data stored to a database |
| | Predefined process or subroutine | | Flowchart beginning or end |
| | Decision point | 1 | Intra-chart connector: Flow continues to next page |
| | Output to a document or input from a document | 1 | Intra-chart connector: Flow continues from previous page |
| | Data transfer to a file on disk | A | Inter-chart connector: Indicates an exit point to another flowchart |
| | Data transfer to a data store | B | Inter-chart connector: Indicates an entry point from another flowchart |

**Art Symbols**
Use the following table of the art symbols as a resource for understanding the graphics included in this guide.

| Symbol | Meaning | Symbol | Meaning |
|---|---|---|---|
| | Workstation | | Macintosh client |
| | Portable computer | | Tablet computer |
| | Terminal | | Cellular phone |
| | Portable digital assistant (PDA) | | Document |
| | File folder | | E-mail |
| | Chart | | Wireless network adapter |
| | Modem | | Video camera |
| | Network adapter | | Digital camera |
| | Facsimile | | Printer |
| | Telephone | | Scanner |
| | Hard disk | | Tape drive |
| | Database | | Tape |
| | Compact disc | | Security key |
| | Digital certificate | | Padlock |

| | | | |
|---|---|---|---|
| | Padlock | | Uninterruptable power supply |
| | Access token | | Hub |
| | Modem bank | | Automated library |
| | Windows NT–based server | | Generic server |
| | Mainframe computer | | Host |
| | Server farm | | Clustered servers |
| | Router | | Switch |
| | Shadowed router | | Windows 2000–based router |
| | Data jack | | Input/output (I/O) filter |
| | Firewall | | Tunnel |
| Internet | Internet | Intranet | An intranet |
| | Transceiver | | Script |
| | Interface | | Packets |
| | Process or communication failure | “ · ” | DNS root |
| | Directory tree root | | Root |
| | Organization | | Organizational unit |
| | Common name | | Generic node |
| | Active Directory domain | | User group |
| Windows 2000 Domain | Windows 2000 domain | | Site *or* Windows NT 4.0 domain |
| | Active Directory™ | | |

**Reader Alert Conventions**

Reader alerts are used throughout this guide to notify you of both supplementary and essential information. The following table explains the meaning of each alert.

| Reader Alert | Meaning |
|---|---|
| **Tip** | Alerts you to supplementary information that is not essential to the completion of the task at hand. |
| **Note** | Alerts you to supplementary information. |
| **Important** | Alerts you to supplementary information that is essential to the completion of a task. |
| **Caution** | Alerts you to possible data loss, breaches of security, or other more serious problems. |

| | |
|---|---|
| **Warning** | Alerts you that failure to take or avoid a specific action might result in physical harm to you or to the hardware. |

**Command-line Style Conventions**

The following style conventions are used in documenting scripting and command-line tasks throughout this book.

| Element | Meaning |
|---|---|
| **bold font** | Characters that you type exactly as shown, including commands and parameters. User interface elements are also bold. |
| *Italic font* | Variables for which you supply a specific value. For example, *Filename.ext* can refer to any valid file name. |
| `Monospace font` | Code samples. |
| **`Command`** | Command that is typed at the command prompt. |
| `Syntax` | Syntax of script elements. |
| `Output` | Output from running a script. |

# Support Policy

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Microsoft does not support the software supplied in the *Windows Server 2003 Deployment Kit*. Microsoft does not guarantee the performance of the scripting examples, job aids, or tools, bug fixes for the tools, or response times for answering questions. However, we do provide a way for customers who purchase the *Windows Server 2003 Deployment Kit* to report any problems with the software and receive feedback for such issues. You can do this by sending e-mail to rkinput@microsoft.com. This e-mail address is only for issues related to the *Windows Server 2003 Deployment Kit*. For issues related to the Windows Server 2003 operating systems, please refer to the support information included with your product.

# Deployment Guide for the Security Configuration Wizard

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic discusses the deployment of the Security Configuration Wizard (SCW) and SCW policies.

Security Configuration Wizard (SCW) is a tool for reducing the attack surface of computers running Microsoft® Windows Server™ 2003 with Service Pack 1 (SP1). It determines the minimum functionality required for a server's role or roles, and disables functionality that is not required. Specifically, SCW helps you author and deploy a security policy that:

- Disables unneeded services.
- Blocks unused ports.
- Allows additional address or security restrictions for ports that are left open.
- Prohibits unnecessary Internet Information Services (IIS) Web extensions, if applicable.
- Reduces protocol exposure to server message block (SMB), LAN Manager, and Lightweight Directory Access Protocol (LDAP).
- Defines a high signal-to-noise audit policy.

SCW guides you through the process of creating, editing, applying, or rolling back a security policy based on the selected roles of the server.

This deployment guide guides you through the process of deploying SCW and SCW policies to your computers running Windows Server 2003 with SP1.

**Requirements for Installing and Running SCW**
SCW is included with Windows Server 2003 SP1, and works only with computers running Windows Server 2003 with SP1. It is not for use with Microsoft Small Business Server or client operating systems like Windows XP Professional.

**SCW Deployment Overview**
Before you deploy SCW to your servers, you should become familiar with the SCW user interface and the Scwcmd.exe command-line tool.

Once you are familiar with SCW, perform a test deployment of SCW and SCW policies. Make the test environment as similar as practicable to the production environment but on a smaller scale. Be sure to include the server types and Active Directory organizational unit (OU) structure that are used in your production environment. When you are confident that SCW policy application is working correctly in the lab, you are ready to move to the production environment.

Install Windows Server 2003 SP1 on all servers and then install SCW on each server. If you have to manage many servers, you can perform an unattended installation of Windows Server 2003 SP1 and SCW in one step.

In an Active Directory environment, your next step is to adjust Active Directory OU structure according to server types.

You also need to complete policy prototyping, where you create policies for each type.

Finally, you deploy the policies by using one of the following three ways:

- SCW user interface
- Scwcmd.exe
- Group Policy

At each step, you will have choices to make, such as:

- What to do on each wizard page
- Whether and how to use security templates
- Whether to use Group Policy to deploy policies

**SCW Deployment Steps**

This section lists the steps you take for deploying SCW.

1. Pre-plan, gather information, lab test, and back up your servers.
2. Install SP1 and SCW.
    - If you have only a few servers to manage, install SP1 manually and locally on each server. Then install SCW on each server.
    - If you do have many servers to manage, do an unattended installation of SP1 and SCW simultaneously with SCW=On in the [Components] section of Unattend.txt. Using Systems Management Server (SMS) with Service Pack 1 is another option for deploying SCW.

**SCW Policy Deployment Steps**

After you have deployed SCW, you are ready to deploy SCW policies. This section lists the steps you take for deploying SCW policies.

1. Pre-plan, gather information, lab test, and back up your servers.
2. Back up your current security configuration.
3. If you apply policy to servers by using Active Directory, arrange server roles in organizational units (OUs).
4. Create a prototype policy per server role.
5. If you need to apply settings that SCW cannot create, attach an .inf security template.
6. Internet Information Services (IIS) settings and rollback capability will be lost if you use Group Policy to deploy the settings. Use Group Policy anyway? If so, create a Group Policy object (GPO) through the **scwcmd transform** command and link the GPO by using Group Policy Management Console (GPMC). This completes your SCW policy deployment.
7. If you have arrived at this step you are not using Group Policy. Are you going to target multiple servers? If so, apply policy as .xml through the **scwcmd configure** command, specifying a list of servers as a parameter. This completes your SCW policy deployment.
8. If you have arrived at this step you are targeting a single server. Apply policy as .xml through the Wizard interface of SCW. This completes your SCW policy deployment.

# Planning the SCW Deployment

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic discusses planning for SCW deployment.

Safe use of any technology that affects the settings, configuration, or behavior of multiple computers requires planning before deployment. Safe use of SCW includes lab-testing of tools and policies prior to live rollout into a production environment. This and other best practices for SCW are covered in this section.

After a discussion of additional resources that can help you become familiar with SCW, this section includes guidelines for defining exactly which computers support local installation of SCW and the tools included with SCW and which computers are valid targets for policy that you author by using SCW.

**Review SCW resources**

Additional information about SCW is available at the following sources:

- SCW documentation from the Download Center on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=45183)
    - SCW Quick Start Guide
    - SCW Deployment Guide
    - ExtendingSCW
    - SCW Troubleshooting Guide
- SCW online Help

  Each page of SCW contains a link to online help that is specific to that wizard page. You can view the online help file in its entirety from the command line by **hh scwhelp.chm**. There is also a link to the help file on the desktop once SP1 is installed. The help file is available in SP1 regardless of whether SCW itself is installed.

- Scwcmd.exe command-line tool help

  After SCW is installed, help for the command-line tool can be obtained from the command line by typing scwcmd. This displays the following:

  ```
  Syntax: scwcmd [ analyze | configure | register | rollback | transform | view ]
  ```

  Help for each of these six options is obtained by typing scwcmd option_name.

| **Note** |
| --- |
| The **scwcmd view** command allows the use of a template (.xsl file) to format the display in the SCW viewer. The correct syntax is to have the template first, for example **scwcmd view /s:scwpolicy.xsl /x:main.xml**. The command-line help that you get by typing **scwcmd view** incorrectly shows the **/x:** parameter first. |

**Review requirements for local installation of SCW**

You can install SCW only on computers running Windows Server 2003 with Service Pack 1 (SP1), which includes SCW as an optional Windows component. SCW is not installed by default, but you can install it by clicking **Add/Remove Windows Components** in **Add or Remove Programs** in **Control Panel**. To install SCW, you need to be a member of the Administrators group on the server.

SCW should not be used with Windows Small Business Server 2003 or client operating systems like Windows XP Professional.

**Determine valid targets for applying SCW security policy**

The security policies that are created with SCW should be applied only to servers and groups of servers. They should not be applied to client operating systems such as Windows XP Professional, nor should they be applied to systems running Windows Small Business Server 2003.

**Identify valid targets for SCW policy prototyping**
In the context of SCW, "policy prototyping" means using SCW to author security policy for groups of similarly configured computers by targeting SCW at a prototype computer: a model server whose configuration is representative of every computer in the group. Only computers running Windows Server 2003 with SP1 are valid targets for SCW security policy authoring.

When SCW is installed and run locally but targeted at a remote server for authoring policies, it is best for the remote server to also have SCW installed. This is because SCW includes so-called "helper functions" that inspect the computer. If SCW is installed on the remote computer, the locally-run wizard can make these determinations about the remote computer:

- Whether unknown services are listening on a port.
- Whether approved applications are installed.
- The list of named pipes.
- Whether an IPsec policy is applied

**Review SCW Best Practices**
This section explains how to get the most out of SCW by following best practices.

**Identify and target similar servers.**
SCW helps to reduce the attack surface of servers by creating a security policy that is specifically designed for their specific roles. Administrators can simplify policy authoring and distribution by identifying groups of servers that perform the same, or similar, tasks.

**Author one policy for a group of servers.**
SCW authors a security policy based on the roles and functions performed by a server. Others servers that perform the same, or very similar, functions can be configured with the same security policy. Administrators can use SCW once to author a security policy, save it, and apply it to all servers that perform the job function. A single security policy that contains all desired security settings for a server also simplifies configuration, rollback, and analysis.

For simple configuration and rollback, a single security policy for a computer, or set of computers, is much easier to understand and update than a series of policies. The scwcmd analyze command has a p*:/policyname* parameter that only accepts a single SCW native policy file as a parameter.

**Group similar servers in one organizational unit (OU).**
Grouping servers by OUs in Active Directory domains facilitates the application of security policy through Group Policy. The SCW transform operation can create an unlinked security policy containing GPO in Active Directory. To simplify policy distribution, an administrator can group servers that perform similar functions into a single OU, and link the GPO to the OU.

**Create different policies for different platforms.**
For services or ports specific to 64-bit computers, create the policies on a 64-bit computer. Then deploy these policies to other 64-bit computers only (not 32-bit computers) to ensure the services are properly identified and configured.

It is highly recommended that the prototype server from which the security policy will be created resembles the target servers to be configured as closely as possible. Not only are there options in the wizard that are not shown unless the prototype server has those options, the modifications done to services and other items could cause severe interoperability problems unless the prototype resembles the target.

The security policy might disable any service that was not present on the prototype server when the policy was created. Any service defined in the security configuration database but not present on the prototype server will be disabled. The configured state of a service that is not present on the prototype and that is not in the security configuration database is configurable in the wizard. For example, if the DCOM Server Process Launcher service is listed in the Security Configuration Database, but is not present on the prototype server, the security policy created from the prototype server will set the DCOM Server Process Launcher state to disabled. When you apply the security policy to other servers, the DCOM Server Process Launcher service will be disabled on those servers.

**Test new security policies before deployment.**
The settings configured in the new security policies may cause compatibility issues with applications or services. Therefore,

thoroughly test new security policies in a test environment before applying the policies to production servers. Virtual machines are particularly well suited for this purpose.

# Deploying SCW to multiple servers

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic explains how to deploy SCW to multiple servers.

Your options for installing Windows Server 2003 SP1 and SCW on multiple servers include:

- Systems Management Server (SMS) with Service Pack 1 (SP1)
- Unattended installation

**SMS with SP1**

Systems Management Server (SMS) is a full-featured change and configuration management, software deployment, and license-tracking system that is part of the Windows Server System. It is available from Microsoft at an additional cost.

SMS can be used to deploy operating system updates including Windows Server 2003 SP1 and SCW to your servers.

For more information about SMS, see What Is Windows Server System? on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=48227).

The Group Policy Object Editor and Group Policy Management Console (GPMC) include the ability to assign patches and software updates, but only for Windows Installer packages. SCW is part of Windows Server 2003 SP1 and is not available as a stand-alone Windows Installer package. Therefore you can not deploy SCW itself by using Group Policy.

SCW policies can, however, be deployed by using Group Policy.

**Unattended installation of SCW**

You can create an answer file that installs Windows Server 2003 SP1 and SCW automatically. To do so, follow these steps:

**To install SCW as part of an unattended installation**

- Before initiating the unattended installation, add the following entry to the [Components] section of Unattend.txt:

  **SCW=On**

**To apply an SCW security policy during the unattended installation, also carry out the following steps.**

1. Create the security policy file on a server that already has SCW installed.
2. Either create a Cmdlines.txt file or modify the existing one so that it has a [Commands] section containing the following line:

   **scwcmd configure /p:SCWPolicy.xml**

3. Copy the Cmdlines.txt file and the previously created policy file (SCWPolicy.xml in this case) to the $OEM$ directory.

For detailed instructions about using unattended installation, see Automating and Customizing Installations in the Microsoft Windows Server 2003 Deployment Kit on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkID=4748).

# Creating SCW security policy files

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic tells how to create SCW security policy files.

Before you can deploy an SCW policy, you need to author it. This section covers using the SCW user interface to author a security policy. SCW security policies are always created from prototype servers of the same type as the servers that will receive the policy.

**To create a security policy**

1. Click **Start**, click **Administrative Tools**, and then click **Security Configuration Wizard**.
2. Read the Welcome page and click **Next.**
3. Select **Create a new security policy**, and then click **Next**.
4. Type the name of the prototype server, and then click **Next**.
5. Wait for the Security Configuration Database to be processed, and then click **Next**.
6. For each of the next five wizard pages, just click **Next**:
   - **Role-Based Service Configuration** page.
   - **Select Server roles** page.
   - **Select Client Features** page.
   - **Select Administration and Other Options** page.
   - **Select Additional Services** page.
7. On the **Handling Unspecified Services** page, click **Next**.
8. For each of the next 20 wizard pages, just click **Next**:
   - **Confirm Service Changes** page.
   - **Network Security** page.
   - **Open Ports and Confirm Applications** page.
   - **Confirm Service Changes** page.
   - **Confirm Port Configuration** page.
   - **Registry Settings** page.
   - **Require SMB Security Signatures** page.
   - **Require LDAP Signing** page.
   - **Outbound Authentication Methods** page.
   - **Outbound Authentication Methods using Domain Accounts** page.
   - **Registry Settings Summary** page.

- **Audit Policy** page.
- **System Audit Policy** page.
- **Audit Policy Summary** page.
- **Internet Information Services** page.
- **Select Web Service Extensions for Dynamic Content** page.
- **Select the Virtual Directories to Retain** page.
- **Prevent Anonymous Users from Accessing Content Files** page.
- **IIS Settings Summary** page.
- **Save Security Policy** page.

9. On the **Security Policy File Name** page, type a name for the prototype policy, and then click **Next**.

   Do not name the security policy by using the name of the prototype computer because scwcmd.exe uses *computername.xml* to save analysis results, and you do not want the security policy to have the same name as the analysis results. That would risk confusion or overwriting.

   | **Note** |
   | --- |
   | The security policy settings that you can configure within SCW overlap with those that can be set by using security templates (.inf files). On the Security Policy File Name page, you can include a security template if you want to add settings that cannot be configured directly from SCW. If you attach a security template, and it contains settings that conflict with some SCW-configured settings, the SCW-configured settings have precedence. |

10. On the **Completing the Security Configuration Wizard** page, click **Finish**.

    The policy will now be created.

# Deploying SCW security policy files

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic discusses the deployment of SCW security policy files.

Security policy files authored with SCW are created as .XML files that are saved by default in %systemdir%\security\msscw\Policies. They can be deployed by using the SCW user interface or by using the scwcmd.exe command-line tool included with SCW.

**Using the SCW user interface**

This method is best suited for a single server. To apply an SCW security policy to multiple servers, use the command-line method or Group Policy instead.

**To apply an SCW security policy to a server**

1. Click **Start**, click **Administrative Tools**, and then click **Security Configuration Wizard**.
2. Read the **Welcome page**, and click **Next**.
3. On the **Configuration Action** page, select **Apply an existing security policy**, type the full path and file name of the policy, and then click **Next**.
4. On the **Select Server** page, type the name of the server to which the policy will be applied, and then click **Next**.
5. On the **Apply Security Policy** page, click **Next**.
6. On the **Applying Security Policy** page, wait for processing to finish, and then click **Next**.
7. On the **Completing the Security Configuration Wizard** page, click **Finish**.

**Using the Command-line method**

To configure multiple servers with a policy, you can use **scwcmd configure /p:***PolicyFile* **/i:***MachineList* at the command prompt, rather than this SCW UI procedure. Type **scwcmd configure** at the command prompt to learn about the parameters.

# Converting of SCW security policy files into Group Policy objects (GPOs)

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic discusses the conversion of SCW security policy files into GPOs.

SCW saves its security policies as .xml files, and the Scwcmd.exe command-line tool allows you to convert these files and save them as GPOs by using the **scwcmd transform** command. The SCW user interface itself does not support GPOs.

**Scwcmd transform**. Creates a new GPO and defines the settings for these Group Policy extensions:

- **Security Settings**. Contains service settings, registry values, audit policy and security template settings that were imported into the SCW XML policy.
- **IP Security Policies**. Contains the IPsec configuration that is defined in the SCW policy.
- **Windows Firewall**. Contains Windows Firewall settings that are defined in the SCW policy.

Any Internet Information Services (IIS) settings that are defined in the SCW policy will be lost during the **scwcmd transform** operation because Group Policy does not support configuration of IIS settings.

After the GPO is created, the administrator must manually link the GPO to the target organizational unit (OU) by using Active Directory Users and Computers, or by using the Group Policy Management Console (GPMC).

**To save an SCW security policy in native Group Policy format**

- At the command prompt, type

  **scwcmd transform /p:** *PathAndPolicyFileName* **/g:** *GPODisplayName*

  where *PathAndPolicyFileName* is the policy you created earlier with SCW, including its .xml file name extension and *GPODisplayName* is the name of the Group Policy object (GPO) as it appears in Group Policy Object Editor or in Group Policy Management Console (GPMC).

  When the **scwcmd transform** command is complete, the GPO gets created in Active Directory, but the policy it contains is not applied until the GPO is linked to an organizational unit. For instructions about linking GPOs, see the GPMC Help.

# Using Group Policy and Active Directory with SCW

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic is about using Group Policy and Active Directory with SCW.

SCW is not a replacement for the security settings available in Group Policy; it is a security tool to supplement Active Directory and its policy infrastructure, and to make the familiar Active Directory tools such as the Active Directory Users and Computers snap-in more useful to you.

Active Directory best practices include using Active Directory Users and Computers to group computer objects into organizational units (OUs) for convenient administration. This helps you deploy SCW policies by using Group Policy objects (GPOs). You can create an SCW security policy by prototyping a server with the SCW user interface, convert it into a GPO by using scwcmd.exe, and link the GPO to an OU. If all the functionally similar servers are in the OU, they all receive your SCW-authored security policy.

**Group Policy Object Editor**
The Group Policy Object Editor is the user and computer configuration management tool that is included with Active Directory. Group Policy settings include security settings in the Group Policy Object Editor even though security settings are displayed and processed differently from most of the other Group Policy settings. For example, security settings are persistent in the registry, whereas Group Policy administrative templates settings are rewritten whenever policy is refreshed.

The Group Policy Object Editor is used to edit all Group Policy objects, including those converted from SCW format. So SCW makes the Group Policy Object Editor more useful by supplying GPOs tailored to server types.

**Group Policy Management Console**
Group Policy Management Console (GPMC) answered the need for easier analysis, planning, and backup of policy in an Active Directory environment, where multiple GPOs frequently apply to the same system and custom OU arrangements affect inheritance. GPMC is made available as a free download. It supports all enterprise-wide Group Policy tasks with the exception of editing individual GPOs, which is still done with Group Policy Object Editor.

In particular, GPMC is used for linking GPOs to OUs. Linking is the mechanism by which GPOs are applied to the users and computers within the OUs.

If you use Group Policy Object Editor to edit a GPO that includes SCW security policies, be aware that security settings authored manually in Group Policy Object Editor take precedence over the same settings applied using SCW.

If SCW-authored settings are transformed into a GPO, the decision as to which settings take precedence is determined by ordinary GPO inheritance rules.

**Security Templates and Precedence**
In addition to using SCW to author security policies, you can also apply security settings by using security templates. Security templates are .inf files such as securedc.inf that are located by default in %systemroot%\security\templates\. You can see the security template settings in Group Policy Object Editor and GPMC in the following location:

*GPO_Name*\Computer Configuration\Windows Settings\Security Settings\

The configuration changes that can be made by using the SCW user interface without the use of security templates partially overlap the configuration changes available by using security templates alone. Neither set of configuration changes totally includes the other. For example, the SCW user interface includes IIS settings that are not included in any security template. Conversely, security templates can include such items as Software Restriction policies, which are not configurable through SCW user interface. Some configuration changes, such as IP Security (IPsec) policies, can be set by using the SCW user interface, or by attaching a security template to the native SCW policy file (.xml file), or by using both methods. If you use both methods, however, conflicting policy settings are resolved by using the precedence rules explained later in this section.

In addition, the scwcmd.exe command-line tool with its transform option supports the creation of new, unlinked GPOs from SCW policies. This means that there are, in effect, three ways to use security templates:

- If you are familiar with Group Policy, and have used the Group Policy Object Editor and GPMC, then you are familiar with attaching a security template to a GPO by right-clicking **Security Settings**, clicking **Import Policy**, and then browsing to the .inf file.

- A second way is to include a security template in an SCW policy from the Security Policy File Name page of SCW by

clicking **Include Security Templates**, and then clicking **Add**. As with the Group Policy method, you then browse to an .inf file.

- The third way is to attach a template to a .xml policy file (as just described) and then type at the command line **scwcmd transform /p:***policyfile.xml* **/g:***GPOdisplayname* to create a GPO, which you then link using GPMC.

In an environment utilizing Group Policy, SCW, and multiple security templates, use the following guidelines to anticipate the precedence of security settings:

- Security policy applied through Active Directory-based GPOs has higher precedence than security policy applied through SCW policy files (.xml files).

- Precedence among GPOs is unaffected by whether each GPO was created by scwcmd.exe or not: Only the standard Active Directory inheritance rules (in which local, site, domain, and organization unit GPOs are applied in succession) and link order determine precedence for GPOs.

- Security policy set in the SCW user interface has higher precedence than conflicting policy set in .inf security templates that are attached to the .xml policy file.

- If multiple security templates are attached to the .xml security template, a template that is listed higher in the Include Security Templates dialog box has precedence over a template that appears lower in the list.

Always test security policy in a lab before deploying it to your live production servers.

# Deploying SCW security policy as Group Policy objects

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic discusses deploying SCW security policy as Group Policy objects.

Once you have used **scwcmd transform** to convert SCW policies into GPOs, those GPOs are no different than any other Active Directory GPOs from the standpoint of GPMC and Group Policy Object Editor.

Group Policy does not support the rollback of security settings. If you apply SCW security settings by using Group Policy, you cannot roll them back.

See the Group Policy and GPMC Help for instructions about linking GPOs.

# Rollback considerations

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

This topic discusses rolling back SCW policy.

Rolling back SCW policies is not part of routine SCW deployment, but you might face circumstances where you want to roll back an SCW security policy. In those cases, keep the following rollback considerations in mind.

Security settings are persistent in the registry. This behavior is called tattooing. If you apply SCW security settings through Group Policy, the registry will be tattooed, and you will not be able to roll them back.

A best practice for facilitating rollback of SCW policies is to put the policy settings for a server type into just one SCW policy file rather than several.

Rollback can be carried out through the SCW user interface, or alternatively through the command-line tool by using the **scwcmd rollback** command. Type **scwcmd rollback** to see how the rollback parameter is used.

XML files supporting rollback are created and stored by default in %systemdir%\security\msscw\RollbackFiles. SCW and scwcmd.exe search in that location, so you will not generally need to do anything with these files yourself. This is just for your information.

If, after you roll back a security policy, some services do not behave as expected, check whether services that were started manually were stopped. If you apply a security policy that disables manually-started services and then roll back this policy, those services might need to be restarted manually.

There are special rollback considerations for Windows Firewall and Internet Information Services (IIS) settings:

**Windows Firewall**
Keep in mind that SCW policies affect Windows Firewall and IPsec settings based on server roles, approved applications, and port behavior. If you make changes to Windows Firewall and IPsec outside of SCW, .the system might not behave exactly as you might expect after rolling back SCW policies.

**Internet Information Services (IIS)**
IIS settings within SCW policies are lost when the .XML policy files are transformed into GPOs. This means that neither the application nor the rollback of IIS settings are supported by GPMC. To apply or roll back IIS settings, you need to use the SCW user interface or **scwcmd configure** at the command line.

You will only see the IIS section of SCW if you have selected the Web Server role on the **Select Server Roles** page of SCW.

# Network Load Balancing: Security Best Practices for Windows 2000 and Windows Server 2003

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

**In This White Paper**

- General Assumptions
- Deployment and Operational Management
- Summary of Security Attributes

**General Assumptions**

There are a number of general assumptions that need to hold around the infrastructure and operational best practices to ensure a secure environment in which to run NLB clusters:

1. Servers and storage are in physically secure locations.
2. Practical security implementations such firewalls, network probes and management tools to detect irregular traffic are in place.
3. Best practices and common sense in terms of security are adhered to in areas like administration, storage of logs, backup and restore, etc.
4. Platform level security best practices are adhered to in terms of assigning administrative permissions, Access Control Limiting resources, and other housekeeping roles.
5. The network infrastructure services such as Active Directory, DNS, DHCP, WINS, etc. must be secure. Any compromise of these infrastructure services can lead to a compromise of the NLB itself.
6. Administration tools or other applications that administer NLB clusters can be run from remote workstations. The administrator must ensure that the applications are run from trusted computers. Any compromise on the computers on which the applications are executing (that the cluster administrator runs), can compromise the cluster. For example, if there are untrusted users with elevated privileges on the workstation where the administration tools are run, untrusted or malicious code can be run against the cluster by the cluster administrator without the cluster administrator realizing.
7. NLB creates and maintains a set of objects in the operating system such as files, devices, registry keys, etc. These objects have a default security setting that ensures non-privileged users cannot impact the cluster configuration or the applications running on the cluster. Changing these security settings to less restrictive security settings can lead to the cluster being compromised and application data being corrupted.

# Deployment and Operational Management

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

**Cluster administrators**
Administrators can specify groups or individuals that are allowed to manage the cluster. Because NLB does not implement a cluster-wide administrative account, the cluster administrator must ensure that an appropriate administrative account with Administrator privileges has been enabled on all cluster hosts. This account is used by NLB management tools, such as NLB Manager and the NLB control program, wlbs.exe, to administer individual NLB hosts. To simplify this process and ensure uniform access on all hosts, it is preferable to use a single domain or global group account for this purpose.

**Using the cluster administrative tools through a firewall**
The NLB control program, wlbs.exe, should only be used on NLB hosts or, when remote control operations have been enabled, only on a trusted, internal computer within the firewall. By default, remote control operations are disabled, and they must only be enabled if the NLB cluster has been protected by a firewall that blocks UDP control ports 1717 and 2504. Otherwise, unauthorized remote control packets could be delivered to NLB hosts and thereby cluster operations.

The NLB Manager administrative tool can safely be used on trusted computers outside the firewall. This tool uses a secure method of communication to access NLB hosts. NLB Manager uses WMI interface to manage NLB hosts. Please refer to WMI/DCOM documentation to see what ports to unblock to allow WMI/DCOM access from outside the firewall. Nevertheless, make sure that this tool is only executed on a trusted, remote computer.

**Using Kerberos Authentication in an NLB Cluster**
NLB does not use its own cluster-wide authentication mechanism for cluster administration. Instead, NLB management tools use an appropriate administrative account, which must be enabled with administrative privileges on each NLB host. If a domain account is used for this purpose, it will use Kerberos authentication to control access to NLB hosts.

**Using NLB to support VPN connections**
NLB can be used to load balance virtual private network connections using the PPTP protocol in Windows 2000 and using both the PPTP or IPSec protocols in Windows Server 2003. When using IPSec, some client sessions may be disrupted when a new NLB host joins the cluster. This issue has been corrected in Windows XP SP1 and in Windows Server 2003.

**Network Security**
To coordinate their actions, all NLB hosts communicate with each other by periodically exchanging heartbeat messages on a common subnet, which is also used to receive incoming client requests. This subnet must be physically protected from intrusion. Otherwise, unauthorized heartbeat messages could be delivered to NLB hosts and disrupt cluster operations. Note that NLB heartbeat messages use a uniquely assigned Ethertype (0x886F) which is not normally routed across subnets. However, the cluster administrator must ensure that unauthorized computers and devices which could emit invalid NLB heartbeat packets are not placed directly on the NLB subnet. The effects of these disruptions are described below in the subsection "Rogue Servers".

**Network Flooding**
NLB cluster hosts may be affected by denial of service attacks, which flood the cluster with invalid network packets. These attacks can create additional CPU and network load on the cluster hosts and thereby delay the handling of valid client requests. In addition, they can cause NLB hosts to increase their memory usage up to parameterized limits. These limits are adjustable by setting registry variables on each NLB host, as described in the Windows 2000 Resource Kit. In extreme cases, a high volume of invalid network packets can disrupt extant client connections and require affected clients to reconnect to the cluster. Note that the Windows network protocol stack and server applications, such as Web servers, also may be affected by denial of service attacks.

**Rogue Servers**
Rogue NLB servers on an NLB subnet could emit heartbeat packets that disrupt cluster operations. Disruptions can include impeding NLBs convergence process such that cluster hosts cannot be added and recovery for a failed host cannot be completed. In addition, disruptions can block some or all of NLBs service to clients. NLB subnets must be physically protected from intrusion by unauthorized computers and devices.

**Best practices**
To summarize, best practices for NLB cluster administrators:

- Cluster administrators should establish a common administrative account on all NLB hosts that have Administrator privileges. To simplify cluster management, it is preferable that a single domain or global group account be used for this

purpose.

- The NLB subnet must be physically protected from intrusion by unauthorized computers and devices to avoid interference from unauthorized heartbeat packets.

- NLBs remote control mechanism is disabled by default. It should remain disabled unless the administrator can ensure that the NLB subnet has been physically protected from intrusion and that UDP control ports 1717 and 2504 have been firewalled to prevent unauthorized remote control.

- If remote control has been enabled, remote control operations using the NLB control program wlbs.exe must only be performed from a trusted computer within the firewall.

- NLB Manager provides a secure method for remote cluster management and should be used instead of wlbs.exe whenever possible. NLB Managers optional host list file should only be saved to a file that is accessible by user accounts (such as the NLB cluster administrators account) that have local Administrator privileges.

# Summary of Security Attributes

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section outlines the various objects and their associated security attributes needed to ensure that NLB runs successfully. This section lists the minimum security requirements. If the security attributes are made more restrictive, NLB may not run. If the security attributes are less restrictive, it may result in malicious attacks being able to compromise the cluster or corrupt end-user data. We recommend that the security attributes on the objects not be changed from the default settings.

**Directory and file protection**

| Object | Description | Minimum recommended security attributes |
|---|---|---|
| **<filespec>** | **NLB Manager host list file** | **BUILTIN\Administrators: Full control** |

**System resources**

The cluster service uses other system resources that are protected by default.

| Object | Description | Minimum recommended security attributes |
|---|---|---|
| **HKLM*** | **HKLM registry hive** | **SYSTEM:Full control**<br><br>**BUILTIN\Administrators: Full control** |

# Windows Cluster Technologies: Remote Setup, Unattended Installations and Image-based Installations of Network Load Balancing

Updated: June 1, 2002

Applies To: Windows Server 2003 with SP1

Published: June 1, 2002

**In This White Paper**

Unattended Installation of NLB Clusters

Image-based Installations of NLB Clusters

Generating and Distributing a Virtual Hard Disk

Appendix A - Windows Cluster Technologies: Remote Setup, Unattended Installations and Image-based Installations of Network Load Balancing

**Overview**

You can install Network Load Balancing (NLB) clusters remotely in the following ways:

1. Using WMI to install and configure NLB cluster
2. Unattended installation of NLB clusters during the operating system install
3. Image-based installation of NLB clusters during the operating system install

**Unattended installation of the operating system and the cluster service**

To perform a clean install or to upgrade the operating system, you can either perform a hands-on installation (you must manually provide all of the answers required for setup), which this document will not address, or an unattended installation using a so-called answer file. Server clusters can be installed after the operating system installation is complete, by specifying certain switches in the answer file. Unattended installation of the operating system and server clusters is discussed in detail in the Unattended installation of NLB Clusters section of this document.

**Image-based installation of the operating system and the cluster service**

Another way to perform a clean install of the operating system is to use image-based installations, also known as disk cloning or simply cloning. Cloning is the fastest method of deploying Microsoft Windows Server 2003, Enterprise Server. Image-based installations are useful if you are deploying computers that have similar hardware and you want to perform quick installations with no or minimal manual interaction. You cannot use image-based installation to upgrade an operating system. Image-based installation is discussed in more detail in the Image-based installations of NLB Clusters section of this document.

# Unattended Installation of NLB Clusters

Updated: June 1, 2002

Applies To: Windows Server 2003 with SP1

Unattended installation of NLB clusters consists of the following steps:

1. Planning and Preparation for operating system installation
2. Preparing an answer file for unattended installation of the Windows Server 2003, Enterprise Edition operating system
3. Creating a Master Installation
4. Running winnt32.exe
5. Enabling and configuring Network Load Balancing

**Planning and Preparation for Operating System installation**
For detailed instructions on how to plan and prepare for Windows Server 2003, Enterprise Server operating system installation, please refer to the *Microsoft Windows XP Preinstallation Guide*. This document is located in Deploy.cab on the Windows Server 2003 CD. Although the Guide contains the instructions on preparing for Windows XP installation, the same instructions apply to Windows Server 2003, Enterprise Edition as well.

**Answer file**
To automate the Windows Server 2003 installation completely you must prepare an answer file, usually called unattend.txt, which contains all of the answers for a series of graphical user interface (GUI) dialog boxes. Unattend.txt tells Setup how to interact with the distribution folders and files you create and supplies Setup with all of the information that the end user provides during a typical Windows Setup. For example, Unattend.txt contains a FullName entry in the **[UserData]** section that instructs Windows Setup to prompt the end user to provide a full name.

Although the answer file for Setup is commonly called Unattend.txt, for a network pre-installation you can name the file anything you like. For a CD-based Setup, you must name the answer file Winnt.sif.

If you are using the OPK toolkit (available only to OEMs), you can create or modify a Unattend.txt file by using a tool called Setup Manager. You can also use any text editor to create or modify the answer file.

**Operating System Sections and Entries for Unattended Install**
A fully unattended operating system setup requires the following sections and entries:

| Required section | Required entries in that section | Comments |
|---|---|---|
| [Unattended] | UnattendMode<br><br>TargetPath | |
| [GuiUnattended] | AdminPassword<br><br>TimeZone | |
| [Identification] | JoinWorkgroup | You may instead specify JoinDomain, DomainAdmin, and DomainAdminPassword. |
| [LicenseFilePrintData] | AutoMode<br><br>AutoUsers | Requires **AutoUsers** if AutoMode = PerServer. |
| [Networking] | | Required to configure network protocols. |
| [UserData] | ComputerName | |

**[Unattended]**

This section contains entries for running Setup, such as whether to extend the partition on which you install the Windows operating system, specifies location of files necessary for installation during Setup, etc. You must instruct Setup to accept the EULA if you want your installation to be fully automated:

```
 [Unattended]
OemSkipEula = Yes
```

**[GuiUnattended]**
This section of Sysprep.inf contains entries for preparing the graphical user interface (GUI) for unattended Setup. To completely automate operating system setup you need to include the following entries:

```
[GuiUnattended]
AutoLogon = Yes
AdminPassword = *** <replace the asterisks with the actual password>
OemSkipWelcome = 1
OemSkipRegional = 1
TimeZone = 20 <specify your time zone here>
```

**[Identification]**
This section contains entries for specifying the network identification of a computer. If these entries are not present, Setup adds the computer to the default workgroup called WORKGROUP. If there is not enough information for this entry, Setup will prompt the end user to provide this information.

Prior to adding the first node to a cluster or adding additional nodes, all nodes must have joined a domain (instead of a workgroup) and be members of the same domain. When you create a cluster or join nodes to a cluster, you specify the domain user account under which the Cluster service runs. Therefore, you need to specify in this section which domain a destination computer should join, and provide the valid credentials under which to join

```
[Identification]
DomainAdmin = your_domain\user
DomainAdminPassword = ***** <replace the asterisks with the actual password>
JoinDomain = your_domain
```

**[LicenseFilePrintData]**
This section contains entries for installing licensing information for the Windows Server 2003 family.

```
[LicenseFilePrintData]
AutoMode = PerSeat
```

**[Networking]**
This section contains no entries. However, to configure network protocols during an unattended setup, you must include the **[Networking]** section name in your answer file. In addition, you must include additional sections that describe your network adapters, protocols to be installed, and static IP address information.

If you decide to change your Network Load Balancing model, add, remove or modify virtual clusters during the unattended installation, you must make sure you have all of the required information (new cluster virtual IP addresses, additional static IP addresses, etc.) available. You will need to provide all of that information in the [Networking] section of the answer file.

Depending on the particular scenario in which you use NLB clusters the [Networking] section can contain different sets of information. For example, if you use multiple network adapters, you need to configure them both here; otherwise you only need to configure one network adapter. If you use multiple virtual clusters, you also need to configure the network adapter(s) and bind NLB in this section. Below is an example of a [Networking] section that configures two network adapters that are configured for use with NLB later in the [params.MS_WLBS.Adapter] sections.

For a complete list of instructions for configuring and enabling NLB and NLB best practices, please refer to Windows Advanced Server 2003 Online Help/Availability and Scalability/Network Load Balancing.

Use the following entries in unattend.txt to enumerate your network cards:

```
[NetAdapters]
;list your network adapters here
Adapter01 = params.Adapter01
Adapter02 = params.Adapter02
```

Next, you need to uniquely identify each network adepter. You can either use the INFID entry where you need to specify the Plug and Play IDs of your network adapters or the NetCardAddress entry to specify MAC addresses. You need to run a special tool called pnpids.exe to retrieve the PnP IDs for your network cards. For computers with multiple adapters of the same type (that is, the Plug and Play ID for each is the same), you must specify the **NetCardAddress** or PCI location information. If you do not specify the **NetCardAddress** or PCI location, only the first adapter enumerated/detected that matches the PnP ID receives

the answer file entries.

If you specify the **NetCardAddress** or PCI location, Setup does not use the INFID entry because it is the least specific entry.

Therefore, we recommend that you simply identify your network cards by their MAC addresses as follows:

```
[params.Adapter01]
NetCardAddress = 0x0002A5D0510F
[params.Adapter02]
NetCardAddress = 0x000476D5F57D
;Install Client for MS Networks
[NetClients]
MS_MSClient = params.MS_MSClient
[params.MS_MSClient]
;Specify which network protocols to install
[NetProtocols]
MS_TCPIP = params.MS_TCPIP
;TCP/IP properties
[params.MS_TCPIP]
AdapterSections = params.MS_TCPIP.Adapter01, params.MS_TCPIP.Adapter02
```

Now we need to configure both network cards with static IP address information since NLB does not allow DHCP-assigned addresses.

```
;Adapter01 is used for intra-cluster communication.
 [params.MS_TCPIP.Adapter01]
DHCP = No
IPAddress = 172.24.23.91
SpecificTo = Adapter01
SubnetMask = 255.255.0.0
DNSServerSearchOrder = 157.5.0.1,157.6.0.2
WINS = Yes
WINSServerList = 157.5.0.1,157.5.1.2
;Adapter02 represents a public network
[params.MS_TCPIP.Adapter02]
DefaultGateway = 157.6.8.1
DHCP = No
IPAddress = 157.5.4.1
SpecificTo = Adapter02
SubnetMask = 255.255.252.0
DNSServerSearchOrder = 157.5.0.1,157.6.0.2
WINS = Yes
WINSServerList = 157.5.0.1,157.5.1.2
```

**[UserData]**
This section contains entries for specifying user settings during setup:

```
[UserData]
ComputerName = SV-NODE1
FullName = User Name
OrgName = Organization Name
ProductKey = 11111-22222-33333-44444-55555
```

Of course you need to replace all of the names, passwords and the cluster IP address with real ones.

**NLB-specific Sections and Entries**
**[params.MS_WLBS]**
This section contains parameters for configuring NLB and binding NLB to network adapters. For unique Configuration/Binding, see the [NetBindings] section below.

```
[params.MS_WLBS]
AdapterSections=params.MS_WLBS.Adapter01,params.MS_WLBS.Adapter02
[params.MS_WLBS.Adapter01]
SpecificTo=Adapter01
ClusterIpAddress=172.24.23.10
ClusterNetworkMask=255.255.252.0
IGMPSupport=0
MulticastSupportEnable=1
RemoteControlEnabled=1
HostPriority=1
ClusterModeOnStart=1
DedicatedIPAddress=172.24.23.91
```

```
DedicatedNetworkMask=255.255.255.0
Ports=1,65535,Both,Multiple,Single,Equal
[params.MS_WLBS.Adapter02]
SpecificTo=Adapter02
ClusterIpAddress=172.24.23.10
ClusterName = nlbcluster.domain.com
ClusterNetworkMask=255.255.252.0
IGMPSupport=0
MulticastSupportEnable=1
RemoteControlEnabled=1
HostPriority=1
ClusterModeOnStart=1
DedicatedIPAddress=157.5.4.1
DedicatedNetworkMask=255.255.252.0
Ports= 1,65535,Both,Multiple,Single,Equal
```

What each line means:

ClusterIpAddress - This address is a virtual IP address and it must be set identically for all hosts in the NLB cluster

ClusterName - Specifies a full Internet name for the NLB cluster

ClusterNetworkMask - Specifies the subnet mask for the NLB cluster IP address

IGMPSupport - Specifies whether or not to use IGMP support to prevent switch flooding

MulticastSupportEnable - Specifies whether or not to use a multicast MAC address for NLB cluster operations

RemoteControlEnabled - Specifies whether or not to enable remote-control operations

HostPriority - Specifies hosts unique priority ID in the NLB cluster

ClusterModeOnStart - Specifies whether a host joins the NLB cluster upon startup or waits for an explicit command to do so

DedicatedIPAddress Specifies hosts unique IP address

DedicatedNetworkMask - Specifies the subnet mask for the dedicated IP address

Ports - Specifies rules for distributing traffic among NLB cluster hosts according to protocol and destination ports

For a complete list of all available NLB configuration options in the answer file, please refer to the following document: *Microsoft Windows XP Preinstallation Guide*. This document is located in Deploy.cab on the Windows Server 2003 CD.

**[NetBindings]**
This section contains entries for disabling, enabling, and demoting binding rules for network components such as services, protocols, and adapters.

[NetBindings]

Disable=MS_WLBS,Adapter01

Enable=MS_WLBS,Adapter02

For more information about unattend.txt, please refer to the following document: *Microsoft Windows XP Preinstallation Guide*. This document is located in Deploy.cab on the Windows Server 2003 CD.

**Creating a Master Installation**
There are no cluster-specific items in this step. Please refer to the *Microsoft Windows XP Preinstallation Guide*, located in Deploy.cab on the Windows Server 2003 CD for detailed instructions on how to create a Master Installation.

**Running winnt32.exe**
You can run Winnt32.exe from a command prompt to start Windows Setup.

For a complete list of the Winnt32.exe command-line options, see Winnt32.exe Command-Line Options topic in the *Microsoft Windows XP Preinstallation Guide*. This document is located in Deploy.cab on the Windows Server 2003 CD. Although the Guide contains the instructions on preparing for Windows XP installation, the same instructions apply to Windows Server 2003, Enterprise Edition as well.

To install Windows from a network share, boot the computer using your Windows Server 2003 CD (or any other startup media) and then connect to the desired network location. Placing the distribution share and the configuration set on the

network adds considerable flexibility to the pre-installation process.

To run Setup using Winnt32.exe

Prepare an Unattend.txt file as part of building a configuration set as described above.

1. Start the computer where you want to install Windows.

2. Click **Start**, click **Run**, and then type:

   path_to_winn32**winnt32** /**unattend**:filename

   where:

   path_to_winnt32

   Specifies the path to the location of Winnt32.exe. For example, \\server\share\Lang\Eng\sku\pro\x86\I386.

   filename

   Specifies the name of the answer file, which contains answers to installation questions you want to automate. The value of *filename* is usually Unattend.txt.

**Installing and Configuring NLB**

If you specified all of the information in the [params.MS_WLBS] section of unattend.txt as described in section NLB-specific Sections and Entries above, you need to do nothing further you have already installed and configured an NLB cluster with at least one host in it. You can now use NLB Manager or WMI to add hosts to this cluster, or you can add hosts to the cluster when you perform an unattended install on those computers with the [params.MS_WLBS] section of the answer file configured as described above.

# Image-based Installations of NLB Clusters

Updated: June 1, 2002

Applies To: Windows Server 2003 with SP1

**Image-based Installations of NLB Clusters**
Image-based installations, also known as disk cloning or simply cloning, is the fastest method of deploying Windows Server 2003, Enterprise Server. Image-based installations are useful if you are deploying computers that have similar hardware and you want to perform quick, clean installations with minimal end user interaction

Cloning NLB Clusters consists of the following steps:

1. Building a master installation on a master computer. Building a master installation includes installing and configuring the operating system and any software and drivers you need to include on your virtual hard disk.

2. Preparing the master installation with the Sysprep tool. This includes configuring and running the Sysprep tool on the master computer.

3. Generating a virtual hard disk of the master installation with the disk-imaging tool. This includes saving each virtual hard disk to a permanent storage location.

4. Loading virtual hard disks on destination computers that will make up a cluster.

**Using SYSPREP to prepare for imaging**
**Building a Master Installation**
You need to setup a master computer which you will use to build a master installation and later to create a virtual hard disk.

Building a master installation includes installing and configuring the operating system and any software and drivers you need to include on your virtual hard disk.

**Prepare the master installation.**
After you have prepared a master installation on the master computer, you need to prepare a virtual hard disk for cloning. Microsoft provides a tool called sysprep that allows you to prepare an image for cloning. The tool can be found on **the Windows Advanced Server 2003 CD in the \support\tools directory**. When you run sysprep on the master computer, you can supply one of the following two switches: **-factory or reseal**.

You can use Factory mode to install additional drivers and applications at the stage after the reboot that follows Sysprep. Normally, running Sysprep as the last step in the pre-installation process prepares the computer for delivery. When rebooted, the computer starts Mini-Setup. By running Sysprep with the -factory option, the computer reboots in a network-enabled state without starting Mini-Setup. In this state, Factory.exe processes its answer file, Winbom.ini, and performs the following actions:

1. Copies drivers from a network source to the computer

2. Starts Plug and Play enumeration

3. Stages, installs, and uninstalls applications on the computer from source files located on either the computer or a network source

4. Adds customer data

When finished, run Sysprep with the -reseal option to prepare the virtual hard disk for cloning.

For example, you can create a master installation that contains a minimal set of drivers, run sysprep -factory, create an image of the installation, and copy the image to multiple destination computers. If any destination computers require additional drivers, run sysprep -factory on the destination computer and load those drivers at that time.

For more information about the Factory mode and winbom.ini file, refer to *Microsoft Windows XP Preinstallation Guide*. This document is located in Deploy.cab on the Windows Server 2003 CD.

If you do not need to install any additional drivers or applications on the destination computers, run sysprep in the Reseal mode.

**Sysprep and Sysprep.inf Answer file**
To completely automate NLB cluster installation, you will need to use the sysprep.inf file which is an answer file used by sysprep during and after Mini-Setup.

**Required Sections and Entries in sysprep.inf**
A fully unattended Setup requires the following sections and entries:

| Required section | Required entries in that section | Comments |
|---|---|---|
| [Unattended] | UnattendMode<br><br>TargetPath | |
| [GuiUnattended] | AdminPassword<br><br>TimeZone | |
| [Identification] | JoinWorkgroup | You may instead specify JoinDomain, DomainAdmin, and DomainAdminPassword. |
| [LicenseFilePrintData] | AutoMode<br><br>AutoUsers | Requires **AutoUsers** if AutoMode = PerServer. |
| [Networking] | | Required to configure network protocols. |
| [UserData] | ComputerName<br><br>FullName | |

Please refer to the Operating System Sections and Entries for Unattended Install section of this document for an explanation of what each of these entries is used for.

**NLB-specific Sections and Entries**
See section NLB-specific Sections and Entries for NLB specific configuration options in the sysprep.inf answer file.

# Generating and Distributing a Virtual Hard Disk

Updated: June 1, 2002

Applies To: Windows Server 2003 with SP1

**Creating a Virtual Hard Disk**
After you have prepared a virtual hard disk for cloning, you need to create a virtual hard disk of your master installation with a disk-imaging tool and save the virtual hard disk to a permanent storage location. You can use a third-party disk imaging software or a Microsoft technology called iBIG. If you are using a third-party product, refer to the accompanying documentation on how to create and distribute a virtual hard disk.

**Startup Media**
Before you can load virtual hard disks on destination computers, you need some kind of startup media to boot your computers from. Startup media contains the system files and device drivers that are necessary to start a computer so that the primary hard disk is accessible but not in use. Startup media might also contain network adapter and network drivers, CD and DVD device drivers, disk configuration tools, and scripts or batch files. You can use a floppy, CD, DVD or network boot as your startup media, depending on the capabilities of your destination computers.

If you use third-party disk imaging products, they often provide tools to create different startup media. Otherwise you need to create your own.

Follow these guidelines when creating your startup media:

- Your startup media must provide network support if you are distributing virtual hard disks across a network.
- Your startup media must provide CD or DVD device support if you are distributing virtual hard disks on media and you are using a floppy disk as your startup media.
- Your startup media must support the tools you need to copy a virtual hard disk from a storage location to a destination computer. For example, if your startup media is an MS-DOS startup disk then you need to use MS-DOS tools to copy the virtual hard disk onto the destination computer.

For more information about choosing and creating startup media, refer to the Microsoft Windows Server 2003 Corporate Deployment Tools User's Guide (Deploy.chm). Deploy.chm is included in the Deploy.cab file in the Support folder on the Windows Server 2003 operating CD.

**Distributing Virtual Hard Disks**
After an image (or images) has been created and placed on a distribution share (or distribution media such as CD or DVD) and you have a startup media to boot your destination computers, you are ready to distribute the images to destination computers.

You need to make sure that your cluster hardware and networks are set up as described in the Windows Advanced Server 2003 Online Help/Availability and Scalability/Cluster Servers. All of your cluster nodes that you will be installing already have to be connected to the shared storage.

You can load virtual hard disks to all of your cluster nodes simultaneously. Many third-party tools support multicast image distribution. You can also use iBIG to distribute virtual hard disks to your cluster nodes.

After you have distributed virtual hard disks to destination computers, sysprep runs Mini-Setup. After Mini-Setup finishes, you should verify that all of the nodes have successfully joined the cluster. Open NLB Manager to see which nodes participate in the cluster, and whether everything is up and running. If it is, your cluster is ready.

# Appendix A - Windows Cluster Technologies: Remote Setup, Unattended Installations and Image-based Installations of Network Load Balancing

Updated: June 1, 2002

Applies To: Windows Server 2003 with SP1

**Sample sysprep.inf file**

This is a sample sysprep.inf file that can be used for unattended installation of a server cluster.

All computer names, cluster name, user data, passwords and IP addresses need to be replaced with real ones before you can use this file

# Print Server Upgrade, Migration, and Interoperability

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Microsoft® Windows® 2000 introduced a dramatic new version of the Microsoft Windows NT® operating system. The printing subsystem was among the many areas of Windows 2000 that experienced substantial changes from previous versions of Windows NT. Even though the benefits of these changes have proven their worth in terms of the stability and robustness of the operating system, they come at a price. During the upgrade and migration to Windows 2000 or Windows Server 2003, companies often find themselves in a mixed environment that includes Windows NT 4.0 as well as Windows 2000, Windows XP, or the Windows Server 2003 family.

Adding to the complexity of the interoperability impact is the fact that network printing involves rendering of print jobs using both local and remote (client and server) driver functions and settings. For this reason, network printing in an environment with Windows NT 4.0 and Windows 2000, Windows XP, or the Windows Server 2003 family can present challenges to corporations.

The purpose of this document is to help explain the procedural and environmental conditions that exist in a network printing environment, especially as they relate to mixed versions of the Windows NT operating system. Additionally, various methods for dealing with these problems are discussed.

Some of the interoperability concerns that arise in a mixed environment of Windows NT 4.0 and later versions of Windows are rooted in changes to the printer driver architectural model. This document examines the move from kernel-mode to user-mode process space, as well as the upgrade of the Microsoft Universal Printer Driver. Other issues related to device limitations in the printer hardware are presented only when interoperability problems arise in the driver model. This document also reviews how device font support affects the transitional period for customers upgrading from Windows NT 4.0.

It is important to note that this discussion focuses on the transitional period that corporations face due to the challenge of upgrading tens of thousands of clients in order to migrate to Windows 2000 or later. The benefits of Windows 2000 and later printing improvements are not fully accessible to mixed or legacy clients. This paper assumes the customers' goal is to achieve a network printing environment in which all clients and servers are running Windows 2000 or later.

**In This White Paper**

Windows 2000 and Windows Server 2003 Printing Architecture

Changes to Printer Drivers in Windows 2000

Upgrading to Windows 2000 Server or the Windows Server 2003 Family

Migrating to Windows 2000

Point and Print for Windows 2000

# Windows 2000 and Windows Server 2003 Printing Architecture

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have a mixed environment that includes Windows NT, Windows 2000, or the Windows Server 2003 family, it can be useful to understand the Windows print subsystem to identify interoperability issues that may arise. The printing architecture of Windows 2000 (and later versions of Windows) consists of a print spooler and a set of printer drivers. By calling device-independent Win32® printing and Graphics Device Interface (GDI) functions, applications can create print jobs and send them to any of a variety of devices, including laser printers, vector plotters, raster printers, and fax machines. Printer drivers include a user interface (UI) component that allows users to control a printer's selectable options.

An application's calls to Win32 GDI functions are passed to the GDI graphics engine, which either spools the drawing instructions as an enhanced metafile (EMF) or, in conjunction with a printer driver, renders a printable image that can be sent to the spooler. Spooler components interpret EMF files, and they can insert page layout information and job control instructions into the data stream. The spooler then sends the data stream to the serial, parallel, or network port driver associated with the target printer's I/O port. The device interprets the job, which is formatted in printer description language (PDL) for the device, and outputs the printed document.

Spooler and driver components are designed to be replaceable so that hardware vendors can easily add support for new hardware.

# Changes to Printer Drivers in Windows 2000

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Printer drivers are the software that allows application data to be converted into a format that a print device can use to create a printed page. In Windows NT 4.0, all printer drivers ran in kernel mode. These drivers are referred to as version 2 drivers in the Windows printing environment. Windows 2000 and later support user-mode drivers natively and kernel-mode drivers solely for backward compatibility. Microsoft moved to user-mode drivers (also called version 3 drivers) for system reliability and robustness. With a kernel-mode driver, an error can crash the entire server, whereas the effect of an error with a user-mode driver is restricted to the process the driver runs in—usually the spooler. Restarting the spooler is much faster than rebooting the entire system. In addition, a server's additional services remain available to users when the spooler is down. Windows Server 2003 provides for automatic recovery of the Spooler service by default. (A setting in the service control manager)

Moving printer drivers from kernel mode to user mode wasn't the only change introduced with Windows 2000. The Microsoft Universal Printer Driver (Unidrv) was also introduced. This printer driver core replaced the Raster Device Driver (RASDD) interface used in Windows NT 4.0 and earlier versions. The concept behind Unidrv is that independent hardware vendors (IHVs) are not required to write an entire driver, but instead can use the core printing functionality of the Unidrv "engine," and only need to provide device-specific functionality through the use of a minidriver. A minidriver is typically a customization file, or possibly a plug-in, that allows special rendering functions or customized UI options. The core printer control language (PCL) engine (Unidriv.dll) and the PostScript engine (PScript5.dll) both allow the use of minidrivers. The customization file for a Unidrv minidriver is a .gpd file, and for a PostScript minidriver it is a .ppd file.

Windows Server 2003 includes drivers for over 3,800 print devices. Although these drivers are supplied by Microsoft as part of Windows Server 2003, most were provided to Microsoft by the respective printer manufacturer. These so-called inbox drivers ship in the product itself. Although these standard print drivers are adequate for the majority of corporate printing devices, printer manufacturers may choose to make their own drivers available to customers instead of using Unidrv. These drivers are often referred to as monolithic, because they are not implemented as UniDrv minidrivers. (Many manufacturers are beginning to develop all of their drivers using the UniDrv model rather than the traditional monolithic model.)

To summarize, there are several driver types:

- Kernel mode (version 2) or user mode (version 3)
- PostScript (PS) or PCL
- Minidriver or monolithic

**Note**

Drivers can be a combination of these types—for example, kernel-mode PCL driver, user-mode monolithic driver, PostScript minidriver. (Drivers that ship with Windows 2000 or Windows Server 2003 are all user mode.)

All of these driver types are available from the printer manufacture depending on the type of device. The inbox drivers supplied with Windows 2000 and later are also supplied by the printer manufacturer and distributed with their permission. All drivers supplied by Microsoft with Windows 2000, Windows XP, and Windows Server 2003 are Unidrv or PostScript minidrivers and are compatible across these platforms.

Independent hardware manufacturers (IHV) also provide minidrivers that do not ship on the Windows CD.

When you understand the differences among the types of printer drivers, it becomes more clear how mixing and matching can cause problems in a network printing environment. Because Windows NT 4.0 can run only kernel-mode print drivers, and Windows 2000 and Windows Server 2003 can support both user-mode and kernel–mode drivers, resolving an incompatibility sometimes involves modifying the servers running Windows 2000 or Windows Server 2003 so they match the Windows NT 4.0 server.

# Upgrading to Windows 2000 Server or the Windows Server 2003 Family

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Prior to upgrading to Windows 2000 or Windows Server 2003 from Windows NT 4 Server, many IHVs recommend uninstalling all IHV printer drivers and reinstalling the latest versions of those drivers for Windows 2000 and the Windows Server 2003 family of products. Microsoft recommends that you use the Fixprnsv.exe utility that is located in the \Printers\Fixprnsv directory on the Windows Server CD. This utility will help identify known bad drivers and replace them with compatible drivers prior to an upgrade. If no replacement is available on the Windows CD, the utility prompts you to obtain an updated driver from the printer manufacturer. Microsoft recommends that you follow the IHV directions to update the print drivers on your system, and then use the Fixprnsv.exe utility to locate any remaining print drivers that could be problematic during the upgrade.

The following sections describe the behavior if drivers are not uninstalled prior to upgrading to Windows 2000 or the Windows Server 2003 family operating system.

**Upgrade Process for Drivers**
When upgrading from Windows NT 4.0 to Windows 2000 or later, there are a number of possible actions with respect to printer drivers. Each situation is described in this section.

- Windows NT 4.0 inbox drivers (PCL and PostScript) that shipped with the operating system are upgraded to the new version of these drivers in Windows 2000 or the Windows Server 2003 family. (The same replacement/update occurs when upgrading Windows 2000 Server to the Windows Server 2003 family.)

- IHV drivers (PCL or PostScript) with exact driver model names matching Windows 2000 or the Windows Server 2003 family driver names are upgraded to inbox drivers with no user intervention.

- Drivers that are blocked for stability reasons are not used. Printers that use these drivers are removed during the upgrade process. If a printer is connected directly to a computer and has a recognized Plug and Play ID, Windows searches for a suitable driver. If one is found, the printer is installed during the upgrade as a new printer.

- Drivers that are not blocked and do not have name matches are carried through the upgrade unchanged.

**Windows NT 4.0 Inbox Drivers**
All Windows NT 4.0 PCL drivers (RASDD) are upgraded to the latest Unidrv drivers as part of the upgrade process. (UNIDRV5 is used for Windows 2000 and UNIDRV5.1 for the Windows Server 2003 family.) PostScript drivers that were shipped with Windows NT 4.0 are upgraded to PostScript version 5.0 in Windows 2000 or PostScript version 5.2 in the Windows Server 2003 family. Both versions 5.0 and 5.2 support PostScript levels 1, 2 and 3.

**Windows 2000 Inbox Drivers**
All Windows 2000 inbox drivers are updated to the Windows Server 2003 version as well.

| **Note** |
| --- |
| Drivers that are changed (updated to a driver with a new name) are no longer associated with the additional drivers that were used on the original server. (Additional drivers are those added through the **Additional Drivers** option in the Printers dialog box.) After a Windows 2000 or later print server is configured, the additional drivers—such as those for Windows NT as well as Windows 95, Windows 98, and Windows Millennium Edition clients—need to be reinstalled accordingly. The association of additional drivers is done per model, so it is only necessary to install these down-level drivers once per model driver, not for each printer queue. |

**IHV Drivers with Matching Names**
IHV Windows NT 4.0 drivers are upgraded to Windows 2000 or the Windows Server 2003 family drivers with no user intervention if the driver model name matches the existing Windows NT 4.0 driver name.

In this situation, the IHV driver is treated exactly the same as the Microsoft driver. Due to interaction problems between Windows 2000 drivers and Windows NT 4.0 drivers in Point and Print environments, many IHVs recommends that their

Windows NT 4.0 driver be reloaded following the upgrade. This issue applies to users who plan to use Point and Print between Windows NT and Windows 2000, Windows XP, and the Windows Server 2003 family of products. (For more information and supported configurations, see "Point and Print for Windows 2000" later in this paper.)

**Blocked IHV Drivers (User Intervention Required)**

Microsoft designed the upgrade path from Windows NT 4.0 so that if the new operating system has a newer driver available, the old driver is replaced. If Windows cannot find a newer driver version, and the driver is not identified with any known problems in Windows 2000, Windows XP, or the Windows Server 2003 family of products, the existing driver is used.

A list of known problematic drivers is maintained in the system file, Printupg.inf. Drivers in this list are not upgraded during the operating system installation. Instead, a newer version of the driver from the IHV must be installed, or an alternate driver selected from the inbox drivers available in Windows 2000 (and later versions of Windows). The information found in Printupg.inf can be helpful in identifying whether a new version from an IHV is blocked or not. Additionally, the Fixprnsrv.exe utility can be used to replace known bad drivers with inbox substitutes if available. If a compatible driver cannot be located and installed, Fixprnsv.exe reports that and refers the user to an IHVs Web site. By running Fixprnsv.exe prior to upgrade, you can identify printers that need to be removed during the upgrade in advance so that sudden service disruptions are avoided.

| **Note** |
| --- |
| Drivers are blocked either because Microsoft has determined, through testing, that they cause substantial instability of the operating system, or because the IHV has requested they be blocked based on their own testing and available updates. |

**Non-Blocked IHV Drivers (No User Intervention Required)**

Certain Windows NT 4.0 drivers are not blocked and do not match the driver name of an inbox driver. These drivers are not altered for replaced during the upgrade process. Microsoft recommends using the Fixprnsv.exe utility to identify drivers that should be replaced. For drivers that are not blocked (either because they are not in the Printupg.inf file or because they have a later date than the date in Printupg.inf), Fixprnsv.exe takes no action.

# Migrating to Windows 2000

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Unlike the previous section, in which print server upgrades were discussed, this section deals with the common practice of deploying a new (replacement) Windows 2000 or Windows .NET print server to replace an existing Windows NT 4 or Windows 2000 print server. For the purposes of this discussion, the migration process can be used to either replace a print server (move printers from one server to a new server), or to consolidate print servers (moving printers from multiple print servers to a single print server) Administrators have two main methods for moving printers from one Windows print server to another: manual or automated. It is possible to perform a partially-automated migration of printers as well. This is covered in the following sections also.

**Manual Print Server Migration**

The manual migration process is very straightforward. After you document the current printing environment on the existing Windows print server (that is, the ports, printer names, share names, driver models and versions, and so on), you can recreate each printer manually on the new Windows 2000 print server using the Add Printer Wizard. The advantage to this method is that you can create all of the queues using the latest corporate standards (such as for naming) and the newest driver versions available. The most obvious disadvantage to this method is that it can be very time consuming for large print environments– and tends to be more error-prone than an automated method.

**Automated Print Server Migration**

Microsoft has developed a utility call Print Migrator. In the first two releases of this utility, printers can be moved from one server to another as long as both servers used the same operating system. With the release of version 3, the following key features will be added:

- **Cross-platform support:** Print Migrator 3 lets you move printers from a Windows NT 4 print server to Windows 2000 or Windows. NET Server print servers.
- **Cluster support:** You can migrate printers from a standalone Windows NT 4 or Windows 2000 print server to a clustered print server running Windows 2000 or Windows . NET Server.
- **LPR port conversion:** During backup and restore operations you can convert LPR ports to standard TCP/IP printer ports.

Clearly, it's faster and more accurate to back up and restore these printers automatically. It is, however, important to note that the printers are moved to Windows 2000 or Windows .NET Server without changing their driver versions. That is, drivers previously used on a Windows NT 4.0 print server are created as kernel-mode (version 2) drivers on Windows 2000 or Windows .NET Server. Kernel-mode drivers in use on Windows 2000 are also preserved. As detailed in the "Point and Print" section later in this document, this process provides a much higher level of interoperability with any legacy (Windows NT 4) clients that may still be using print services from a server.

| **Note** |
| --- |
| For more information about the capabilities and limitations of Print Migrator 3.0, see its product documentation.<br><br>Print Migrator 3.0 is available via the Microsoft Print Server web site. See Related Links section below for additional information. |

**Partially-Automated Server Migration Method**

Administrators can migrate printers using a combination of the manual and automated methods. There are several scriptable actions supported by Windows 2000, Windows XP and Windows .NET Server that perform some of the necessary tasks. These scripts are documented in the Windows resource kits.

# Point and Print for Windows 2000

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section describes the Point and Print feature, explains methods of installing printer drivers and shared printers for Point and Print, and discusses using Point and Print.

**Using Printer Drivers and Point and Print**

Point and Print refers to the capability of allowing a Windows user to create a connection to a remote printer without providing disks or other installation media. All necessary files and configuration information are automatically downloaded from the print server to the client.

Clients that use the same driver architecture as a print server do not require any additional drivers to be installed on the print server for full support. Other clients require that you install the appropriate driver on the print server so that updates can be downloaded automatically at connection time. For example, a Windows 2000 print server using a version 3 (user-mode) driver for a shared printer does not require any additional drivers to be installed to provide full Point and Print support for Windows 2000 and later clients, because those clients also support the version 3 drivers. However, to vend version 2 drivers for a Windows NT 4.0 client, a Windows 2000 print server requires the appropriate version 2 driver, which can be installed as an using the Additional Drivers option. Other platform architectures, such as Intel x86, Intel IA64 or Alpha, also require specific drivers to be installed. For more information about network printing, including point and Print driver installation, see the *Windows Server Resource Kit*.

Generally, there are four Point and Print methods commonly used by clients to connect to a shared network printer hosted on a Windows 2000 or later print server:

- **UNC path.** From the **Start** menu, choose **Run**, type **\\PrintServer\Printer**, and then click **OK**.
- **Add Printer Wizard.** Select **Network printer** in the wizard, and then specify the path to the shared printer.
- **Drag and Drop.** Use Net View or the **Run** command from the **Start** menu to view shared printers on a remote print server; for example, \\PrintServer. Then drag the desired printer icon into the local workstation's **Printers & Faxes** folder.
- **Double-click.** Use Net View of the Run command as above to view shared printers, and then double-click the shared printer icon to install the printer.

| **Note** |
| --- |
| Windows 2000 and later operating systems also support command line and scriptable interfaces for printer installation and configuration, such as PRNADMIN.DLL or any Microsoft Visual Basic® scripts that use the Windows Management Instrumentation (WMI) print provider. For more information, see the Windows Server resource kits. |

**Point and Print from Windows 2000 Professional to Windows 2000 Server**
**Expected Driver Behavior**

In a Point and Print installation, the printer properties and settings from the server are passed to the client machine. This configuration includes settings for installable options and certain job-processing features. Clients have a local cache of printing preferences, which determine how a job is printed. To perform remote administration on the server, in which the actual device settings or global printing preferences are modified, a user must be logged on with credentials that include administrative rights on the remote server. If the user has administrative rights on the server, the server's printer object can be modified through the Advanced and Device Settings tabs. This functionality does not exist on down-level clients such as Windows 95 or Windows 98.

**Point and Print from Windows NT 4.0 to Windows 2000 Server**
**Expected Driver Behavior**

**Figure 1. Additional Drivers**

Setting up printer drivers on a Windows 2000 server for Point and Print support for Windows NT 4.0 is generally the same as for Windows Server 2003. However, there are a couple of specific differences.

As Figure 1 shows, the **Additional Drivers** dialog box contains three entries under the Intel environment for Windows 2000 drivers, **Windows 2000 or XP**, **Windows 95, 98 and Me** and **Windows NT 4.0 or 2000**. They differ as follows:

If **Windows 2000 or XP** is checked before any additional drivers are loaded, the server is currently running a user-mode driver written specifically for the Windows 2000 or Windows XP platform. That driver cannot be vended to a Windows NT 4.0 client for Point and Print functionality. Microsoft refers to these drivers as version 3 drivers.

If **Windows NT 4.0 or 2000** is checked, the driver running on the server is a Windows NT 4.0 driver that is running under Windows 2000. Microsoft calls these drivers version 2 (or kernel-mode) drivers. In this case, no additional drivers are required to support Point and Print for Windows NT 4.0 clients along with Windows 2000 or XP client computers.

**Server Running Version 3 Driver**

When a version 3 printer driver written specifically for the Windows 2000, Windows XP or Windows Server 2003 platform is installed on a server, a Windows NT 4.0 (version 2) driver with the same model name must be installed in order to support Point and Print for Windows NT 4.0 clients. Changes in the internal data structures that were made to the version 3 Unidrv.dll file might cause a problem in sharing or preserving settings between the clients and the server. This problem can be manifested in two primary ways:

- The Print Server might have new or advanced settings that are simply not visible from a client printer properties dialog box.
- The client properties might not be correctly interpreted by the print server, causing them to be lost.

As a result, the Point and Print connection allows the client to print but might not allow modification of certain device settings or preferences if they do not match those on the server.

| **Note** |
| --- |
| Incompatible data structures can cause certain printer settings—such as Print Text as Graphics or Print Optimization—to be lost between the Windows NT 4.0 and Windows 2000 machines. Additionally, settings such as paper tray assignments and media types might not be preserved between driver models. |

Microsoft and Adobe Systems have developed the latest version of the PostScript driver through a joint development program. Adobe has compiled the latest version of the PostScript driver core for Windows NT 4.0 and later versions of Windows. As a result, the same PSCRIPT core code can be run by Windows NT 4.0, Windows 2000, Windows XP, and the Windows Server 2003 family. By using common PostScript minidrivers (.PPD) files, a higher level of interoperability may be obtained. To increase compatibility, Microsoft recommends that PostScript drivers be considered in mixed environments that include Windows NT with Windows 2000 or the Windows Server 2003 family systems. Another benefit of this situation is that Windows 2000 and later systems run version 3 (user-mode) drivers; only the legacy Windows NT 4.0 machines run the version 2 (kernel-mode) printer drivers. Using PostScript version 5.0 and later is recommended.

**Server Running Version 2 Driver**

When a server has a version 2 driver (Windows NT 4.0) installed as its primary driver, no additional drivers need to be installed to support Point and Print on Windows 2000, Windows XP or Windows NT clients. Further, because the driver being vended to the clients is the same one used by the server, there are virtually no compatibility issues between the Windows Server 2003 server and Windows NT 4.0 clients. After the Version 2 driver is installed on the Windows Server 2003, and the installed printer

is shared through the Sharing tab in the Printer Properties dialog box, Windows 2000 and Windows NT 4.0 clients can connect to the shared printer by either method described above.

On the **Sharing Tab** (accessed through the **Additional Drivers** button), all drivers listed as **Windows NT 4.0 and Windows 2000** are version 2 drivers.

If driver incompatibility or mismatches cause problems and a PostScript solution is not available, Microsoft recommends using these drivers as a solution to support Point and Print between Windows 2000 (and later versions) and Windows NT.

If you are unsure about Point-and-Print compatibility among the different versions of Windows operating systems, contact the manufacturer of your print hardware and ask for drivers that work with a Windows Point-and-Print connection.

**Point and Print from Other Windows Versions to Windows 2003**
**Expected Driver Behavior**
The behavior for Point and Print from Windows Server 2003 to Windows 95, Windows 98 or Windows Millennium Edition differs from that of Windows NT and later versions. No configuration settings are vended from the server to the client. The client user must configure the driver to match the physical device after installation. Additionally, after a driver is downloaded initially, a client running Windows 95, Windows 98, Windows Millennium Edition does not receive driver updates from the print server. The same connection methods are available: drag and drop, the Add Printer Wizard, referencing the UNC path, or double-clicking the shared printer icon.

# Customer Actions Moving Forward

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The methods listed above are intended to provide organizations with the maximum interoperability during transitional periods when clients and print servers are running both Windows Server 2003 and Windows NT.

It is strongly recommended to minimize the transitional period during which your environment mixes Windows NT with Windows Server 2003 or Windows XP clients and servers. The highest levels of network printing functionality and interoperability are achieved in environments with clients and servers running Windows 2000 and later.

To help minimize the impact during migrations and upgrades, try the following:

- **Upgrade servers and associated client bases at the same time or close together.** In a very large organization, you might not be able to move the entire installed based to a new operating system as quickly as you can upgrade the servers. By targeting specific servers to the user population that most utilizes them, you can move groups of users and their servers together.

- **Upgrade device font support in older print hardware and maintain updated drivers from the printer manufacturer.** Doing this can help resolve issues related to missing font or character support in many older PCL devices (for example, the Euro symbol).

- **Take advantage of the PostScript printer driver architecture whenever possible.** See your printer manufacture for Point and Print "stacks" that contain all the drivers necessary to support mixed clients. (Windows NT 4.0 plus Windows 2000, Windows XP, or Windows Server 2003).

- **Allow one server to remain at its current operating-system level, and plan for it to be used by clients that have not yet been upgraded.**

- **If the impact of interoperability issues is substantial, use version 2 drivers during the transition.** Microsoft recommends tracking the printers or print servers that are using version 2 drivers so that they can be upgraded to version 3 drivers after the client migration is complete.

- **Use like-model drivers.** If you cannot find a version 2 driver for a particular model, check with the printer manufacturer for a compatible driver that achieves the most functionality and quality. Many IHVs provide drivers for a class, series, or family of devices. Using one of these drivers can help if a manufacturer stops producing version 2 drivers for a specific model.

It is also important to note that the Windows Server 2003 family has a **local policy** that blocks version 2 (kernel-mode) printer drivers from being installed by default. Upon upgrade, existing version 2 drivers are preserved, but an error message appears when an administrator attempts to install new version 2 drivers onto the print server. Installation blocking does not occur when a driver is being installed solely to vend to Windows NT clients. Such a driver is not active on the server but simply shared for the network printing clients, so this action is not blocked. This policy can be disabled using the Local Policy snap-in.

# Summary (Print Server Upgrade, Migration, and Interoperability)

Updated: April 22, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As described in the preceding sections, the Windows printing model provides flexibility to support a wide variety of operating system versions, printer driver languages (PostScript and PCL), IHV driver customization, and automatic downloading. In some scenarios, these features conflict with each other leading to interoperability problems. Using a common PostScript driver core on the clients and servers prevents most of these issues. For PCL printers, the solution for interoperability issues can be the use of version 2 drivers, which are supported by Windows 2000 and the Windows Server 2003 family to provide legacy compatibility.

# Windows Print Server Scalability and Sizing Technical Overview

Updated: February 7, 2005

Applies To: Windows Server 2003

Print server scalability plays a key role in the purchase and deployment of Microsoft Windows print servers. The maximum load and performance level of a Windows print server is greatly dependent upon key configuration decisions. This paper provides information that helps you size a server to meet an organization's needs by identifying and investigating the main issues and configuration details to maximize print server performance.

**In This White Paper**

Introduction (Windows Print Server Scalability and Sizing Technical Overview)

Factors Influencing Print Server Performance

Performance Monitoring and Baseline Measurement

Reference Systems

Resources (Windows Print Server Scalability and Sizing Technical Overview)

# Introduction (Windows Print Server Scalability and Sizing Technical Overview)

Updated: February 7, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Capacity and scalability are key factors in planning the purchase and deployment of Microsoft Windows print servers. This paper describes several of the key factors that influence the capacity of a given print server configuration. While this paper cannot provide a predictive formula to determine the printing throughput of a given configuration, it does describe several reference systems and their capacity. This paper also presents the information necessary to help the system administrator or capacity planner to estimate and later monitor their server workload.

Some of the factors that influence print server performance and capacity include:

- The number of print server clients
- The operating system version or versions on each client's machine
- The number, size, and frequency of print jobs
- The types of print jobs sent to the print server
- The number and type of printers served by the print server and the types of printer drivers each printer uses

Based on customer feedback, analysis of past print server deployments and performance testing Microsoft has performed in its labs, Microsoft can recommend certain system configurations for specific workloads.

# Factors Influencing Print Server Performance

Updated: February 7, 2005

Applies To: Windows Server 2003

This section examines some of the different factors that can influence print server performance.

**Number of Print Server Clients**
Print server clients are those client computers and applications that have established connections to a print server. These clients may currently be in the process of a submitting a print job or they may have finished submitting a print job and not yet closed their connection to the print server.

Each connection, or named pipe, to the print spooler on a print server uses some limited system resources. Depending on the application used to connect to the print server, some of these connections may remain open, continuing to use resources for many hours or, in some cases, many days. It is possible for a print server to become resource-constrained simply because there are too many open client connections. Because of these lingering connections, there may be more active clients on the print server than you might expect.

The Windows Point and Print Technical Overview presents more information about these connections and provides information about using Named Pipes with remote procedure call (RPC) connections.

**Client Operating System**
Client computers running older versions of Microsoft Windows, such as Windows 95, Windows 98, or Windows Millennium Edition, perform more print processing on the client computer than those clients running Windows 2000 or later versions of Microsoft Windows. As a result, clients running the older versions of Windows place less of a load on the print server than clients running a later version of Windows. Upgrading a client to Windows 2000 or later will shift some of the print processing to the print server which will improve print performance on the client computer but add an additional workload to the server.

The system administrator or capacity planner should consider the additional print server workload resulting from the upgrade of many machines to Windows 2000 or later versions of Windows during the capacity planning process. The overall change in print server performance depends on the percentage of clients originally running older versions of Microsoft Windows—the greater the percentage of older versions of Windows that are upgraded, the greater the change in print server performance.

The Windows Point and Print Technical Overview provides more information about this topic.

**Type of Print Jobs**
Complex print jobs, such as those containing detailed graphics, PDF files, or many different fonts, require more CPU processing than simpler documents. The proportion of this processing performed on the client computer versus the print server depends on the operating system the client computer is running. If the client computer is running Windows 2000 or a later version of Windows, the print server will perform more of this processing workload.

This is an important factor to consider as it will affect both the overall server requirements as well as the change in server workload resulting from the upgrade of older clients to newer versions of Windows.

**Number, Size, and Frequency of Print Jobs**
The available network bandwidth to a print server computer will affect the number, size, and frequency of print jobs that print server will be able to process. The size and type of disk drives installed the print server will determine how many jobs may be queued and processed at one time. For example, in an environment where clients frequently submit small jobs the disk space requirements are different than in one where clients submit larger print jobs, less often. Further, if your organization needs to save print jobs after printing, the number, size, and frequency of print jobs will be important factors when determining the size of the print server hard disk configuration.

**Printer Hardware**
The types of printer devices served by the print server affect the throughput and performance of a Windows print server. Higher-end printers can typically accept more complex data and perform the necessary rendering, processing and production steps internally. Less expensive devices, those having less internal processing and memory capacity, require the Windows print server to perform the necessary rendering, processing and formatting.

The processing speed and internal storage of a printer device also influence the time required for the printer to accept a print job from a Windows print server. The longer it takes to send a print job to the printer, the longer that job remains on the print server's hard disks and the more disk space the job requires on the print server.

When selecting printer hardware for your organization, consider the installable options that may help improve printer and

print server performance. Standardizing printer models and selecting configurations that enable the printer to perform more print-job processing can help improve print server performance.

Printer device and driver reliability are also important considerations for selecting printers. Microsoft recommends using the user-mode printer drivers supplied with Microsoft windows 2000 and Microsoft Windows Server 2003 or drivers provided by printer manufacturers displaying the Designed for Windows logo.

**Types of Printer Drivers**
The number of different driver types supported by a print server has a direct influence on the scalability of the print server. Each additional printer driver requires additional system resources and registry accesses. The fewer system resources used to support a printer, the more of those printers the print server may support and the fewer system resources each print job uses.

For more information about driver architecture, testing, and selection, read Choosing the Right Printer Drivers, found at http://www.microsoft.com/windows2000/technologies/fileandprint/print/default.asp.

**Print Server Configuration**
To achieve maximum performance and capacity for dedicated print servers, consider the following configuration settings.

**Server Service**
Microsoft recommends that the **Maximize performance for file sharing** option be set on dedicated print servers. This setting configures the server to dedicate as many resources as possible to file and print server services.

To view or change server optimization settings:

1. From the **Start** menu, point to **Settings**, and then click **Control Panel**.

2. Double-click **Network and Dial-up Connections**.

3. Double-click **Local Area Connection**, and then click the **Properties** button.

4. In the **Local Area Connection Properties** dialog box, double-click **File and Printer Sharing for Microsoft Networks**.

5. Under **Optimization**, if you are running Windows Server 2003, the **Maximize Data Throughput for File Sharing** option is selected by default.

6. Click **OK**.

The following table shows the values for the **LargeSystemCache** entry with the corresponding options under **File and Printer Sharing for Microsoft Networks Properties**.

| Registry value | User interface option | Description | Notes |
|---|---|---|---|
| 0 | Maximize data throughput for network applications | Optimizes systems for distributed applications that typically do their own memory caching (such as SQL Server, which sets this option by default). This setting is useful for computers providing application services because it favors the working sets of processes over the working set of the file system cache. | This setting is useful for larger server applications and database servers such as SQL Server that need to maximize process working sets over the file system cache working set. |
| 1 | Maximize data throughput for file sharing | Optimizes the system for file and printer sharing resources. This is the default set by Windows 2000 Server Setup.<br><br>If you have at least 128 MB of RAM, this value results in a very high maximum size for the cache working set.<br><br>The Maximize Data Throughput for File Sharing option is useful for computers that typically run the Server service for file sharing | On Windows 2000 the file system cache working set can be increased by 464 MB of additional virtual address space (up to 960 MB) if the system has less than 16 GB of RAM, is not configured to start with the /3GB Boot.ini switch, and the PagedPoolSize entry is set to a value other than 0xFFFFFFFF (or 0 on systems with more than 1 GB of RAM), such as 192000000, the system is not running Terminal Services, and the SystemPages entry is not set to 0xFFFFFFFF. For more information about how various memory-management registry entries interact, see "Optimizing Your Memory Configuration" later in this chapter. |

**Spool Directory**

While accepting jobs and processing them for de-spooling, the print server can perform many disk input/output (I/O) operations. Print server activity also uses memory that can cause excessive page faulting during periods of high print server activity. Overall system performance may degrade because of the system becoming I/O constrained from the combination of high page file and disk file activity.

Microsoft recommends storing spooler files on a physical disk drive or drive array that is different from the physical disk drive used by the operating system for the paging file or the operating system files. This configuration helps to minimize the influence spooler-related disk access has on the dynamic management and allocation of the paging file. The performance of SCSI hard drives can be improved by assigning each hard drive to a different SCSI RAID controller channel.

The spool folder is defined using the Advanced Settings tab on the Server Properties page shown in the following screen shot below.

# Performance Monitoring and Baseline Measurement

Updated: February 7, 2005

Applies To: Windows Server 2003

It is difficult to predict the exact mix of client operating system versions, number of active clients, and the types and sizes of print jobs in advance. The most effective and quantitative approach to server sizing is to observe existing print server performance. There are 13 new performance counters available in Windows 2000 and later versions of Windows that enable administrators to monitor the general load of the print server on the server computer as well as monitor other printer-specific information.

A summary of the performance objects related to print server performance is presented here.

**Performance Objects**
Windows performance counters are grouped into related sets called performance objects. In any performance analysis project, the performance counters of the Processor, Physical Disk, Memory, and Network performance objects should always be examined. They provide a general overview of the system's performance and can also help identify processing bottlenecks and other issues requiring further investigation.

In addition to the performance objects that provide an overview of the system, there are also performance objects that provide information about specific aspects of system and print server operation. Two of these more specific performance objects are the Process object and the Print Queue object.

**Process Object**
The process object reports performance information about each process running on the system. To monitor the performance and load of the print server using System Monitor, select the Spoolsv.exe from the list of performance instances and add the following performance counters:

| Counter Name | Description |
|---|---|
| % Processor Time | The percentage of elapsed time that all process threads used to execute instructions.<br><br>An instruction is the basic unit of execution in a computer, a thread is the object that executes instructions, and a process is the object created when a program is run. This count includes code executed to handle some hardware interrupts and trap conditions. |
| Handle Count | The total number of handles currently open by this process.<br><br>This number is equal to the sum of the handles currently open by each thread in this process. |
| Virtual Bytes | The current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and by using too much, the process can limit its ability to load libraries. |
| Virtual Bytes Peak | The maximum size, in bytes, of virtual address space the process has used at any one time. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. However, virtual space is finite, and the process might limit its ability to load libraries by using too much. |
| Pool Paged Bytes | The size, in bytes, of the paged pool, an area of system memory (physical memory used by the operating system) for objects that can be written to disk when they are not being used. Memory\\Pool Paged Bytes is calculated differently than Process\\Pool Paged Bytes, so it might not equal Process\\Pool Paged Bytes_Total. This counter displays the last observed value only; it is not an average. |
| Pool Nonpaged Bytes | The size, in bytes, of the nonpaged pool, an area of system memory (physical memory used by the operating system) for objects that cannot be written to disk, but must remain in physical memory as long as they are allocated. Memory\\Pool Nonpaged Bytes is calculated differently than Process\\Pool Nonpaged Bytes, so it might not equal Process\\Pool Nonpaged Bytes_Total. This counter displays the last observed value only; it is not an average. |

| | |
|---|---|
| Working Set | The current size, in bytes, of the working set of this process. The working set is the set of memory pages touched recently by the threads in the process. If free memory in the computer is above a threshold, pages are left in the working set of a process even if they are not in use. When free memory falls below a threshold, pages are trimmed from working sets. If they are needed, they will then be soft-faulted back into the working set before leaving main memory. |
| Working Set Peak | The maximum size, in bytes, in the working set of this process at any point in time. If free memory in the computer is above a certain threshold, pages are left in the working set of a process even if they are not in use. When free memory falls below a certain threshold, pages are trimmed from working sets. If they are needed, they are then soft-faulted back into the working set before they leave main memory. |

**Print Queue Object**

Windows Server 2003 provides the Print Queue performance object for tracking activity in the print server print queues. The counter values are reset when either the print server or the spooler service is restarted.

| **Counter Name** | **Description** |
|---|---|
| Add Network Printer Calls | Shows the total number of calls from other print servers to add shared network printers to this server since last restart. |
| Bytes Printed/sec | Shows the number of bytes per second printed in a print queue and provides a rough indication of how busy a printer is. This counter can be used for bottleneck detection. |
| Enumerate Network Printer Calls | Shows the total number of calls from browse clients to this print server to request network browse lists since last restart. |
| Job Errors | Shows the total number of job errors in a print queue since last restart. Job errors can occur if the connection to the printer has errors due to network problems. |
| Jobs | Shows the current number of jobs in a print queue. Use this counter to identify excessive use. |
| Jobs Spooling | Shows the current number of spooling jobs (incoming or incomplete) in a print queue. |
| Max Jobs Spooling | Shows the maximum number of spooling jobs (incoming or incomplete) in a print queue since last restart. |
| Max References | Shows the peak number of references (open handles) to this printer. |
| Not Ready Errors | Shows the total number of printer-not-ready errors in a print queue since the last restart. |
| Out of Paper Errors | Shows the total number of out-of-paper errors in a print queue since the last restart. |
| References | Shows the current number of references to a print queue. A reference can be a user or a program that is connecting to a printer and opening a print queue. |
| Total Jobs Printed | Shows the total number of jobs printed on a print queue since the last restart. |
| Total Pages Printed | Shows the total number of pages printed through GDI on a print queue since the last restart. Since RAW print jobs do not provide page-count data, they are not included in this counter. (Windows 98 and Windows 95 clients submit RAW jobs. The print volume of a RAW job is not captured by this counter.) |

Performance monitoring helps you tune your deployments and anticipate when to add more or more powerful processors, increase the system memory, or modify the disk configuration.

# Reference Systems

Updated: February 7, 2005

Applies To: Windows Server 2003

Microsoft has studied print server performance at external customer sites and also studied print server performance internally. Two sample configurations from this testing are presented in this section to provide additional reference information that can be used when sizing your print server requirements.

**Standalone Print Server**
Workgroup-class hardware like the HP/Compaq DL560 or DL580 with 1.5GB RAM, ample, high-performance disks and sufficient network throughput can host approximately 1,500 printers, serving 5,000-10,000 customers.

It is important to note that the primary limitation of the print server in this configuration is related to remote management and not the result of constraints imposed by the print server hardware or core spooler component. Specifically, when viewing and sorting columns in the **Printers and Faxes** folder, one may begin to experience delays if the server is hosting more than 1,500 printers.

Another important factor to consider is the number of client connections handled by the server. Often, a single client will have multiple connections to the print server. For example, one for each document, one for monitoring the printer status and possibly more resulting from other applications running on the client. Because of this, the factors traditionally considered in server capacity planning play a less significant role in print server capacity planning than they might when planning more traditional server functions. Factors such as CPU speed, RAM usage, Virtual Memory consumption, and Disk Read/Write times, are not constraining factors until there are more than several thousand printers per server or there are more than 10,000 clients using the server.

The table below shows the hardware configuration used by Microsoft for performance testing and benchmarking. In actual customer deployments, Microsoft expects the system configuration selected and deployed by customers to be superior to the system described in the table below. Specifically, Microsoft believes that faster processors, additional RAM, and higher capacity drives will be deployed by customers.

| | |
|---|---|
| System Manufacturer | Compaq |
| System Model | ProLiant DL580 |
| System Type | X86-based computer |
| Processor | x86 Family 6 Model 10 Stepping 4 GenuineIntel ~902 Mhz |
| Processor | x86 Family 6 Model 10 Stepping 4 GenuineIntel ~902 Mhz |
| BIOS Version/Date | Compaq P20, 4/5/2002 |
| SMBIOS Version | 2.3 |
| Total Physical Memory | 1,024.00 MB |
| Available Physical Memory | 473.55 MB |
| Total Virtual Memory | 3.41 GB |
| Available Virtual Memory | 2.47 GB |
| Page File Space | 2.41 GB |
| Disk | Compaq SCSI Drive Array (4 Ultra3 18GB disks) |

**Clustered Print Server**

Microsoft has studied clustered print server performance at many customer sites. Using this information, a clustered print server consisting of a two-node cluster was selected to test print server performance internally. Each system in the cluster was configured as described in the following table.

| | |
|---|---|
| System Manufacturer | Compaq |
| System Model | ProLiant DL380 G2 |
| System Type | X86-based computer |
| Processor | x86 Family 6 Model 11 Stepping 1 GenuineIntel ~1396 Mhz |
| BIOS Version/Date | Compaq P24, 12/11/2001 |
| SMBIOS Version | 2.3 |
| Total Physical Memory | 256.00 MB |
| Available Physical Memory | 53.66 MB |
| Total Virtual Memory | 875.91 MB |
| Available Virtual Memory | 517.17 MB |
| Page File Space | 620.38 MB |

Based on these tests, Microsoft found that such a clustered system could be used to host up to 2,500 printers and service up to 10,000 clients running a mix of Windows operating system versions.

# Introduction (Best Practices for Deploying Printer Location with Active Directory)

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

In network environments, most users do not need to know the physical location of files, databases, or Web sites. However, they do need to know the physical location of hardware devices, such as printers. The printer location tracking feature in Microsoft Windows 2003 helps users find printers by storing their actual location in the Microsoft Active Directory service. When this feature is enabled, the location string is displayed automatically for each printer.

To use this feature, your network environment must have the following characteristics:

- A Windows 2000 or Windows 2003 domain controller (which, by definition, runs Active Directory) and preferably more than one subnet.
- A network IP addressing scheme that corresponds roughly to the physical layout of your enterprise (not required but very helpful).
- Client computers that can query the directory service.
- A subnet object for each site. Subnet objects can be created using Active Directory Sites and Services.
- Your own naming convention for printer location
- Administrator privileges on the print server to set the printers location field, and permissions to create sites/subnets on the Domain Controller to populate the location field.

Group Policy lets you configure printer location tracking for a group of computers using the Computer Location and Pre-Populate Printer search location text policies.

| **Note** |
| --- |
| For more information about these policies, see the Explain tab for each policy.<br><br>For the steps to set up printer location tracking, type "printer location tracking" in the index of Windows 2003 Server Help and Support Center.<br><br>The location search ability can be very useful for your clients, as long as all printers in your organization use a consistent schema that allows users to search. The location schema used for printers should be planned out thoroughly before deployment as it will be used throughout your printing organization. This white paper outlines some best practices for creating and maintaining a useful location schema. |

The major steps involved in this effort are:

1. Verify the printer names and their subnets. It's best to keep this information in a spreadsheet or database and update it regularly. This information is helpful when upgrading print servers and for general maintenance as well.
2. Define the location tree structure.
3. Configure the printer locations.
4. Enable the printer location tracking policy.
5. Test the final setup.

# Creating the Location Schema

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

As noted, you must first create and maintain a location schema to allow users to search for location. It is important to think carefully about your location schema before deploying it. You want to make sure that it will be flexible enough to describe all locations where printers can be placed. This schema will be used by your entire organization, so its worth spending the time up front to design it properly.

Because location names are used by end users, the names should be simple and easy to recognize. Avoid using special names known only to facilities management. For better readability, avoid using special characters in a name, and keep names to a maximum of 32 characters to make sure that the whole name string is visible in the user interface. Names should conform to the following characteristics:

- Location names are in the form *name/name/name/name/...* (The slash (/) must be the dividing character.)
- A name can consist of any characters except for the slash (/).
- The number of levels to a name is limited to 256.
- The maximum length of name is 32 characters.
- The maximum length of an entire location name is 260 characters.

In particular, you should make certain that the schema is flexible enough to allow for future changes in your organization. Ideally, the schema can follow the subnet layout of your organization (assuming you have a geographical-based subnet hierarchy), because then it is possible to write scripts that will automatically populate the location field of all of your printers based on the subnet.

As an example, consider an organization with multiple locations in North America and Europe. The naming scheme for the organization might be as follows:

| **Top level** | **Level** | **Level** | **Level** |
|---|---|---|---|
| NorthAmerica | | | |
| | NewYork | | |
| | | HQ | |
| | | | Floor1 |
| | | | Floor2 |
| | | Buffalo | |
| | | | Design |
| | | | Plant |
| | | | Admin |
| | Vancouver | | |
| | | Building1 | |

| | | | |
|---|---|---|---|
| | | Building2 | |
| | Dallas | | |
| Europe | | | |
| | Paris | | |
| | | Design | |
| | London | | |
| | | ... | |
| | Madrid | | |

Note that the tree varies in depth depending on the complexity of the organization and the amount of detail available in the IP network. The naming convention for this example includes more levels than for a smaller organization located in a single city, or a single building. The full name of the design building in Buffalo, New York is **NorthAmerica/NewYork/Buffalo/Design**; for the design building in Paris, the full name is **Europe/Paris/Design**, and the smaller office in Dallas has the name as **NorthAmerica/Dallas**.

# Configuring Printer Location and Setting Location Policies

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

To enable printer location tracking and set the automatic print population policy, do the following:

1. Open **Active Directory Sites and Services**.

2. Create the sites you want, if you haven't done so already.

3. Associate a subnet for this newly created site, if you haven't done so already.

4. Right-click each subnet you created, and then click **Properties**.

5. Click the **Location** tab, type the location of the subnet in the following format based on your location naming convention, and then click **OK**:

   *location/location*

6. Using Group Policy, double-click the **Pre-populate printer search location** policy setting, and then click to enable it.

   The following example demonstrates how to set the policy to a group (organizational unit in Active Directory terms) of users that use that printer. However, you can set the policy to a different object using the appropriate Active Directory utility.

   a. Start **Group Policy** from **Active Directory Users and Computers**.

   b. Right-click the organizational unit you want to apply the policy to, and then click **Properties**.

   c. Click the **Group Policy** tab, and then click **New** to create a new object. Type the name of the new object, and then click **OK**.

   d. Select the newly created object, and then click **Edit**.

   e. Expand **Computer Configuration**, then **Administrative Templates**, and then **Printers**.

   f. Double-click the policy setting **Pre-populate printer search location**, and then click to enable it. When you search the directory service for printers, it fills in your location field using the value specified in the Location tab of the Subnet properties page. If this policy is disabled (default), the location will be empty.

   | **Note** |
   | --- |
   | It is also possible to set location manually per-computer by Group Policy. |

7. Open **Printers and Faxes**.

8. Right-click the printer and then click **Properties**.

9. Type the printer location based on your schema, or click **Browse** to find it. You probably want to be more precise in describing the printer location than the subnet location. For example, for the subnet location NorthAmerica/Dallas, you might type *NorthAmerica/Dallas/Floor42/Room4207*.

10. Repeat the last two steps for each printer in Active Directory.

It is recommended to script Steps 710 by using the prnadmin.dll utility that ships in the resource kit. To use this utility, you must refer to your existing spreadsheet or database of printers and their locations and then, rather than opening each printers properties to set the location, you can use the tool to set the printer locations according to the inputted information.

The following is an example of how one can set the location using prnadmin.dll. Typing **cscript prncfg.vbs /?** in the command prompt will show this example.

```
cscript prncfg.vbs -s -b PrinterName -l "Building A/Floor 100/Office 1"
```

Where PrinterName can be a UNC name.

| **Note** |
| --- |
| To open Active Directory Sites and Services, click **Start**, point to **Programs**, point to **Administrative Tasks**, and then click **Active Directory Sites and Services**. |

# Setting Standards When Printer Location Tracking is Disabled

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

As mentioned previously, you can add information to **Location** in the **General** tab of the printer property page even if printer location tracking is disabled. However, this imposes a potential problem. When users search for printers on the tenth floor, they need to know exactly what to type in the **Find Printers** property page when they click **Start**, then **Search**, and then **For Printers**. Incidentally, wildcards such as * (asterisk) may be used to help find printers when exact or complete location names are unknown. When printer location tracking is enabled, the **Location** field in the **Find printer** property page is filled in automatically.

# Summary (Best Practices for Deploying Printer Location with Active Directory)

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

As described in the preceding sections, the location search ability can be very useful for your clients, as long as all printers in your organization use a consistent schema that allows users to search. Following the recommendations in this white paper will help create a consistent and useful schema that you can deploy throughout your print organization.

# Introduction (Certificate Autoenrollment in Windows Server 2003)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

Microsoft Windows Server 2003, Enterprise Edition introduces the capability to automatically enroll users and computers for certificatesincluding smart cardbased certificates.

Using the autoenrollment feature, organizations can manage the certificate lifecycle for users, which includes:

- Certificate renewal
- Superseding of certificates
- Multiple signature requirements

Certificate autoenrollment is based on the combination of Group Policy settings and version 2 certificate templates. This combination allows the Windows XP Professional or Windows Server 2003 client to enroll users when they log on to their domain, or a machine when it boots, and keeps them periodically updated between these events.

Automatic enrollment of user certificates provides a quick and simple way to issue certificates to users and to enable public key infrastructure (PKI) applications, such as smart card logon, Encrypting File System (EFS), Secure Sockets Layer (SSL), Secure/Multipurpose Internet Mail Extensions (S/MIME), and others, within an Active Directory directory service environment. User autoenrollment minimizes the high cost of normal PKI deployments and reduces the total cost of ownership (TCO) for a PKI implementation when Windows XP Professional clients are configured to use Active Directory.

**Supports Pending Certificate Requests and Certificate Renewal**
User autoenrollment in Windows XP Professional and Windows Server 2003 supports both pending certificate requests and renewal features.

**Requesting a Certificate**
You can manually or automatically request a certificate from a Windows Server 2003 certification authority (CA). This request is held until administrative approval is received or the verification process is completed. Once the certificate has been approved or issued, the autoenrollment process completes and installs your certificate automatically.

**Renewing a Certificate**
The process for renewing an expired user certificate also takes advantage of the autoenrollment mechanism. Certificates are automatically renewed on behalf of the userdependent on the specifications in the certificate template.

**Dependencies**
The autoenrollment feature has several infrastructure requirements. These include:

- Windows Server 2003 schema and Group Policy updates
- Windows 2000 Server domain controllers running Service Pack 3 or later
- Windows XP Professional or Windows Server 2003 clients
- Windows Server 2003, Enterprise Edition or Datacenter Edition running as an Enterprise CA

| **Note** |
| --- |
| Autoenrollment Group Policy settings may only be applied when using a Windows XP Professional or Windows Server 2003 computer. |

# How Autoenrollment Works

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section discusses how autoenrollment works, including autoenrollment and Winlogon, an analysis of the components of the autoenrollment process, and working with certification authority interfaces.

**Key Points**

Autoenrollment works best in a Windows Server 2003 Enterprise environment where the Windows XP client is integrated with Active Directory.

Only domain-joined machines can use certificate autoenrollment. Although the autoenrollment process does not explicitly look for domain-joined machines, the Winlogon process will not activate userinit.exe unless the machine/user is part of a domain.

**Autoenrollment Timing**

The autoenrollment process is normally triggered by the Winlogon process, and is designed to be activated and managed by a domain-based Group Policy. Both machine-based and user-based Group Policy can activate autoenrollment for machines and users. By default, the Group Policy is applied at reboot for machines, or at logon for users, and is refreshed every eight hours. The refresh interval can be configured using Group Policy. Autoenrollment is also triggered by an internal timer that activates every eight hours after the last time autoenrollment was activated.

For additional information, see Updating Group Policy.

| **Note** |
| --- |
| Unlocking the workstation does not trigger autoenrollmentonly a full interactive logon or a Group Policy refresh will initiate the Winlogon trigger. |

**The Autoenrollment Process**

The autoenrollment feature handles all aspects of certificate enrollment, renewal, and certificate housekeepingexcept in the case where user interaction is explicitly defined on a certificate template in Active Directory. When the autoenrollment process is triggered by Winlogon or a Group Policy refresh interval, the operating system queries Active Directory to download the appropriate certificate stores into the local store on the client machine; for example, root CA certificates, cross-certificates, and the NTAuth container. The autoenrollment process also downloads certificate templates from the forest and caches the list in the registry at the same time. The last step performed by autoenrollment is user-object cleanup (userCertificate attribute) in Active Directory. Revoked, expired, and superseded certificates are removed from the user object automatically; however, expired certificates are not removed unless a new valid certificate is issued at the same time. Certificates in the local user profile or on the user object in Active Directory are only managed if the certificate corresponds to a certificate template in Active Directory. Foreign certificates and certificates that do not contain the template extension are not managed. This is a transparent activity that is processed asynchronously.

**Requirements List**

The autoenrollment process will then process the list of templates and create a requirements list for any templates that have an autoenroll access control entry (ACE) set on the template for the current machine or user. The machine and/or user must also have the Read ACE set on the template or the template will not be enumerated. The users or machines MY (personal) store will also be processed at this time to look for revoked certificates, certificates without private keys, time invalid certificates and so on, and add these certificates to the requirements list. For more information about certificate stores, refer to the Microsoft Platform SDK: http://go.microsoft.com/fwlink/?LinkID=116205

It is very possible that a user may have a certificate in the MY store but not have permissions set on a template access control list (ACL) in Active Directory. These will be processed and added to the list, but enrollment will most likely fail due to the fact that the template permissions do not allow enrollment/renewal at the updated point in time.

Items in the requirements list may be removed if an appropriate valid certificate is found in the MY store. If a certificate template is marked to check Active Directory for an existing certificate, Active Directory will be queried for an existing duplicate certificate on the userCertificate attribute of the user object and the requirement will be removed from the list, if successful.

| **Note** |
| --- |

Checking Active Directory for the presence of an existing certificate associated with the user or machine object can affect performance and may delay autoenrollment processing due to the network and directory requirements for performing this operation. This is because the actual certificates in the userCertificate attribute will be downloaded and examined. When this happens, the directory cannot be queried via Light Weight Directory Access Protocol (LDAP) to simply respond whether a given certificate type exists without downloading and processing the certificates locally.

**Autoenrollment also manages the CryptoAPI REQUEST store for the user.** This process enumerates each pending request in the store and then installs the pending certificate, if possible, from the issuing CA. If a certificate is to be archived or deleted, based on the certificate template rule, it will be processed as follows:

- If a request already exists in the REQUEST store, this certificate will be removed from the summarized requirements list.
- If a request has been pending for more than 60 days, the request will be deleted and the requirements list will remain as-is.

Autoenrollment can be used to retrieve pending requests only for certificates with template information, for example, an initial request involving a certificate template. The autoenroll ACL on the certificate template is not necessary for the autoenrollment process to retrieve a pending certificate request. If the user enrolls via a Web page and the certificate request is pending, autoenrollment will retrieve the pending request for the user.

Template supersede rules will be evaluated and appropriate additions and deletions will be processed for the requirements list. For example, if the template says "X supersedes Y ", it means that if you have been told to enroll for X and Y, you really only need X. If you only have Y, you still must get X. This is the last step in rule processing. After it is done, the requirements list is complete.

**For each template that does not require user interaction**, the autoenrollment process will create the requests in the background and submit them to a CA. Once this is done, the requirements list is updated.

Autoenrollment always performs a revocation check of the entire certificate chain starting with the issuing certification authority to ensure that the CA offering enrollment services is not revoked before performing enrollment. If the CA is revoked, autoenrollment will not send requests to that certification authority. However, autoenrollment will ignore revocation errors if a CDP (CRL Distribution Point) extension does not exist in the CA certificate or if the revocation status is offline.

If a certificate is issued from the CA, it is installed in the users or machines MY store. If the certificate is pended [specified by the CA Manager approval check box in the Certificate Template Microsoft Management Console (MMC) snap-in], the request information is saved in the REQUEST store.

**Balloon User Interface**

For each request that requires user interaction as per the certificate template, the balloon user interface (UI) is invoked.

- Approximately 60 seconds after logon, the balloon UI is displayed. If no user interaction is explicitly defined on the certificate template, no UI will be displayed to the user. This delay is incorporated to allow for speedy application and shell response times during the logon and booting of the client machine.
- If the 60-second delay is not desired, the following registry key may be added on a per-user basis.

HKEY_CURRENT_USER\SOFTWARE\Microsoft\Cryptography\AutoEnrollment\AEExpress

Using this key in a normal production environment is not recommended. If it is used, it must be created on a per-user basis.

| **Important** |
| --- |
| Machine certificates do not support user interaction and should not be configured to require this setting. |

- The balloon UI waits for the user to see the balloon and is activated by a mouse click. Note that after approximately 15 seconds, the balloon pop-up window is replaced in the notification area by a certificate icon that may be activated by a mouse click.
- If no activation occurs within seven hours, the taskbar icon will disappear and the silent thread will re-activate at the next

logon, machine reboot, or Group Policy refresh interval, whichever is first.

- Once the user activates the UI, the REQUEST store is checked first for pending requests.

**Issuing the Template**
Once a certificate template with the proper ACE has been enumerated, the autoenrollment process will search for a Microsoft Enterprise Certification Authority in Active Directory that can issue the template. If more than one Enterprise CA is found, the client will try each CA in the list in random order (for load balancing) until a CA responds and is able to issue a certificate.

The client contacts a CA through a Distributed Component Object Model (DCOM) interface and supplies a security context through DCOM to provide an authenticated request. The default policy module of the Microsoft Enterprise CA enforces certificate profiles and enrollment security as defined by the templates.

If the certification authority is set to pend the request for an administrator or certificate manager to examine and approve, autoenrollment will periodically query the CA during every Group Policy refresh interval for approved requests. Autoenrollment will also re-enroll templates when **Reenroll all certificate holders** has been set in Group Policy. For more information, see Certificate Renewal.

**Certification Authority Interfaces**
The following methods are used by the autoenrollment process for contacting and enrolling against a Microsoft Enterprise CA.

- GetCAProperty
- Submit
- GetLastStatus
- GetRequestId
- GetFullResponseProperty
- GetCertificate
- Release
- RetrievePending

These methods can be found in the Platform SDK at http://msdn.microsoft.com/library/default.aspConfiguring the Certificate Templates

This section covers how to configure certificate templates and provides a step-by-step example of how to create a new template for the autoenrollment of a smart card. Certificate template permissions are also explained.

**Key Point**
A version 2 certificate template must first be created in Active Directory to enable autoenrollment.

**Default Settings**
The following are default settings.

- Only root domain administrators or explicitly delegated users in Active Directory may configure templates in a domain that has been upgraded from Windows 2000 Server.
- Both domain administrators from the root domain and enterprise administrators for fresh installations of Windows Server 2003 domains may configure templates.
- Certificate template ACLs are viewed in the Certificate Templates MMC snap-in.
- Certificate templates can be cloned or edited using the Certificate Templates MMC snap-in.

| **Note** |
| --- |
| Only a domain with the Windows Server 2003 schema will support version 2 templates, and only a Windows Server 2003, Enterprise Edition or Datacenter Edition certification authority may issue a version 2 template certificate. |

**Creating a New Template for the Autoenrollment of a Smart Card**

To create a new template for autoenrollment of a smart card

1. Log on as a domain administrator.
2. Click the **Start** button, and then click **Run**.
3. In the **Run** dialog box, in the **Open** box, type **mmc.exe**, and then click **OK**.
4. On the **File** menu, click **Add/Remove Snap-in**.
5. In the **Add/Remove Snap-in** dialog box, click **Add**.
6. In the **Add Standalone Snap-in** dialog box, click **Certificate Templates**, and then click **Add**.

   | **Note** |
   | --- |
   | The Certificate Templates MMC snap-in is available on the Server version of Windows Server 2003 or on Windows XP Professional through the Administration Tools Pack installation on the Server media. |

7. Click **Close**.
8. Click **OK**.

   | **Note** |
   | --- |
   | The Certificate Templates MMC snap-in may also be invoked using the Certification Authority MMC snap-in by selecting the **Certificate Templates** folder, right-clicking, and then selecting **Manage**. |

9. In the console tree, click **Certificate Templates**.
10. In the details pane, right-click the **Smartcard User** template, and then click **Duplicate Template** (Figure 1).

    The **General** tab of the new template properties dialog box appears.

**Figure 1: Creating a New Template for Autoenrollment of a Smart Card**

11. In the **Template display name** field, type a unique name for the template (Figure 2).

**Figure 2: Naming the Template**

| **Note** |
| --- |
| If the **Do not automatically reenroll if a duplicate certificate exists in Active Directory** is enabled, autoenrollment will not enroll a user for the certificate template, even if a certificate does not exist in the users MY store. Active Directory is queried and determines if the user should be enrolled. This is an extremely valuable feature for users who do not have roaming profiles and log on to multiple machines. Without this setting and without roaming profiles, the user will automatically be enrolled on every machine that is logged on to (including servers). |

12. Click the **Request Handling** tab (Figure 3).

This tab is used to define how the certificate request should be processed, including the cryptographic service providers (CSP) and minimum key sizes that will be used by the enrollment template.

**Figure 3: Defining How the Certificate Request Should Be Processed**

| **Important** |
| --- |
| If more than one smart card CSP is made available on this tab, the user may be prompted for every CSP that is selected when enrolling for this template. The behavior may vary depending on the CSPs available on the client machine. If the user has only one smart card, the prompts for the unavailable CSPs will have to be cancelled. This behavior is by design. It is also important to select a minimum key size that is supported by the selected CSP; otherwise, enrollment will fail. |

13. Select the **Prompt the user during enrollment** check box (Figure 3). (Enrollment for smart card requires user input to succeed.)

| **Important** |
| --- |
| If the certificate template is not going to be used for smart cards or if it is not desired for the user to be prompted to enroll for certificates, this option is not required. Machine certificates should not have this enabled or machine autoenrollment will fail. |

14. Click the **Subject Name** tab.

    This tab is used to define how the subject name and certificate properties will be built. It is recommended to use the default selections when enrolling for a smart card template.

15. Click the **Extensions** tab.

    This tab is used to define how the various extensions will be added to this certificate template during enrollment. It is recommended that you use the default settings.

| **Note** |
| --- |
| Application Policies is a replacement for Extended Key Usage (EKU) in Windows Server 2003, although EKU is still supported for legacy applications and client operating systems. |

16. Click the **Security** tab.

    This tab is used to define which users or groups may enroll or autoenroll for a certificate template. A user or group must have the Read, Enroll, and Autoenroll permissions to automatically be enrolled for a certificate template.

17. Click **OK** when finished.

    The Autoenrollment column should now show **Allowed**.

| **Note** |
| --- |
| The Autoenrollment column will automatically indicate if a template is suitable for autoenrollment. The user will not be able to change the status. If a template has more than one registration authority (RA) signature required or if the subject is supplied by the requester, autoenrollment will not be allowed. The column does not reflect the state of the autoenroll ACL on the template. |

| **Important** |
| --- |
| A smart card that has been issued on Windows XP client or Windows XP Enrollment Station (RA) might only be compatible with a Windows XP client. The compatibility varies between various smart card and CSP vendors. If you need to be able to log on to both Windows 2000 and Windows XP, see your smart card and CSP vendor for additional information. |

**Certificate Template Permissions**

For a user or computer to enroll for a certificate template, it must have appropriate permissions (ACEs) set on the template in Active Directory. A user or computer must have both Enroll and Read permissions to enroll for a selected certificate template.

- **Read permission** allows the template to be discovered by the user.

- **Enroll permission** is enforced by the Enterprise CA when a user requests a certificate for a selected template. The Enterprise CA must also have Read permissions on a template to enumerate the template in the directory and issue certificates based on that template. Normally, the Enterprise CA is included in the Authenticated Users group, which has Read permissions by default on a template.

- **Full Control permission** is given to enterprise administrators and the primary domain administrators group by default when installing a fresh Windows Server 2003 domain. If a domain has been upgraded from Windows 2000, enterprise administrators will not have this permission by default. The Full Control permission allows a user to set or modify the permissions on a selected template.

- **Autoenroll permission** is set on a template when it is desired for a user or computer to automatically enroll for a selected certificate template. The Autoenroll permission is needed in addition to the Enroll permission for a user to enroll for a given certificate template. Only version 2 templates or newly created templates may have the Autoenroll ACE set.

- **Write permission** allows a user to modify the contents of a certificate template. Note that only version 2 certificates with a Windows Server 2003 schema may be modified. Version 1 certificate templates only allow ACLs to be modified.

# Configuring an Enterprise CA

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section shows how a Microsoft Enterprise CA must be configured to issue a certificate template after it has been created.

**How to Configure an Enterprise CA**
To configure an Enterprise CA

1. On the **Administrative Tools** menu on a Windows Server 2003 console, open the **Certification Authority** snap-in.

2. In the console tree, expand the Certification Authority, and then click **Certificate Templates** (Figure 4).

**Figure 4: Selecting Certificate Templates**

3. Right-click **Certificate Templates**, click **New**, and then click **Certificate Template** to Issue.

4. In the **Enable Certificate Templates** dialog box (Figure 5), click **Auto Enroll Smartcard User** (this is the certificate template name that was created previously), and then click **OK**.

   (See Creating a New Template for the Autoenrollment of a Smart Card.)

**Figure 5: Enabling a Certificate Template on a CA**

| **Note** |
| --- |
| Due to replication latency and template caching in the registry, a certification authority may not be able to issue a certificate template immediately. The timing of issuance is dependent on replication latency between domain controllers. |

5. Close the **Certification Authority** MMC snap-in.

# Configuring Group Policy

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section shows how to configure the Group Policy settings for a site, domain, or organizational unit (OU).

**How to Configure Group Policy**
Group Policy settings for a site, domain, or OU must be configured to enable certificate autoenrollment in a domain.

To configure Group Policy

1. Open the Active Directory **Users and Computers** MMC snap-in.

2. Right-click the site, domain, or OU that you want to configure Group Policy for, and then click **Properties**.

3. Click the **Group Policy** tab, and then click **Edit** (Figure 6).

**Figure 6: Selecting Group Policy Configuration Options**

| **Note** |
| --- |
| Machine policy for automatic enrollment of machine and domain controller certificates is configured identically, even though it is controlled through the machine policy of a Group Policy object. |

4. Click **User Configuration**, **Windows Settings**, **Security Settings**, and finally **Public Key Policies**. In **Object Type**, right-click **Autoenrollment Settings** (Figure 7), and then click **Properties**.

**Figure 7: Selecting Autoenrollment Settings**

5. Ensure that **Enroll certificates automatically** is selected as well as the two check boxes under this option (Figure 8). Automatic renewal, certificate cleanup, and publishing in Active Directory are only enabled with all options selected.

| **Note** |
| --- |
| Both machine and user policy must be configured to enable certificate enrollment for both types. |

**Figure 8: Selecting Autoenrollment Settings**

6. Click **OK**.

   Autoenrollment is now enabled.

# User Autoenrollment

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section illustrates manually pulsing autoenrollment and smart card enrollment.

**Key Points**
User autoenrollment for a smart card requires mandatory manual steps and user interaction, unlike other certificate types. Once autoenrollment has been enabled, the user will receive an informational balloon on the taskbar at the next Group Policy pulse interval (default of eight hours) or at the next logon.

**Manually Pulsing Autoenrollment**
Autoenrollment may be pulsed manually through the Certificates MMC snap-in.

To manually trigger autoenrollment

1. Log on to the domain with the appropriate user account.

2. Click the **Start** button, and then click **Run**.

3. Type **mmc.exe**, and press ENTER.

   An empty MMC shell starts.

4. Select the **File** menu, and then select **Add/Remove Snap-In**.

   A dialog box appears with a list of the snap-ins that have been added to the MMC shell.

5. Click **Add**.

   A list of the registered snap-ins on the current machine appears.

6. Double-click the **Certificates** snap-in, select **My User Account**, and then click **Finish**. If enrolling the machine for a certificate, such as a domain controller or a Web server, select **Computer account**.

7. Click **Next**.

8. Select **Local Computer**, and then click **Finish**.

9. In the **Add Standalone Snap-in** dialog box, click **Close**. In the **Add/Remove Snap-in** dialog box, click **OK**.

   The MMC now contains the personal certificate store for the user.

10. Right-click the top of the tree on **CertificateCurrent User**, select **All Tasks** on the context menu, and then select **Automatically Enroll Certificates** (Figure 9).

**Figure 9: Automatically Enrolling Certificates**

| **Note** |
| --- |
| It will take approximately one minute for the Certificate Enrollment balloon to be displayed, unless the registry key mentioned previously has been set. (See Balloon User Interface.) |

**Smart Card Enrollment**

1. Click the balloon or the corresponding certificate icon in the notification area once the **Certificate Enrollment** balloon is displayed. After a short period of time, the balloon will automatically disappear, and only the icon in the notification area will remain. After clicking the balloon, the Autoenrollment UI will start.

| **Note** |
| --- |
| The certificate enrollment balloon and wizard are not only for smart card enrollment but also for self-registration authority. |

2. Click the **Start** button (Figure 10).

   The wizard will begin. (The **Remind Me Later** button will cause the Certificate Enrollment balloon to re-appear at the next Group Policy pulse interval or the next interactive logon.)

**Figure 10: Begin Enrolling Certificates**

3. If a smart card with the required CSP on the certificate is not inserted in the smart card reader, the user will be prompted to insert a smart card. Insert the smart card and click **OK**.

| **Note** |
| --- |
| If the certificate template on the users machine contains more than one CSP, the user may have to cycle through the wizard to reach the desired smart card CSP. |

4. If the displayed smart card CSP is not the desired CSP, click **Cancel**.

   The next CSP listed in the certificate template will be displayed.

5. After inserting an appropriate smart card, click **OK**.

   The wizard will continue.

| **Note** |
| --- |
| If the smart card contains a private key and certificate in Slot0 (default container), the user will be warned about replacing the credentials on the smart card. |

| **Important** |
| --- |
| Due to limitations with the smart card CSPs, smart card logon with both Windows 2000 and Windows XP requires that Slot0, or the default container on the card, be used to hold the certificate and private key used for smart card logon. If the card contains multiple keys and certificates, the last generated key and certificate will be marked as the default container on the card. |

6. If it is desired to replace the credentials on the smart card, click **Yes** (Figure 11).

   The wizard will continue (Figure 12).

   (The following is only one example of the dialog box a user may see. The smart card UI varies depending on the CSP being used.)

**Figure 11: Replacing Credentials Dialog Box**

**Figure 12: Enrolling Certificates**

7. If a PIN is necessary for the smart card, a dialog box will be displayed. Enter the appropriate PIN and click **Enter**.

   Enrollment completes.

| **Note** |
| --- |
| If you enter the PIN incorrectly, the number of times you can retry will be limited. |

The success or failure of the autoenrollment process will be logged in the Application event log on the local computer.

Also, a summary dialog box will appear for failed certificate requests that involved user interaction. If a failure occurs during enrollment, the user will be notified of the failure (Figure 13).

**Figure 13: Notifying the User of Errors While Enrolling Certificates**

| **Note** |
| --- |
| Users are not prompted when enrollment succeeds. |

# Certificate Renewal

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section discusses renewal intervals, forced re-enrollment, and smart card renewal.

**Renewal Intervals**
Windows XP Professional or Windows Server 2003 clients, when combined with a Windows Server 2003, Enterprise Edition certification authority, will perform automatic renewal of certificates as specified on a per-template basis. Renewal intervals are dictated by the certificate template, which is set to six weeks (before expiration) by default. When certificate renewal is performed, the old (previous) certificate enrollment is always archived automatically on the client machine, and the user directory object is updated.

Important certificate renewal criteria include the following:

- Automatic certificate renewal will only occur when 80 percent of the certificate lifetime has passed, or when the renewal interval period specified on the template has been reachedwhichever timeframe is smaller.

- If the renewal period is greater than 20 percent of the certificate lifetime, autoenrollment will not automatically attempt certificate renewal until the 80 percent threshold has been reached.

**Forcing Re-Enrollment**
An administrator may force all users to re-enroll for a given template by updating the major version number of the template. When Active Directory is queried during logon for required certificate templates, the version number is examined. If the version number has incremented, the certificate template is considered to be updated and the user must re-enroll for that template.

To manually force the template version to be updated (thereby forcing re-enrollment)

- Right-click the template and select **Reenroll All Certificate Holders** (Figure 14).

| **Note** |
| --- |
| Templates are not updated automatically. By default, templates are updated at a minimum interval of 10 minutes. |

**Figure 14: Manually Forcing Certificate Re-Enrollment**

**Smart Card Renewal**

The renewal behavior of a smart card may vary depending on the type of smart card CSP being used and the state of the card at the time of renewal. In general, if the smart card being used has available space for an additional enrollment and the CSP supports multiple keys on a single card, autoenrollment will request the card to generate a new key for enrollment. If this succeeds, the certificate is written to the card and the container is marked as default. The default container is the only container that the Winlogon process will enumerate for a smart card logon certificate and key. If the smart card or CSP cannot generate a new key on the card, the existing key will be reused and a new certificate will be forced onto the card. This action will generate an event in the machines application event log.

| **Note** |
| --- |
| Autoenrollment will always use a newly generated key for all enrollment and renewal requests. The only exception to this rule is in the case of some smart card CSPs that cannot support a new key due to storage limitations on the smart card. If a key is reused, an event will be entered in the Client application log. |

**Revoked Certificates and Renewal**

Revoked certificates may not be renewed and may not be used to sign a renewal request. This scenario is explicitly blocked by autoenrollment. In this scenario, a user must perform a new manual enrollment request instead of renewal.

# Autoenrollment Functions

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section discusses various functions performed by the autoenrollment process on Active Directory domain-joined machines.

**Download of Active Directory Certificates and Trust Objects**
Autoenrollment automatically downloads and manages trusted root certificates, cross-certificates, and NTAuth certificates from Active Directory into the local machine registry for domain-joined machines. All users who log on to the machine inherit the trust and downloaded certificates that are downloaded and managed by autoenrollment.

**Deleting Expired and Revoked Certificates**
Autoenrollment deletes expired and revoked certificates in the userCertificate attribute on the user object in Active Directory. This feature can be enabled through user or machine Group Policy to help ensure that only valid and active certificates are used for encryption operations.

The exit module on the Windows Server 2003 CA also helps to manage the user account in Active Directory, but only deletes expired certificatesit does not remove revoked certificates due to performance reasons. In general, there is no value in publishing a signing certificate to the user object in Active Directory, except for purposes of record-keeping.

**Managing User Certificates in the CryptoAPI MY Store**
Certificates in the users local **MY certificate store** may also be managed through the autoenrollment process. On a per-template basis, autoenrollment can be enabled to delete expired and revoked signature certificates. Encryption certificates and keys are never automatically deleted. However, autoenrollment only manages certificates that correspond to certificate templates defined in Active Directory that contain the certificate template extension. This feature is enabled by setting this policy on the Request Handling tab in the Properties of a given certificate template (Figure 15).

**Figure 15: Managing Certificates**

If the Delete revoked or expired certificates check box is not enabled, autoenrollment will archive all expired and revoked certificates in the users MY store. As mentioned previously, this setting does not affect the userCertificate attribute in Active Directory for the user object.

| **Note** |
| --- |
| This feature is only enabled with encryption keys, not signature key types, which are not normally published to Active Directory. |

# Updating Group Policy

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section discusses how to update User and Machine Group Policy.

**User and Machine Group Policy**
User autoenrollment is triggered by the Winlogon process (interactive logon with CTRL+ALT+DELETE keys) or at Group Policy refresh intervals. Normally, User Group Policy is refreshed at logon and Machine Group Policy is refreshed at machine reboot. Group Policy may be manually refreshed using the gpupdate.exe tool that is included in Windows XP.

**Manually Forcing a Group Policy Update**
To manually force a Group Policy update (for a user or a machine)

- Run gpupdate.exe with the -Force option at the command line (Figure 16).

**Figure 16: Forcing a Group Policy Update**

# Advanced Features

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section discusses templates that require certificate manager approval, self-registration authority, and how to supersede a certificate template.

**Requiring Certificate Manager Approval**
A specific certificate template can require that a certificate manager (CA officer) approve the request prior to the CA actually signing and issuing the certificate. This advanced security feature works in conjunction with autoenrollment and is enabled on the Issuance Requirements tab of a given certificate template (Figure 17). This setting overrides any pending setting on the CA itself.

Once certificate manager approval is required, all automatic enrollment requests are not issued until a certificate manager manually approves the request.

**Figure 17: Setting the Requirement for Certificate Manager Approval**

The autoenrollment process will periodically check the CA for approved requests and install the certificates automatically. Smart cards, user certificates, and machine certificates support pending requests. In the case of smart cards, the user will be prompted to insert the smart card when the certificate is issued so that the certificate may be written to the card.

| **Note** |
| --- |
| The autoenrollment process supports a maximum of one signature requirement on the template. This limitation exists to support the self-registration authority feature described in Self-Registration Authority. If multiple signatures are desired for a given certificate enrollment, manual enrollment should be used. |

**Self-Registration Authority**
The self registration authority (Self RA) is an advanced feature of certificate enrollment that may be combined with the autoenrollment process.

Self RA refers to certificate enrollment based on the existence of a previously enrolled certificate in which the users private key is used to sign the new certificate request. The Certificate Management Messages over CMS (CMC) protocol provides for this feature where one or more signatures may be used or required for a given certificate enrollment. Self RA requirements are defined in a certificate template which may be managed using the Certificate Templates MMC snap-in.

- To add an issuance (signature) requirement to a certificate template, open the template and click the **Issuance**

**Requirements** tab.

To add a signature or issuance requirement, select the **This number of authorized signatures** check box and add the appropriate number in the following number field (Figure 18).

Now you may add specific requirements for the signing certificate.

**Figure 18: Setting the Number of Authorized Signatures**

The previous setting is a useful configuration for customers who want to manually enroll users for smart cards with an enrollment station. Then they can supersede the original template with a new template with the previous settings to allow automatic renewal through the autoenrollment process, which will require the user to sign the renewal request with the old certificate.

**Additional Self RA Example:** You could add the Application Policy for a smart card logon certificate that would be used to enroll for an EFS certificate. This would mandate that users sign their request for an autoenrolled EFS certificate with a valid smart card certificate. The user would then be prompted to insert a smart card and enter a PIN when autoenrollment was activated for the EFS certificate.

**Superseding Certificate Templates**

Certificate autoenrollment also supports the concept of superseding a template or a previously enrolled certificate. Superseding a template allows an administrator to re-enroll, change, or combine previously issued certificate enrollments into a new certificate enrollment. Autoenrollment always examines existing certificates in the users store and determines if the template used in the issued certificate has been superseded. If a certificate template has been superseded, the user will automatically be enrolled with the new template, and the old certificates will be deleted or archived depending on the template setting.

**Benefits**

Superseding certificate templates is especially useful in the following scenarios.

- Changing certificate lifetime
- Increasing key size
- Adding extended key usage or application policies
- Correcting enrollment policy errors
- Updating users from version 1 templates to version 2 templates

To create or modify a template to supersede an existing certificate

1. Open the **Properties** of the template to take precedence, click the **Superseded Templates** tab (Figure 20), and then click **Add**.

2. Select the template you want to supersede (Figure 19), and then click **OK**.

**Figure 19: Selecting a Template to Supersede**

3. The template will be added to the **Superseded Templates** tab (Figure 20). If you wish to add additional templates that should be superseded with this new template, click **Add** and repeat. Otherwise, click **OK**.

**Figure 20: Listing Superseded Templates**

| **Note** |
| --- |
| Superseding a certificate always generates a new private key for the user or machine. |

# Supported Hardware (Certificate Autoenrollment in Windows Server 2003)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section lists the smart card readers and smart cards that are supported in the default installations of Windows 2000 and Windows Server 2003.

**Table 1 Smart Card Readers**

| Name | Type | Common Name | Windows 2000 | Windows XP/Server 2003 |
|---|---|---|---|---|
| BULL SmarTLP3 | Serial | | Yes | Yes |
| GEMPLUS GCR410P | Serial | GemPC410 | Yes | Yes |
| GEMPLUS GPR400 | PCMCIA | GemPC400 | Yes | Yes |
| Litronic 220 | Serial | | Yes | Yes |
| Rainbow Technologies SCR3531 | Serial | | Yes | No |
| Schlumberger Reflex 20 | PCMCIA | | Yes | Yes |
| Schlumberger Reflex 72 | Serial | | Yes | Yes |
| SCM Microsystems SCR120 | PCMCIA | | Yes | Yes |
| SCM Microsystems SCR200 | Serial | | Yes | Yes |
| SCM Microsystems SCR300 | USB | | Yes | Yes |
| GEMPLUS GemPC430 | USB | | No | Yes |
| HP ProtectTools | Serial | | No | Yes |
| Schlumberger Reflex Lite | Serial | | No | Yes |
| SCM Microsystems SCR111 | Serial | | No | Yes |
| Systemneeds External | Serial | | No | Yes |
| Omnikey AG CardMan 2020 | USB | Utimaco CardMan | No | Yes |
| Omnikey AG CardMan 4000 | PCMCIA | Utimaco CardMan | No | Yes |
| Omnikey AG CardMan 2010 | Serial | Utimaco CardMan | No | Yes |

**Table 2 Smart Cards**

| Name | Capacity | Windows 2000 | Windows XP/Server2003 |
|---|---|---|---|

| | | | |
|---|---|---|---|
| Gemplus GemSAFE | 4k | Yes | Yes |
| Schlumberger Cryptoflex | 4k | Yes | Yes |
| Schlumberger Cryptoflex | 8k | Yes | Yes |
| Gemplus GemSAFE | 8k | No | Yes |
| Infineon (formerly Siemens) | | No | Yes |
| Schlumberger Cyberflex Access | 16k | No | Yes |

| **Note** |
|---|
| The GEMPLUS GemPC430 is not supported on Windows Server 2003. |

# Troubleshooting (Certificate Autoenrollment in Windows Server 2003)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This section outlines key scenarios that need to be considered when troubleshooting autoenrollment. It also covers how to prepare for autoenrollment failures and lists event logging messages.

**Key Issues**
The following key issues need to be considered when troubleshooting autoenrollment.

**Infrastructure Requirements**
Windows XP clients and Windows Server 2003 CAs will always request LDAP-signed communications with domain controllers as a security function. Before deploying autoenrollment or a Windows Server 2003 CA, all domain controllers running Windows 2000 should be upgraded to Service Pack 3 or greater.

**Root and Cross-Certificate Download from Active Directory**
Autoenrollment automatically downloads root certificates and cross-certificates from Active Directory whenever a change is detected in the directory or when a different domain controller is contacted. If a third-party root certificate or cross-certificate is deleted from the local machine store, autoenrollment will not download the certificates again until a change occurs in Active Directory or a new domain controller is contacted.

To manually force a new download, delete the following registry key and all subordinate keys on all affected machines.
**HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Cryptography\AutoEnrollment\AEDirectoryCache**

**EFS and Autoenrollment**
EFS always attempts to enroll for the Basic EFS template by default. The EFS component driver generates an autoenrollment request that autoenrollment tries to fulfill. For customers who want to ensure that a specific template is used for EFS (such as to include key archival), the new template should supersede the Basic EFS template. The Basic EFS template should also be removed from any Enterprise CA. This will ensure that autoenrollment will not attempt enrollment for the Basic EFS template any more. For customers who wish to replace the Basic EFS template with a certificate and key that is archived through the Windows Server 2003, Enterprise Edition CA, the proper procedure is to supersede the Basic EFS template with a new version 2 certificate template.

**Smartcard Renewal**
The Smartcard Logon and Smartcard User version 1 templates may not be renewed through autoenrollment. To renew a version 1 Smartcard Logon or Smartcard User template, the proper procedure is to supersede these templates with a new version 2 template.

Autoenrollment always attempts to generate a new key when performing certificate renewal. For smart cards with limited space that do not support additional key generation, autoenrollment will attempt to reuse the key; however, additional space will still be required to install the new certificate. If no space is available on the card for these operations, the renewal through autoenrollment may fail.

**Autoenrollment and Strong Private Key Protection**
The version 2 certificate template properties on the Request Handling tab support the ability to require a user password when the private key is used by applications. This is set by selecting the Prompt the user during enrollment option and requires user input when the private key is used. It is important to never use this option for smart card certificates as smart card CSPs also do not support this capability. If this option is chosen, autoenrollment may fail.

**Removal of Certificates on Domain Join/Change Domain**
When a machine is removed from a domain or added to a new domain, all the downloaded certificates from Active Directory will be removed and refreshed if applicable. Certificates that were issued or autoenrolled from a previous forest will not be removed unless the machine is a domain controller. All client machines will automatically update certificates when the domain or machine information changes. When machines or users have certificates that are required for secure network communications, wireless communications, and so on, it may be necessary to delete the old certificates after joining a new domain or forest.

**Autoenrollment Failures**
Autoenrollment will warn the user with a warning dialog box when an autoenrollment failure occurs. This feature is only enabled when user interaction is required on the certificate template.

To enable the warning feature for an autoenrollment failure

1. Open the specified template in the **Certificate Templates** MMC snap-in.

2. Click the **Request Handling** tab.

3. Click **Prompt the user during enrollment** on the Request Handling tab of the certificate template properties.

**Re-Initialized Smart Cards**
If enrollment for a certificate is based on the existence of a smart card certificate and if the smart card has been re-initialized, the smart card Insertion dialog box will ask the user to insert a smart card matching the key container identified by the old certificate. Since the key container has been deleted, the Insertion dialog box will continue to display despite the fact that the user has removed and inserted the card. The only choice is to click Cancel and fail the enrollment.

**Enhanced Event Logging**
By default, autoenrollment logs errors/failures and successful enrollments in the Application event log on the client machine.

To enable enhanced logging of autoenrollment processes to include warning and informational messages, the following registry values must be created.

**User Autoenrollment**
**HKEY_CURRENT_USER\Software\Microsoft\Cryptography\Autoenrollment**: Create a new DWORD value named AEEventLogLevel"; set value to 0.

**Machine Autoenrollment**
**HKEY_LOCAL_MACHINE\Software\Microsoft\Cryptography\Autoenrollment**: Create a new DWORD value named "AEEventLogLevel", set value to 0.

| **Note** |
|---|
| All failures and errors are automatically logged. It is not necessary to enable the registry key to turn on failure logging. |

**Event Log Messages**
The following event log messages only appear when additional event logging is enabled.

**Success Event Log Messages**
The following are samples of successful event log messages.

| | |
|---|---|
| Event Type: | Information |
| Event Source: | AutoEnrollment |

| Event Category: | None |
| Event ID: | 29 |
| Date: | 7/17/2001 |
| Time: | 9:37:29 AM |
| User: | CONTOSO\user1 |
| Computer: | TESTCA |
| Description: | Automatic certificate enrollment for CONTOSO\user1 reused the private key when requesting one Autoenroll Smart card User certificate. |

| **Note** |
|---|
| This event signifies the fact that the private key was reused during a certificate renewal. |

**Failed Event Log Messages**

The following are samples of failed event log messages.

| | |
|---|---|
| Event Type: | Error |
| Event Source: | AutoEnrollment |
| Event Category: | None |
| Event ID: | 15 |
| Date: | 7/8/2001 |
| Time: | 3:09:41 PM |
| User: | N/A |
| Computer: | TEST1 |
| Description: | Automatic certificate enrollment for CONTOSO\User1 failed to contact Active Directory (0x8007054b). The specified domain either does not exist or could not be contacted. Enrollment will not be performed. |

| **Note** |
|---|
| This error most often occurs when a user is logged on to a machine with cached credentials and is offline. Therefore, autoenrollment cannot continue and will be attempted later. |

| | |
|---|---|
| Event Type: | Error |
| Event Source: | AutoEnrollment |
| Event Category: | None |
| Event ID: | 15 |
| Date: | 2/24/2001 |
| Time: | 10:36:08 AM |
| User: | N/A |
| Computer: | TEST1 |
| Description: | Automatic certificate enrollment for local system failed to contact a directory server (0x80072751). A socket operation was attempted to an unreachable host. Enrollment will not be performed. |

| **Note** |
|---|
| This error most often occurs when a domain controller is not available or is not accessible by the client. Common causes include network errors, network connectivity, and so on. |

| | |
|---|---|
| Event Type: | Error |
| Event Source: | AutoEnrollment |
| Event Category: | None |

| | |
|---|---|
| Event ID: | 13 |
| Date: | 7/5/2001 |
| Time: | 9:37:44 AM |
| User: | N/A |
| Computer: | TEST1 |
| Description: | Automatic certificate enrollment for local system failed to enroll for one CONTOSO IPSEC certificate (0x800706ba). The RPC server is unavailable. |

| **Note** |
|---|
| This error typically occurs when the certification authority is not available on the network or the service is stopped. |

| | |
|---|---|
| Event Type: | Error |
| Event Source: | AutoEnrollment |
| Event Category: | None |
| Event ID: | 13 |
| Date: | 7/5/2001 |
| Time: | 7:41:27 AM |
| User: | N/A |
| Computer: | TEST1 |
| Description: | Automatic certificate enrollment for local system failed to enroll for one CONTOSO IPSEC certificate (0x8009400f). An attempt was made to open a certification authority database session, but there are already too many active sessions. The server may need to be configured to allow additional sessions. |

| **Note** |
|---|
| This is a rare event when the certification authority is under heavy load and cannot respond to the request in a timely manner. Autoenrollment will automatically try again at a later time. |

| | |
|---|---|
| Event Type: | Error |
| Event Source: | AutoEnrollment |
| Event Category: | None |
| Event ID: | 16 |
| Date: | 7/5/2001 |
| Time: | 2:53:34 AM |
| User: | N/A |

| | |
|---|---|
| Computer: | TEST1 |
| Description: | Automatic certificate enrollment for local system failed to renew one CONTOSO IPSEC certificate (0x8009400f). An attempt was made to open a Certification Authority database session, but there are already too many active sessions. The server may need to be configured to allow additional sessions. |

| **Note** |
|---|
| This is the same error as the previous one, but it involves a renewal. |

| | |
|---|---|
| Event Type: | Warning |
| Event Source: | AutoEnrollment |
| Event Category: | None |
| Event ID: | 7 |
| Date: | 7/24/2001 |
| Time: | 7:48:27 PM |
| User: | CONTOSO\USER1 |
| Computer: | TEST1 |
| Description: | Automatic certificate enrollment for CONTOSO\USER1 could not enroll for Key Recovery Agent certificate template due to one of the following situations. |

- Enrollment access is not allowed to this template.
- Template subject name, signature, or hardware requirements cannot be met.
- No valid certification authority can be found to issue this template.

| **Note** |
|---|
| This is an autoenrollment error that occurs when a user has a certificate and private key installed that corresponds to a given template that is now expiring. Autoenrollment attempts to automatically renew the certificate; however, the user does not have applicable permissions for this template and therefore autoenrollment fails. Autoenrollment is based on certificates in the store as well as certificate template settings. |

| | |
|---|---|
| Event Type: | Error |
| Event Source: | AutoEnrollment |
| Event Category: | None |
| Event ID: | 13 |
| Date: | 7/17/2001 |
| Time: | 9:22:10 AM |

| | |
|---|---|
| User: | CONTOSO\user1 |
| Computer: | TESTCA |
| Description: | Automatic certificate enrollment for CONTOSO\user1 failed to enroll for one Autoenroll smart card user certificate (0x80094812). The e-mail name is unavailable and cannot be added to the Subject or Subject Alternate name. |

| **Note** |
|---|
| This error occurs when the user account in Active Directory does not have a valid e-mail address on the user property page in Active Directory Users and Computers MMC snap-in. Enrollment for certificate templates in Active Directory requires an e-mail address to exist prior to enrollment. |

**Event Log Tools**

A new tool (script) is included on the Windows XP Professional and Windows Server 2003 client to query a local system for various events. This script can be used to identify autoenrollment errors on the client and perform appropriate actions. The command line help for this tool is noted and provided as follows:

```
Z:\>eventquery /?
Microsoft (R) Windows Script Host Version 5.6
Copyright © Microsoft Corporation 1996-2001. All rights reserved.
---------------------------------------------------------------------
EVENTQUERY.vbs [/S system [/U user name [/P password]]] [/FI filter]
        [/FO format] [/R range] [/NH] [/V] [/L logname | *]
Description:
  The EVENTQUERY.vbs script enables an administrator to list
  the events and event properties from one or more event logs.
Parameter List:
  /S   system     Specifies the remote system to connect to.
  /U   [domain\]user  Specifies the user context under which the
             command should execute.
  /P   password    Specifies the password for the given
             user context.
  /V           Specifies that the detailed information
             should be displayed in the output.
  /FI  filter     Specifies the types of events to
             filter in or out of the query.
  /FO  format     Specifies the format in which the output
             is to be displayed.
             Valid formats are "TABLE", "LIST", "CSV".
  /R   range      Specifies the range of events to list.
             Valid Values are:
               'N' - Lists 'N' most recent events.
              '-N' - Lists 'N' oldest events.
             'N1-N2' - Lists the events N1 to N2.
  /NH          Specifies that the "Column Header" should
             not be displayed in the output.
             Valid only for "TABLE" and "CSV" formats.
  /L   logname     Specifies the log(s) to query.
 /?          Displays this help/usage.
  Valid Filters Operators allowed  Valid Values
  ------------- ------------------ ------------
  DATETIME    eq,ne,ge,le,gt,lt  mm/dd/yy(yyyy),hh:mm:ssAM(/PM)
  TYPE      eq,ne        ERROR, INFORMATION, WARNING,
                   SUCCESSAUDIT, FAILUREAUDIT
  ID       eq,ne,ge,le,gt,lt  non-negative integer
  USER      eq,ne        string
  COMPUTER    eq,ne        string
  SOURCE     eq,ne        string
  CATEGORY    eq,ne        string
```

| **Note** |

| Filter "DATETIME" can be specified as "FromDate-ToDate" |

```
   Only "eq" operator can be used for this format.
Examples:
  EVENTQUERY.vbs
  EVENTQUERY.vbs /L system
  EVENTQUERY.vbs /S system /U user /P password /V /L *
  EVENTQUERY.vbs /R 10 /L Application /NH
  EVENTQUERY.vbs /R -10 /FO LIST /L Security
  EVENTQUERY.vbs /R 5-10 /L "DNS Server service"
  EVENTQUERY.vbs /FI "Type eq Error" /L Application
  EVENTQUERY.vbs /L Application /FI "Datetime eq 06/25/00,03:15:00AM-
06/25/00,03:15:00PM"
  EVENTQUERY.vbs /FI "Datetime gt 08/03/00,06:20:00PM"           /FI "Id gt 700" /FI
"Type eq warning" /L System
  EVENTQUERY.vbs /FI "Type eq error OR Id gt 1000 "
```

# Summary (Certificate Autoenrollment in Windows Server 2003)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

Windows Server 2003, Enterprise Edition through the Certificate Services component provides user certificate autoenrollment. This allows administrators to easily deploy certificates throughout the enterprise while requiring no user interaction. User certificate autoenrollment in the Windows XP Professional and Windows Server 2003 operating systems builds on Microsofts long-established reputation for shipping robust PKI components that have a low TCO. Since PKI is an integral part of the Windows XP Professional operating system, Windows Server 2003 PKI provides some distinct advantages over third-party add-in components. These advantages include:

- No per-certificate fees or per-user PKI licenses
- Centralized user security management
- Integration with normal enterprise management tasks
- Single sign-on capabilities to networks and applications
- Managed trust capabilities
- Support for all applications through CryptoAPI

Keep in mind that almost all third-party PKIs must be purchased separately, and require per-certificate license fees and increased management tasks.

Overall, certificate autoenrollment features in Windows Server 2003 should provide organizations and enterprises with the ability to effortlessly deploy digital certificates and PKI-enabled applications with little or no additional cost to a normal IT operations budget.

# Account Passwords and Policies in Windows Server 2003

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Microsoft Windows NT Server 4.0, Windows 2000, Windows XP, and the Windows Server 2003 Family

Password and account lockout settings are designed to protect accounts and data in your organization by mitigating the threat of brute force guessing of account passwords. Settings in the Account Lockout and Password Policy nodes of the Default Domain policy settings enable account lockout and control how account lockout operates. This white paper describes how these settings affect account lockout and makes some general recommendations for configuring and troubleshooting account lockout issues.

This document describes the reasons why you should take a structured approach to setting the account and password policy features. The document also provides information about the tools and log files that you can use to troubleshoot account lockouts. After you read this document, you should be able to determine from which computer the account lockouts are being generated, as well as the program or service that is generating the lockout.

**In This White Paper**

# Account Lockout and Password Concepts

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Passwords are an important step in a security plan for your network. Users may see passwords as a nuisance; however, the security of your enterprise relies on a combination of password length, password uniqueness, and password lifespan. These three items help defend against dictionary attacks and brute force attacks. A dictionary attack occurs when a malicious user tries known words that are in the dictionary and a number of common password names to try and guess a password. A brute force attack occurs when a malicious user tries all of the possible permutations until one is successful.

Because most users prefer passwords that they can easily remember, dictionary attacks are often an effective method for a malicious user to find a password in significantly less time than they would with brute force attacks. Therefore, the strength of a password depends on how many characters are in the password, how well the password is protected from being revealed by the owner, how well the password is protected if it is intercepted by a malicious user on the network, and how difficult the password is to guess. Even good passwords that are protected by cryptography on the network and that are not subject to dictionary attacks can be discovered by brute force in a few weeks or months by a malicious user who intercepts the password on the network.

Currently, several attack methods are based on guessing weak passwords by using dictionary and brute force attacks. For a few simple ways to help prevent these attacks, see "Protecting from External Lockout Denial of Service Attacks" in this document for ports to block and registry values that you can set to help prevent such attacks.

Frequently, a malicious user will guess a number of passwords during a password-based attack. To help prevent the attacks from being successful, you can configure account lockout settings. The result of this configuration is that the associated account is temporarily disabled after a specified number of incorrect passwords are tried. This helps to prevent a successful attack by preventing the account from being used. However, a legitimate user cannot use that account until it is unlocked. This paper discusses the balance between the benefits and risks of account lockout.

**Understanding Password Complexity**

A complex password that is enforced by the operating system is one of the most effective methods that you can use to deter the opportunity for a successful attack. When you configure both an expiration time and a minimum length for a password, you decrease the time in which a successful attack could occur. For example, when you enforce password complexity with a password length of 6 and set the password to expire in 60 days, a user can choose from a permutation of:

- 26 lowercase characters
- 26 uppercase characters
- 32 special characters
- 10 numbers

This means that:

- 26 + 26 + 32 + 10 = 94 possible characters in a password
- Password length policy = 6
- $94^6$ = 689,869,781,056 unique password permutations

With a 60-day password expiration time, the malicious user would have to make 133,076 password attempts every second to attempt all of the possible passwords during that password's limited lifetime. If it takes only 50 percent of the permutations to guess the password, a malicious user would have to attempt to log on to the computer about 66,538 (133,076 * .50) times every second to discover the password before it expires.

To decrease the chances that a malicious user has to discover the password, you can use a password length of 7. When you set the minimum password length to 7, the possible password permutations exceed 64 trillion (947= 64,847,759,419,264). When you compare the calculations above that have a password length of 6 to the calculations below that have a password length of

7, you will notice that the malicious user would have to log on to the computer about 6,254,606 times for each second that the password is valid in the 60-day expiration time that you set.

The following list describes how increasing password length deters both dictionary and brute force attacks. Note that the examples that are in this list assume that you are have applied a policy that requires users to create complex passwords. When you do this, there are 94 possible characters from which the users can choose their password.

- 6 characters: $94^6$ = 689,869,781,056
- 7 characters: $94^7$ = 64,847,759,419,264
- 8 characters: $94^8$ = 6,095,689,385,410,816
- 9 characters: $94^9$ = 572,994,802,228,616,704
- 10 characters: $94^{10}$ = 53,861,511,409,489,970,176

| **Note** |
| --- |
| A few of these password possibilities are not valid. By default, users cannot choose any part of their user name for their password and they cannot use all of the same characters as a password. Because of this, these password possibilities must be deducted from the total number of possible passwords that are listed above. Because there are very few passwords that apply to these exceptions and because the number of passwords that do apply to these exceptions can vary (based on the number of letters that are in the user's logon name), this document does not account for these exceptions. |

These statistics explain how difficult it is for a malicious user to discover a password when you require the users in your network to use a complex password. Because of this, Microsoft recommends that you enforce a complex password policy that requires users to choose passwords with a specific number of characters for the security needs of your organization. The "Password Policies Settings" section in this document describes the complex password policies and settings for Microsoft® Windows NT® Server 4.0, the Windows® 2000 family, and the Windows Server 2003 family of operating systems.

Microsoft recommends that you use the account lockout feature to help deter malicious users and some types of automated attacks from discovering user passwords. The following section provides more information about how you can use the account lockout feature.

**Authentication**

Authentication is the process of validating a user name and password on a domain controller for:

- The initial logon to either a workstation or domain that uses the CTRL+ALT+DELETE secure logon sequence.
- An attempt to unlock a locked workstation by using the CTRL+ALT+DELETE secure logon sequence.
- An attempt to type a password for a password-protected screen saver.
- A user, script, program, or service that attempts to connect to a network resource by using either a mapped drive or a Universal Naming Convention (UNC) path.

| **Note** |
| --- |
| An account that is locked out may still be able to gain access to some resources if the user has a valid Kerberos ticket to the resource. The ability to access the resource ends when the Kerberos ticket expires. However, neither a user who is locked out nor a computer account can renew the ticket. Kerberos cannot grant a new ticket to the resource because the account is locked out. |

There are two primary authentication protocols used by Windows: NTLM and Kerberos. This paper assumes you are familiar with these authentication protocols and does not focus on authentication details. Instead, the focus is placed on how authentication plays a role in account lockout. For more information about authentication protocols, see online help in Windows XP and the Windows Server 2003 family.

**How Domain Controllers Verify Passwords**
To illustrate the authentication process, the following diagram describes the steps that occur when a logon attempt does not work.

**Figure 1: Process for a Failed Logon Attempt**

1. The client computer presents the user logon information to a domain controller. This includes the users account name and a cryptographic hash of their password. This information can be sent to any domain controller and is typically sent to the domain controller that is identified as the closest domain controller to the client computer.

2. When a domain controller detects that an authentication attempt did not work and a condition of STATUS_WRONG_PASSWORD, STATUS_PASSWORD_EXPIRED, STATUS_PASSWORD_MUST_CHANGE, or STATUS_ACCOUNT_LOCKED_OUT is returned, the domain controller forwards the authentication attempt to the primary domain controller (PDC) emulator operations master. Essentially, the domain controller queries the PDC to authoritatively determine if the password is current. The domain controller queries the PDC for this information because the domain controller may not have the most current password for the user but, by design, the PDC emulator operations master always has the most current password.

3. The authentication request is retried by the PDC emulator operations master to verify that the password is correct. If the PDC emulator operations master rejects the bad password, the PDC emulator operations master increments the **badPwdCount** attribute for that user object. The PDC is the authority on the user's password validity.

4. The failed logon result information is sent by the PDC emulator operations master to the authenticating domain controller.

5. The authenticating domain controller also increments its copy of the **badPwdCount** attribute for the user object.

6. The authenticating domain controller then sends a response to the client computer that notifies the domain controller that the logon attempt did not work.

As long as that user, program, or service continues to send incorrect credentials to the authenticating domain controller, logon attempts that failed because of an incorrect password continue to be forwarded to the PDC until the threshold value for incorrect logon attempts is reached (if you set it in a policy). When this occurs, the account is locked out.

For more information, see "How the Bad Password Count Is Incremented in Windows NT" in the Microsoft Knowledge Base.

**New Features in the Windows Server 2003 Family**
In the Windows Server 2003 family of operating systems, Microsoft has improved the function of the Account Lockout feature on both servers and client computers.

**Computers Running Windows Server 2003 That Act As Network Servers**
To improve the experience for users and to decrease the overall total cost of ownership, Microsoft made the following changes to the behavior of domain controllers in the Windows Server 2003 family:

- **Password history check (N-2):** Before a Windows Server 2003 operating system increments **badPwdCount**, it checks the invalid password against the password history. If the password is the same as one of the last two entries that are in the password history, **badPwdCount** is not incremented for both NTLM and the Kerberos protocol. This change to domain controllers should reduce the number of lockouts that occur because of user error.

- **Single user object on demand replication:** See the "Urgent Replication" section in this document for more information.

- **Optimized replication frequency:** The default frequency for replication between sites is to replicate every 15 minutes with a 3-second offset to stagger the replication interval. This optimization improves the replication of a password change in a site because it decreases the chances that the domain controller would have to contact the PDC operations master.

**Computers Running Windows Server 2003 Family Acting As Network Clients**

Microsoft has added the following features in the Windows Server 2003 family to gather the process ID that is using the credentials that fail authentication:

- **Auditing logon changes:** There are entries for all logon and logoff events (528 and 540, as well as 529 through 539).
- **Auditing of processes encountering authentication failures:** New information is added to the Security event log when authentication failures occur:
  - Caller User Name
  - Caller Domain
  - Caller Logon ID
  - Caller Process ID

| **Note** |
| --- |
| To use the process ID, turn on success auditing for **Audit process tracking** events so that you can obtain the process identifier (PID) for the associated Event 592. If you do not do this, the PID is not useful after the process stops. To view audit process tracking, in the Group Policy Microsoft Management Console (MMC), in the console tree, double-click **Computer Configuration**, double-click **Windows Settings**, double-click **Security Settings**, double-click **Local Policies**, and then double-click **Audit Policy**. |

Microsoft has added the following administrative enhancements to provide more account lockout information than the information that is available in the default configuration of the Windows Server 2003 family:

- **AcctInfo.dll:** The AcctInfo.dll file is a property page extension for user objects in the Active Directory Users and Computers MMC that provides detailed information about user password attributes. An administrator can use the AcctInfo.dll file to reset user account passwords on a domain controller that is in the user's Active Directory site.
- **LockoutStatus.exe:** The LockoutStatus.exe tool displays bad password count and time information from all of the domain controllers that are in a domain. You can run this tool as either a stand-alone tool or as an extension to the AcctInfo.dll file when you place it in the Systemroot\System32 folder on your computer.

More information about both AcctInfo.dll and LockoutStatus.exe is available in "Account Lockout Tools" in this document.

# Configuring Account Lockout Settings

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

To enable the Account Lockout policy settings for both domain and local users, configure the settings that are described in this section.

**Recommended Service Packs and Hotfixes**
Security issues in Windows operating systems are discovered and fixed often. These fixes often have an impact on account lockout and password policy features, as well as their dependent components. Therefore, you should apply the latest service packs and hotfixes to all of the domain controllers, servers, and clients to ensure that the account security settings that you want are applied and to ensure that the domain controllers and operating systems are up-to-date. Note that service packs resolve groups of issues and hotfixes resolve a specific issue.

You should have an ongoing strategy to keep your computers updated and protected against viruses, trojans, and so on, that may use vulnerabilities that are already fixed. For more information about how to create a software update strategy, refer to Help and Support Center in the Windows Server 2003 family and Windows XP, or refer to Help in Windows 2000.

Because these issues are discovered and fixed on an ongoing basis, they are not listed in this document. For more information, see "Service Packs and Hotfixes Available to Resolve Account Lockout Issues" in the Microsoft Knowledge Base.

# Configuring Account Lockout

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

The account lockout policy settings are designed to help prevent a brute force attack on user passwords. This section describes where you can configure the setting, as well as some things that you should consider before you use the settings.

**Configuring Account Lockout for Domain Users**
For domain users, set the appropriate values by configuring the default domain policy in the console tree. To configure the default domain policy, open the Group Policy MMC, double-click **Computer Configuration**, double-click **Windows Settings**, double-click **Security Settings**, double-click **Account Policies**, and then double-click **Account Lockout Policy**. For more detailed steps, see "Account Lockout Settings" in this document.

**Configuring Account Lockout for Local Users**
For a stand-alone workstation, set the appropriate registry values by configuring the local policy:

1. Click **Start**, click **Run**, type **gpedit.msc**, and then press ENTER.
2. In the Group Policy Object Editor MMC, double-click **Computer Configuration**, double-click **Windows Settings**, double-click **Security Settings**, double-click **Account Policies**, and then double-click **Account Lockout Policy**.
3. In the details pane, right-click the policy setting that you want, and then click **Properties**.
4. If you are defining this policy setting for the first time, click **Define this policy setting**.
5. Select the options that you want, and then click **OK**.

Microsoft recommends that you do not exempt the privileged accounts from password policies. Your privileged accounts should have complex passwords, an expiration period, and the passwords should be a minimum of fifteen characters in length. Microsoft also recommends that you also protect the local accounts (non-domain clients) by using a local password policy for all users. For all workstations in a domain, set a domain-level Group Policy object (GPO) and filter it to apply to the domain member computer.

**Choosing Account Lockout Settings for Your Deployment**
This section describes the ramifications of changing the various settings and a way to estimate the difficulty of using the brute force method of password guessing with a certain configuration. Like other settings that are associated with passwords, choosing settings for account lockout involves balancing the benefits and drawbacks between security, usability, and cost. The primary consideration is how much risk is acceptable when you configure the password policy of the domain. For example, consider the following two domain configurations:

- User accounts that are in domain A have a minimum password length of 3 characters, no password complexity requirements, and passwords never expire.
- User accounts that are in domain B have a minimum password length of 6 characters, password complexity, and passwords in the domain expire in 42 days.

There is less risk of a malicious user guessing the password of a domain B user; for the same risk tolerance, domain B can have a less stringent account lockout policy. Whether you set the **LockoutDuration** registry value to 0 or not also has an important on the setting that is permitted for both the **ObservationWindow** and **LockoutThreshold** registry values.

As an example, assume that the administrator resets the password when the account is locked with **LockoutDuration** registry value of 0. With the **LockoutDuration** registry value set to 0 and the **LockoutThreshold** registry value set to 20, the malicious user has 20 guesses to use against that password. If the lockout duration is 30 minutes, the malicious user has 20 guesses every 30 minutes against that password until it is changed. This is a very significant difference in the total number of guesses that are available to the malicious user.

In comparison, if the administrator sets the maximum password age to 42 days, the first malicious user has only 20 guesses against any given password, while the second malicious user has 40,320 guesses (20 tries for ever lockout, multiplied by 48

lockouts every day, multiplied by 42 days before the user changes the password). With the default password settings, there are approximately 1012 possible passwords. This means that the malicious user has approximately a .000004 percent (%) chance of guessing the password. With an optimized guessing scheme, this percentage would most likely be a larger percentage.

This example demonstrates that setting the **LockoutDuration** registry value to 0 allows the **LockoutThreshold** registry value to be a significantly higher number for equivalent risk tolerance. If you increase the **LockoutThreshold** registry value, you help to reduce the behavior of a user accidentally locking themselves out of their computer.

When you choose the setting for account lockout, it is important that you consider the inherent denial of service that is associated with a locked out account. Ideally, the only accounts that are locked out are the accounts that are being attacked. However, the computer cannot determine the difference between a user typing an incorrect password or an automated task that is using an incorrect password. As a result, from the users perspective, users who are trying to perform their daily tasks may be suddenly unable to perform their work, which incurs both the cost of support to the domain and the cost of lost work. The lower the value that you set for the **LockoutThreshold** registry value, the more likely this behavior is to occur. The length of the **ObservationWindow** registry value has much less effect on this behavior than the **LockoutThreshold** registry value.

Microsoft recommends that you regularly review the Security event logs of all computers so that you are aware of any patterns that might show an attack or user error. The values that are necessary to identify specific malicious users and targets can be obtained only after you implement the auditing policies that are mentioned in the "Appendix Two: Gathering Information to Troubleshoot Account Lockout Issues" section in this document. Microsoft offers an event log monitoring solution, Microsoft Operations Manager (MOM), that you can script with responses. This tool also has many other built-in actions that you can use. For more information about MOM, see the MOM Web site.

| **Note** |
| --- |
| Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here. |

#### LockoutThreshold vs. ObservationWindow

In general, the **LockoutThreshold** value has more of an effect on how the computer behaves than the **ObservationWindow** value. Most logon attempts that do not work occur during a very short period of time. Because of this, the period of time is inside of the **ObservationWindow** time. Users rarely type a bad password many times in a row, so the **LockoutThreshold** value is rarely exceeded. The exception to this is the environment where the **LockoutThreshold** registry value is set so low that a user could accidentally mistype their password often enough to lock themselves out (for example, if you set the **LockoutThreshold** value to 2). Malicious password attacks are almost always automated. A user typically locks themselves out of their computer when they type a bad password once and try to type that same bad password over and over again.

#### Recommended Account Lockout Settings

The security configuration for an organization is determined by the level of protection that is required in the organization's environment. In some low-security scenarios (such as in a small office where no sensitive information is stored in the system), a simple password policy may be sufficient to protect the resources. However, in a high-security environment (such as in a banking system), much stronger security protection is desired. You should use account lockout and strong password policies in these environments. In all examples, the stronger the security that is implemented, the higher the cost that is associated with maintaining that security.

The following table provides recommended account lockout settings for many different security configurations.

**Table 1 Recommended Account Lockout Settings**

| Security category | Account lockout settings | | | Cost |
| --- | --- | --- | --- | --- |
| | Threshold | Observation window | Lockout duration | |
| **Low** | N/A | N/A | N/A | **Low** |
| **Medium** | 10 | 30 | 30 | **Medium** |
| **High** | 10 | 30 | Infinite/0 | **High** |

| **Note** |
| --- |
| "Cost" includes downtime cost for the user whose account is locked out, as well as support cost for servicing the locked out account. |

#### Recommended Password Policy Settings

The table below provides recommended password policy settings for various security configurations.

**Table 2 Recommended Password Policy Settings**

| Security Category | Password policy settings | | | | | Cost |
|---|---|---|---|---|---|---|
| | Password history | Maximum password age | Minimum password age | Minimum password length | Complexity | |
| **Low** | 3 | 42 | 0 | 0 | disabled | **Low** |
| **Medium** | 24 | 42 | 1 | 7 | enabled | **Medium** |
| **High** | 24 | 42 | 1 | 8 | enabled | **High** |

**General Recommendations for Account Lockout and Password Policy Settings**
In addition to the specific account lockout and password policy settings in the previous tables, there are some other configuration changes that may help you achieve the level of security that you want. These include:

- When you enable account lockout, set the **ForceUnlockLogon** registry value to 1. This setting requires that Windows re-authenticates the user with a domain controller when that user unlocks a computer. This helps to ensure that a user cannot use a previously-cached password to unlock their computer after the account is locked out.

- False lockouts can occur if you set the **LockoutThreshold** registry value to a value that is lower than the default value of 10. This is because users and programs can retry bad passwords frequently enough to lock out the user account. This adds to administrative costs.

- After you unlock an account that is locked out, verify that the **LockoutDuration** value is set. You should do this because the value may have changed during the account unlock process.

- Carefully consider setting the **LockoutDuration** registry value to 0. When you apply this setting, you may incur additional administrative labor by requiring administrators to manually unlock a locked out user account. Although this does increase security, the increased labor drawback may outweigh the security benefit.

- Define account lockout and password policies once in every domain. Ensure that these policies are defined only in the default domain policy. This helps to avoid conflicting and unexpected policy settings.

- Unlock an account from a computer that is in the same Active Directory site as the account. By unlocking the account in the local site, urgent replication occurs in that site which triggers immediate replication of the change. Because of this, the user account should be able to regain access to resources faster than waiting for replication to occur. Note that the AcctInfo.dll tool helps to identify an appropriate domain controller and unlock the account. For more information about AcctInfo.dll, see the "Account Lockout Tools" section in this document.

**Protecting from External Account Lockout Denial of Service Attacks**
It is possible for a malicious user to launch a denial-of-service attack against your enterprise from outside of your network. Because most networks are interconnected, this can be a difficult attack to mitigate. The following techniques technologies are common techniques and technologies that you can use to help mitigate or prevent such attacks:

- **Require complex passwords:** All accounts should have a complex password. All administrator accounts (local and domain) should have a long, complex password and you should change the password regularly.

- **Rename the administrator account:** Because the administrator account cannot be locked out, it is recommended that you rename the account. Although this does not mitigate all of the attacks against the administrator account, it does help mitigate these attacks most of the time. For more information, see "HOW TO: Rename the Administrator and Guest Account in Windows 2000" on the Microsoft Knowledge Base.

- **Protect your environment with firewalls:** To avoid an account lockout denial of service attack, block the TCP and UDP ports 135 through 139 and port 445 on your routers and firewalls. When you do this, you prevent logon attempts that occur outside of your network.

- **Prevent anonymous access:** Set the **RestrictAnonymous** value to 2 on all computers that are exposed to the internet and to the entire domain if all of the computers are running versions of Windows 2000 or later. This stops malicious users from making anonymous connections to resources and may help defeat some types of attacks. Note that some operating systems have limited support for computers that have this setting. Some programs may also have issues with this setting if the programs use an anonymous connection to gain access to resources. For more information, see "How to Use the RestrictAnonymous Registry Value in Windows 2000" on the Microsoft Knowledge Base.

- **Protect site-to-site traffic by using a VPN tunnel:** If communication between domain members in two sites is required, use a site-to-site VPN tunnel to securely connect site networks together. Do not open all NetBIOS ports on the firewall. You can use the Windows 2000 Server Routing and Remote Access service to create site-to-site VPN tunnels. If no VPN devices are available, you should configure the edge firewall or router filters to limit the traffic that is permitted to flow between the Internet Protocol (IP) address ranges that are used by each site. If sites need to use Active Directory replication only across the Internet, then use Internet Protocol security (IPSec) transport mode through the firewalls to secure all traffic between Active Directory servers.

- **Protecting authentication and NetBIOS ports from Internet attack:** On either the firewall or the router that connects your internal network to the Internet, block access to TCP and UDP ports 135 through 139 and port 445. If no edge filtering device is available, you can use IPSec filters to block these ports. To do this, use the configuration that is described in "How to Block Specific Network Protocols and Ports by Using IPSec" on the Microsoft Knowledge Base.

- In the same IPSec policy, you must create an additional rule that adds filters to permit traffic to these ports when the source address is in a subnet that is used by the internal network. To do this, use the configuration that is described in "How to Block Specific Network Protocols and Ports by Using IPSec" on the Microsoft Knowledge Base.

- **Protecting authentication and NetBIOS ports from internal attack:** If you must protect access to both authentication and NetBIOS ports from internal malicious users, you can restrict the computers that are permitted to gain access to these ports to only domain member computers by using the feature in IPSec that allows you to negotiate security. By allowing only trusted computers (domain member computers) to gain access to both authentication and NetBIOS ports, you reduce the number of computers that can perform the attack. This extra protection provides a defense against any breaches in your security perimeter and against malicious users who can connect to the internal network. For information about how to create a custom IPSec policy to use Kerberos authentication when negotiating IPSec security for access to TCP and UDP ports 135 through 139 and port 445 see the "Step-by-Step Guide to Internet Protocol Security (IPSec)" on the Microsoft Web site.

- **Update the server:** Keep all of your servers up-to-date with current versions of antivirus software, firewall software, and Windows security patches. This helps prevent trojan horse programs and viruses from attacking your resources if the malicious user can launch an attack from your internal network instead of from the Internet. These updates are an important part of an in-depth and defensive security strategy.

# Details of Account Lockout Settings and Processes

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

With the account lockout feature enabled, access to the account is denied when the number of logon attempts that did not work exceeds the **LockoutThreshold** registry value (the account lockout threshold) in a specified amount of time. A locked-out account cannot be used until it is reset by an administrator or until the lockout duration for that account expires.

Account Lockout is disabled on default installations of Windows NT Server 4.0, Windows 2000, and Windows Server 2003 domains. Account lockout operation is enabled after the domain administrator enables settings in the default domain policy. The policy settings remain enabled when you upgrade domain controllers to a later version of an operating system.

Although the Group Policy Object Editor appears to support account lockout and password policy in each organizational unit, these settings actually occur across the domain; you must define the settings on the root organizational unit for the domain. Microsoft recommends that you define account lockout and password policies in only one Group Policy object (GPO) for every domain (in the Default Domain policy settings).

**Password Policy Settings**
The first step that you should use to secure your network is to enforce password policy settings. When you implement a secure password policy, you may not need to implement the account lockout feature.

**Password Complexity**
Passwords, by default, can include any combination of characters; passwords can also be blank. Microsoft recommends that you require the use of complex passwords to help ensure that passwords provide the best security possible. These complex passwords are much more resistant to attack than blank or simple passwords.

To enforce password complexity in your organization, you can enable the **Password must meet complexity requirements** security setting. The complexity requirements enforced by this setting are stored in Passfilt.dll. In Windows 2000 operating systems and later, Passfilt.dll is built into the operating system. In Windows NT Server 4.0, you must add the Passfilt.dll file to the operating system to achieve the same results. Passfilt.dll is included in Windows NT Server 4.0 Service Pack 2 and in later service packs.

By default, complex passwords enforced by Passfilt.dll have the following properties:

- Do not contain all or part of the user's account name.
- Contain characters from three of the following four categories:
  - English uppercase characters (A through Z).
  - English lowercase characters (a through z).
  - Base-10 digits (0 through 9).
  - Non-alphanumeric (for example, !, $, #, %). extended ASCII, symbolic, or linguistic characters.

| **Note** |
| --- |
| Depending on your environment, using extended ASCII, symbolic, or linguistic characters in passwords can have unexpected results. It is highly recommended that you test these characters before using them in production. |

When implementing this policy, it is recommended to inform your users of the change in policy so that a smooth transition can take place from a simple password to a complex password. Otherwise, users may be confused by the new password criteria and circumvent security to avoid the difficulty.

You can create and register your own custom password filter if you want to modify the complexity requirements enforced in the security setting.

**Password History**
You can use the Password History setting to prevent users from repeatedly using the same password. When you use the

password history feature, a user is prevented from using passwords that they used in the past, up to the number of passwords that you specify. You can configure Windows to retain between 0 and 24 passwords by using the Password History feature. Microsoft recommends that you set the password history to the maximum value to help ensure the least amount of password reuse by users.

In the Windows 2000 Server family and later, the location of the password history is in the Default Domain policy settings at Computer Configuration\Windows Settings\Security Settings\Account Policies\Enforce Password History.

Valid non-zero values are between 1 and 24. The default value is 24 for domain controllers running a member of the Windows Server 2003 family, 3 for domain controllers running a member of the Windows 2000 family, and 0 for all other Windows operating systems.

**Minimum Password Length**
You can use the **Minimum Password Length** setting to decrease the chances that a password can be discovered by a malicious user. For more information about the **Minimum Password Length** setting, see "Understanding Password Complexity" in this document.

In versions of Windows 2000 operating systems and later, you can change the **Minimum Password Length** setting in the Group Policy MMC, in the **Default Domain** policy settings at Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\Minimum Password Length.

An administrator can set the value between 0 and 14 characters. Each additional character increases the total possible password permutations. However, if you set the value to 0, blank passwords are not permitted.

Valid non-zero values are between 1 and 14, with a default value of zero.

**Maximum Password Age**
You can use the **Maximum Password Age** setting to limit the time for which a given password is valid. This decreases the odds of being able to crack a password. For more information, see the example in the Passwords section in this document.

In the Windows 2000 family and later, the **Maximum Password Age** setting is located in the Group Policy MMC, in the **Default Domain** policy at Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy\Maximum Password Age.

This setting determines the period of time (in days) that a user can use their password before the computer requires the user to change it. You can set passwords to expire in between 1 and 999 days, or you can specify that passwords never expire by setting the number of days to 0.

Valid non-zero values are between 1 and 999, with a default value of 42.

**Minimum Password Age**
You can use the **Minimum Password Age** setting to preventing users from repeatedly changing passwords until the user is able to use their original password, if you enforce the **Password History** setting.

When you use the **Minimum Password Age** setting, you prevent the circumvention of password expiration and help to assure unique passwords.

The **Minimum Password Age** setting determines the period of time (in days) that a password must be used before the user can change it. You can set the value to between 1 and 999 days, or allow immediate changes by setting the number of days to 0.

Configure the **Minimum Password Age** setting to be a number that is larger than 0 if you want the **Enforce Password History** setting to be effective. If you do not set a minimum password age, users can repeatedly cycle through passwords until they are able to use an old favorite password. This could allow users to circumvent established password policy.

The **Minimum Password Age** setting is located in the Group Policy MMC, in Computer Configuration\Windows Settings\Security Settings\Account Policies\Password Policy.

Valid non-zero values are between 1 and 999, with a default value of one for domain controllers and zero for other computers.

**Account Lockout Settings**
You can set the Account Lockout settings in the Active Directory Users and Computers MMC by using the procedure in this section.

| **Note** |
| --- |
| The value that you set for **LockoutDuration** cannot be a value that is less than **OberservationWindow**. |

1. Click **Start**, click **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

2. In the console tree, right-click the domain on which you want to set a Group Policy object.

3. Click **Properties**, and then click the **Group Policy** tab.

4. In **Group Policy Object Links**, click **Default Domain Policy** or create and name your Group Policy object, and then click **Edit**.

5. In the console tree, double-click **Computer Configuration**, double-click **Windows Settings**, double-click **Security Settings**, double-click **Account Policies**, and then click **Account Lockout Policy**.

6. In the details pane, right-click the policy setting that you want, and then click **Properties**.

7. If you are defining this policy setting for the first time, click **Define this policy setting**.

8. Click the options that you want, and then click **OK**.

**ObservationWindow**

The **ObservationWindow** setting (also known in Group Policy as the **Reset account lockout counter after** setting) is the number of minutes after which an accounts **badPwdCount** registry value is reset. You can use the **ObservationWindow** setting to help mitigate lockout issues that are initiated by users. When you enable this setting, the bad password attempt is removed from the server after a period of time.

Valid non-zero values are between 1 and 99999, with a default value of 30.

**LockoutDuration**

The **LockoutDuration** setting (also known in Group Policy as the **Account lockout duration** setting) is the amount of time, in minutes, that account lockout is enforced on an account that has exceeded the **LockoutDuration** registry value, measured from the time of lockout. If you set the **LockoutDuration** registry value to 0, the account is permanently locked out until either an administrator or a user who has a delegated account resets the account. If the administrator or a delegated user account does not unlock the account, the operating system unlocks the account after the number of minutes that you set in the **LockoutDuration** registry value. Non-zero values for the **LockoutDuration** registry value reduce the administrative overhead of unlocking accounts by having them unlocked automatically; however, non-zero values do not provide the added security of user validation before the account is restored.

Valid non-zero values are between 1 and 99999, with a default value of 30.

**LockoutThreshold**

The **LockoutThreshold** setting (also known in Group Policy as the **Account lockout threshold** setting) is the number of times that the user, computer, service, or program can send a bad password during logon authentication before the account is locked out. Account lockout occurs when the **badPwdCount** registry value is equal to or exceeds the **LockoutThreshold** value. You can adjust the **LockoutThreshold** value to prevent both brute force and dictionary attacks, but you can set the value too low to capture user error and other non-attack errors. Administrators often set this value too low (3 through 5), which causes a large number of account lockouts because of user error, program caching by service accounts, or issues with networking clients. If you set the **LockoutThreshold** value to 0, no account lockouts occur on the domain.

Valid non-zero values are between 1 and 999, with a default value of zero.

**Account Lockout Values**

Account lockout registry values are described in this section. These values store the information that you need to track account lockout information.

| **Note** |
| --- |
| These values are maintained by the operating system, so you should not manually modify them. |

**badPasswordTime**

The **badPasswordTime** value stores the last time that the user, computer, or service account submitted a password that did

not match the password on the authenticating domain controller This property is stored locally on each domain controller that is in the domain. A value of 0 means that the last incorrect password time is unknown. For an accurate value for the user's last incorrect password time in the domain, you must query each domain controller that is in the domain; the largest one is the accurate value. For more information, see the "LockoutStatus.exe" section in this document.

| **Note** |
| --- |
| The **badPasswordTime** registry value is not replicated between domain controllers. This attribute, however, is reported to the PDC operations master. |

**badPwdCount**

The **badPwdCount** value stores the number of times that the user, computer, or service account tried to log on to the account by using an incorrect password. This value is maintained separately on each domain controller in the domain, except for the PDC operations master of the accounts domain that maintains the total number of incorrect password attempts. A value of 0 indicates that the value is unknown. For an accurate total of the user's incorrect password attempts in the domain, you must query each domain controller and use the sum of the values. For more information, see the "LockoutStatus.exe" section in this document.

| **Note** |
| --- |
| The **badPwdCount** registry value is not replicated between domain controllers. This registry value, however, is reported to the PDC operations master. |

**ntPwdHistory**

The **ntPwdHistory** registry value contains the password history for the user in Windows NT Server 4.0 one-way function (OWF). Both Windows 2000 and the Windows Server 2003 family use the Windows NT Server 4.0 OWF. This property is used by only the operating system. Note that you cannot obtain the password from the password in OWF form.

**Other Settings that Affect Account Lockout**

This section describes another setting that affect account lockout behavior. While the setting is focused on authentication, it is closely tied with account lockout policy.

You can set the authentication settings in the Active Directory Users and Computers MMC by using the procedure in this section.

1. Click **Start**, click **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

2. In the console tree, right-click the domain on which you want to set a Group Policy object.

3. Click **Properties**, and then click the **Group Policy** tab.

4. In **Group Policy Object Links**, click **Default Domain Policy** or create and name your Group Policy object, and then click **Edit**.

5. In the console tree, double-click **Computer Configuration**, double-click **Windows Settings**, double-click **Security Settings**, double-click **Local Policies**, and then click **Security Options**.

6. In the details pane, right-click the policy setting that you want, and then click **Properties**.

7. If you are defining this policy setting for the first time, click **Define this policy setting**.

8. Click the options that you want, and then click **OK**.

**ForceUnlockLogon**

The **ForceUnlockLogon** setting (also known as Interactive logon: Require Domain Controller authentication to unlock workstation controls the behavior of a computer running Windows 2000, Windows XP or the Windows Server 2003 family when the computer is unlocked by a user.

- With a value of 1 (or **Enabled**, in Group Policy), unlocking the computer also performs a synchronous logon to the

domain to verify user authenticity. This option is slower than allowing cached authentication because it requires network-based authentication.

- With a value of 0 (or **Disabled**, in Group Policy), cached information is used to verify the users identity. When the verification is successful, the user is logged on. Windows then performs an asynchronous logon to the domain in the background. This means that the user can still unlock a computer when the account is unlocked.

- Valid values are 0 and 1, with a default value of 0.

For additional information about unlocking a workstation, see the following articles:

- "Information About Unlocking a Workstation" in the Microsoft Knowledge Base.

- "Screensaver Password Works Even If Account Is Locked Out" in the Microsoft Knowledge Base.

**Replication and Account Lockout**
Account lockout relies on the replication of lockout information between domain controllers to ensure that all domain controllers are notified of an accounts status. In addition, password changes must be communicated to all domain controllers to ensure that a user's new password is not considered incorrect. This data replication is accomplished by the various replication features of Active Directory and is also discussed in this section.

**Immediate Replication**
When you change a password, it is sent over Netlogon's secure channel to the PDC operations master. Specifically, the domain controller makes a remote procedure call (RPC) to the PDC operations master that includes the user name and new password information. The PDC operations master then locally stores this value.

Immediate replication between Windows 2000 domain controllers is caused by the following events:

- Lockout of an account

- Modification of a Local Security Authority (LSA) secret

- State changes of the Relative ID (RID) Manager

**Urgent Replication**
Active Directory replication occurs between domain controllers when directory data is updated on one domain controller and that update is replicated to all other domain controllers. When a change in directory data occurs, the source domain controller sends out a notice that its directory store now contains updated data. The domain controller's replication partners then send a request to the source domain controller to receive those updates. Typically, the source domain controller sends out a change notification after a delay. This delay is governed by a notification delay. (The Windows 2000 default notification delay is 5 minutes; the Windows Server 2003 default notification delay is 15 minutes.) However, any delay in replication can result in a security risk for certain types of changes. Urgent replication ensures that critical directory changes are immediately replicated, including account lockouts, changes in the account lockout policy, changes in the domain password policy, and changes to the password on a domain controller account. With urgent replication, an update notification is sent out immediately, regardless of the notification delay. This design allows other domain controllers to immediately request and receive the critical updates. Note, however, that the only difference between urgent replication and typical replication is the lack of a delay before the transmission of the change notification. If this does not occur, urgent replication is identical to standard replication. When replication partners request and subsequently receive the urgent changes, they receive, in addition, all pending directory updates from the source domain controller, and not only the urgent updates.

When either an administrator or a delegated user unlocks an account, manually sets password expiration on a user account by clicking **User Must Change Password At Next Logon**, or resets the password on an account, the modified attributes are immediately replicated to the PDC emulator operations master, and then they are urgently replicated to other domain controllers that are in the same site as the PDC emulator. By default, urgent replication does not occur across site boundaries. Because of this, administrators should make manual password changes and account resets on a domain controller that is in that user's site.

The following events are not urgent replications in Windows 2000 domains:

- Changing the account lockout policy

- Changing the domain password policy
- Changing the password on a computer account
- Domain trust passwords

For additional information about urgent and immediate replication, see "Urgent Replication Triggers in Windows 2000" in the Microsoft Knowledge Base.

**Single User Object On Demand Replication**
In the Windows 2000 family, when an administrator resets and immediately expires a user's password on a domain controller in site A (so that the user is given a new password but forced to change it when the user first logs on), the logon may still succeed when the user logs on with that new password in site B. This occurs because the domain controller chains to the PDC operations master during authentication. However, the users password change may not replicate correctly because domain controllers in site B do not yet have the reset password. This occurs because there is replication latency between sites.

An update is available for Windows 2000 that changes this behavior. For more information to help change this behavior by implementing an "on-demand" replication scheme, see "You Cannot Change Your Password After an Administrator Resets It" on the Microsoft Knowledge Base. The updated replication scheme allows the domain controller to contact the PDC operations master to request an update of the user object that failed authentication because of an incorrect password. This helps to ensure that the authenticating domain controller receives the most current user account information as quickly as possible.

**Mixed Environments with Windows NT Server 4.0 and Active Directory Domain Controllers**
If servers that are running Windows NT Server 4.0 and earlier are in the domain, account lockout is not a dependable security feature.

For example, a Windows NT Server 4.0, Enterprise Edition, backup domain controller (BDC) may authenticate a user, even though the account is marked as locked out on a domain controller that is running Windows NT Server 4.0 and earlier. Also, Windows NT Server 4.0, Enterprise Edition, BDCs cannot unlock an account. The server that is running Windows NT Server 4.0, Enterprise Edition, can increment the bad password count when the user logs in with an incorrect password. That server can then report the increment to the other domain controller. However, the Windows NT Server 4.0, Enterprise Edition, BDC does not send this information to the domain controller that is running Windows NT Server 4.0 and earlier if the user logs on with the correct password. Because of this, the bad password count is not reset after the successful logon attempt.

The account lockout feature of Microsoft LAN Manager is not compatible with the account lockout feature on computers that are running Windows NT Server 4.0 and earlier. The domain controller that is running Windows NT Server 4.0 and earlier does not replicate any account lockout information to a LAN Manager BDC. If the account is marked as locked out on the Windows NT Server 4.0 and earlier domain controller, the LAN Manager BDC may still validate the user. The LAN Manager BDC displays the account lockout policy as set to "Never," even in a domain running Windows NT Server 4.0 and earlier where account lockout is enabled.

For these reasons, you should consider ensuring that all domain controllers in your network are running Windows 2000 or the Windows Server 2003 family. This is the only way to ensure that account lockout is enforced consistently across your network.

# Maintaining and Monitoring Account Lockout

Updated: January 5, 2010

Applies To: Windows Server 2003 with SP1

After you configure the account lockout options that you want, set up the computers so that you can capture more data about the accounts that are being locked out. This section describes how to enable auditing, Netlogon logging, and Kerberos logging, as well as which computers to retrieve the logs from. After you configure the logging and capture the appropriate data, this section will show you how to analyze the information so that you can ensure account lockout settings are working and identify attacks.

**Enable Auditing at the Domain Level**
The following sections describe how to enable auditing at the domain level for different operating systems.

To effectively troubleshoot account lockout, enable auditing at the domain level for the following events:

- Account Logon Events – Failure
- Account Management – Success
- Logon Events – Failure

**Windows 2000 and Windows Server 2003 Domains**
The Audit Policy settings are located in the Default Domain policy settings. To view the Auditing policy settings, in the Group Policy MMC, double-click **Computer Configuration**, double-click **Windows Settings**, double-click **Security Settings**, double-click **Local Policies**, and then double-click **Audit Policy**. Enable auditing for the event types listed in the previous section.

**Windows NT Server 4.0 Domain**
Open User Manager, click **Policies**, click **Auditing**, enable **Logon** and **Logoff** auditing for failure events, and then enable User and Group Management auditing for success events.

**Settings for Event Logs**
For troubleshooting purposes, change some of the settings for the Security event logs:

- Set the maximum security log size to 10,000 KB or more. This helps to ensure that important events are not overwritten when the log file becomes large in size.
- Set the event retention method to **Overwrite events as needed** to ensure that the computer is not shut down because there are too many Security event log entries, even when the log file becomes large in size.

For information about how to change the size and retention method of the Security event log, see the Help documentation for the operating system with which you are working.

Because the events can occur on both the client and the server, you can use the following tools to help you gather the information in a single location.

- Use the EventCombMT.exe tool, a multithreaded tool, to gather specific events from event logs from several different computers to one central location and then search those event logs for specific data of interest. Some specific search categories are built into the tool, such as account lockouts, which is already configured to include events 529, 644, 675, 676, and 681. For more information, see the Help file that is included with the tool.
- Use the Eventlog.pl tool to help you manage event logs in Windows 2000. You can use this tool to change the properties of event logs, back up event logs, export event lists to text file, clear event logs, and query the properties of the event logs. For more information, see "HOW TO: Use the Event Log Management Script Tool (Eventlog.pl) to Manage Event Logs in Windows 2000" in the Microsoft Knowledge Base.

**Netlogon Logging**
You can use Netlogon logging to capture Netlogon and NTLM events. It is recommended that you configure Netlogon logging

in a Windows 2000 domain that has Windows 2000 clients.

You must configure Netlogon logging on the primary domain controller (PDC) and on any other domain controllers that are involved in user authentication. To determine the authenticating domain controller, at a command prompt, type **set l** or use the LockoutStatus.exe tool. For more information about the LockoutStatus.exe tool, see the "Account Lockout Tools" section in this document. For enterprises that have less than 10 domain controllers, you should enable Netlogon logging on all domain controllers for each domain.

**Enabling Netlogon Logging on Computers Running Windows 2000 Server**
To enable Netlogon logging on computers that are running Windows 2000 Server, at a command prompt, type **nltest /dbflag:2080ffff**. The log file is created in *Systemroot*\Debug\Netlogon.log. If the log file is not in that location, stop and restart the Netlogon service on that computer. To do this, at a command prompt, type **net stop netlogon & net start netlogon**. For more information, see "Enabling Debug Logging for the Netlogon Service" on the Microsoft Knowledge Base.

If free disk space is low, make sure there is enough space to allow the 40 megabytes (MB) maximum space for the logging. You should also consider the disk space that Netlogon logging uses. When Netlogon.log reaches 20 MB in size, it is renamed to Netlogon.bak and a new Netlogon.log is created with the latest Netlogon data. After that Netlogon.log reaches 20 MB in size, Netlogon.bak is truncated, and the current Netlogon.log file is renamed to Netlogon.bak. Because of this process, the total disk space that is used by Netlogon logging is never more than 40 MB.

| **Note** |
| --- |
| Performance may be slightly degraded by the logging process. Therefore, you should disable Netlogon logging after you have captured the events that you want in the log file. To disable Netlogon logging, at a command prompt, type **nltest /dbflag:0**, press ENTER, type **net start netlogon** and then press ENTER. |

**Kerberos Logging**
If account lockouts involve Kerberos clients that are running a member of the Windows 2000 family or later, you can enable Kerberos logging on those client computers. You would typically perform this step after you have determined that there is an authentication issue that is related to Kerberos.

**To enable Kerberos event logging on a computer**

1. Click **Start**, click **Run**, type **regedit**, and then press ENTER.

2. Add the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Parameters** registry value to the registry key:

   - **Registry value: LogLevel**

   - **Value type: REG_DWORD**

   - **Value data: 0x1**

   If the **Parameters** registry key does not exist, create it.

3. Close Registry Editor and restart the computer.

| **Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

| **Note** |
| --- |
| Performance may be degraded by the logging process. Therefore, you should disable the logging process after you capture the events that you want in the log file. To disable logging, remove the LogLevel registry value, and then restart the computer. |

You can automate this process by using the script that is in the "Account Lockout Tools" section in this document. This script sets the Kerberos logging key in the registry on client computers that are running Windows 2000. If you want to enable logging for groups of computers, you can specify this script as a startup script in an Active Directory Group Policy.

**To disable Kerberos event logging on a computer**

1. Click **Start**, click **Run**, type **regedit**, and then press ENTER.

2. Delete the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Parameters\LogLevel** registry value.

3. Close Registry Editor and restart the computer.

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

For more information, see the "HOW TO: Enable Kerberos Event Logging" in the Microsoft Knowledge Base.

**Event and Netlogon Log Retrieval**

After you set the auditing and logging, wait until account lockouts occur. When the account lockout occurs, retrieve both the Security event log and the System event log, as well as the Netlogon logs for all of the computers that are involved with the client's lockout. This includes the PDC emulator operations master, the authenticating domain controller, and all of the client computers that have user sessions for the locked-out user.

To determine the domain controllers that are involved with the lockout, run the LockoutStatus.exe tool and specify the user account that is locked out. This tool gathers and displays information about the specified user account from all the domain controllers in the domain. In addition, the tool displays the user's **badPwdCount** value on each domain controller. The domain controllers that have a **badPwdCount** value that reflects the bad password threshold setting for the domain are the domain controllers that are involved in the lockout. These domain controllers always include the PDC emulator operations master.

The **badPwdCount** value may appear to be higher than the threshold because of the way that passwords are chained to the PDC emulator operations master. When a bad password is presented by a user or program, both the authenticating domain controller and the PDC emulator operations master increment their **badPwdCount** value for that account. When Active Directory replication occurs, this can result in an increased value. However, the end result—the account becoming locked out—remains the same.

You can also use the EventCombMT.exe tool to gather specific event log data from multiple computers to one central location. For more information about both the EventCombMT.exe and LockoutStatus.exe tools, see the "Account Lockout Tools" section in this document.

**Analyzing Log File Information**

The previous section described the processes that you can use to enable log files to record information that is lockout-specific on your computers. This section focuses on analyzing those log files and determining what behavior occurred that created the log files and caused the issue that you are trying to resolve. This section also describes how to resolve the issues that you find when you analyze the log files.

**Analyzing Netlogon Log Files**

Before you start to analyze the Netlogon log files, you should be familiar with the authentication process works from previous sections in this paper. Although this section describes an NTLM authentication process, a similar chain of events occurs during Kerberos authentication.

The following sample scenario discusses what occurs when a user who is on a client computer tries to gain accesses to a resource that is on a file server in the same domain as the user account. In this process:

1. User credentials are passed to the file server. This is displayed in the Network Logon section in the Netlogon.log file.

2. The file server tries to authenticate the user, but the file server has to forward the credentials to the authenticating domain controller for validation because this account is a domain user account. This behavior is displayed as Transitive Network logon in the Netlogon.log file and is commonly referred to as pass-through authentication.

3. If the password is incorrect or if it is not the same as the password that is stored by the authenticating domain controller, the authenticating domain controller chains the credentials to the PDC for validation. This is displayed as Transitive Network Logon in the Netlogon.log file.

**Netlogon Log File Walkthrough**

The following sections provide a sample Netlogon.log file output from the following three computers:

- The PDC operations master for the domain: DC002
- The authenticating domain controller: DC003
- The member server: MEMSERVER01

The sample output sections show the following participants involved in network authentication:

- Domain name: Tailspintoys
- Logon user name: User1
- Logon computer name: Computer-006

**Transitive Network Logon (Pass-Through Authentication)**

Sample from the DC002 PDC emulator Netlogon log file:

```
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via DC003) 0xC000006A
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via DC003) 0xC000006A
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via DC003) 0xC000006A
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via DC003) 0xC000006A
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via DC003) 0xC000006A
29-Mar 14:28:31 Transitive Network logon Tailspintoys\User1
Computer-006 (via DC003) 0xC0000234
```

Sample from the DC003 authentication domain controller Netlogon log file:

```
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via MEMSERVER01) 0xC000006A
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via MEMSERVER01) 0xC000006A
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via MEMSERVER01) 0xC000006A
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via MEMSERVER01) 0xC000006A
29-Mar 14:28:31 Transitive Network logon Tailspintoys\User1
Computer-006 (via MEMSERVER01) 0xC000006A
29-Mar 14:28:31 Transitive Network logon Tailspintoys\User1
Computer-006 (via MEMSERVER01) 0xC0000234
```

Sample from the MEMSERVER01 member server Netlogon log file:

```
29-Mar 14:28:31 Network logon Tailspintoys\User1
Computer-006 0xC000006A
29-Mar 14:28:31 Network logon Tailspintoys\User1
Computer-006 0xC000006A
29-Mar 14:28:32 Network logon Tailspintoys\User1
Computer-006 0xC000006A
29-Mar 14:28:32 Network logon Tailspintoys\User1
Computer-006 0xC000006A
29-Mar 14:28:32 Network logon Tailspintoys\User1
Computer-006 0xC000006A
29-Mar 14:28:32 Network logon Tailspintoys\User1
```

```
Computer-006 0xC0000234
```

These Netlogon.log file samples provide an example of the information contained in the Netlogon logs. This information is used to trace the account lockout from the domain controller back to the member server on which a user or application tried to gain access with the incorrect credentials.

**Stepping Through the Netlogon Log File Sample**
This section describes the standard analysis process of log files when attempting to determine the cause of an account lockout issue.

In most troubleshooting scenarios, you should begin your log file analysis by examining the Netlogon.log file on the PDC operations master. Because this is a transitive network logon, you can find the authenticating domain controller by viewing the "Via" line in the Netlogon.log file for the domain controller that is chaining logon to the PDC operations master.

**Sample from the PDC Emulator (DC002) Netlogon Log File**
On the "Via" line from the PDCs Netlogon.log file in the following example, note that the authentication is being chained from DC003.

```
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer006 (via DC003) 0xC000006A
```

This is an illustration of step 3 of the authentication process that was detailed in "Analyzing Netlogon Log Files" previously in this document.

**Sample from the Authentication Domain Controller (DC003) Netlogon Log File**
In the Netlogon log file on DC003, this authentication is still a transitive network logon, because credentials were sent to DC003 for verification. Because of this, note where the credentials are sent from. In this example, the credentials are being sent via MEMSERVER01":

```
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer006 (via MEMSERVER01) 0xC000006A
```

This is an illustration of step 2 of the authentication process that was detailed in "Analyzing Netlogon Log Files" previously in this document.

The file server tries to authenticate the user, but the file server has to forward the credentials to the authenticating domain controller for validation because this is a domain user account. This is displayed as Transitive Network logon in the FileServername section of the Netlogon.log file.

**Sample from the Member Server (MEMSERVER01) Netlogon Log File**
From the Netlogon.log file on MEMSERVER01 from the same time period, verify the actual client computer name where the original logon or session setup request came from. In this example, the request came from Computer-006:

```
29-Mar 14:28:31 Network logon   Tailspintoys\User1
Computer-006 0xC000006A
```

This is an illustration of step 1 of the authentication process that was detailed in "Analyzing Netlogon Log Files" previously in this document.

User credentials are passed to the file server. This is displayed in the Network Logon section in the Netlogon.log file.

Even though the log file does not display the exact process that is sending the incorrect credentials, Netlogon log files do provide the following information to help you troubleshoot the lockout:

- Netlogon output displays the number of unsuccessful logon attempts (0xC000006A) for a user's account in a certain time period. Logs in which there are several 0xC000006A events in one second indicate that the lockout is most likely caused by a process, program, or script that is sending incorrect credentials.

- Netlogon output provides a complete picture of all computers that are involved in the account lockout. You can narrow down the culprit by determining the common elements, such as programs, among the computers involved. For example, from the Netlogon output above, after you determined that MEMSERVER01 was common to all user lockouts, the troubleshooting focus changed to the particular network services or user accounts that are used by MEMSERVER01.

- In this example, MEMSERVER01 is the Microsoft Exchange server. After you examine the Microsoft Outlook client and Exchange server settings, you may want to use the information that is in the following two articles to help resolve the issue. These articles describe how to remove unnecessary RPC bindings from the Exchange server. For example, remove Named Pipe support if there is no client that requires the named pipes.

- "Outlook Locks Your Account Because of a Directory Service Referral with Exchange 2000 Server" in the Microsoft Knowledge Base.

- "Unexpected Account Lockouts Caused When Logging On to Outlook from an Untrusted Domain" in the Microsoft Knowledge Base.

- If the Netlogon logs from all domain controllers from the time of lockout but do not display data that pertains to any of the locked-out user accounts that you are analyzing, then NTLM authentication is not involved in the lockouts. This normally indicates that the authentication issues are between computers running Windows 2000 or later, because earlier versions of Windows used NTLM authentication exclusively. You should focus on Kerberos authentication troubleshooting by using Kerberos logging and examining the Security event logs.

**Netlogon Log File Error Codes**

Each event in the Netlogon log contains a corresponding error code. The following table describes these error codes.

**Table 3 Netlogon Log Error Codes**

| Log Code | Description |
|---|---|
| 0x0 | Successful login |
| 0xC0000064 | The specified user does not exist |
| 0xC000006A | The value provided as the current password is not correct |
| 0xC000006C | Password policy not met |
| 0xC000006D | The attempted logon is invalid due to a bad user name |
| 0xC000006E | User account restriction has prevented successful login |
| 0xC000006F | The user account has time restrictions and may not be logged onto at this time |
| 0xC0000070 | The user is restricted and may not log on from the source workstation |
| 0xC0000071 | The user account's password has expired |
| 0xC0000072 | The user account is currently disabled |
| 0xC000009A | Insufficient system resources |
| 0xC0000193 | The user's account has expired |
| 0xC0000224 | User must change his password before he logs on the first time |
| 0xC0000234 | The user account has been automatically locked |

**Note**

Many of these codes provide information in the log file that is redundant with the corresponding Netlogon event log. This allows you to analyze the events in a variety of ways.

**Frequently Asked Questions**

This section answers common questions that might be helpful in troubleshooting the Account Lockout feature in the Windows Server 2003 family.

- Do the logon attempts happen seconds apart or are there many invalid logon attempt events (error code 0xC000006A) in the same second?

  The pattern shows whether this is a user error or a process or program that is creating the lockout. Users take several seconds between events, however, a process or program typically register many invalid or unsuccessful logon attempt

events in one second.

| Note |
| --- |
| You can use the NLParse.exe tool to parse Netlogon logs for specific events that are related to account lockout, such as events 0xC000006A and 0xC0000234. The parsed data is sent to a .csv file that you can read by using a program like Microsoft Excel. For more information about NLParse, see the "Account Lockout Tools" section in this document. |

- From which computers are the invalid logon attempt events generated?

  When you review the Netlogon logs and event logs, you can isolate from which computer the user was logged on during the account lockouts. In many situations, you will discover that a user is logged onto multiple computers; after the user changes their password on one computer, the user account is locked out.

- What client computers are displayed in the Netlogon log files?

  If only Windows 98 or Windows 95 clients are locked out, you may need to install the directory service client for those clients. For example, below, the Computer-006 computer generates the invalid logon attempt event:

```
29-Mar 14:28:30 Transitive Network logon Acme\User1
Computer-006 (via DC003) 0xC000006A
```

- Which user accounts are associated with the invalid logon attempt events?

  If privileged accounts (such as the administrator, service accounts, and well-known application account names) are receiving a large number of incorrect password attempts, first review the information for the computers that have made the attempts with the incorrect passwords, and then determine if there is a wrong password for the account. After you do this, if the passwords on all of the accounts are reset and incorrect password attempts persist, perform a trace to determine if the computer is under an attack. You can place an event trigger to stop the trace and determine where the attempt may be coming from. Internal or external computers can be a threat if there are worm viruses or compromises. The following example shows that the 0xC000006A error code is generated from the Tailspintoys\User1 user:

```
29-Mar 14:28:30 Transitive Network logon Tailspintoys\User1
Computer-006 (via DC003) 0xC000006A
```

- Is there an obvious pattern to the invalid logon attempt events and account lockouts?

  **Pattern:** All users on the domain are locked out, including users who did not change their password. There are many unsuccessful authentication attempts per second.

  **Possible Solution:** If you determine that the log files show that most or all of the user accounts are locked out in your domain, you must perform a trace to determine whether the source of the attack is internal or external to your network. If the attack appears to come from a internal computer, examine the processes running on these computers as this likely indicates a common process that uses outdated or incorrect credentials. Attacks from outside your network often indicate denial of service or brute force attacks against your user accounts.

  **Pattern:** Alphabetical list of users in the log files.

  **Possible Solution:** If the log files show that all of the user accounts are locked out in a list that is almost alphabetical, it is most likely that this behavior is caused by an attempt to break passwords or a denial of service attack. You must perform a network trace to the source of the attack.

  **Pattern:** A specific number of logon attempts are made on each locked-out account.

  **Possible Solution:** If you determine that the log files display a specific number of logon attempts for a each user, add the number of occurrences of 0xC000006A and 0xC0000234 errors for the user. In some scenarios, you may see a pattern of a specific number of attempts for one user, and then the same number of attempts for another user, and so on. This behavior may be an attack on the network or a program could be sending a specific set of attempts. 16 or 17

attempts per user is a common figure for these types of attacks.

In most account lockout situations, you must use Netlogon log files to determine which computers are sending bad credentials. When you analyze Netlogon log files, look for the 0xC000006A event code, because this event will help you determine where the bad password attempts began to occur. When you see the 0xC000006A event code and it is followed by a 0xC0000234 event code, the event codes that come after these event codes help you determine what caused the account lockout. If you see patterns in the log files, the patterns can help you determine if the event code was logged because of either a program attack or user error.

**Analyzing Event Logs**

You cannot determine the authentication type that was used when an account is locked out unless you enable Netlogon logging before the account lockout. However, because of differences in authentication, there may be situations in which Netlogon logging does not capture the data that you need to determine which computers were involved in an account lockout. Configuring the appropriate computers to create event logs may provide additional information in these situations.

Before the problems occur, you should enable security auditing and Kerberos logging on all computers that might be involved in the account lockout event. Enabling auditing and Netlogon log files is discussed elsewhere in this document. If the auditing is not configured before the initial error occurs, it can be done afterwards.

Once the account lockout occurs, there are several tasks that should be completed to help identify the cause of the issue:

1. Obtain both the Security and System event logs from all of the computers that are locked out if those computers were logged on when the lockout occurred. Also, obtain these log files from the PDC emulator operations master and all domain controllers that may be involved in the account lockout.

2. Look for Event 675 (Preauthentication Failures) in the Security event log for the domain controllers for the locked-out user account. This event displays the IP address of the client computer from which the incorrect credentials were sent. When you view these events in the Security event log from the PDC, an IP address with Event 675 may be the IP address of another domain controller because of password chaining from other domain controllers. If this is true, obtain the Security event log from that domain controller to see the Event 675. The IP address that is listed in that Event 675 should be the IP address for the client computer that sent the invalid credential.

3. After you know which client computer is sending the invalid credentials, determine the services, programs, and mapped network drives on that computer. If this information does not reveal the source of the account lockout, perform network traces from that client computer to isolate the exact source of the lockout.

| **Note** |
| --- |
| You can use the EventCombMT.exe tool to gather event log dates from different domain controllers at the same time. For more information about EventCombMT.exe, see the Account Lockout Tools section in this document. |

For more information, see the following articles:

- "Windows 2000 Security Event Descriptions (Part 1 of 2)" in the Microsoft Knowledge Base.

- "Windows 2000 Security Event Descriptions (Part 2 of 2) in the Microsoft Knowledge Base.

**Example Event Log Entry: Incorrect Password Processed by Kerberos**

The following example displays a sample Event 675 in the Security event log from the PDC emulator operations master:

```
Event Type: Failure Audit
Event Source: Security
Event Category: Account Logon
Event ID: 675
Date: 12/5/2001
Time: 5:47:26 PM
User: NT AUTHORITY\SYSTEM
Computer: COMPUTER-006
Description:
Pre-authentication failed:
User Name: user1
```

```
User ID: %{S-1-5-21-4235101579-1759906425-16398432-1114}
Service Name: krbtgt/Tailspintoys.com
Pre-Authentication Type: 0x2
Failure Code: 0x18
Client Address: 172.16.1.85
```

In this example, failure code 0x18 is listed because an incorrect user name or password was used. The client address of 172.16.1.85 identifies the network client that caused this failure. The user name "user1" is also included in this event. The client address and user name should provide enough information for you to begin to address the issue, because you know which user is attempting to logon from which computer.

**Example Event Log Entry: Account is Locked Out**
The following example displays a sample of Event 644, which indicates that the account is locked out:

```
Event Type: Success Audit
Event Source: Security
Event Category: Account Management
Event ID: 644
Date: 12/5/2001
Time: 5:47:26 PM
User: Everyone
Computer: COMPUTER-006
Description:
User Account Locked Out:
Target Account Name: user1
Target Account ID:%{S-1-5-21-4235101579-1759906425-16398432-1114}
Caller Machine Name:COMPUTER-006
Caller User Name:USER1$
Caller Domain:TAILSPINTOYS
Caller Logon ID:(0x0,0x3E7)
```

For more information about account lockout events, see "Audit Account Lockout" on the Microsoft TechNet Web site.

**Example Event Log Entry: Logon Failure**
The following example displays a sample of Event 529, which results from an unsuccessful logon attempt due to an invalid user name or password. This event is often useful in identifying the source of the lockout:

```
Event Type: Failure Audit
Event Source: Security
Event Category: Logon/Logoff
Event ID: 529
Date: 12/21/2001
Time: 2:05:20 PM
User: NT AUTHORITY\SYSTEM
Computer: COMPUTER-006
Description:
Logon Failure:
   Reason: Unknown user name or bad password
   User Name: user1
   Domain: Tailspintoys
   Logon Type: 2
   Logon Process: User32
   Authentication Package:    Negotiate
   Workstation Name: COMPUTER-006
```

This event contains several useful elements. It identifies the name of the computer that is attempting authentication, as well as the user and domain name. It also displays the logon type, which is discussed later in this section.

When Event 529 is logged, you should look for patterns in the event. Determine if there are several 529 events logged and determine if they all occur in one second or if they occur at specific time intervals. If so, there is a process or service that is running on the computer that is sending incorrect credentials. Look at the Logon Process and Logon Type entries in the log to determine the type of process that is passing incorrect credentials and to determine how the process is logging on.

**Example Event Log Entry: Account Is Disabled**
When there is an attempt to logon using a disabled account, a specific event is created in the event log. This can help you quickly identify intruders, because normal operations should not allow for the use of locked out accounts. You should analyze and respond quickly to these events.

```
Event Type:    Failure Audit
Event Source: Security
Event Category: Logon/Logoff
```

```
Event ID: 531
Date: 12/21/2001
Time: 2:05:21 PM
User: NT AUTHORITY\SYSTEM
Computer: COMPUTER-006
Description:
   Logon Failure:
   Reason: Account currently disabled
   User Name: user1
   Domain: TAILSPINTOYS
   Logon Type: 2
   Logon Process: User32
   Authentication Package: Negotiate
```

**Kerberos Events Logged During an Account Lockout**

Once Kerberos logging is enabled, certain events will be logged when an account lockout occurs. These events are described in this section.

**Incorrect Password**

This event is logged when an incorrect password is received by Kerberos as part of an authentication request.

```
Event Type:   Error
Event Source: Kerberos
Event Category: None
Event ID: 4
Date: 12/21/2001
Time: 2:02:05 PM
User: N/A
Computer: COMPUTER-006
Description:
   The function LogonUser received a Kerberos Error Message:
   on logon session TAILSPINTOYS\user1
   Client Time:
   Server Time: 19:2:5.0000 12/21/2001 (null)
   Error Code: 0x18 KDC_ERR_PREAUTH_FAILED
   Client Realm:
   Client Name:
   Server Realm: TAILSPINTOYS.COM
   Server Name: krbtgt/TAILSPINTOYS.COM
   Target Name: krbtgt/TAILSPINTOYS@TAILSPINTOYS
   Error Text:
   File:
   Line: Error Data is in record data.
```

**Kerberos Event When a User Account Is Locked Out**

This event is logged when Kerberos is used for authentication and an account lockout occurs.

```
Event Type: Error
Event Source: Kerberos
Event Category: None
Event ID: 4
Date: 12/21/2001
Time: 2:05:21 PM
User: N/A
Computer: COMPUTER-006
Description:
   The function LogonUser received a Kerberos Error Message:
   on logon session TAILSPINTOYS\user1
   Client Time:
   Server Time: 19:5:21.0000 12/21/2001 (null)
   Error Code: 0x12 KDC_ERR_CLIENT_REVOKED
   Client Realm:
   Client Name:
   Server Realm: TAILSPINTOYS.COM
   Server Name: krbtgt/TAILSPINTOYS.COM
   Target Name: krbtgt/TAILSPINTOYS@TAILSPINTOYS
   Error Text:
   File:
   Line: Error Data is in record data
```

**Logon Events**

Many different events can be created by various logon and logoff actions. The following table describes each logon event.

**Table 4 Logon Event IDs**

| Event ID | Description |
|---|---|
| 528 | A user successfully logged on to a computer. For information about the type of logon, see the Logon Types table below. |
| 529 | Logon failure. A logon attempt was made with an unknown user name or a known user name with a bad password. |
| 530 | Logon failure. A logon attempt was made, but the user account tried to log on outside of the allowed time. |
| 531 | Logon failure. A logon attempt was made using a disabled account. |
| 532 | Logon failure. A logon attempt was made using an expired account. |
| 533 | Logon failure. A logon attempt was made by a user who is not allowed to log on at this computer. |
| 534 | Logon failure. The user attempted to log on with a type that is not allowed. |
| 535 | Logon failure. The password for the specified account has expired. |
| 536 | Logon failure. The Netlogon service is not active. |
| 537 | Logon failure. The logon attempt failed for other reasons.<br>**Note**<br>In some cases, the reason for the logon failure may not be known. |
| 538 | The logoff process was completed for a user. |
| 539 | Logon failure. The account was locked out at the time the logon attempt was made. |
| 540 | A user successfully logged on to a network. |
| 541 | Main mode Internet Key Exchange (IKE) authentication was completed between the local computer and the listed peer identity (establishing a security association), or quick mode has established a data channel. |
| 542 | A data channel was terminated. |
| 543 | Main mode was terminated.<br>**Note**<br>This might occur as a result of the time limit on the security association expiring, policy changes, or peer termination. (The default expiration time for security associations is eight hours.) |
| 544 | Main mode authentication failed because the peer did not provide a valid certificate or the signature was not validated. |
| 545 | Main mode authentication failed because of a Kerberos failure or a password that is not valid. |
| 546 | IKE security association establishment failed because the peer sent a proposal that is not valid. A packet was received that contained data that is not valid. |
| 547 | A failure occurred during an IKE handshake. |
| 548 | Logon failure. The security identifier (SID) from a trusted domain does not match the account domain SID of the client. |
| 549 | Logon failure. All SIDs that correspond to untrusted namespaces were filtered out during an authentication across forests. |
| 550 | A denial-of-service attack may have taken place. |
| 551 | A user initiated the logoff process. |

| | |
|---|---|
| 552 | A user successfully logged on to a computer using explicit credentials while already logged on as a different user. |
| 672 | An authentication service (AS) ticket was successfully issued and validated. |
| 673 | A ticket-granting service (TGS) ticket was granted. |
| 674 | A security principal renewed an AS ticket or TGS ticket. |
| 675 | Preauthentication failed. This event is generated on a Key Distribution Center (KDC) when a user types in an incorrect password. |
| 676 | Authentication ticket request failed. This event is not generated in Windows XP or in the Windows Server 2003 family. |
| 677 | A TGS ticket was not granted. This event is not generated in Windows XP or in the Windows Server 2003 family. |
| 678 | An account was successfully mapped to a domain account. |
| 681 | Logon failure. A domain account logon was attempted. This event is not generated in Windows XP or in the Windows Server 2003 family. |
| 682 | A user has reconnected to a disconnected terminal server session. |
| 683 | A user disconnected a terminal server session without logging off.<br>**Note**<br>This event is generated when a user is connected to a terminal server session over the network. It appears on the terminal server. |

**Netlogon Logon Types**

When many Netlogon logon events are logged, a logon type is also listed in the event details. The following table describes each logon type.

**Table 5 Netlogon Logon Types**

| Logon type | Logon title | Description |
|---|---|---|
| 2 | Interactive | A user logged on to this computer. |
| 3 | Network | A user or computer logged on to this computer from the network. |
| 4 | Batch | The batch logon type is used by batch servers, where processes may be executing on behalf of a user without their direct intervention. |
| 5 | Service | A service was started by the Service Control Manager. |
| 7 | Unlock | This workstation was unlocked. |
| 8 | NetworkCleartext | A user logged on to this computer from the network. The user's password was passed to the authentication package in its unhashed form. The built-in authentication packages all hash credentials before sending them across the network. The credentials do not traverse the network in plaintext (also called cleartext). |
| 9 | NewCredentials | A caller cloned its current token and specified new credentials for outbound connections. The new logon session has the same local identity, but uses different credentials for other network connections. |
| 10 | RemoteInteractive | A user logged on to this computer remotely using Terminal Services or Remote Desktop. |
| 11 | CachedInteractive | A user logged on to this computer with network credentials that were stored locally on the computer. The domain controller was not contacted to verify the credentials. |

# Troubleshooting Account Lockout

Updated: June 9, 2008

Applies To: Windows Server 2003 with SP1

In an environment where you set the account lockout feature, you may notice a large number of lockouts that occur. To determine if these lockouts are false lockouts or a real attack:

1. Verify that the domain controllers and client computers are up-to-date with service packs and hotfixes. For more information, see the "Recommended Service Packs and Hotfixes" section in this document.

2. Configure your computers to capture data:

   a. Enable auditing at the domain level.

   b. Enable Netlogon logging.

   c. Enable Kerberos logging.

   For more information, see the "Appendix Two: Gathering Information to Troubleshoot Account Lockout Issues" section in this document.

3. Analyze data from the Security event log files and the Netlogon log files to help you determine where the lockouts are occurring and why.

4. Analyze the event logs on the computer that is generating the account lockouts to determine the cause.

   For more information, see the Account Lockout Tools section in this document.

The following section further describes the account lockout troubleshooting process.

**Common Causes for Account Lockouts**

This section describes some of the common causes for account lockouts The common troubleshooting steps and resolutions for account lockouts are also described in this section.

To avoid false lockouts, check each computer on which a lockout occurred for the following behaviors:

- **Programs:** Many programs cache credentials or keep active threads that retain the credentials after a user changes their password.

- **Service accounts:** Service account passwords are cached by the service control manager on member computers that use the account as well as domain controllers. If you reset the password for a service account and you do not reset the password in the service control manager, account lockouts for the service account occur. This is because the computers that use this account typically retry logon authentication by using the previous password. To determine whether this is occurring, look for a pattern in the Netlogon log files and in the event log files on member computers. You can then configure the service control manager to use the new password and avoid future account lockouts.

- **Bad Password Threshold is set too low:** This is one of the most common misconfiguration issues. Many companies set the Bad Password Threshold registry value to a value lower than the default value of 10. If you set this value too low, false lockouts occur when programs automatically retry passwords that are not valid. Microsoft recommends that you leave this value at its default value of 10. For more information, see "Choosing Account Lockout Settings for Your Deployment" in this document.

- **User logging on to multiple computers:** A user may log onto multiple computers at one time. Programs that are running on those computers may access network resources with the user credentials of that user who is currently logged on. If the user changes their password on one of the computers, programs that are running on the other computers may continue to use the original password. Because those programs authenticate when they request access to network

resources, the old password continues to be used and the users account becomes locked out. To ensure that this behavior does not occur, users should log off of all computers, change the password from a single location, and then log off and back on.

| **Note** |
| --- |
| Computers running Windows XP or a member of the Windows Server 2003 family automatically detect when the users password has changed and prompt the user to lock and unlock the computer to obtain the current password. No logon and logoff is required for users using these computers. |

- **Stored user names and passwords retain redundant credentials:** If any of the saved credentials are the same as the logon credential, you should delete those credentials. The credentials are redundant because Windows tries the logon credentials when explicit credentials are not found. To delete logon credentials, use the Stored User Names and Passwords tool. For more information about Stored User Names and Passwords, see online help in Windows XP and the Windows Server 2003 family.

| **Note** |
| --- |
| Computers that are running Windows 95, Windows 98, or Windows Millennium Edition do not have a Stored User Names and Passwords file. Instead, you should delete the user's .pwl file. This file is named *Username*.pwl, where *Username* is the user's logon name. The file is stored in the Systemroot folder. |

- **Scheduled tasks:** Scheduled processes may be configured to using credentials that have expired.

- **Persistent drive mappings:** Persistent drives may have been established with credentials that subsequently expired. If the user types explicit credentials when they try to connect to a share, the credential is not persistent unless it is explicitly saved by Stored User Names and Passwords. Every time that the user logs off the network, logs on to the network, or restarts the computer, the authentication attempt fails when Windows attempts to restore the connection because there are no stored credentials. To avoid this behavior, configure **net use** so that is does not make persistent connections. To do this, at a command prompt, type **net use /persistent:no**. Alternately, to ensure current credentials are used for persistent drives, disconnect and reconnect the persistent drive.

- **Active Directory replication:** User properties must replicate between domain controllers to ensure that account lockout information is processed properly. You should verify that proper Active Directory replication is occurring.

- **Disconnected Terminal Server sessions:** Disconnected Terminal Server sessions may be running a process that accesses network resources with outdated authentication information. A disconnected session can have the same effect as a user with multiple interactive logons and cause account lockout by using the outdated credentials. The only difference between a disconnected session and a user who is logged onto multiple computers is that the source of the lockout comes from a single computer that is running Terminal Services.

- **Service accounts:** By default, most computer services are configured to start in the security context of the Local System account. However, you can manually configure a service to use a specific user account and password. If you configure a service to start with a specific user account and that accounts password is changed, the service logon property must be updated with the new password or that service may lock out the account.

| **Note** |
| --- |
| You can use the System Information tool to create a list of services and the accounts that were used to start them. To start the System Information tool, click **Start**, click **Run**, type **winmsd**, and then click **OK**. |

#### Other Potential Issues

Some additional considerations regarding account lockout are described in the following sections.

#### Account Lockout for Remote Connections

The account lockout feature that is discussed in this paper is independent of the account lockout feature for remote connections, such as in the Routing and Remote Access service and Microsoft Internet Information Services (IIS). These services

and programs may provide their own unrelated account lockout features.

**Internet Information Services**

By default, IIS uses a token-caching mechanism that locally caches user account authentication information. If lockouts are limited to users who try to gain access to Exchange mailboxes through Outlook Web Access and IIS, you can resolve the lockout by resetting the IIS token cache. For more information, see "Mailbox Access via OWA Depends on IIS Token Cache" in the Microsoft Knowledge Base.

**MSN Messenger and Microsoft Outlook**

If a user changes their domain password through Microsoft Outlook and the computer is running MSN Messenger, the client may become locked out. To resolve this behavior, see "MSN Messenger May Cause Domain Account Lockout After a Password Change" in the Microsoft Knowledge Base.

# Account Lockout Tools

Updated: November 9, 2007

Applies To: Windows Server 2003 with SP1

After you determine the pattern for the account lockouts and narrow down your scope to a specific client computer or member server, you should gather detailed information about all of the programs and services that are running on that computer. Some of the information that you should obtain includes:

- Mapped network drives
- Logon scripts that map network drives
- **RunAs** shortcuts
- Accounts that are used for service account logons
- Processes on the client computers
- Programs that may pass user credentials to a centralized network program or middle-tier application layer

The following sections discuss the tools that you can use to help you gather information from the network environment.

**The LockoutStatus.exe Tool**

The LockoutStatus.exe displays information about a locked out account. It does this by gathering account lockout-specific information from Active Directory. The following list describes the different information that is displayed by the tool:

- **DC Name:** Displays all domain controllers that are in the domain.
- **Site:** Displays the sites in which the domain controllers reside.
- **UserState:** Displays the status of the user and whether that user is locked out of their account.
- **Bad Pwd Count:** Displays the number of bad logon attempts on each domain controller. This value confirms the .domain controllers that were involved in the account lockout.
- **Last Bad Pwd:** Displays the time of the last logon attempt that used a bad password.
- **Pwd Last Set:** Displays the value of the last good password or when the computer was last unlocked.
- **Lockout Time:** Displays the time when the account was locked out.
- **Orig Lock:** Displays the domain controller that locked the account (the domain controller that made the originating write to the **LockoutTime** attribute for that user).

**Where to Obtain the LockoutStatus.exe Tool**

LockoutStatus.exe is included with the ALTools.exe package that is available at "Account Lockout and Management Tools" on the Microsoft Web site.

**How to Install the LockoutStatus.exe Tool**

To install the LockoutStatus.exe tool, install the ALTools package on your domain controller.

**How to Use the LockoutStatus.exe Tool**

To run the LockoutStatus.exe tool and display information about a locked out user account:

1. Double-click **LockoutStatus.exe**.

2. On the **File** menu, click **Select target**.

3. Type the user name whose lockout status on the enterprise's domain controllers you want information about.

The following figure displays an example where two domain controllers have a **badPwdCount** value of 5, which is also the bad password threshold. One domain controller is the PDC operations master, and the other domain controller is the authenticating domain controller. These two domain controllers are displayed because of password chaining from the authenticating domain controller to the PDC.

**Figure 2: The LockoutStatus.exe Tool**

**The ALockout.dll Tool**

The ALockout.dll tool and the Appinit.reg script are included in the ALTools package. ALockout.dll is a logging tool that may help you determine the program or process that is sending the incorrect credentials in an account lockout scenario. The tool attaches itself to a variety of function calls that a process might use for authentication. The tool then saves information about the program or process that is making those calls into the *Systemroot*\Debug\Alockout.txt file. The events are time stamped so that you can match them to the events that are logged in either the Netlogon log files or the Security event log files.

You can use Appinit.reg to initialize the .dll file. This file provides no other functionality.

| **Note** |
| --- |
| Microsoft does not recommend that you use this tool on servers that host network programs or services. You should not enable ALockout.dll on Exchange servers because the ALockout.dll tool may prevent the Exchange store from starting. |

| **Important** |
| --- |
| Before you install the ALockout.dll tool on any mission-critical computer, make a full backup copy of the operating system and any valuable data. |

For more information, see "Errors Installing Exchange Server with CleanSweep" on the Microsoft Knowledge Base.

In most account lockout scenarios, you should install ALockout.dll on client computers. Use the information that is stored in both the Netlogon log file and the Security event log to determine the computers from which the incorrect credentials are being sent that are locking out the user's account. When you install the ALockout.dll tool on the client computer that is sending the incorrect credentials, the tool logs the process that is sending the incorrect credentials.

**Where to Obtain the ALockout.dll Tool**

ALockout.dll is included with the ALTools.exe package that is available at "Account Lockout and Management Tools" on the Microsoft Web site.

**How to Install the ALockout.dll Tool**

There two versions of the ALockout.dll file. One version of the file is for computers that are running a Windows 2000 operating system, and the other version of the file is for computers that are running a Windows XP operating system. View the Readme.txt file that is included with the ALTools package.

**To install ALockout.dll**

1. On the computer that has generated account lockout error messages in the Security event log, copy both the ALockout.dll and Appinit.reg files to the *Systemroot*\System32 folder .

2. Double-click the Appinit.reg file to run the script. When you do this, the ALockout.dll file is registered and can begin providing information.

3. Restart the computer to complete the installation.

**How to Remove the ALockout Tool**

**To remove the ALockout.dll file from the computer**

1. At a command prompt, type **regsvr32 /u alockout.dll**.

2. Delete the Alockout.dll value that is under the following registry key:

   HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\

   Windows AppInit_DLLs

   After you delete the **Alockout.dll** value, the **AppInit_DLLs** registry key is blank.

3. Restart the computer.

4. Delete the ALockout.dll file from the *Systemroot*/System32 folder.

**How to Use the ALockout.dll Tool**

You should use the ALockout.dll tool with Netlogon logging and security auditing. To use the ALockout.dll tool:

1. Wait for an account to lock out on the computer.

2. When an account is locked out, the ALockout.txt file is created in the *Systemroot*\Debug folder.

3. Compare event time stamps in ALockout.txt with the time stamps in both the Netlogon log files and the Security event log files. When you do this, you can determine the process that is causing the lockouts.

You can use the ALockout.dll tool if you have already set up Netlogon logging, as well as Kerberos and logon auditing on the local computer. ALockout.dll does not interfere with any other logging or event generation.

**The ALoInfo.exe Tool**

If account lockouts seem to happen most frequently after a user is forced to change their password, you may want to determine which users' passwords are about to expire. You can use the ALoInfo.exe tool to display all user account names and the password age for those user accounts. This will allow you to use the ALockout.dll tool and other account lockout tools to set up the tools prior to the initial account lockout. You can also obtain a list of all local services and startup account information by using the ALoInfo.exe tool.

| **Note** |
| --- |
| You can also use the SecDump tool to display password expiration information in a Windows NT Server 4.0 domain. You can download this tool from the SystemTools Web site. Note that Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here. |

**Where to Obtain the ALoInfo.exe Tool**

The ALoInfo.exe file is included with the ALTools.exe package that is available at "Account Lockout and Management Tools" on

the Microsoft Web site.

**How to Install the ALoInfo.exe Tool**
To install the ALoInfo.exe tool, install the ALTools package on your domain controller. The ALTools package contains the ALoInfo.exe tool.

**How to Use the ALoInfo.exe Tool**
You can use ALoInfo.exe at a command prompt with either of the following methods:

- To display an accounts password ages from a domain controller, at a command prompt, type the following:

```
aloinfo /expires /server:Domain_Controller_Name
```

- To display all local service startup account information and mapped drive information for a user who is currently logged on, at a command prompt, type the following command:

```
aloinfo /stored /server:Computer_Name
```

You can redirect the output of ALoInfo.exe to a text file and then sort the results to determine which users may be involved in the account lockout. This information can also be stored for later analysis.

**The AcctInfo.dll Tool**
You can use the AcctInfo.dll tool to add new property pages to user objects in the Active Directory Users and Computers MMC Snap-in. You can use these property pages to help isolate and troubleshoot account lockouts and to reset a users password on a domain controller in that user's local site.

AcctInfo.dll displays the following user account information that you may be able to use to identify and resolve account lockout issues:

- Last time the password was set
- When the password will expire
- User Account Control Raw Value and Decode
- Time the account was locked out
- If the account is locked out now, when it will be unlocked
- Security identifier (SID) of the account, and its SIDHistory
- Globally unique identifier (GUID) of the account
- These account properties:
    - Last Logon
    - Last Logoff
    - Last Bad Logon Time
    - Logon Count
    - Bad Password Count

You can also use the AcctInfo.dll tool to obtain the domain password information (expiration, lockout time, and so on). You can type the user's computer name in the tool, and then reset the user's password on a domain controller in that user's site.

**Note**

Because of replication latency, domain controllers may store different information about the same user account. AcctInfo.dll displays information that is retrieved from a single domain controller.

**Where to Obtain the AcctInfo.dll Tool**
The AcctInfo.dll tool is included in the ALTools.exe package that is available at "Account Lockout and Management Tools" on the Microsoft Web site.

**How to Install the AcctInfo.dll Tool**
On the computer where you want to run Active Directory Users and Computers MMC Snap-in:

1. Copy the AcctInfo.dll file to the System32 folder.

2. At a command prompt, type **regsvr32 acctinfo.dll**, and then press ENTER.

The AcctInfo.dll file is registered and is displayed on a user's property sheet in the Active Directory Users and Computers MMC Snap-in after you follow these steps.

To use the **Account Lockout Status** button in the tool, verify that LockoutStatus.exe is in the *Systemroot*\System32 folder. If LockoutStatus.exe is not installed in this location, this button is unavailable.

**How to Use the AcctInfo.dll Tool**
To use the AcctInfo.dll tool, open the Active Directory Users and Computers MMC, right-click a user, click **Properties**, and then click **Additional Account Info**. An example of the information that is provided by AcctInfo.dll is shown in the following figure.

**Figure 3: Main Property Box**

The following figure displays the domain password policy information that you can view to determine the password policy that applies to the domain controller.

**Figure 4: Domain Password Policy**

**Change Password on a Domain Controller in the User's Site**
The AcctInfo.dll tool allows you to increase the functionality of the Active Directory Users and Computers MMC by adding the ability to reset a user's password in that user's local site. When you reset the password in the remote site, you avoid replication delays that can occur before that user logs on.

When you reset the password, you can also unlock the account and set the **User must change password** value. These options are in the **Change Password On a DC In The Users Site** box as displayed in the following figure.

**Figure 5: Change Password On a DC In The Users Site**

**How to Remove the AcctInfo.dll Tool**
To remove the AcctInfo.dll tool, delete the AcctInfo.dll file from the Systemroot/System32 folder, and then type the following command at a command prompt:

**regsvr32 /u acctinfo.dll**

**The EventCombMT.exe Tool**
You can use the EventCombMT.exe tool to gather specific events from event logs from several different computers into one central location. You can configure EventCombMT.exe to search for events and computers. Some specific search categories are built into the tool, such as account lockouts. Note that the account lockouts category is preconfigured to include events 529, 644, 675, 676, and 681.

**Figure 6: The EventCombMT.exe Tool**

**Where to Obtain the EventCombMT.exe Tool**
The EventCombMT.exe tool is included in the ALTools.exe package that is available at "Account Lockout and Management Tools" on the Microsoft Web site.

**How to Install the EventCombMT.exe Tool**
You do not need to install this tool separately. When you install ALTools on the domain controller, EventCombMT.exe is also installed to the directory you specified during setup.

**How to Use the EventCombMT.exe Tool**
To use the EventCombMT.exe tool, open the folder you specified during setup for ALTools, double-click **EventCombMT.exe**, click the **Searches** menu, click **Built in searches**, and then click **Account lockouts**. When you do this, the events that will be

pulled from the event logs are automatically displayed in the tool. These events are from all of the domain controllers in your environment. In addition to 529, 644, 675, and 681, type **12294** in the **Event Ids** box, and then click **Search**. The tool then searches the computers for these events, and then saves them to a .txt file that you specify.

**The NLParse.exe Tool**

Because Netlogon log files may become more than 10 MB in size, you may want to parse the files for the information that you want to view. You can use the NLParse.exe tool to parse Netlogon log files for specific Netlogon return status codes. The output from this tool is saved to a comma-separated values (.csv) file that you can open in Excel to sort further.

| **Note** |
| --- |
| The return codes that are specific to account lockouts are 0xC000006A and 0xC0000234. |

The following figure displays the interface for the NLParse.exe tool.

**Figure 7: Netlogon-Parse Return Status Codes**

**Where to Obtain the NLParse.exe Tool**

The NLParse.exe tool is included in the ALTools.exe package that is available at "Account Lockout and Management Tools" on the Microsoft Web site.

**How to Install the NLParse.exe Tool**

You do not need to install this tool separately; when you install ALTools on the domain controller, NLParse.exe is also installed.

**How to Use the NLParse.exe Tool**

To use the NLParse.exe tool, open the folder you specified during setup for ALTools, double-click **Nlparse.exe**, click **Open** to open the Netlogon.log file that you want to parse, select the check boxes for the status codes that you want to search for, and then click **Extract**. After you do this, view the output from the NLParse.exe tool. Typically, you may want to look at both the 0xC000006A and 0xC0000234 code statuses to determine from where the lockouts are coming.

**The FindStr.exe Tool**

You can also use the FindStr.exe tool to parse Netlogon log files. FindStr.exe is a command-line tool that you can use to parse several Netlogon.log files at the same time. After you gather the Netlogon.log files from several domain controllers, extract information about a specific user account from the files (user1, error code 0xC000006A, or error code0xC0000234). You can use this tool to help you obtain output about a user, computer, or error code in the Netlogon.log files.

**Where to Obtain the FindStr.exe Tool**

The FindStr.exe tool is included in the default installation of Windows 2000, Windows XP, and the Windows Server 2003 family operating systems. No additional installation or configuration is required for the FindStr.exe tool.

**How to Use the FindStr.exe Tool**

To use the FindStr.exe tool, rename the Netlogon.log files, and then save the files to one folder. To parse all of the Netlogon log

files, type the following command at a command prompt:

**FindStr /I User1** **netlogon** **.log >c:** *user1* **.txt**

**The Replmon and Repadmin Tools**
If you have not already verified Active Directory replication on a domain controller, at a command prompt, type **repadmin /showreps** or **replmon** to verify that proper Active Directory replication is occurring. In many scenarios, you may find that you unlock an account but the new credentials do not work. This behavior typically occurs because of replication latency. Change the users password in their local site to avoid replication latency issues.

**Where to Obtain the Relmon and Repadmin Tools**
Both of these tools are included with the support tools on the Windows 2000 CD-ROM.

**How to Install and Configure the Replmon and Repadmin Tools**
For more information about how to obtain and installing Replmon and Repadmin, see the Windows Support Tools documentation.

**Network Monitor**
Network Monitor is a powerful tool that you can use to capture unfiltered network communication.

If the account lockout occurs because of a process or program and an account is already locked out on a specific client computer, gather network traces of all traffic to and from that client computer while the account is still locked out. The program or process most likely will continue to send incorrect credentials while trying to gain access to resources that are on the network. Capturing all traffic to and from the client may help you determine which network resource the process is trying to gain access to. After you determine the network resource, you can determine which program or process is running on that client computer.

If you can narrow your search to a specific computer but the user account is not yet locked out, keep running Network Monitor until the lockout occurs for that user. After the lockout occurs, compare the time stamps of events when the in the Netlogon or Security event logs with the data that was captured in the trace. You should see that the network resource that is being accessed with incorrect credentials.

After you identify a program or service as the cause of the lockout, view the software manufacturers Web site for known resolutions. This behavior typically occurs because the program is running with the currently logged on user's credentials. If a service is causing the lockout, consider creating accounts that are specifically for running services so user account password changes do not affect the services.

**Where to Obtain Network Monitor**
The full version of Network Monitor is included with Microsoft System Management Server (SMS). A limited version of the tool is included with Windows XP and the Windows 2000 and Windows Server 2003 families.

**How to Install Network Monitor on Supported Operating Systems**
This section describes how to install Network Monitor on both the Windows 2000 Server family and Windows XP.

**Windows 2000 Server**
**To install Network Monitor on computers that are running Windows 2000 Server**

1. Right-click My Network Places, and then click Advanced.

2. Click Optional networking components, and then click Management and Monitoring.

For more information, see "HOW TO: Install Network Monitor in Windows 2000" in the Microsoft Knowledge Base.

**Windows XP**
Network Monitor is included with the Windows support tools. For more information about how to install and configure Network Monitor on computers that are running Windows XP, view the following articles:

- "How to Install the Support Tools from the Windows XP CD-ROM" on the Microsoft Knowledge Base.

- Description of the Network Monitor Capture Utility on the Microsoft Knowledge Base.

**How to Use Network Monitor**
For information about how to use Network Monitor to capture information, view the documentation that is provided with the tool or read "How to Capture Network Traffic with Network Monitor" on the Microsoft Knowledge Base.

# Appendix One: Additional References for Account Lockout

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

For more information about how to lock down your environment, as well as for more information about security features that are not addressed in this document, see the following Microsoft Web sites:

- "Microsoft Solution for Securing Windows 2000 Server" on the Microsoft TechNet Web site
- "Checklist: Create Strong Passwords" on the Microsoft Web site
- "New Registry Key to Remove LM Hashes from Active Directory and Security" on the Microsoft Web site
- "HOW TO: Configure Remote Access Client Account Lockout in Windows 2000" on the Microsoft Web site
- "HOW TO: Prevent Users From Changing a Password Except When Required in Windows 2000" on the Microsoft Web site
- "HOW TO: Prevent Users From Submitting Alternate Logon Credentials in Windows 2000" on the Microsoft Web site
- "HOW TO: Manage Stored User Names and Passwords on a Computer in a Domain in Windows XP" on the Microsoft Web site
- "Best Practices for Enterprise Security" on the Microsoft Web site

# Appendix Two: Gathering Information to Troubleshoot Account Lockout Issues

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

You can use the information in this section to help you gather information before you start to troubleshoot account lockout issues. Collect the following information to troubleshoot account lockout issues:

**Client Platform**
If client account lockouts are occurring on a single, common operating system, there may be specific issues with the operating system. Different operating systems use different processes for name resolution and authentication protocols, and they have different levels of security, so there might be an infrastructure or program issue. For more information, see the Microsoft Knowledge Base article "Service Packs and Hotfixes Available to Resolve Account Lockout Issues" on the Microsoft Web site.

You should gather the following information in these situations:

- Do users log on to multiple computers at the same time?
- Are there any common patterns? For example:
    - Do the computers have the same mapped drives?
    - Do the computers have the same mapped printers?
    - Do the computers have the same antivirus software?
    - Do the computers use management software?
    - Is another networking client installed on the computers?
    - Is SMS installed on the computers?
- Does the network include a Wide Area Network (WAN)?
- If the computer is running Windows 95, Windows 98, Windows 98 SE, or Windows Millennium Edition, what is the version of the Vredir.vxd file?
- If the computer is running Windows 95, Windows 98, Windows 98 SE, or Windows Millennium Edition, is the Directory Services Client installed on the computer?

**Domain Platform**
When you know the domain environment, the security boundaries, and how the user is gaining access to the resources that are in other domains, you can better determine the cause of the account lockouts. You should gather the following information:

- The number of domain controllers, including operating system, location, service pack level, and so on.
- Is Active Directory and Netlogon replication occurring?
- What domain does the user log onto?
- List all domain trusts that the user uses.
- Is there a matching account with the same logon name in the trusted domain?
- Are there any third-party SMB servers running in the environment?

**Background**
Look at the client and the network resources that the user might be contacting to help you determine the cause of the lockouts. You should gather the following information:

- When did you first notice the lockouts?
- When did the lockouts start?
- What has changed in the environment (new programs, new network services, and so on)?
- Are there any identifiable patterns:
    - After a password change?
    - When the user logs on?
    - When the user gains access to mapped drives?
    - When the user uses Outlook?
    - When the user uses Outlook Web Access?
    - Are there no identifiable patterns?
- How many user accounts are locked out each day, a small group of users or a large group?
- Is there an account password policy?
    - How many bad attempts are allowed before a lockout occurs?
    - How much time must elapse before the count resets?
    - What is the **LockoutDuration** registry value?

**Gathering Diagnostic Information**
Gather all of the different log files from Netlogon, Kerberos, and the event logs to help you determine the cause of the lockout. Diagnostic information that you gather from the computer from which the lockout is originating may help you determine the cause for the lockout. You should gather the following information:

- Netlogon log files
- Traces
- Event log files from client computers and domain controllers that are involved in the lockout

# Introduction (Guide to Creating and Configuring a Server Cluster under Windows Server 2003 White Paper)

Updated: November 11, 2003

Applies To: Windows Server 2003 with SP1

A server cluster is a group of independent servers working collectively and running the Microsoft Cluster service (MSCS). Server clusters provide high availability, failback, scalability, and manageability for resources and applications

Server clusters allow client access to applications and resources in the event of failures and planned outages. If one of the servers in the cluster is unavailable because of a failure or maintenance requirements, resources and applications move to other available cluster nodes.

For Windows Clustering solutions, the term “high availability” is used rather than “fault tolerant.” Fault-tolerant technology offers a higher level of resilience and recovery. Fault-tolerant servers typically use a high degree of hardware redundancy plus specialized software to provide near-instantaneous recovery from any single hardware or software fault. These solutions cost significantly more than a Windows Clustering solution because organizations must pay for redundant hardware that waits in an idle state for a fault.

Server clusters do not guarantee non-stop operation, but they do provide sufficient availability for most mission-critical applications. The cluster service can monitor applications and resources and automatically recognize and recover from many failure conditions. This provides flexibility in managing the workload within a cluster. It also improves overall system availability.

Cluster service benefits include:

- **High Availability**: With server clusters, ownership of resources such as disk drives and Internet protocol (IP) addresses is automatically transferred from a failed server to a surviving server. When a system or application in the cluster fails, the cluster software restarts the failed application on a surviving server, or disperses the work from the failed node to the remaining nodes. As a result, users experience only a momentary pause in service.

- **Failback**: The Cluster service will automatically re-assign the workload in a cluster when a failed server comes back online to its predetermined preferred owner. This feature can be configured, but is disabled by default.

- **Manageability**: You can use the Cluster Administrator tool (CluAdmin.exe) to manage a cluster as a single system and to manage applications as if they were running on a single server. You can move applications to different servers within the cluster. Cluster Administrator can be used to manually balance server workloads and to free servers for planned maintenance. You can also monitor the status of the cluster, all nodes, and resources from anywhere on the network.

- **Scalability**: Cluster services can grow to meet increased demand. When the overall load for a cluster-aware application exceeds the cluster’s capabilities, additional nodes can be added.

This document provides instructions for creating and configuring a server cluster with servers connected to a shared cluster storage device and running Windows Server 2003 Enterprise Edition or Windows Server 2003 Datacenter Edition. Intended to guide you through the process of installing a typical cluster, this document does not explain how to install clustered applications. Windows Clustering solutions that implement non-traditional quorum models, such as Majority Node Set (MNS) clusters and geographically dispersed clusters, also are not discussed. For additional information about server cluster concepts as well as installation and configuration procedures, see the Windows Server 2003 Online Help.

# Checklists for Server Cluster Configuration

Updated: November 11, 2003

Applies To: Windows Server 2003 with SP1

This checklist helps you prepare for installation. Step-by-step instructions begin after the checklist.

**Software Requirements**

- Microsoft Windows Server 2003 Enterprise Edition or Windows Server 2003 Datacenter Edition installed on all computers in the cluster.
- A name resolution method such as Domain Name System (DNS), DNS dynamic update protocol, Windows Internet Name Service (WINS), HOSTS, and so on.
- An existing domain model.
- All nodes must be members of the same domain.
- A domain-level account that is a member of the local administrators group on each node. A dedicated account is recommended.

**Hardware Requirements**

- Clustering hardware must be on the cluster service Hardware Compatibility List (HCL). To find the latest version of the cluster service HCL, go to the Windows Hardware Compatibility List at http://www.microsoft.com/whdc/hcl/default.mspx, and then search for cluster. The entire solution must be certified on the HCL, not just the individual components. For additional information, see the following article in the Microsoft Knowledge Base:

  309395 The Microsoft Support Policy for Server Clusters and the Hardware

  | **Note** |
  | --- |
  | If you are installing this cluster on a storage area network (SAN) and plan to have multiple devices and clusters sharing the SAN with a cluster, the solution must also be on the "Cluster/Multi-Cluster Device" Hardware Compatibility List. For additional information, see the following article in the Microsoft Knowledge Base: 304415 Support for Multiple Clusters Attached to the Same SAN Device |

- Two mass storage device controllers—Small Computer System Interface (SCSI) or Fibre Channel. A local system disk for the operating system (OS) to be installed on one controller. A separate peripheral component interconnect (PCI) storage controller for the shared disks.
- Two PCI network adapters on each node in the cluster.
- Storage cables to attach the shared storage device to all computers. Refer to the manufacturers instructions for configuring storage devices. See the appendix that accompanies this article for additional information about specific configuration needs when using SCSI or Fibre Channel.
- All hardware should be identical, slot for slot, card for card, BIOS, firmware revisions, and so on, for all nodes. This makes configuration easier and eliminates compatibility problems.

**Network Requirements**

- A unique NetBIOS name.
- Static IP addresses for all network interfaces on each node.

| Note |
| --- |
| Server Clustering does not support the use of IP addresses assigned from Dynamic Host Configuration Protocol (DHCP) servers. |

- Access to a domain controller. If the cluster service is unable to authenticate the user account used to start the service, it could cause the cluster to fail. It is recommended that you have a domain controller on the same local area network (LAN) as the cluster is on to ensure availability.

- Each node must have at least two network adapters—one for connection to the client public network and the other for the node-to-node private cluster network. A dedicated private network adapter is required for HCL certification.

- All nodes must have two physically independent LANs or virtual LANs for public and private communication.

- If you are using fault-tolerant network cards or network adapter teaming, verify that you are using the most recent firmware and drivers. Check with your network adapter manufacturer for cluster compatibility.

**Shared Disk Requirements:**

- An HCL-approved external disk storage unit connected to all computers. This will be used as the clustered shared disk. Some type of a hardware redundant array of independent disks (RAID) is recommended.

- All shared disks, including the quorum disk, must be physically attached to a shared bus.

| Note |
| --- |
| The requirement above does not hold true for Majority Node Set (MNS) clusters, which are not covered in this guide. |

- Shared disks must be on a different controller then the one used by the system drive.

- Creating multiple logical drives at the hardware level in the RAID configuration is recommended rather than using a single logical disk that is then divided into multiple partitions at the operating system level. This is different from the configuration commonly used for stand-alone servers. However, it enables you to have multiple disk resources and to do Active/Active configurations and manual load balancing across the nodes in the cluster.

- A dedicated disk with a minimum size of 50 megabytes (MB) to use as the quorum device. A partition of at least 500 MB is recommended for optimal NTFS file system performance.

- Verify that disks attached to the shared bus can be seen from all nodes. This can be checked at the host adapter setup level. Refer to the manufacturer's documentation for adapter-specific instructions.

- SCSI devices must be assigned unique SCSI identification numbers and properly terminated according to the manufacturer's instructions. See the appendix with this article for information about installing and terminating SCSI devices.

- All shared disks must be configured as basic disks. For additional information, see the following article in the Microsoft Knowledge Base:

  237853 Dynamic Disk Configuration Unavailable for Server Cluster Disk Resources

- Software fault tolerance is not natively supported on cluster shared disks.

- All shared disks must be configured as master boot record (MBR) disks on systems running the 64-bit versions of Windows Server 2003.

- All partitions on the clustered disks must be formatted as NTFS.
- Hardware fault-tolerant RAID configurations are recommended for all disks.
- A minimum of two logical shared drives is recommended.

# Cluster Installation

Updated: November 11, 2003

Applies To: Windows Server 2003 with SP1

**Installation Overview**
During the installation process, some nodes will be shut down while others are being installed. This step helps guarantee that data on disks attached to the shared bus is not lost or corrupted. This can happen when multiple nodes simultaneously try to write to a disk that is not protected by the cluster software. The default behavior of how new disks are mounted has been changed in Windows 2003 Server from the behavior in the Microsoft® Windows® 2000 operating system. In Windows 2003, logical disks that are not on the same bus as the boot partition will not be automatically mounted and assigned a drive letter. This helps ensure that the server will not mount drives that could possibly belong to another server in a complex SAN environment. Although the drives will not be mounted, it is still recommended that you follow the procedures below to be certain the shared disks will not become corrupted.

Use the table below to determine which nodes and storage devices should be turned on during each step.

The steps in this guide are for a two-node cluster. However, if you are installing a cluster with more than two nodes, the Node 2 column lists the required state of all other nodes.

| **Step** | **Node 1** | **Node 2** | **Storage** | **Comments** |
|---|---|---|---|---|
| Setting up networks | On | On | Off | Verify that all storage devices on the shared bus are turned off. Turn on all nodes. |
| Setting up shared disks | On | Off | On | Shutdown all nodes. Turn on the shared storage, then turn on the first node. |
| Verifying disk configuration | Off | On | On | Turn on the first node, turn on second node. Repeat for nodes 3 and 4 if necessary. |
| Configuring the first node | On | Off | On | Turn off all nodes; turn on the first node. |
| Configuring the second node | On | On | On | Turn on the second node after the first node is successfully configured. Repeat for nodes 3 and 4 as necessary. |
| Post-installation | On | On | On | All nodes should be on. |

Several steps must be taken before configuring the Cluster service software. These steps are:

- Installing Windows Server 2003 Enterprise Edition or Windows Server 2003 Datacenter Edition operating system on each node.
- Setting up networks.
- Setting up disks.

Perform these steps on each cluster node before proceeding with the installation of cluster service on the first node.

To configure the cluster service, you must be logged on with an account that has administrative permissions to all nodes. Each node must be a member of the same domain. If you choose to make one of the nodes a domain controller, have another domain controller available on the same subnet to eliminate a single point of failure and enable maintenance on that node.

**Installing the Windows Server 2003 Operating System**
Refer to the documentation you received with the Windows Server 2003 operating system package to install the system on each node in the cluster.

Before configuring the cluster service, you must be logged on locally with a domain account that is a member of the local administrators group.

**Note**

The installation will fail if you attempt to join a node to a cluster that has a blank password for the local administrator account. For security reasons, Windows Server 2003 prohibits blank administrator passwords.

**Setting Up Networks**

Each cluster node requires at least two network adapters with two or more independent networks, to avoid a single point of failure. One is to connect to a public network, and one is to connect to a private network consisting of cluster nodes only. Servers with multiple network adapters are referred to as "multi-homed." Because multi-homed servers can be problematic, it is critical that you follow the network configuration recommendations outlined in this document.

Microsoft requires that you have two Peripheral Component Interconnect (PCI) network adapters in each node to be certified on the Hardware Compatibility List (HCL) and supported by Microsoft Product Support Services. Configure one of the network adapters on your production network with a static IP address, and configure the other network adapter on a separate network with another static IP address on a different subnet for private cluster communication.

Communication between server cluster nodes is critical for smooth cluster operations. Therefore, you must configure the networks that you use for cluster communication are configured optimally and follow all hardware compatibility list requirements.

The private network adapter is used for node-to-node communication, cluster status information, and cluster management. Each node's public network adapter connects the cluster to the public network where clients reside and should be configured as a backup route for internal cluster communication. To do so, configure the roles of these networks as either "**Internal Cluster Communications Only**" or "**All Communications**" for the Cluster service.

Additionally, each cluster network must fail independently of all other cluster networks. This means that two cluster networks must *not* have a component in common that can cause both to fail simultaneously. For example, the use of a multiport network adapter to attach a node to two cluster networks would not satisfy this requirement in most cases because the ports are not independent.

To eliminate possible communication issues, remove all unnecessary network traffic from the network adapter that is set to **Internal Cluster communications only** (this adapter is also known as the heartbeat or private network adapter).

To verify that all network connections are correct, private network adapters must be on a network that is on a different logical network from the public adapters. This can be accomplished by using a cross-over cable in a two-node configuration or a dedicated hub (not a smart hub) in a configuration of more than two nodes. Do not use a switch, smart hub, or any other routing device for the heartbeat network.

**Note**

Cluster heartbeats cannot be forwarded through a routing device because their Time to Live (TTL) is set to 1. The public network adapters must be only connected to the public network. If you have a virtual LAN, then the latency between the nodes must be less then 500 milliseconds (ms). Also, in Windows Server 2003, heartbeats in Server Clustering have been changed to multicast; therefore, you may want to make a Madcap server available to assign the multicast addresses. For additional information, see the following article in the Microsoft Knowledge Base: 307962 Multicast Support Enabled for the Cluster Heartbeat.

Figure 1 below outlines a four-node cluster configuration.

**Figure 1. Connections for a four-node cluster.**

**General Network Configuration**

| **Note** |
| --- |
| This guide assumes that you are running the default **Start** menu. The steps may be slightly different if you are running the Classic **Start** menu. Also, which network adapter is private and which is public depends upon your wiring. For the purposes of this white paper, the first network adapter (Local Area Connection) is connected to the public network, and the second network adapter (Local Area Connection 2) is connected to the private cluster network. Your network may be different. |

**To rename the local area network icons**

It is recommended that you change the names of the network connections for clarity. For example, you might want to change the name of *Local Area Connection 2* to something like *Private*. Renaming will help you identify a network and correctly assign its role.

1. Click **Start**, point to **Control Panel**, right-click **Network Connections**, and then click **Open**

2. Right-click the **Local Area Connection 2** icon.

3. Click **Rename**.

4. Type **Private** in the textbox, and then press ENTER.

5. Repeat steps 1 through 3, and then rename the public network adapter as **Public**.

**Figure 2. Renamed icons in the Network Connections window.**

6. The renamed icons should look like those in Figure 2 above. Close the Network Connections window. The new connection names will appear in Cluster Administrator and automatically replicate to all other cluster nodes as they are brought online.

**To configure the binding order networks on all nodes**

1. Click **Start**, point to **Control Panel**, right-click **Network Connections**, and then click **Open**

2. On the **Advanced** menu, click **Advanced Settings**.

3. In the **Connections** box, make sure that your bindings are in the following order, and then click **OK**:

    a. Public

    b. Private

    c. Remote Access Connections

**Configuring the Private Network Adapter**

1. Right-click the network connection for your heartbeat adapter, and then click **Properties**.

2. On the **General** tab, make sure that only the **Internet Protocol (TCP/IP)** check box is selected, as shown in Figure 3 below. Click to clear the check boxes for all other clients, services, and protocols.

**Figure 3. Click to select only the Internet Protocol check box in the Private Properties dialog box.**

3. If you have a network adapter that is capable of transmitting at multiple speeds, you should manually specify a speed and duplex mode. Do not use an auto-select setting for speed, because some adapters may drop packets while determining the speed. The speed for the network adapters must be hard set (manually set) to be the same on all nodes according to the card manufacturer's specification. If you are not sure of the supported speed of your card and connecting devices, Microsoft recommends you set all devices on that path to **10 megabits per second** (Mbps) and **Half Duplex**, as shown in Figure 4 below. The amount of information that is traveling across the heartbeat network is small, but latency is critical for communication. This configuration will provide enough bandwidth for reliable communication. All network adapters in a cluster attached to the same network must be configured identically to use the same **Duplex Mode**, **Link Speed, Flow Control**, and so on. Contact your adapter's manufacturer for specific information about appropriate speed and duplex settings for your network adapters.

**Figure 4. Setting the speed and duplex for all adapters**

| **Note** |
| --- |
| Microsoft does not recommended that you use any type of fault-tolerant adapter or "Teaming" for the heartbeat. If you require redundancy for your heartbeat connection, use multiple network adapters set to Internal Communication Only and define their network priority in the Cluster configuration. Issues seen with early multi-ported network adapters, verify that your firmware and driver are at the most current revision if you use this technology. Contact your network adapter manufacturer for information about compatibility on a server cluster. For more information, see the following article in the Microsoft Knowledge Base: 254101 Network Adapter Teaming and Server Clustering. |

4. Click **Internet Protocol (TCP/IP)**, and then click **Properties**.

5. On the **General** tab, verify that you have selected a static IP address that is not on the same subnet or network as any other public network adapter. It is recommended that you put the private network adapter in one of the following private network ranges:

   - 10.0.0.0 through 10.255.255.255 (Class A)
   - 172.16.0.0 through 172.31.255.255 (Class B)
   - 192.168.0.0 through 192.168.255.255 (Class C)

   An example of a good IP address to use for the private adapters is 10.10.10.10 on node 1 and 10.10.10.11 on node 2 with a subnet mask of 255.0.0.0, as shown in Figure 5 below. Be sure that this is a completely different IP address scheme then the one used for the public network.

| **Note** |
| --- |
| For more information about valid IP addressing for a private network, see the following article in the Microsoft Knowledge Base: 142863 Valid IP Addressing for a Private Network. |

**Figure 5. An example of an IP address to use for private adapters.**

6. Verify that there are no values defined in the **Default Gateway** box or under **Use the Following DNS server addresses**.

7. Click the **Advanced** button.

8. On the **DNS** tab, verify that no values are defined. Make sure that the **Register this connection's addresses in DNS** and **Use this connection's DNS suffix in DNS registration** check boxes are cleared.

9. On the **WINS** tab, verify that there are no values defined. Click **Disable NetBIOS over TCP/IP** as shown in Figure 6 on the next page.

**Figure 6. Verify that no values are defined on the WINS tab.**

10. When you close the dialog box, you may receive the following prompt: "*This connection has an empty primary WINS address. Do you want to continue?*" If you receive this prompt, click **Yes**

11. Complete steps 1 through 10 on all other nodes in the cluster with different static IP addresses.

**Configuring the Public Network Adapter**

| **Note** |
| --- |
| If IP addresses are obtained via DHCP, access to cluster nodes may be unavailable if the DHCP server is inaccessible. For this reason, static IP addresses are required for all interfaces on a server cluster. Keep in mind that cluster service will only recognize one network interface per subnet. If you need assistance with TCP/IP addressing in Windows Server 2003, please see the Online Help. |

**Verifying Connectivity and Name Resolution**

To verify that the private and public networks are communicating properly, ping all IP addresses from each node. You should be able to ping all IP addresses, locally and on the remote nodes.

To verify name resolution, ping each node from a client using the node's machine name instead of its IP address. It should only return the IP address for the public network. You may also want to try a **PING –a** command to do a reverse lookup on the IP Addresses.

**Verifying Domain Membership**
All nodes in the cluster must be members of the same domain and be able to access a domain controller and a DNS server. They can be configured as member servers or domain controllers. You should have at least one domain controller on the same network segment as the cluster. For high availability. another domain controller should also be available to remove a single point of failure. In this guide, all nodes are configured as member servers.

There are instances where the nodes may be deployed in an environment where there are no pre-existing Microsoft® Windows NT® 4.0 domain controllers or Windows Server 2003 domain controllers. This scenario requires at least one of the cluster nodes to be configured as a domain controller. However, in a two-node server cluster, if one node is a domain controller, then the other node also must be a domain controller. In a four-node cluster implementation, it is not necessary to configure all four nodes as domain controllers. However, when following a "best practices" model and having at least one backup domain controller, at least one of the remaining three nodes should be configured as a domain controller. A cluster node must be promoted to a domain controller by using the DCPromo tool before the cluster service is configured.

The dependence in Windows Server 2003 on the DNS further requires that every node that is a domain controller also must be a DNS server *if* another DNS server that supports dynamic updates and/or SRV records is not available (Active directory integrated zones recommended).

The following issues should be considered when deploying cluster nodes as domain controllers:

- If one cluster node in a two-node cluster is a domain controller, the other node must be a domain controller
- There is overhead associated with running a domain controller. An idle domain controller can use anywhere between 130 and 140 MB of RAM, which includes having the Cluster service running. There is also increased network traffic from replication, because these domain controllers have to replicate with other domain controllers in the domain and across domains.
- If the cluster nodes are the only domain controllers, then each must be a DNS server as well. They should point to each other for primary DNS resolution and to themselves for secondary resolution.
- The first domain controller in the forest/domain will take on all Operations Master Roles. You can redistribute these roles to any node. However, if a node fails, the Operations Master Roles assumed by that node will be unavailable. Therefore, it is recommended that you do not run Operations Master Roles on any cluster node. This includes Scheme Master, Domain Naming Master, Relative ID Master, PDC Emulator, and Infrastructure Master. These functions cannot be clustered for high availability with failover.
- Clustering other applications such as Microsoft® SQL Server ™ or Microsoft® Exchange Server in a scenario where the nodes are also domain controllers may not be optimal due to resource constraints. This configuration should be thoroughly tested in a lab environment before deployment

Because of the complexity and overhead involved in making cluster-nodes domain controllers, it is recommended that all nodes should be member servers.

**Setting Up a Cluster User Account**
The Cluster service requires a domain user account that is a member of the Local Administrators group on each node, under which the Cluster service can run. Because setup requires a user name and password, this user account must be created before configuring the Cluster service. This user account should be dedicated only to running the Cluster service, and should not belong to an individual.

| **Note** |
| --- |
| The cluster service account does not need to be a member of the Domain Administrators group. For security reasons, granting domain administrator rights to the cluster service account is not recommended. |

The cluster service account requires the following rights to function properly on all nodes in the cluster. The Cluster

Configuration Wizard grants the following rights automatically:

- Act as part of the operating system
- Adjust memory quotas for a process
- Back up files and directories
- Increase scheduling priority
- Log on as a service
- Restore files and directories

For additional information, see the following article in the Microsoft Knowledge Base:

269229 How to Manually Re-Create the Cluster Service Account

**To set up a cluster user account**

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
2. Click the plus sign (+) to expand the domain if it is not already expanded.
3. Right-click **Users**, point to **New**, and then click **User**.
4. Type the cluster name, as shown in Figure 7 below, and then click **Next**.

**Figure 7. Type the cluster name.**

5. Set the password settings to **User Cannot Change Password** and **Password Never Expires**. Click **Next,** and then click **Finish** to create this user.

| **Note** |
| --- |
| If your administrative security policy does not allow the use of passwords that never expire, you must renew the password and update the cluster service configuration on each node before password expiration. For additional information, see the following article in the Microsoft Knowledge Base: 305813 How to Change the Cluster Service Account Password. |

6. Right-click **Cluster** in the left pane of the Active Directory Users and Computers snap-in, and then click **Properties** on the shortcut menu.
7. Click **Add Members to a Group**.

8. Click **Administrators,** and then click **OK**. This gives the new user account administrative privileges on this computer.

9. Quit the Active Directory Users and Computers snap-in.

**Setting up Shared Disks**

| **Important** |
| --- |
| To avoid corrupting the cluster disks, make sure that Windows Server 2003 and the Cluster service are installed, configured, and running on at least one node before you start an operating system on another node. It is critical to never have more then one node on until the Cluster service is configured.<br><br>To proceed, turn off all nodes. Turn on the shared storage devices, and then turn on node 1. |

**About the Quorum Disk**

The quorum disk is used to store cluster configuration database checkpoints and log files that help manage the cluster and maintain consistency. The following quorum disk procedures are recommended:

- Create a logical drive with a minimum size of 50 MB to be used as a quorum disk, 500 MB is optimal for NTFS.

- Dedicate a separate disk as a quorum resource.

| **Important** |
| --- |
| A quorum disk failure could cause the entire cluster to fail; therefore, it is strongly recommended that you use a volume on a hardware RAID array. Do not use the quorum disk for anything other than cluster management. |

The quorum resource plays a crucial role in the operation of the cluster. In every cluster, a single resource is designated as the quorum resource. A quorum resource can be any Physical Disk resource with the following functionality:

- It replicates the cluster registry to all other nodes in the server cluster. By default, the cluster registry is stored in the following location on each node: *%SystemRoot%\Cluster\Clusdb*. The cluster registry is then replicated to the *MSCS\Chkxxx.tmp* file on the quorum drive. These files are exact copies of each other. The *MSCS\Quolog.log* file is a transaction log that maintains a record of all changes to the checkpoint file. This means that nodes that were offline can have these changes appended when they rejoin the cluster.

- If there is a loss of communication between cluster nodes, the challenge response protocol is initiated to prevent a "split brain" scenario. In this situation, the owner of the quorum disk resource becomes the only owner of the cluster and all the resources. The owner then makes the resources available for clients. When the node that owns the quorum disk functions incorrectly, the surviving nodes arbitrate to take ownership of the device. For additional information, see the following article in the Microsoft Knowledge Base: 309186 How the Cluster Service Takes Ownership of a Disk on the Shared Bus.

During the cluster service installation, you must provide the drive letter for the quorum disk. The letter **Q** is commonly used as a standard, and Q is used in the example.

**To configure shared disks**

1. Make sure that only one node is turned on.

2. Right click **My Computer**, click **Manage**, and then expand **Storage**.

3. Double-click **Disk Management**.

4. If you connect a new drive, then it automatically starts the Write Signature and Upgrade Disk Wizard. If this happens, click **Next** to step through the wizard.

> **Note**
> The wizard automatically sets the disk to dynamic. To reset the disk to basic, right-click **Disk** *n* (where *n* specifies the disk that you are working with), and then click **Revert to Basic Disk**.

5. Right-click **unallocated disk space**.

6. Click **New Partition**.

7. The New Partition Wizard begins. Click **Next**.

8. Select the **Primary Partition** partition type. Click **Next**.

9. The default is set to maximum size for the partition size. Click **Next**. (Multiple logical disks are recommended over multiple partitions on one disk.)

10. Use the drop-down box to change the drive letter. Use a drive letter that is farther down the alphabet than the default enumerated letters. Commonly, the drive letter **Q** is used for the quorum disk, then R, S,and so on for the data disks. For additional information, see the following article in the Microsoft Knowledge Base:

    318534 Best Practices for Drive-Letter Assignments on a Server Cluster

> **Note**
> If you are planning on using volume mount points, do not assign a drive letter to the disk. For additional information, see the following article in the Microsoft Knowledge Base: 280297 How to Configure Volume Mount Points on a Clustered Server.

11. Format the partition using NTFS. In the **Volume Label** box, type a name for the disk. For example, **Drive Q**, as shown in Figure 8 below. It is critical to assign drive labels for shared disks, because this can dramatically reduce troubleshooting time in the event of a disk recovery situation.

**Figure 8. It is critical to assign drive labels for shared disks.**

If you are installing a 64-bit version of Windows Server 2003, verify that all disks are formatted as MBR. Global Partition Table (GPT) disks are not supported as clustered disks. For additional information, see the following article in the Microsoft Knowledge Base:

284134 Server Clusters Do Not Support GPT Shared Disks

Verify that all shared disks are formatted as NTFS and designated as MBR Basic.

**To verify disk access and functionality**

1. Start Windows Explorer.

2. Right-click one of the shared disks (such as **Drive Q:**), click **New,** and then click **Text Document**.

3. Verify that you can successfully write to the disk and that the file was created.

4. Select the file, and then press the **Del** key to delete it from the clustered disk.

5. Repeat steps 1 through 4 for all clustered disks to verify they can be correctly accessed from the first node.

6. Turn off the first node, turn on the second node, and repeat steps 1 through 4 to verify disk access and functionality. Assign drive letters to match the corresponding drive labels. Repeat again for any additional nodes. Verify that all nodes can read and write from the disks, turn off all nodes except the first one, and then continue with this white paper.

# Configuring the Cluster Service

Updated: November 11, 2003

Applies To: Windows Server 2003 with SP1

You must supply all initial cluster configuration information in the first installation phase. This is accomplished using the Cluster Configuration Wizard.

As seen in the flow chart, the form (Create a new Cluster) and the Join (Add nodes) take a couple different paths, but they have a few of the same pages. Namely, Credential Login, Analyze, and Re-Analyze and Start Service are the same. There are minor differences in the following pages: Welcome, Select Computer, and Cluster Service Account. In the next two sections of this lesson, you will step through the wizard pages presented on each of these configuration paths. In the third section, after you follow the step-through sections, this white paper describes in detail the Analyze, ,Re-Analyze and Start Service pages, and what the information provided in these screens means.

| Note |
| --- |
| During Cluster service configuration on node 1, you must turn off all other nodes. All shared storage devices should be turned on. |

**To configure the first node**

1. Click **Start**, click **All Programs**, click **Administrative Tools**, and then click **Cluster Administrator**.

2. When prompted by the Open Connection to Cluster Wizard, click **Create new cluster** in the **Action** drop-down list, as shown in Figure 9 below.

**Figure 9. The Action drop-down list.**

3. Verify that you have the necessary prerequisites to configure the cluster, as shown in Figure 10 below. Click **Next**.

**Figure 10. A list of prerequisites is part of the New Server Cluster Wizard Welcome page.**

4. Type a unique NetBIOS name for the cluster (up to 15 characters), and then click **Next**. In the example shown in Figure 11 below, the cluster is named **MyCluster**.) Adherence to DNS naming rules is recommended. For additional information, see the following articles in the Microsoft Knowledge Base:

   163409 NetBIOS Suffixes (16th Character of the NetBIOS Name)

   254680 DNS Namespace Planning

**Figure 11. Adherence to DNS naming rules is recommended when naming the cluster.**

5. If you are logged on locally with an account that is not a **Domain Account with Local Administrative privileges**, the wizard will prompt you to specify an account. This is not the account the Cluster service will use to start.

| **Note** |
| --- |
| If you have appropriate credentials, the prompt mentioned in step 5 and shown in Figure 12 below may not appear. |

**Figure 12. The New Server Cluster Wizard prompts you to specify an account.**

6. Because it is possible to configure clusters remotely, you must verify or type the name of the server that is going to be used as the first node to create the cluster, as shown in Figure 13 below. Click **Next**.

**Figure 13. Select the name of the computer that will be the first node in the cluster.**

**Note**

The Install wizard verifies that all nodes can see the shared disks the same. In a complex storage area network the target identifiers (TIDs) for the disks may sometimes be different, and the Setup program may incorrectly detect that the disk configuration is not valid for Setup. To work around this issue you can click the **Advanced** button, and then click **Advanced (minimum) configuration**. For additional information, see the following article in the Microsoft Knowledge Base: 331801 Cluster Setup May Not Work When You Add Nodes

7. Figure 14 below illustrates that the Setup process will now analyze the node for possible hardware or software problems that may cause problems with the installation. Review any warnings or error messages. You can also click the **Details** button to get detailed information about each one.

**Figure 14. The Setup process analyzes the node for possible hardware or software problems.**

8. Type the unique cluster IP address (in this example 172.26.204.10), and then click **Next**.

   As shown in Figure 15 below, the New Server Cluster Wizard automatically associates the cluster IP address with one of the public networks by using the subnet mask to select the correct network. The cluster IP address should be used for administrative purposes only, and not for client connections.

**Figure 15. The New Server Cluster Wizard automatically associates the cluster IP address with one of the public networks.**

9. Type the **user name** and **password** of the cluster service account that was created during pre-installation. (In the example in Figure 16 below, the user name is "Cluster"). Select the domain name in the **Domain** drop-down list, and then click **Next**.

   At this point, the **Cluster Configuration** Wizard validates the user account and password.

**Figure 16. The wizard prompts you to provide the account that was created during pre-installation.**

10. Review the **Summary** page, shown in Figure 17 below, to verify that all the information that is about to be used to create the cluster is correct. If desired, you can use the quorum button to change the quorum disk designation from the default auto-selected disk.

    The summary information displayed on this screen can be used to reconfigure the cluster in the event of a disaster recovery situation. It is recommended that you save and print a hard copy to keep with the change management log at the server.

| **Note** |
| --- |
| The **Quorum** button can also be used to specify a Majority Node Set (MNS) quorum model. This is one of the major configuration differences when you create an MNS cluster |

**Figure 17. The Proposed Cluster Configuration page.**

11. Review any warnings or errors encountered during cluster creation. To do this, click the plus signs to see more, and then click **Next**. Warnings and errors appear in the Creating the Cluster page as shown in Figure 18.

**Figure 18. Warnings and errors appear on the Creating the Cluster page.**

12. Click **Finish** to complete the installation. Figure 19 below illustrates the final step.

**Figure 19. The final step in setting up a new server cluster.**

| **Note** |
| --- |
| To view a detailed summary, click the **View Log** button or view the text file stored in the following location:<br><br>%SystemRoot%\System32\LogFiles\Cluster\ClCfgSrv.Log |

**Validating the Cluster Installation**

Use the Cluster Administrator (CluAdmin.exe) to validate the cluster service installation on node 1.

**To validate the cluster installation**

1. Click **Start**, click **Programs**, click **Administrative Tools**, and then click **Cluster Administrator**.

2. Verify that all resources came online successfully, as shown in Figure 20 below.

**Figure 20. The Cluster Administer verifies that all resources came online successfully.**

| **Note** |
| --- |
| As general rules, do not put anything in the cluster group, do not take anything out of the cluster group, and do not use anything in the cluster group for anything other than cluster administration. |

**Configuring the Second Node**

Installing the cluster service on the other nodes requires less time than on the first node. Setup configures the cluster service network settings on the second node based on the configuration of the first node. You can also add multiple nodes to the cluster at the same time, and remotely.

| **Note** |
| --- |
| For this section, leave node 1 and all shared disks turned on. Then turn on all other nodes. The cluster service will control access to the shared disks at this point to eliminate any chance of corrupting the volume. |

1. Open **Cluster Administrator** on Node 1.
2. Click **File**, click **New**, and then click **Node**.
3. The Add Cluster Computers Wizard will start. Click **Next**.
4. If you are not logged on with appropriate credentials, you will be asked to specify a domain account that has administrative rights over all nodes in the cluster.
5. Enter the machine name for the node you want to add to the cluster. Click **Add**. Repeat this step, shown in Figure 21 below, to add all other nodes that you want. When you have added all nodes, click **Next**.

**Figure 21. Adding nodes to the cluster.**

6. The Setup wizard will perform an analysis of all the nodes to verify that they are configured properly.

7. Type the password for the account used to start the cluster service.

8. Review the summary information that is displayed for accuracy. The summary information will be used to configure the other nodes when they join the cluster.

9. Review any warnings or errors encountered during cluster creation, and then click **Next**.

10. Click **Finish** to complete the installation.

# Post-Installation Configuration

Updated: November 11, 2003

Applies To: Windows Server 2003 with SP1

**Heartbeat Configuration**

Now that the networks have been configured correctly on each node and the Cluster service has been configured, you need to configure the network roles to define their functionality within the cluster. Here is a list of the network configuration options in Cluster Administrator:

- **Enable for cluster use**: If this check box is selected, the cluster service uses this network. This check box is selected by default for all networks.
- **Client access only (public network)**: Select this option if you want the cluster service to use this network adapter only for external communication with other clients. No node-to-node communication will take place on this network adapter.
- **Internal cluster communications only (private network)**: Select this option if you want the cluster service to use this network only for node-to-node communication.
- **All communications (mixed network)**: Select this option if you want the cluster service to use the network adapter for node-to-node communication and for communication with external clients. This option is selected by default for all networks.

This white paper assumes that only two networks are in use. It explains how to configure these networks as one mixed network and one private network. This is the most common configuration. If you have available resources, two dedicated redundant networks for internal-only cluster communication are recommended.

**To configure the heartbeat**

1. Start Cluster Administrator.
2. In the left pane, click **Cluster Configuration,** click **Networks**, right-click **Private,** and then click **Properties**.
3. Click **Internal cluster communications only (private network)**, as shown in Figure 22 on the next page.

**Figure 22. Using Cluster Administrator to configure the heartbeat.**

4. Click **OK**.
5. Right-click **Public**, and then click **Properties** (shown in Figure 23 below).
6. Click to select the **Enable this network for cluster use** check box.

7. Click the **All communications (mixed network)** option, and then click **OK**.

**Figure 23. The Public Properties dialog box.**

**Heartbeat Adapter Prioritization**

After configuring the role of how the cluster service will use the network adapters, the next step is to prioritize the order in which they will be used for intra-cluster communication. This is applicable only if two or more networks were configured for node-to-node communication. Priority arrows on the right side of the screen specify the order in which the cluster service will use the network adapters for communication between nodes. The cluster service always attempts to use the first network adapter listed for remote procedure call (RPC) communication between the nodes. Cluster service uses the next network adapter in the list only if it cannot communicate by using the first network adapter.

1. Start Cluster Administrator.

2. In the left pane, right-click the cluster name (in the upper left corner), and then click **Properties**.

3. Click the **Network Priority** tab, as shown in Figure 24 below.

**Figure 24. The Network Priority tab in Cluster Administrator.**

4. Verify that the **Private** network is listed at the top. Use the **Move Up** or **Move Down** buttons to change the priority order.

5. Click **OK**.

**Configuring Cluster Disks**

- Start Cluster Administrator, right-click any disks that you want to remove from the cluster, and then click **Delete**.

**Note**

By default, all disks not residing on the same bus as the system disk will have Physical Disk Resources created for them, and will be clustered. Therefore, if the node has multiple buses, some disks may be listed that will not be used as shared storage, for example, an internal SCSI drive. Such disks should be removed from the cluster configuration. If you plan to implement Volume Mount points for some disks, you may want to delete the current disk resources for those disks, delete the drive letters, and then create a new disk resource without a drive letter assignment.

**Quorum Disk Configuration**

The Cluster Configuration Wizard automatically selects the drive that is to be used as the quorum device. It will use the smallest partition that is larger then 50 MB. You may want to change the automatically selected disk to a dedicated disk that you have designated for use as the quorum.

**To configure the quorum disk**

1. Start Cluster Administrator (CluAdmin.exe).

2. Right-click the cluster name in the upper-left corner, and then click **Properties**.

3. Click the **Quorum** tab.

4. In the **Quorum resource** list box, select a different disk resource. In Figure 25 below, Disk Q is selected in the **Quorum resource** list box.

**Figure 25. The Quorum resource list box.**

5. If the disk has more than one partition, click the partition where you want the cluster-specific data to be kept, and then click **OK**.

For additional information, see the following article in the Microsoft Knowledge Base:

Q280353 How to Change Quorum Disk Designation

**Creating a Boot Delay**

In a situation where all the cluster nodes boot up and attempt to attach to the quorum resource at the same time, the Cluster service may fail to start. For example, this may occur when power is restored to all nodes at the exact same time after a power failure. To avoid such a situation, increase or decrease the **Time to Display list of operating systems** setting. To find this setting, click **Start**, point to **My Computer**, right-click **My Computer**, and then click **Properties**. Click the **Advanced** tab, and then click **Settings** under **Startup And Recovery**.

# Test Installation

Updated: November 11, 2003

Applies To: Windows Server 2003 with SP1

There are several methods for verifying a cluster service installation after the Setup process is complete. These include:

- **Cluster Administrator:** If installation was completed only on node 1, start Cluster Administrator, and then attempt to connect to the cluster. If a second node was installed, start Cluster Administrator on either node, connect to the cluster, and then verify that the second node is listed.
- **Services Applet:** Use the services snap-in to verify that the cluster service is listed and started.
- **Event Log:** Use the Event Viewer to check for **ClusSvc** entries in the system log. You should see entries confirming that the cluster service successfully formed or joined a cluster.
- **Cluster service registry entries:** Verify that the cluster service installation process wrote the correct entries to the registry. You can find many of the registry settings under HKEY_LOCAL_MACHINE\Cluster
- Click **Start**, click **Run**, and then type the Virtual Server name. Verify that you can connect and see resources.

**Test Failover**
**To verify that resources will failover**

1. Click **Start**, click **Programs**, click **Administrative Tools**, and then click **Cluster Administrator**, as shown in Figure 26 below.

**Figure 26. The Cluster Administrator window.**

2. Right-click the **Disk Group 1** group, and then click **Move Group**. The group and all its resources will be moved to another node. After a short period of time, the **Disk F: G:** will be brought online on the second node. Watch the window to see this shift. Quit Cluster Administrator.

Congratulations! You have completed the configuration of the cluster service on all nodes. The server cluster is fully operational. You are now ready to install cluster resources such as file shares, printer spoolers, cluster aware services like Distributed Transaction Coordinator, DHCP, WINS, or cluster-aware programs such as Exchange Server or SQL Server.

# Appendix (Guide to Creating and Configuring a Server Cluster under Windows Server 2003 White Paper)

Updated: November 11, 2003

Applies To: Windows Server 2003 with SP1

**Advanced Testing**

Now that you have configured your cluster and verified basic functionality and failover, you may want to conduct a series of failure scenario tests that will demonstrate expected results and ensure the cluster will respond correctly when a failure occurs. This level of testing is not required for every implementation, but may be insightful if you are new to clustering technology and are unfamiliar how the cluster will respond or if you are implementing a new hardware platform in your environment. The expected results listed are for a clean configuration of the cluster with default settings, this does not take into consideration any user customization of the failover logic. This is not a complete list of all tests, nor should successfully completing these tests be considered "certified" or ready for production. This is simply a sample list of some tests that can be conducted. For additional information, see the following article in the Microsoft Knowledge Base:

197047 Failover/Failback Policies on Microsoft Cluster Server

**Test:** Start Cluster Administrator, right-click a resource, and then click "**Initiate Failure**". The resource should go into an failed state, and then it will be restarted and brought back into an online state on that node.

*Expected Result:* Resources should come back online on the same node

**Test:** Conduct the above "**Initiate Failure**" test three more times on that same resource. On the fourth failure, the resources should all failover to another node in the cluster.

*Expected Result:* Resources should failover to another node in the cluster

**Test:** Move all resources to one node. Start Computer Management, and then click **Services** under **Services and Applications**. Stop the Cluster service. Start Cluster Administrator on another node and verify that all resources failover and come online on another node correctly.

*Expected Result:* Resources should failover to another node in the cluster

**Test:** Move all resources to one node. On that node, click **Start,** and then click **Shutdown**. This will turn off that node. Start Cluster Administrator on another node, and then verify that all resources failover and come online on another node correctly.

*Expected Result:* Resources should failover to another node in the cluster

**Test:** Move all resources to one node, and then press the power button on the front of that server to turn it off. If you have an ACPI compliant server, the server will perform an "Emergency Shutdown" and turn off the server. Start Cluster Administrator on another node and verify that all resources failover and come online on another node correctly. For additional information about an Emergency Shutdown, see the following articles in the Microsoft Knowledge Base:

325343 HOW TO: Perform an Emergency Shutdown in Windows Server 2003

297150 Power Button on ACPI Computer May Force an Emergency Shutdown

*Expected Result:* Resources should failover to another node in the cluster

| **Important** |
| --- |
| Performing the Emergency Shutdown test may cause data corruption and data loss. Do **not** conduct this test on a production server |

**Test:** Move all resources to one node, and then pull the power cables from that server to simulate a hard failure. Start Cluster Administrator on another node, and then verify that all resources failover and come online on another node correctly

*Expected Result:* Resources should failover to another node in the cluster

| **Important** |
| --- |

Performing the hard failure test may cause data corruption and data loss. This is an extreme test. Make sure you have a backup of all critical data, and then conduct the test at your own risk. Do **not** conduct this test on a production server

**Test:** Move all resources to one node, and then remove the public network cable from that node. The IP Address resources should fail, and the groups will all failover to another node in the cluster. For additional information, see the following articles in the Microsoft Knowledge Base:

286342 Network Failure Detection and Recovery in Windows Server 2003 Clusters

*Expected Result:* Resources should failover to another node in the cluster

**Test:** Remove the network cable for the Private heartbeat network. The heartbeat traffic will failover to the public network, and no failover should occur. If failover occurs, please see the "Configuring the Private Network Adapter" section in earlier in this document

*Expected Result:* There should be no failures or resource failovers

**SCSI Drive Installations**

This appendix is provided as a generic set of instructions for SCSI drive installations. If the SCSI hard disk vendor's instructions conflict with the instructions here, always follow the instructions supplied by the vendor.

The SCSI bus listed in the hardware requirements must be configured prior to cluster service installation. Configuration applies to:

- The SCSI devices.
- The SCSI controllers and the hard disks so that they work properly on a shared SCSI bus.
- Properly terminating the bus. The shared SCSI bus must have a terminator at each end of the bus. It is possible to have multiple shared SCSI buses between the nodes of a cluster.

In addition to the information on the following pages, refer to documentation from the manufacturer of your SCSI device or to the SCSI specifications, which can be ordered from the American National Standards Institute (ANSI). The ANSI Web site includes a catalog that can be searched for the SCSI specifications.

**Configuring the SCSI Devices**

Each device on the shared SCSI bus must have a unique SCSI identification number. Because most SCSI controllers default to SCSI ID 7, configuring the shared SCSI bus includes changing the SCSI ID number on one controller to a different number, such as SCSI ID 6. If there is more than one disk that will be on the shared SCSI bus, each disk must have a unique SCSI ID number.

**Terminating the Shared SCSI Bus**

There are several methods for terminating the shared SCSI bus. They include:

- **SCSI controllers**

  SCSI controllers have internal soft termination that can be used to terminate the bus, however this method is not recommended with the cluster server. If a node is turned off with this configuration, the SCSI bus will be terminated improperly and will not operate correctly.

- **Storage enclosures**

  Storage enclosures also have internal termination, which can be used to terminate the SCSI bus if the enclosure is at the end of the SCSI bus. This should be turned off.

- **Y cables**

  Y cables can be connected to devices if the device is at the end of the SCSI bus. An external active terminator can then be attached to one branch of the Y cable in order to terminate the SCSI bus. This method of termination requires either disabling or removing any internal terminators that the device may have.

  Figure 27 outlines how a SCSI cluster should be physically connected.

**Figure 27. A diagram of a SCSI cluster hardware configuration.**

| **Note** |
| --- |
| Any devices that are not at the end of the shared bus must have their internal termination disabled. Y cables and active terminator connectors are the recommended termination methods because they will provide termination even when a node is not online. |

**Storage Area Network Considerations**

There are two supported methods of Fibre Channel-based storage in a Windows Server 2003 server cluster: arbitrated loops and switched fabric.

| **Important** |
| --- |
| When evaluating both types of Fibre Channel implementation, read the vendor's documentation and be sure you understand the specific features and restrictions of each. |

Although the term *Fibre Channel* implies the use of fiber-optic technology, copper coaxial cable is also allowed for interconnects.

**Arbitrated Loops (FC-AL)**

A Fibre Channel arbitrated loop (FC-AL) is a set of nodes and devices connected into a single loop. FC-AL provides a cost-effective way to connect up to 126 devices into a single network. As with SCSI, a maximum of two nodes is supported in an FC-AL server cluster configured with a hub. An FC-AL is illustrated in Figure 28.

**Figure 28 FC-AL Connection**

**Figure Error! Reference source not found.1 FC-AL Connection**

FC-ALs provide a solution for two nodes and a small number of devices in relatively static configurations. All devices on the loop share the media, and any packet traveling from one device to another must pass through all intermediate devices.

If your high-availability needs can be met with a two-node server cluster, an FC-AL deployment has several advantages:

- The cost is relatively low.
- Loops can be expanded to add storage (although nodes cannot be added).
- Loops are easy for Fibre Channel vendors to develop.

The disadvantage is that loops can be difficult to deploy in an organization. Because every device on the loop shares the media, overall bandwidth in the cluster is lowered. Some organizations might also be unduly restricted by the 126-device limit.

**Switched Fabric (FC-SW)**
For any cluster larger than two nodes, a switched Fibre Channel switched fabric (FC-SW) is the only supported storage technology. In an FC-SW, devices are connected in a many-to-many topology using Fibre Channel switches (illustrated in Figure 29).

**Figure 29 FC-SW Connection**

When a node or device communicates with another node or device in an FC-SW, the source and target set up a point-to-point connection (similar to a virtual circuit) and communicate directly with each other. The fabric itself routes data from the source to the target. In an FC-SW, the media is not shared. Any device can communicate with any other device, and communication occurs at full bus speed. This is a fully scalable enterprise solution and, as such, is highly recommended for deployment with server clusters.

FC-SW is the primary technology employed in SANs. Other advantages of FC-SW include ease of deployment, the ability to support millions of devices, and switches that provide fault isolation and rerouting. Also, there is no shared media as there is in FC-AL, allowing for faster communication. However, be aware that FC-SWs can be difficult for vendors to develop, and the switches can be expensive. Vendors also have to account for interoperability issues between components from different vendors or manufacturers.

**Using SANs with Server Clusters**
For any large-scale cluster deployment, it is recommended that you use a SAN for data storage. Smaller SCSI and stand-alone Fibre Channel storage devices work with server clusters, but SANs provide superior fault tolerance.

A SAN is a set of interconnected devices (such as disks and tapes) and servers that are connected to a common communication and data transfer infrastructure (FC-SW, in the case of Windows Server 2003 clusters). A SAN allows multiple server access to a pool of storage in which any server can potentially access any storage unit.

The information in this section provides an overview of using SAN technology with your Windows Server 2003 clusters. For additional information about deploying server clusters on SANs, see the Windows Clustering: Storage Area Networks link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

| **Note** |
| --- |
| Vendors that provide SAN fabric components and software management tools have a wide range of tools for setting up, configuring, monitoring, and managing the SAN fabric. Contact your SAN vendor for details about your particular SAN solution. |

**SCSI Resets**
Earlier versions of Windows server clusters presumed that all communications to the shared disk should be treated as an isolated SCSI bus. This behavior may be somewhat disruptive, and it does not take advantage of the more advanced features of Fibre Channel to both improve arbitration performance and reduce disruption.

One key enhancement in Windows Server 2003 is that the Cluster service issues a command to break a RESERVATION, and the StorPort driver can do a targeted or device reset for disks that are on a Fibre Channel topology. In Windows 2000 server

clusters, an entire bus-wide SCSI RESET is issued. This causes all devices on the bus to be disconnected. When a SCSI RESET is issued, a lot of time is spent resetting devices that may not need to be reset, such as disks that the CHALLENGER node may already own.

Resets in Windows 2003 occur in the following order:

1. Targeted logical unit number (LUN)
2. Targeted SCSI ID
3. Entire bus-wide SCSI RESET

| **Note** |
| --- |
| Targeted resets require functionality in the host bus adapter (HBA) drivers. The driver must be written for StorPort and not SCSIPort. Drivers that use SCSIPort will use the Challenge and Defense the same as it is currently in Windows 2000. Contact the manufacturer of the HBA to determine if it supports StorPort. |

**SCSI Commands**
The Cluster service uses the following SCSI commands:

- SCSI reserve: This command is issued by a host bus adapter or controller to maintain ownership of a SCSI device. A device that is reserved refuses all commands from all other host bus adapters except the one that initially reserved it, the initiator. If a bus-wide SCSI reset command is issued, loss of reservation occurs.
- SCSI release: This command is issued by the owning host bus adapter; it frees a SCSI device for another host bus adapter to reserve.
- SCSI reset: This command breaks the reservation on a target device. This command is sometimes referred to globally as a "bus reset."

The same control codes are used for Fibre Channel as well. These parameters are defined in this partner article:

309186 How the Cluster Service Takes Ownership of a Disk on the Shared Bus

317162 Supported Fibre Channel Configurations

The following sections provide an overview of SAN concepts that directly affect a server cluster deployment.

**HBAs**
Host bus adapters (HBAs) are the interface cards that connect a cluster node to a SAN, similar to the way that a network adapter connects a server to a typical Ethernet network. HBAs, however, are more difficult to configure than network adapters (unless the HBAs are preconfigured by the SAN vendor). All HBAs in all nodes should be identical and be at the same driver and firmware revision

**Zoning and LUN Masking**
Zoning and LUN masking are fundamental to SAN deployments, particularly as they relate to a Windows Server 2003 cluster deployment.

**Zoning**
Many devices and nodes can be attached to a SAN. With data stored in a single *cloud*, or storage entity, it is important to control which hosts have access to specific devices. Zoning allows administrators to partition devices in logical volumes and thereby reserve the devices in a volume for a server cluster. That means that all interactions between cluster nodes and devices in the logical storage volumes are isolated within the boundaries of the zone; other noncluster members of the SAN are not affected by cluster activity.

Figure 30 is a logical depiction of two SAN zones (Zone A and Zone B), each containing a storage controller (S1and S2, respectively).

**Figure 30 Zoning**

In this implementation, Node A and Node B can access data from the storage controller S1, but Node C cannot. Node C can access data from storage controller S2.

Zoning needs to be implemented at the hardware level (with the controller or switch) and not through software. The primary reason is that zoning is also a security mechanism for a SAN-based cluster, because unauthorized servers cannot access devices inside the zone (access control is implemented by the switches in the fabric, so a host adapter cannot gain access to a device for which it has not been configured). With software zoning, the cluster would be left unsecured if the software component failed.

In addition to providing cluster security, zoning also limits the traffic flow within a given SAN environment. Traffic between ports is routed only to segments of the fabric that are in the same zone.

**LUN Masking**

A LUN is a logical disk defined within a SAN. Server clusters see LUNs and think they are physical disks. LUN masking, performed at the controller level, allows you to define relationships between LUNs and cluster nodes. Storage controllers usually provide the means for creating LUN-level access controls that allow access to a given LUN to one or more hosts. By providing this access control at the storage controller, the controller itself can enforce access policies to the devices.

LUN masking provides more specific security than zoning, because LUNs provide a means for zoning at the port level. For example, many SAN switches allow overlapping zones, which enable a storage controller to reside in multiple zones. Multiple clusters in multiple zones can share the data on those controllers. Figure 31 illustrates such a scenario.

**Figure 31 Storage Controller in Multiple Zones**

LUNs used by Cluster A can be masked, or hidden, from Cluster B so that only authorized users can access data on a shared storage controller.

**Requirements for Deploying SANs with Windows Server 2003 Clusters**

The following list highlights the deployment requirements you need to follow when using a SAN storage solution with your server cluster. For a white paper that provides more complete information about using SANs with server clusters, see the Windows Clustering: Storage Area Networks link on the Web Resources page at

http://www.microsoft.com/windows/reskits/webresources.

Each cluster on a SAN must be deployed in its own zone. The mechanism the cluster uses to protect access to the disks can have an adverse effect on other clusters that are in the same zone. By using zoning to separate the cluster traffic from other cluster or noncluster traffic, there is no chance of interference.

All HBAs in a single cluster must be the same type and have the same firmware version. Many storage and switch vendors require that all HBAs on the same zone—and, in some cases, the same fabric—share these characteristics.

All storage device drivers and HBA device drivers in a cluster must have the same software version.

Never allow multiple nodes access to the same storage devices unless they are in the same cluster.

Never put tape devices into the same zone as cluster disk storage devices. A tape device could misinterpret a bus rest and rewind at inappropriate times, such as during a large backup.

**Guidelines for Deploying SANs with Windows Server 2003 Server Clusters**
In addition to the SAN requirements discussed in the previous section, the following practices are highly recommended for server cluster deployment:

In a highly available storage fabric, you need to deploy clustered servers with multiple HBAs. In these cases, always load the multipath driver software. If the I/O subsystem sees two HBAs, it assumes they are different buses and enumerates all the devices as though they were different devices on each bus. The host, meanwhile, is seeing multiple paths to the same disks. Failure to load the multipath driver will disable the second device because the operating system sees what it thinks are two independent disks with the same signature.

Do not expose a hardware snapshot of a clustered disk back to a node in the same cluster. Hardware snapshots must go to a server outside the server cluster. Many controllers provide snapshots at the controller level that can be exposed to the cluster as a completely separate LUN. Cluster performance is degraded when multiple devices have the same signature. If the snapshot is exposed back to the node with the original disk online, the I/O subsystem attempts to rewrite the signature. However, if the snapshot is exposed to another node in the cluster, the Cluster service does not recognize it as a different disk and the result could be data corruption. Although this is not specifically a SAN issue, the controllers that provide this functionality are typically deployed in a SAN environment.

# Introduction (Deploying SQL Server Logging with Windows Server 2003 Internet Authentication Service (IAS))

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

SQL Server logging is a new feature for Internet Authentication Service (IAS) in Microsoft® Windows® Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition.

IAS is the Microsoft implementation of a Remote Authentication Dial-in User Service (RADIUS) server and proxy. As a RADIUS server, IAS performs centralized connection authentication, authorization, and accounting for many types of network access including wireless, 802.1X authenticating switch, and remote access dial-up and virtual private network (VPN) connections. As a RADIUS proxy, IAS forwards authentication and accounting messages to other RADIUS servers. RADIUS is an Internet Engineering Task Force (IETF) standard.

Figure 1 shows the components of a RADIUS infrastructure when the IAS server is configured to log to a computer running SQL Server.

**Figure 1: Components of a RADIUS infrastructure**

A RADIUS server has access to user account information and can check network access authentication credentials. If the user's credentials are authenticated and the connection attempt is authorized, the RADIUS server authorizes the user's access on the basis of specified conditions and logs the network access connection in an accounting log. The use of RADIUS allows the network access user authentication, authorization, and accounting data to be collected and maintained in a central location, rather than on each access server.

The centralization of accounting data simplifies both troubleshooting and the log file backup process. In addition, as networks and IAS deployments scale up and out, you can deploy IAS SQL Server logging to centralize logging for multiple IAS servers.

**Using accounting logs**

IAS accounting logs can be used for a variety of purposes, including the following:

- Connection troubleshooting
- Billing and auditing
- Report creation

- Session state information

IAS provides the following logging options to address these purposes:

**Event logging for IAS.** IAS errors are automatically recorded in the system event logs of Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. IAS authentication events are recorded in the system event log on the basis of event log settings, which you can customize for your logging needs. You can log rejected authentication requests, successful authentication requests, or both. Event logging is used primarily for auditing and troubleshooting connection attempts.

**To configure event logging for IAS**

1. Open the Internet Authentication Service Microsoft Management Console (MMC) snap-in.
2. Right-click **Internet Authentication Service (IAS)**, and then click **Properties**.
3. On the **General** tab, select each required option, and then click **OK**.

For more information, see "Related Links" later in this white paper.

**Logging user authentication and accounting requests to local text files.** Recording user authentication and accounting requests in log files is used primarily for connection analysis and billing purposes, and is also useful as a security investigation tool, providing you with a method of tracking the activity of a malicious user after an attack. You can configure IAS to log in IAS format or database-import format, both of which are text file formats.

**To select requests to be logged in IAS format or database-import format**

1. Open the Internet Authentication Service snap-in.
2. In the console tree, click **Remote access logging**.
3. In the details pane, right-click **Local File**, and then click **Properties**.
4. On the **Settings** tab, select one or more check boxes for recording authentication and accounting requests in the IAS log files:
    - To capture accounting requests and responses, select **Accounting requests**.
    - To capture authentication requests, Access-Accept messages, and Access-Reject messages, select **Authentication requests**.
    - To capture periodic status updates, such as interim accounting packets, select **Periodic status**.

For more information, see "Related Links" later in this white paper.

**IAS SQL Server logging.** IAS SQL Server logging is used when you need session state information, for report creation and data analysis purposes, and to centralize and simplify management of your accounting data. Windows Server 2003 Internet Authentication Service provides the ability to use SQL Server logging to record user authentication and accounting requests received from one or more network access servers (NASs) to a data source on a computer running the Microsoft SQL Server Desktop Engine (MSDE 2000) or SQL Server 2000. Accounting data is passed from IAS in XML format to a stored procedure in an MSDE 2000 or SQL Server 2000 database, which supports both structured query language (SQL) and XML (SQLXML). Recording user authentication and accounting requests in an XML-compliant SQL Server database enables multiple IAS servers to share one data source, and provides the advantages of using a relational database.

#### Introduction to SQL Server 2000

Microsoft SQL Server is a relational database management and analysis product for e-commerce, line-of-business, and data warehousing solutions. SQL Server 2000 includes support for XML and HTTP, performance and availability features to partition loads and ensure uptime, and advanced management and tuning functionality to automate routine tasks and lower total cost of ownership. For more information, see "Related Links" later in this white paper.

#### Advantages of SQL Server logging

Logging to a SQL Server 2000 relational database instead of a standard text file (that is, either IAS format or database-compatible format) has the following advantages:

- Relationships between data tables enable the flexible creation of dynamic data views by using queries and reports.
- SQL Server 2000 has high-speed optimizations that can effectively support very large, terabyte-sized databases.
- Multiple bulk copy operations can be performed concurrently against a single table in SQL Server to speed data entry.
- The Transact-SQL BACKUP and RESTORE statements are optimized to read through a database serially and write in parallel to multiple backup devices. In addition, SQL Server 2000 supports differential backups, which replicate only the data changed after the last backup.
- You can configure SQL Server logging to provide failover and redundancy, and multiple IAS servers can log to the same database, providing ease of administration.
- Data from multiple IAS servers can be stored in the same database, providing a centralized data source for many IAS servers and the ability to achieve a more comprehensive data view for applications that query the database, such as Help Desk applications.

In addition, you can improve logging performance and, in some circumstances, reduce the cost of deploying IAS SQL Server logging by using MSDE 2000 databases installed on each IAS server.

**Stored procedures**
All three of the scenarios depicted in this white paper require the use of SQL Server 2000 stored procedures. A stored procedure is a group of Transact-SQL statements compiled into a single execution plan, or program. A stored procedure centralizes business rules, tasks, and processes within the server. When you use IAS SQL Server logging with MSDE 2000 or SQL Server 2000, the Transact-SQL programming language is the primary programming interface between your IAS server and the MSDE 2000 or SQL Server 2000 database.

When you use Transact-SQL programs, you must store the programs as stored procedures in MSDE 2000 and SQL Server 2000. IAS is configured to send data in XML format to a stored procedure called report_event, which then processes the results. Stored procedures in SQL Server 2000 and MSDE 2000 are similar to procedures and functions in other programming languages in that they can:

- Accept input parameters and return multiple values in the form of output parameters to the calling procedure or batch.
- Contain programming statements that perform operations in the database, including calling other procedures.
- Return a status value to a calling procedure or batch to indicate success or failure (and the reason for failure).

For more information, see “Related Links” later in this white paper.

**Note**

The stored procedure in the SQL Server 2000 or MSDE 2000 database that is called by IAS must be named report_event, or IAS SQL Server logging will fail.

Installing, designing, coding, and administering SQL Server 2000 databases requires extensive knowledge of relational database design and administration, as well as familiarity with SQL Server 2000 or later. Do not attempt to deploy IAS SQL Server logging in a production environment without previous experience with SQL Server 2000.

You can use IAS with any RFC-compliant RADIUS client, including dial-up servers, virtual private network (VPN) servers, wireless access points, and 802.1X authenticating switches. For more information about RADIUS, see RFC 2865, "Remote Authentication Dial-in User Service (RADIUS)."

You can configure IAS on a computer running Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of two remote RADIUS server groups. You can define a RADIUS client by using a fully qualified domain name (FQDN) or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the FQDN of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS on a computer running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range. IAS is not included on computers running the Windows Server 2003, Web Edition, operating system.

# Key concepts for IAS SQL Server logging

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following sections describe key logging concepts such as requests logged by IAS, IAS log file contents, and how IAS creates an XML document from accounting and authentication data.

**Data logged by IAS**

By default, IAS does not log any data until you configure it to do so. When you configure SQL Server logging, all required attributes, accounting, and authentication data that is normally logged in either IAS or database-compatible format is logged to the SQL Server 2000 or MSDE 2000 database.

Initially, it is recommended that you enable the logging of accounting and user authentication requests. You can refine your logging settings after you determine your required data.

**Requests logged by IAS**

You can log the following information in a SQL Server database:

- **Accounting-on requests**, which are sent by the access server to indicate that it is online and ready to accept connections.
- **Accounting-off requests**, which are sent by the access server to indicate that it is going offline.
- **Accounting-start requests**, which are sent by the access server (after the user is authenticated and authorized by the IAS server) to indicate the start of a user session.
- **Accounting-stop requests**, which are sent by the access server to indicate the end of a user session.
- **Accounting interim requests**, which are sent periodically by some access servers during a user session, and which can be logged by IAS. This type of request can be used when the Acct-Interim-Interval RADIUS attribute is configured to support periodic requests in the remote access profile on the IAS server. The access server must support the use of accounting interim requests if you want the interim requests to be logged on the IAS server. If the access server does not send accounting interim requests, they are not logged.
- **Authentication requests**, which are sent by the access server on behalf of the connecting user. These entries in the log contain only incoming attributes.
- **Authentication accepts and rejects**, which are sent by IAS to the access server, indicating whether the user should be accepted or rejected. These entries contain only outgoing attributes.

**IAS log file contents**

Unlike database-import log files, which use a fixed sequence of attributes, the sequence of the attributes in a SQL Server 2000 or MSDE 2000 log file depends upon the sequence used by the access server. For more information about the sequence of these records, see the documentation for your access server.

For lists of attributes that are logged and are not logged in the MSDE 2000 and SQL Server databases, see “Interpreting IAS-formatted log files” in “Related Links” later in this white paper.

For information about vendor-specific attributes (VSAs), see “Interpreting IAS IDs for vendor-specific attributes” in “Related Links” later in this white paper.

**Required database fields for session correlation**

When you create the fields in the tables of your MSDE 2000 and SQL Server databases, you must provide all fields that allow applications to query the database, correlate related fields, and return a cohesive view of each session in the query results. This is called session correlation. At a minimum, to provide *session correlation*, you must log the following IAS accounting data in the MSDE 2000 and SQL Server 2000 databases:

- NAS-IP-Address

- NAS-Identifier (You need both NAS-IP-Address and NAS-Identifier because the network access server, or NAS, can send one or the other.)
- Class
- Acct-Session-Id
- Acct-Multi-Session-Id
- Packet-Type
- Acct-Status-Type
- Acct-Interim-Interval
- NAS-Port
- Event-Timestamp

**Configuring accounting to provide the best session correlation**
When you use an application to query your SQL Server 2000 database, it is important that sufficient data is logged to provide the application with the ability to correlate related fields and information into a cohesive view of any particular user session. To provide the best session correlation, take the following actions:

- Use NASs that send the Class attribute in all accounting-requests. The Class attribute is sent to the RADIUS client in an Access-Accept message, and is useful for correlating Accounting-Request messages with authentication sessions.
- If the Class attribute is sent by the NAS in the accounting request messages, it can be used to match the accounting and authentication records. The combination of the attributes Unique-Serial-Number, Service-Reboot-Time, and Server-Address must be a unique identification for each authentication that the server accepts.
- Use NASs that support interim accounting.
- Use NASs that send Accounting-on and Accounting-off messages.
- Use NASs that support the storing and forwarding of accounting data. NASs that support this feature can store accounting data in circumstances when it cannot communicate with the IAS server. When the IAS server is available, the NAS forwards the stored records to the IAS server, providing increased reliability in accounting over NASs that do not provide this feature.
- Always configure the Acct-Interim-Interval attribute in remote access policies. The Acct-Interim-Interval attribute sets the interval (in seconds) between each interim update that the NAS sends. You can add the Acct-Interim-Interval attribute on the Advanced tab on the profile settings of the remote access policy. According to RFC 2869, the value of the Acct-Interim-Interval attribute must not be smaller than 60 seconds, or one minute, and should not be smaller than 600 seconds, or 10 minutes. For more information, see RFC 2869, "RADIUS Extensions."
- Ensure that logging of periodic status is enabled on your IAS servers.

**How IAS creates an XML document from accounting and authentication data**
If you select SQL Server logging in the IAS snap-in, attribute-value pairs are converted to XML format.

When IAS creates an XML document from attributes, accounting, and authentication data, the XML document includes the attribute ID or name, the attribute value, and the data type of the attribute value. With SQL Server logging, there are five data types for attribute values:

- Non-negative integers (data_type=0)

- Strings (data_type=1)
- Hexadecimal numbers (data_type=2)
- IPv4 addresses (data_type=3)
- Date and time (data_type=4)

The following example XML document created by IAS includes the attribute name (User-Name), the attribute value (DOMAIN*username*), and the data type (1), indicating a value data type of string:

```
<Event>
    <User-Name data_type="1">DOMAIN\username</User-Name>
</Event>
```

The next example XML document created by IAS includes the attribute name (NAS-IP-Address), the attribute value (192.168.0.1), and the data type (3), indicating a value data type of IP address:

```
<Event>
    <NAS-IP-Address data_type="3">192.168.0.1</NAS-IP-Address>
</Event>
```

The next example XML document created by IAS includes the attribute name (Provider-Type), the attribute value (1), and the data type (0), indicating a value data type of non-negative integers:

```
<Event>
    <Provider-Type data_type="0">1</Provider-Type>
</Event>
```

The last example XML document, which is created by IAS, includes the three previous examples combined into one XML document:

```
<Event>
    <User-Name data_type="1">DOMAIN\username</User-Name>
    <NAS-IP-Address data_type="3">192.168.0.1</NAS-IP-Address>
    <Provider-Type data_type="0">1</Provider-Type>
</Event>
```

Following is an example of a typical XML document sent by IAS configured for SQL Server logging:

```
    <Event>
<Computer-Name data_type="1">MYNAS</Computer-Name>
<Event-Source data_type="1">IAS</Event-Source>
<Acct-Session-Id data_type="1">10</Acct-Session-Id>
<NAS-IP-Address data_type="3">10.10.1.1</NAS-IP-Address>
<Service-Type data_type="0">2</Service-Type>
<Framed-Protocol data_type="0">1</Framed-Protocol>
<NAS-Port data_type="0">7</NAS-Port>
<NAS-Port-Type data_type="0">5</NAS-Port-Type>
<Tunnel-Type data_type="0">1</Tunnel-Type>
<Tunnel-Medium-Type data_type="0">1</Tunnel-Medium-Type>
<Calling-Station-Id data_type="1">10.10.1.2</Calling-Station-Id>
<Tunnel-Client-Endpt data_type="1">10.10.1.2</Tunnel-Client-Endpt>
<User-Name data_type="1">MYDOMAIN\Administrator</User-Name>
<Client-IP-Address data_type="3">10.10.1.1</Client-IP-Address>
<Client-Vendor data_type="0">0</Client-Vendor>
<Client-Friendly-Name data_type="1">MYNAS</Client-Friendly-Name>
<MS-RAS-Vendor data_type="0">311</MS-RAS-Vendor>
<MS-RAS-Version data_type="1">MSRASV5.20</MS-RAS-Version>
<MS-RAS-Client-Version data_type="1">MSRASV5.20</MS-RAS-Client-Version>
<MS-RAS-Client-Name data_type="1">MSRAS-0-MYCLIENT</MS-RAS-Client-Name>
<Provider-Type data_type="0">1</Provider-Type>
<Class data_type="1">311 1 192.168.0.123 02/20/2003 19:03:02 9</Class>
<SAM-Account-Name data_type="1">MYDOMAIN\Administrator</SAM-Account-Name>
<Fully-Qualified-User-Name data_type="1">MYDOMAIN\Administrator</Fully-Qualified-User-
Name>
<Authentication-Type data_type="0">4</Authentication-Type>
```

```
<Packet-Type data_type="0">1</Packet-Type>
<Reason-Code data_type="0">0</Reason-Code>
    </Event>
```

**Example stored procedure**

Following is an example stored procedure that creates an IAS database within the SQL Server 2000 database environment and processes XML documents sent to the computer running SQL Server by IAS servers configured to log to this specific computer running SQL Server. If you want to use this stored procedure in a test environment, you can copy the text below into Notepad, then save the document with the file name extension *.sql. Import the stored procedure into a database in SQL Server 2000, and run the stored procedure.

| **Note** |
| --- |
| This stored procedure is provided solely as an example, and is unsupported. |

**IAS SQL Server logging scenarios**

The following three deployment scenarios provide SQL Server logging solutions tuned to organizations with specific logging requirements:

- **Local IAS SQL Server logging.** This scenario depicts IAS servers that log to a local SQL Server 2000 database. Distributed queries can be run against databases on multiple IAS servers by using SQL Query Analyzer or a third-party product. This scenario is optimal for medium-sized organizations that need local collection of accounting data for reporting and billing.

- **IAS SQL Server logging with a central database.** This scenario depicts IAS servers that log to a local SQL Server 2000 database. SQL Server 2000 replication is deployed to publish records from the SQL Server database on each IAS server to a central SQL Server 2000 database. This scenario is optimal for large-sized organizations that need centralized collection of accounting data for reporting and billing.

- **IAS SQL Server logging using MSDE 2000.** This scenario depicts IAS servers that log to a local MSDE 2000 database. A custom accounting-forwarder component installed on each IAS server manages the local databases and then publishes records to a central SQL Server 2000 database. This scenario is optimal for enterprises.

In the sets of instructions that follow, these assumptions are made:

1. Your organization has already deployed Windows Server 2003 Internet Authentication Service on your network, and your network access solution is functioning properly with another form of logging (either IAS format or database-compatible format). If you have not already deployed IAS on your network, see "Deploying IAS as a RADIUS server" and "Deploying IAS as a RADIUS proxy" in Help and Support Center for Windows Server 2003.

2. You have SQL Server 2000 relational database development experience and you understand how to use SQL Server 2000 to create, modify, administer, and manage SQL Server 2000 databases. For more information, see "Related Links" later in this white paper.

3. For **the SQL Server logging using MSDE 2000** scenario, you have software development experience that allows you to create the custom accounting-forwarder component that is installed and run on each IAS server configured for SQL Server logging.

**Deployment in stages**

Before you deploy any of the three scenarios depicted in this white paper, it is recommended that you first deploy the scenario in a test lab environment.

After your test lab solution is functioning properly and you are prepared to deploy SQL Server logging in a production environment, you can deploy SQL Server logging in stages, as follows:

**Stage 1**: Use a text file format for logging. Configure IAS accounting to use either IAS format or database-compatible format and then verify that it is functioning properly.

**Stage 2**: Use both a text file format and SQL Server logging. With all instances of SQL Server 2000 or MSDE 2000 configured and in place in the production environment, enable SQL Server logging by using the IAS snap-in of each IAS server without disabling logging in IAS format or database-compatible format. Log in both formats for a duration that allows you to verify that your SQL Server logging solution is functioning properly. In this circumstance, if either SQL Server logging or text logging fails, IAS will halt processing of network connection attempts, and service to users will be interrupted.

**Stage 3**: Use SQL Server logging format. Disable text file logging after you have verified that your SQL Server logging solution is functioning properly.

# Local IAS SQL Server logging

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following scenario depicts local IAS SQL Server logging for medium-sized organizations. In this scenario, SQL Server 2000 is installed on each IAS server. Each IAS server is then configured to log to the local SQL Server 2000 database. Queries against multiple databases are performed using SQL Query Analyzer or a third-party product with similar capabilities.

**Components of local IAS SQL Server logging**
Figure 2 shows the components of IAS SQL Server logging.

**Figure 2: Components of local IAS SQL Server logging**

This configuration consists of the following components:

**IAS server running SQL Server**
A computer running Windows Server 2003 and Internet Authentication Service (IAS) configured to use SQL Server logging. The IAS server is also running SQL Server 2000. In the IAS snap-in, SQL Server logging is enabled, with a data link configured between IAS and SQL Server 2000 on the local computer.

Within the SQL Server 2000 database environment on the IAS server, the following components are configured:

- **IAS database.** A database configured to store IAS accounting data.
- **Stored procedure.** A program that runs inside the IAS database that accepts and processes the XML documents sent by IAS, and then stores accounting data in SQL Server 2000 tables.

**How local SQL Server logging works**
Local IAS SQL Server logging, including data collection, storage, processing, and querying for data views, works in three basic stages:

1. Accounting data is produced by a client connection attempt
2. IAS logs accounting data to the stored procedure in the local SQL Server 2000 database
3. Applications query the IAS databases

**1. Accounting data is produced by a client connection attempt**
IAS performs centralized connection authentication, authorization, and accounting for many types of network access and router-to-router connections. When an access client attempts to connect to the network, it does so by using a network access server, such as a dial-up server, VPN server, wireless access point, or 802.1X authenticating switch. When these access servers are configured as RADIUS clients to an IAS-RADIUS server, IAS attempts to authenticate the user or computer with the Active Directory user accounts database for the domain, and then IAS performs authorization (with user account properties and/or remote access policies configured on the IAS server) to discover whether the user or computer has the necessary permissions to access network resources.

**2. IAS logs accounting data to the stored procedure in the local SQL Server 2000 database**
Data from the access server and data produced by IAS are sent in XML format to a stored procedure in the SQL Server 2000 database on the local computer.

When IAS logs to a local SQL Server 2000 database, the following interactions occur:

1. The IAS server receives or produces the data to be logged to a SQL Server 2000 database. For example, a network access server configured as a RADIUS client to the IAS server sends the IAS server incoming attributes for an authentication request by a user or computer.

2. The IAS server packages the data as an XML document.

3. The IAS server initiates a connection with SQL Server 2000. If the IAS server cannot establish a connection with SQL Server 2000, the IAS server stops processing authentication and accounting requests and users cannot log on to the network.

    - When you configure IAS to log to a SQL Server 2000 database installed on the local computer, select **Use Windows NT integrated security** on the IAS server **Connection** tab in the **Data Link Properties** dialog box. The IAS server then attempts to authenticate the connection by using the Local System account. For more information, see "Configure log file properties" in Help and Support Center for Windows Server 2003.

4. If a connection with SQL Server 2000 is successful, the IAS server signals SQL Server 2000 to run a stored procedure named report_event. IAS then sends the accounting data (an XML document) to the report_event stored procedure in the SQL Server 2000 database. The stored procedure that is called by IAS must be named report_event, or IAS SQL Server logging will fail. If the IAS server is unable to write to the SQL Server 2000 database, IAS SQL Server logging will fail and users cannot log on.

5. The report_event stored procedure uses only one parameter. This parameter is a Unicode string of type *ntext*. The Unicode string contains an XML document which in turn contains the accounting data to be logged.

6. The report_event stored procedure in the SQL Server 2000 database processes the XML document and stores the processed data in SQL Server 2000 database tables.

7. SQL Server 2000 notifies the IAS server that the transaction is successful.

8. The IAS server is free to process additional data, repeating this process as required.

**3. Applications query the IAS databases**

You can create a custom application, such as a Help Desk application, to view data stored in the SQL Server databases on each IAS server. You can write a stand-alone application with a software development program such as the Microsoft® Visual Basic® development system, or you can use Microsoft® Access 2002, SQL Server 2000 Enterprise Manager, or SQL Query Analyzer to view the data.

Figure 3 depicts a query against SQL Server databases on two IAS servers by using SQL Query Analyzer on a portable computer.

**Figure 3: SQL Query Analyzer runs a SQL query**

For more information, see "SQL Server Connection Basics" in "Related Links" later in this white paper.

**To deploy local IAS SQL Server logging**

1. Install SQL Server 2000 on each IAS server that you want to configure for SQL Server logging. For more information, see "Overview of Installing SQL Server 2000" in "Related Links" later in this white paper.

2. By using SQL Server 2000 tools, you can create the database structure in the SQL Server 2000 database for storage of IAS accounting log data. For more information, see "Creating a database" in "Related Links" later in this white paper.

3. Create a stored procedure in the SQL Server 2000 database called report_event that will process the data passed to it by IAS in XML format. For more information, see "Create Procedure" in "Related Links" later in this white paper.

4. Configure log file properties and the data link for each IAS server. Configure the data link on each IAS server to log to the local SQL Server 2000 database.

To configure log file properties and the data link, do the following on each IAS server:

1. Open the IAS snap-in.

2. In the details pane, right-click **SQL Server**, and then click **Properties**.

3. In **Log the following information**, select the information that you want to log:

   a. To log all accounting requests, click **Accounting requests**.

   b. To log authentication requests, click **Authentication requests**.

   c. To log periodic status, such as interim accounting requests, click **Periodic status**.

   d. To configure the number of concurrent sessions allowed between the IAS server and the SQL Server database, type a number in **Maximum number of concurrent sessions**.

   e. To configure the SQL Server data source, click **Configure**, and then, on the **Connection** tab, specify the following:

      To specify the name of the server on which the database is stored, type or select a name in **Select or enter a server name**.

      To specify the authentication method with which to log on to the server, click **Use Windows NT integrated security**. Or, click **Use a specific user name and password**, and then type credentials in **User name** and **Password**.

      To allow a blank password, click **Blank password**.

      To store the password, click **Allow saving password**.

      To specify which database to connect to on the computer running SQL Server, click **Select the database on the server**, and then select a database name from the list.

To test the connection between the IAS server and the computer running SQL Server, click **Test Connection**.

For more information, see "Configure log file properties" in Help and Support Center for Windows Server 2003.

# IAS SQL Server logging with a central database

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following scenario depicts IAS SQL Server logging with a central database for large-sized organizations. In this scenario, SQL Server 2000 is installed on each IAS server. Each IAS server is then configured to log to the local SQL Server 2000 database. In addition, a computer or computer cluster running SQL Server 2000 is deployed as a central database. All records from IAS servers are periodically published to the central SQL Server database. Queries against the central SQL Server database are performed using SQL Query Analyzer or a third-party product with similar capabilities.

**Components of IAS SQL Server logging with a central database**

Figure 4 depicts the components of SQL Server logging with a central database.

**Figure 4: The components of IAS SQL Server logging with a central database**

This configuration consists of the following components:

**IAS servers running SQL Server**

Two or more computers running Windows Server 2003 and Internet Authentication Service (IAS) configured to use SQL Server logging. The IAS servers are also running SQL Server 2000. In the IAS snap-in, SQL Server logging is enabled, with a data link configured between IAS and SQL Server 2000 on the local computer.

Within the SQL Server 2000 database environment on each IAS server, the following components are configured:

- **IAS database.** A database configured to store IAS accounting data.
- **Stored procedure.** A program that runs inside the IAS database. The stored procedure accepts and processes the XML documents sent by IAS and stores accounting data in SQL Server 2000 tables.

**Central computer running SQL Server**

Within the SQL Server 2000 database, the following components are configured:

- **Central IAS database.** A database that stores IAS accounting data that is published by the IAS servers running SQL Server.

**How IAS SQL Server logging with a central database works**

IAS SQL Server logging, including data collection, storage, processing, and querying for data views, works in five basic stages:

1. Accounting data is produced by a client connection attempt

2. IAS logs accounting data to the stored procedure in the local SQL Server 2000 database

3. IAS servers running SQL Server publish records to the central SQL Server database

4. The central SQL Server database warehouses data from one or more IAS servers

5. Applications query the IAS database on the computer running SQL Server

**1. Accounting data is produced by a client connection attempt**
IAS performs centralized connection authentication, authorization, and accounting for many types of network access and router-to-router connections. When an access client attempts to connect to the network, it does so by using a network access server, such as a dial-up server, VPN server, wireless access point, or 802.1X authenticating switch. When these access servers are configured as RADIUS clients to an IAS-RADIUS server, IAS attempts to authenticate the user or computer with the Active Directory user accounts database for the domain, and then IAS performs authorization (with user account properties and/or remote access policies configured on the IAS server) to discover whether the user or computer has the necessary permissions to access network resources.

**2. IAS logs accounting data to the stored procedure in the local SQL Server 2000 database**
Data from the access server and data produced by IAS is sent in XML format to a stored procedure in the SQL Server 2000 database on the local computer. The access server is configured at the IAS server as a RADIUS client.

When IAS logs to a local SQL Server 2000 database, the following interactions occur:

1. The IAS server receives or produces the data to be logged to a SQL Server 2000 database. For example, a network access server configured as a RADIUS client to the IAS server sends the IAS server incoming attributes for an authentication request by a user or computer.

2. The IAS server packages the data as an XML document.

3. The IAS server initiates a connection with SQL Server 2000. If the IAS server cannot establish a connection with SQL Server 2000, the IAS server stops processing authentication and accounting requests and users cannot log on to the network.

    - When you configure IAS to log to a SQL Server 2000 database installed on the local computer, select **Use Windows NT integrated security** on the IAS server **Connection** tab in the **Data Link Properties** dialog box. The IAS server then attempts to authenticate the connection by using the Local System account. For more information, see "Configure log file properties" in Help and Support Center for Windows Server 2003.

4. If a connection with SQL Server 2000 is successful, the IAS server signals SQL Server 2000 to run a stored procedure named report_event. IAS then sends the accounting data (an XML document) to the report_event stored procedure in the SQL Server 2000 database. The stored procedure that is called by IAS must be named report_event, or IAS SQL Server logging will fail. If the IAS server is unable to write to the SQL Server 2000 database, IAS SQL Server logging will fail and users cannot log on.

5. The report_event stored procedure uses only one parameter. This parameter is a Unicode string of type *ntext*. The Unicode string contains an XML document which in turn contains the accounting data to be logged.

6. The report_event stored procedure in the SQL Server 2000 database processes the XML document and stores the processed data in SQL Server 2000 database tables.

7. SQL Server 2000 notifies the IAS server that the transaction is successful.

8. The IAS server is free to process additional data, repeating this process as required.

**3. IAS servers running SQL Server publish records to the central SQL Server database**
After a time period that you specify, the IAS servers running SQL server act as publishers and replicate data to the central SQL Server database, which acts as the subscriber. SQL Server 2000 replication is a set of technologies for copying and distributing

data and database objects from one database to another and then synchronizing between databases for consistency. You can also configure the SQL Server database on IAS servers to delete previously published records. For more information, see "Replication Overview" in "Related Links" later in this white paper.

**4. The central SQL Server database warehouses data from two or more IAS servers**
The IAS database on the computer running SQL Server contains all records from all IAS servers configured with the SQL Server logging components and configured to log to the computer running SQL Server. The central IAS database provides a comprehensive view of accounting data for network access administrators and others who need to view the IAS accounting data.

**5. Applications query the IAS database on the central SQL Server**
You can create a custom application, such as a Help Desk application, to view data stored in the SQL Server database. You can write a stand-alone application with a software development program such as Visual Basic, or you can use Access 2002, SQL Server 2000 Enterprise Manager, or SQL Query Analyzer to view the data. For more information, see "Creating a Data Warehouse" in "Related Links" later in this white paper.

**To deploy IAS SQL Server logging with a central database**

1. Install SQL Server 2000 on each IAS server that you want to configure for SQL Server logging.

2. By using SQL Server 2000 tools, you can create the database structure in the SQL Server 2000 database for storage of IAS accounting log data.

3. Create a stored procedure in the SQL Server 2000 database called report_event that will process the data passed to it by IAS in XML format.

4. Create the central IAS database. On the computer or computer cluster running SQL Server 2000 that will function as the central SQL Server, create an IAS database to hold records from all IAS servers configured to use SQL Server logging.

5. Configure replication from the IAS servers running SQL Server to the central SQL Server database.

6. Configure log file properties and the data link for each IAS server.

To configure log file properties and the data link, do the following on each IAS server:

1. Open the IAS snap-in.

2. In the details pane, right-click **SQL Server**, and then click **Properties**.

3. In **Log the following information**, select the information that you want to log:

    a. To log all accounting requests, click **Accounting requests**.

    b. To log authentication requests, click **Authentication requests**.

    c. To log periodic status, such as interim accounting requests, click **Periodic status**.

    d. To configure the number of concurrent sessions allowed between the IAS server and the SQL Server database, type a number in **Maximum number of concurrent sessions**.

    e. To configure the SQL Server data source, click **Configure**, and then, on the **Connection** tab, specify the following:

    To specify the name of the server on which the database is stored, type or select a name in **Select or enter a server name**.

    To specify the authentication method with which to log on to the server, click **Use Windows NT integrated security**. Or, click **Use a specific user name and password**, and then type credentials in **User name** and **Password**.

To allow a blank password, click **Blank password**.

To store the password, click **Allow saving password**.

To specify which database to connect to on the computer running SQL Server, click **Select the database on the server**, and then select a database name from the list.

To test the connection between each IAS server and the central computer running SQL Server, click **Test Connection**.

For more information, see "Configure log file properties" in Help and Support Center for Windows Server 2003.

# IAS SQL Server logging using MSDE 2000

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following scenario depicts IAS SQL Server logging for the enterprise. This scenario uses both SQL Server 2000 and MSDE 2000, as well as a custom accounting-forwarder component that manages the MSDE 2000 databases installed on each IAS server.

| **Important** |
| --- |
| **To deploy this scenario you must have software development experience.** You must create the custom accounting-forwarder component described in this scenario. This component is installed and run on each IAS server configured for SQL Server logging. |

**Introduction to MSDE 2000**

The Microsoft SQL Server 2000 Desktop Engine (MSDE 2000) is a data engine built and based on core SQL Server technology. With support for single- and dual-processor computers, MSDE 2000 is a reliable storage engine and query processor for desktop extensions of enterprise applications. The common technology base shared between SQL Server and MSDE 2000 enables developers to build applications that can scale from portable computers to multiprocessor clusters. This common technology base also allows IAS to use either a MSDE 2000 database or a database configured on SQL Server 2000 as storage for accounting data.

Designed to run in the background, supporting transactional desktop applications, MSDE 2000 does not have its own user interface (UI). Users typically interact with MSDE 2000 through the application in which it is embedded. MSDE 2000 is packaged in a self-extracting archive for ease of distribution and embedding. The only tool that is provided with MSDE 2000 is the **osql** utility. The executable file, Sql.exe located in the MSSQL\Binn folder, provides a default instance of MSDE 2000.

When you use MSDE 2000 in conjunction with SQL Server 2000, you can use the client tools included with SQL Server 2000, such as SQL Server Enterprise Manager and SQL  Query Analyzer, to configure and administer MSDE 2000 databases.

For more information about MSDE, see "Related Links" later in this white paper.

**Components of IAS SQL Server logging using MSDE 2000**

Figure 5 shows the components of IAS SQL Server logging using MSDE 2000.

**Figure 5: Components of IAS SQL Server logging using MSDE 2000**

This configuration consists of the following components:

**IAS server**

A computer running Windows Server 2003 and Internet Authentication Service (IAS) configured to use SQL Server logging.

To implement SQL Server logging, the following components are required on the IAS server:

- **MSDE 2000 database.** MSDE 2000 installed on the computer running Windows Server 2003 and IAS. If there are multiple IAS servers configured for SQL Server logging, each server must have MSDE 2000 locally installed and configured for logging.

- **Stored procedure.** A program that runs inside the MSDE 2000 database on the computer running Windows Server 2003 and IAS. The stored procedure must be named report_event. Report_event accepts and processes data from the IAS server and stores it in MSDE 2000 tables.

- **Custom accounting-forwarder component.** A custom accounting-forwarder component, service, or application installed on the computer running Windows Server 2003 and IAS. The custom accounting-forwarder component periodically publishes records from the MSDE database on the IAS server to the IAS database on the computer running SQL Server. The custom component also flags local records as published, and deletes previously published records from the MSDE 2000 database during off-peak hours. If there are multiple IAS servers configured for SQL Server logging, each server must have the custom component installed to process records in the local MSDE 2000 database and forward records to the SQL Server database.

**Computer running SQL Server**
A computer or computer cluster running SQL Server 2000. If you have a small IAS deployment, you might need only one computer running SQL Server; however if you have a large IAS deployment in an enterprise network environment, you might need more than one computer or cluster running SQL Server.

To implement SQL Server logging, the following component is required on the computer running SQL Server:

- **IAS database.** A database on the computer running SQL Server that is dedicated to storing the records from all IAS servers.

**How IAS SQL Server logging works with MSDE 2000**
IAS SQL Server logging, including data collection, storage, processing, and querying for data views, works in five basic stages:

1. Accounting data is produced by a client connection attempt
2. IAS logs accounting data to the stored procedure in the local MSDE 2000 database
3. A custom accounting-forwarder component manages the local MSDE 2000 database
4. SQL Server warehouses data from one or more IAS servers
5. Applications query the IAS master database on the computer running SQL Server

**1. Accounting data is produced by a client connection attempt**
IAS performs centralized connection authentication, authorization, and accounting for many types of network access and router-to-router connections. When an access client attempts to connect to the network, it does so by using a network access server, such as a dial-up server, VPN server, wireless access point, or 802.1X authenticating switch. When these access servers are configured as RADIUS clients to an IAS-RADIUS server, IAS attempts to authenticate the user or computer with the Active Directory user accounts database for the domain, and IAS performs authorization (with user account properties and/or remote access policies configured on the IAS server) to discover whether the user or computer has the necessary permissions to access network resources.

If the RADIUS server is configured to provide accounting, or logging of session information, accounting data is produced that can be logged to an XML-compliant database on a computer running SQL Server 2000.

**2. IAS logs accounting data to the stored procedure in the local MSDE 2000 database**
Data from the access server and data produced by IAS are sent in XML format to a stored procedure called report_event in the MSDE 2000 database. The access server is configured at the IAS server as a RADIUS client.

Figure 6 depicts how RADIUS accounting data flows from an access server to the MSDE 2000 database on the IAS server.

**Figure 6: RADIUS accounting data flow from access server to the MSDE 2000 database**

When IAS SQL Server logging logs to a local MSDE 2000 database, the following interactions occur:

1. The IAS server receives or produces the data to be logged to a MSDE 2000 database. For example, a network access server configured as a RADIUS client to the IAS server sends the IAS server incoming attributes for an authentication request by a user or computer.

2. The IAS server packages the data as an XML document.

3. The IAS server initiates a connection with MSDE 2000. If the IAS server cannot establish a connection with MSDE 2000, the IAS server stops processing authentication and accounting requests and users cannot log on to the network.

    - When you configure IAS to log to an MSDE 2000 database installed on the local computer, select **Use Windows NT integrated security** on the IAS server **Connection** tab in the **Data Link Properties** dialog box. The IAS server then attempts to authenticate the connection by using the Local System account. For more information, see "Configure log file properties" in Help and Support Center for Windows Server 2003.

4. If a connection with MSDE 2000 is successful, the IAS server signals MSDE 2000 to run a stored procedure named report_event. IAS then sends the accounting data (an XML document) to the report_event stored procedure in the MSDE 2000 database. The stored procedure that is called by IAS must be named report_event, or IAS SQL Server logging will fail. If the IAS server is unable to write to the MSDE 2000 database (for example, if the database maximum size limit of 2 gigabytes (GBs) is reached), IAS SQL Server logging will fail and users cannot log on.

5. The report_event stored procedure uses only one parameter. This parameter is a Unicode string of type *ntext*. The Unicode string contains an XML document which in turn contains the accounting data to be logged.

6. The report_event stored procedure in the MSDE 2000 database processes the XML document and stores the processed data in MSDE 2000 database tables.

7. MSDE 2000 notifies the IAS server that the transaction is successful.

8. The IAS server is free to process additional data, repeating this process as required.

**3. A custom accounting-forwarder component manages the local MSDE 2000 database**

For the IAS SQL Server logging solution to work, you must write a custom component that manages the MSDE 2000 database on IAS servers. Due to the 2-GB limit of MSDE 2000, records must be periodically published by a custom accounting-forwarder component from MSDE 2000 to a designated database on the computer running SQL Server. The accounting-forwarder component can be installed as a service, a scheduled task in MSDE 2000, or as an application.

The custom accounting-forwarder component has two primary functions:

- Publish records from the MSDE 2000 database to the SQL Server database

- Delete previously published records from the MSDE 2000 database

The custom accounting-forwarder component performs these actions to protect against possible data loss and to save system resources during peak hours. Differential backups from the MSDE 2000 database to the computer running SQL Server provide the ability to publish small amounts of records at periodic intervals. Deletion of previously published records during off-peak hours saves resources during peak hours.

You can design your custom accounting-forwarder component to perform in the following manner:

- **Connect to a SQL Server 2000 database**. The component creates a data link with the computer running SQL Server and publishes records to the designated SQL Server database. The connection is opened when the custom component starts. The connection between the custom component and the computer running SQL Server is left open unless the custom component is stopped.

- **Perform differential backups to a SQL Server database**. At a specific interval, the component performs a differential

backup, publishing new records from the MSDE 2000 database to the computer running SQL Server. (*New records* means IAS accounting records that are added to the MSDE 2000 database after the previous differential backup.) You can design the component to publish new records at an interval that best suits your IAS deployment and your degree of network access traffic, however the interval must be calculated to publish records before the MSDE database reaches its 2-GB storage limit. If you have a large number of network access requests processed and logged by the IAS server, the 2-GB limit of the MSDE 2000 database will be reached much more quickly than on a network with few network access requests to the IAS server.

- **Flag published records in the MSDE 2000 database**. To save hardware resources during peak hours, records published to the computer running SQL Server are not immediately deleted in the MSDE 2000 database, they are flagged for deletion during off-peak hours.

- **Delete flagged records during off-peak hours**. To free up space in the MSDE 2000 database, records that are flagged as previously published are deleted during off-peak hours. You can design the component to delete flagged records at an interval that best suits your IAS deployment, however the interval must be calculated to delete flagged records before the MSDE database reaches its 2-GB storage limit.

- **Close the connection to the computer running SQL Server**. The component must be capable of closing the data link connection to the computer running SQL Server when the component is stopped.

**Example of the performance of a custom accounting-forwarder service**

Following is an example of the performance of the custom accounting-forwarder component within the data flow process, on a network with a large volume of network access traffic. In the example, IAS-01 is an IAS server configured to use SQL Server logging with a local MSDE 2000 database. The custom accounting-forwarder component, called the Accounting Forwarder service, is also installed on IAS-01. In addition, SQL-01 is a computer running SQL Server 2000 that is configured with a database dedicated to storing records from the IAS server. The database on the computer running SQL Server is named IAS_db.

In this example, authentication, authorization and accounting for network access is provided by IAS-01. When the Accounting Forwarder service on IAS-01 is started, it creates a connection to SQL-01 using a valid user name and password. The connection is open between the service and the computer running SQL Server for this example of the recommended data flow process:

1. IAS-01 logs accounting data to the local MSDE 2000 database.

2. The Accounting Forwarder service on IAS-01 reads the MSDE 2000 database, seeking only new records that are not flagged as previously published.

3. The Accounting Forwarder service on IAS-01 publishes all new, unflagged records by executing a stored procedure on SQL-01 with the data read from the MSDE 2000 database on IAS-01. The Accounting Forwarder service publishes the IAS accounting data at a 15-second interval.

4. The stored procedure on SQL-01 processes and stores the records as they are received from the Accounting Forwarder service on IAS-01. The records are stored in the IAS_db database by the stored procedure.

5. The Accounting Forwarder service on IAS-01 flags the records in the MSDE 2000 database as published.

6. At the off-peak time of 2 A.M., the Accounting Forwarder service on IAS-01 deletes all flagged records from the MSDE 2000 database.

**4. SQL Server warehouses data from one or more IAS servers**

The IAS database on the computer running SQL Server contains all records from all IAS servers configured with the SQL Server logging components and configured to log to the computer running SQL Server, providing a comprehensive view of accounting data for network access administrators and others who need to view the IAS accounting data.

**5. Applications query the IAS database on the computer running SQL Server**

You can create a custom application, such as a Help Desk application, to view data stored in the SQL Server database. You can write a stand-alone application with a software development program such as Visual Basic, or you can use Access 2002, SQL Server 2000 Enterprise Manager, or SQL Query Analyzer to view the data.

**To deploy IAS SQL Server logging with MSDE 2000**

When you deploy IAS SQL Server logging, you can configure IAS to log directly to a computer running SQL Server 2000 or you can log to an MSDE 2000 database on the local computer.

Logging directly to a computer running SQL Server presents the following issues:

- Heavy network traffic can slow logging performance, possibly resulting in a timeout between the IAS server and the computer running SQL Server.
- Network hardware failure between the IAS server and the computer running SQL Server can cause IAS logging to fail. For example, if a router or switch between the IAS server and the computer running SQL Server fails, IAS logging will fail and users cannot log on.
- SQL Server hardware or software failure can cause IAS logging to fail and prevent users from logging on.

If IAS logging stops for any reason, users attempting to authenticate against the RADIUS server or RADIUS proxy server will fail, and users will be unable to log on to the network and access network resources. For this reason, install MSDE 2000 on each IAS server used for logging, and then configure a data link between the IAS server and the local MSDE 2000 database. Because MSDE 2000 has a 2-GB database size limit, local storage of IAS logging data is temporary, and you can instead periodically publish the data to a central computer running SQL Server using a custom component, service, or application.

Figure 7 shows the recommended deployment model for IAS SQL Server logging with MSDE 2000.

**Figure 7: Deployment model for IAS SQL Server logging with MSDE 2000**

To deploy IAS SQL Server logging, the basic steps are as follows:

1. Install MSDE 2000 on each IAS server that you want to configure for SQL Server logging.
2. By using SQL Server 2000 tools, you can create the database structure in the MSDE 2000 database for storage of IAS accounting log data.
3. Create a stored procedure in the MSDE 2000 database called report_event that will process the data passed to it by IAS in XML format.
4. Create a custom accounting-forwarder component, application, or service that performs the functions described earlier in this paper.
5. On the computer running SQL Server 2000, create an IAS server database to hold records from each IAS server configured to use SQL Server logging. Create a stored procedure in the database to process the data passed to it by the custom accounting-forwarder component on each IAS server that the database serves.
6. Install the custom accounting-forwarder component, application, or service on each IAS server.
7. Configure each IAS server for SQL Server 2000 logging, including configuring the data you want to log and the data link

between IAS and the local MSDE 2000 database.

To configure log file properties and the data link, do the following on each IAS server:

1. Open the IAS snap-in.

2. In the details pane, right-click **SQL Server**, and then click **Properties**.

3. In **Log the following information**, select the information that you want to log:

   a. To log all accounting requests, click **Accounting requests**.

   b. To log authentication requests, click **Authentication requests**.

   c. To log periodic status, such as interim accounting requests, click **Periodic status**.

   d. To configure the number of concurrent sessions allowed between the IAS server and the SQL Server database, type a number in **Maximum number of concurrent sessions**.

   e. To configure the SQL Server data source, click **Configure**, and then, on the **Connection** tab, specify the following:

      To specify the name of the server on which the database is stored, type or select a name in **Select or enter a server name**.

      To specify the authentication method with which to log on to the server, click **Use Windows NT integrated security**. Or, click **Use a specific user name and password**, and then type credentials in **User name** and **Password**.

      To allow a blank password, click **Blank password**.

      To store the password, click **Allow saving password**.

      To specify which database to connect to on the computer running SQL Server, click **Select the database on the server**, and then select a database name from the list.

To test the connection between each IAS server and the computer running SQL Server, click **Test Connection**.

For more information, see “Configure log file properties” in Help and Support Center for Windows Server 2003.

# Deploying Windows Server 2003 Internet Authentication Service (IAS) with Virtual Local Area Networks (VLANs)

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This white paper describes how to configure remote access policy in Internet Authentication Service (IAS) for use with virtual local area networks (VLANs). When you configure the profile of an IAS remote access policy for use with VLANs, you must configure the attributes Tunnel-Medium-Type, Tunnel-Pvt-Group-ID, Tunnel-Type, and Tunnel-Tag. VLANs allow network architects and administrators to logically group network resources (such as servers, printers, and client computers) even when they are not on the same physical subnet.

**In This White Paper**

Introduction (Deploying Windows Server 2003 Internet Authentication Service (IAS) with Virtual Local Area Networks (VLANs))

Configuring Active Directory

Configuring IAS

Summary (Deploying Windows Server 2003 Internet Authentication Service (IAS) with Virtual Local Area Networks (VLANs))

# Introduction (Deploying Windows Server 2003 Internet Authentication Service (IAS) with Virtual Local Area Networks (VLANs))

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By using VLAN-aware network access servers and Internet Authentication Service (IAS) in Microsoft® Windows Server™ 2003, you can provide groups of users with access only to the network resources that are appropriate for their security permissions. For example, you can provide visitors with wireless access to the Internet without allowing them access to your organization network.

In addition, VLANs allow you to logically group network resources that exist in different physical locations or on different physical subnets. For example, members of your sales department and their network resources, such as client computers, servers, and printers, might be located in several different buildings at your organization, but you can place all of these resources on one VLAN using the same IP address range; the VLAN then functions, from the end-user perspective, as a single subnet.

You can also use VLANs when you want to segregate a network between different groups of users. After you have determined how you want to define your groups, you can create security groups in Active Directory and add members to the groups. You can define groups of users in several ways:

- **By role.** You can create groups for the sales team, the finance department, and other departments.
- **By position.** You can create groups for knowledge workers, managers, executives, and other positions.
- **By access level.** You can create groups for visitors, partners, full-time employees, and other categories with different access levels.

After you have created groups in Active Directory, you can open the IAS Microsoft Management Console (MMC) snap-in and create a remote access policy for each group. Within the remote access policy configuration process, you can define the VLAN to which the group will be assigned.

Configuration of VLAN-aware network hardware, such as VLAN-aware routers, switches, wireless access points, and access controllers, is beyond the scope of this white paper. When you have one or more of these devices configured as a Remote Authentication Dial-In User Service (RADIUS) client to your IAS server, however, you can use IAS to designate which VLAN the connecting user is placed on.

For information about how to configure your VLAN-aware network access server, see your access server documentation.

IAS is included in the following products:

- Windows Server 2003, Standard Edition
- Windows Server 2003, Enterprise Edition
- Windows Server 2003, Datacenter Edition
- Microsoft Windows Server 2003, 64-Bit Enterprise Edition
- Microsoft Windows Server 2003, 64-Bit Datacenter Edition
- Microsoft Windows Small Business Server 2003, Standard Edition
- Microsoft Windows Small Business Server 2003, Premium Edition

**Requirements**

To deploy IAS with VLANs as described in this white paper, the following components are required:

- A computer running Windows Server 2003 and IAS
- An Active Directory® directory service user accounts database
- RADIUS clients that are VLAN-aware, such as wireless access points, switches, or access controllers

**Remote access policy**

When you use Active Directory as your user accounts database, IAS performs network access authentication and authorization using Active Directory user account dial-in properties and remote access policies, which are configured in the IAS snap-in.

*Authentication* is the process of verifying identity, while *authorization* is the process of verifying that the user or device connecting to the network has permissions to do so.

A *remote access policy* is an ordered set of rules that define how a connection is either authorized or rejected by IAS. For each rule, there are one or more conditions, a set of profile settings, and a remote access permission setting.

If a connection is authorized, the remote access policy profile settings specify a set of connection restrictions that can include the assignment of the connection to a VLAN.

**Authorization by group**

It is recommended that you manage authorization by security group rather than by individual user. Managing authorization by group provides the ability to create one remote access policy, or rule, for network connection attempts by all members of the group. For example, if you have a sales department that you want to place on a VLAN, you can create a security group named Sales in the Active Directory Users and Computers snap-in, and then you can add all members of the sales department as members of the group. When a member of the Sales group attempts to connect to the network, the connection attempt is processed by IAS with the remote access policy for the group.

If the user is authenticated and authorized, IAS applies connection restrictions, and can instruct a VLAN-aware access server to place the member of the Sales group onto the VLAN for the sales department.

IAS authorizes connection attempts with both the dial-in properties of the user account, which are configured in the Active Directory Users and Computers snap-in, and remote access policies, which are configured in the IAS snap-in.

**User account remote access permission**

One of the dial-in properties of user accounts in Active Directory is **Remote Access Permission (Dial-in or VPN)**. You can use this property to set remote access permission to be explicitly allowed, denied, or determined through remote access policies. In all cases, remote access policies are used to authorize the connection attempt.

If access is explicitly allowed, remote access policy conditions, user account properties, or profile properties can still deny the connection attempt. The **Control access through Remote Access Policy** option is only available on user accounts in a Windows 2000 native domain, a Windows Server 2003 domain, or for local accounts on stand-alone servers running Windows 2000; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition.

New accounts that are created on a stand-alone server or in a Windows 2000 native domain are set to **Control access through Remote Access Policy**. New accounts that are created in a Windows 2000 mixed domain are set to **Deny access**.

When you manage authorization by security group, the remote access permission setting in user account dial-in properties can be set to one of the following:

- **Allow access**. Only apply this setting for users who are members of groups to whom you want to grant remote access permission. You can use this setting when your domain functional level is Windows 2000 mixed. Windows 2000 mixed supports Windows NT 4.0, Windows 2000, and Windows Server 2003 family domain controllers. With user account remote access permission set to **Allow access**, authorization is performed by IAS in circumstances where you have created a policy that matches the conditions of the connection.
- **Control access through Remote Access Policy**. This setting is recommended for domains with a functional level of Windows 2000 native or Windows Server 2003.

**Important**

To set user account dial-in properties to **Control access through remote access policy**, the domain functional level must be Windows 2000 native or higher. For more information, see "Domain and forest functionality" in Help and Support Center for Windows Server 2003 or on the Web at http://go.microsoft.com/fwlink/?LinkId=30600.

**Ignoring the user account dial-in properties**

You can configure IAS to ignore the dial-in properties of user accounts. This setting is useful for circumstances where you want IAS remote access policy to determine authorization for all connections to your network. For example, you can configure IAS to ignore the dial-in properties of user accounts when:

- Your domain functional level is Windows 2000 mixed.
- Changing the current settings on user accounts is not cost-effective.

For more information about configuring IAS to ignore the dial-in properties of user accounts, see "Dial-in properties of a user account" in Help and Support Center for Windows Server 2003 or on the Web at http://go.microsoft.com/fwlink/?LinkId=30601.

For more information about remote access policies, see "Introduction to remote access policies" in Help and Support Center for Windows Server 2003 or on the Web at http://go.microsoft.com/fwlink/?LinkId=30602.

# Configuring Active Directory

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you want to create security groups in Active Directory or raise the domain functional level, perform the following procedures.

| **Important** |
| --- |
| If you have or will have any domain controllers running Windows NT 4.0 and earlier, then do not raise the domain functional level to Windows 2000 native. After the domain functional level is set to Windows 2000 native, it cannot be changed back to Windows 2000 mixed.<br><br>If you have or will have any domain controllers running Windows NT 4.0 and earlier or Windows 2000, then do not raise the domain functional level to Windows Server 2003. After the domain functional level is set to Windows Server 2003, it cannot be changed back to Windows 2000 mixed or Windows 2000 native. |

If you want to raise the domain functional level to either Windows 2000 native or Windows Server 2003, do the following:

1. Open the **Active Directory Domains and Trusts** snap-in. To open Active Directory Domains and Trusts, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Domains and Trusts**.

2. In the console tree, right-click the domain for which you want to raise the domain functional level, and then click **Raise Domain Functional Level**.

3. In **Select an available domain functional level**, do one of the following:

   - To raise the domain functional level to Windows 2000 native, click **Windows 2000 native**, and then click **Raise**.

   - To raise the domain functional level to Windows Server 2003, click **Windows Server 2003**, and then click **Raise**.

| **Note** |
| --- |
| To perform this procedure, you must be a member of the Domain Admins group in the domain for which you want to raise functionality or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority.<br><br>The current domain functional level is displayed under **Current domain functional level** in the **Raise Domain Functional Level** dialog box. |

To create a group and add members to the group, do the following:

1. Open the **Active Directory Users and Computers** snap-in.

2. In the console tree, right-click the folder in which you want to add a new group.

3. Point to **New**, and then click **Group**.

4. Type the name of the new group. By default, the name you type is automatically entered in **Group name (pre-Windows 2000)**.

5. In **Group scope**, click one of the options.

6. In **Group type**, click one of the options, and then click **OK**.

7. In the details pane, right-click the group you just created, and then click **Properties**.

8. On the **Members** tab, click **Add**.

9. In **Enter the object names to select**, type the name of the user, group, or computer that you want to add to the group, and then click **OK**.

For more information, see "To create a new group" at http://go.microsoft.com/fwlink/?LinkId=20018 and "Assign user rights to a group in Active Directory" at http://go.microsoft.com/fwlink/?LinkId=20019.

# Configuring IAS

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To configure IAS for use with VLANs, do the following:

1. Install Internet Authentication Service on a computer running Windows Server 2003. For more information, see "To install IAS" in Help and Support Center for Windows Server 2003 or on the Web at http://go.microsoft.com/fwlink/?LinkId=20028.

2. Register IAS in Active Directory. In order for IAS to have permission to read user accounts in Active Directory, IAS must be registered with Active Directory. For more information, see "To enable the IAS server to read user accounts in Active Directory" in Help and Support Center for Windows Server 2003 or on the Web at http://go.microsoft.com/fwlink/?LinkId=20030.

3. Add RADIUS clients. In the IAS snap-in, right-click **RADIUS Clients**, and then click **New RADIUS Client**. Use the **New RADIUS Client Wizard** to both add and configure your network access servers as RADIUS clients.

4. Delete the default remote access policies. To delete the policies, open the IAS snap-in, and then click **Remote Access Policies**. Select each existing policy, right-click the policy, and then click **Delete**.

5. Create a new remote access policy. In the console tree of the IAS snap-in, right-click **Remote Access Policies**, and then click **New Remote Access Policy**. Use the **New Remote Access Policy Wizard** to create a policy.

As an example policy, you can choose the following:

- For **How do you want to set up this policy?** select **Use the wizard to set up a typical policy for a common scenario**.

- For **Policy name**, type a name for your policy. For example, type **Sales policy**.

- For **Select the method of access for which you want to create a policy**, select the appropriate type of access, such as **Wireless** or **Ethernet**.

- For **Grant access based on the following**, click **Group**, and then click **Add**. In **Enter the object name to select**, type the name of a security group that you defined when configuring Active Directory. For example, if you created a group named Sales, type **Sales**, and then click **OK**.

- In **Authentication Methods**, select the authentication method that you would like to enforce for users who will be placed on this VLAN. Your choices will differ based upon the access method you have chosen for the policy, such as Wireless or VPN. When you have completed configuring an authentication method, click **Finish**.

After you have completed creating the policy and have closed the wizard, you need to configure additional items for the remote access policy. In the IAS snap-in, click **Remote Access Policies**, and then double-click the policy you just created. Make the following configuration changes to the policy:

1. In the policy **Properties** dialog box, for **Policy conditions**, click **Add**.

2. In **Attribute Types**, click **Day-And-Time-Restrictions**, and then click **Add**. In **Time of day restraints**, select **Permitted**, configure the days and times that access is permitted, and then click **OK**.

3. In the policy **Properties** dialog box, click **Grant remote access permission**.

4. Click **Edit Profile**, and then click the **Advanced** tab. By default, the **Service-Type** attribute appears in **Attributes** with a value of **Framed**. By default, for policies with access methods of VPN and dial-up, the **Framed-Protocol** attribute

appears in **Attributes** with a value of **PPP**. To specify additional connection attributes required for VLANs, click **Add**, and then add the following attributes:

- **Tunnel-Medium-Type**. Select a value appropriate to the previous selections you have made. For example, if the remote access policy you are configuring is a wireless policy, select: **Value: 802 (Includes all 802 media plus Ethernet canonical format)**.
- **Tunnel-Pvt-Group-ID**. Enter the integer that represents the VLAN number to which group members will be assigned. For example, if your Sales VLAN is on VLAN 4, type the number **4**.
- **Tunnel-Type**. Select the value **Virtual LANs (VLAN)**.
- **Tunnel-Tag**. Obtain this value from your hardware documentation.

5. Configure IAS connection request policies as you require.

| **Important** |
| --- |
| IAS evaluates remote access policies in the order in which they appear in the IAS snap-in under **Remote Access Policies**. |

For more information about remote access policies, see "Elements of a remote access policy" in Help and Support Center for Windows Server 2003 or on the Web at http://go.microsoft.com/fwlink/?LinkId=30605.

For more information about connection request processing, see "Introduction to connection request processing" in Help and Support Center for Windows Server 2003 or on the Web at http://go.microsoft.com/fwlink/?LinkId=30607.

# Summary (Deploying Windows Server 2003 Internet Authentication Service (IAS) with Virtual Local Area Networks (VLANs))

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you use VLAN-aware network hardware, such as routers, switches, and access controllers, you can configure remote access policy in Internet Authentication Service in Windows Server 2003 to instruct the access servers to place members of Active Directory groups on VLANs. When you configure the profile of an IAS remote access policy for use with VLANs, you must configure the attributes Tunnel-Medium-Type, Tunnel-Pvt-Group-ID, Tunnel-Type, and Tunnel-Tag. This ability to group network resources logically with VLANs provides flexibility when designing and implementing network solutions.

# Related Links (Deploying Windows Server 2003 Internet Authentication Service (IAS) with Virtual Local Area Networks (VLANs))

Updated: June 30, 2004

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more information about IAS, see the following:

- The Internet Authentication Service home page at http://go.microsoft.com/fwlink/?LinkId=16171.
- "Deploying IAS" in the *Windows Server 2003 Deployment Kit* at http://go.microsoft.com/fwlink/?LinkId=30603.
- "Internet Authentication Service" in Windows Server 2003 Help on the Web at http://go.microsoft.com/fwlink/?LinkId=30604.

# Kerberos authentication for load balanced web sites

Updated: July 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Published: July 1, 2003

**In This White Paper**

Introduction (Kerberos authentication for load balanced web sites)

Setting up Kerberos Authentication against the cluster name Service Principal Name

# Introduction (Kerberos authentication for load balanced web sites)

Updated: July 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Problem Statement**

Kerberos is an authentication mechanism used to verify user or host identity. This document explains how to configure Kerberos to allow applications to take advantage of its authentication capabilities while also being load balanced with NLB.

| **Note** |
| --- |
| The procedures described in this document apply only to products in the Windows Server 2003 family. Using Kerberos in an application load balanced with NLB is not supported in Windows 2000. |

**Outline of Solution**

Follow the steps in this white paper to register the cluster name service principal name (SPN) on a domain user account and configure IIS 6.0 to run in Worker Process Isolation Mode under the identity of that user account.

**Prerequisite Steps**

Complete these steps before implementing the Kerberos Authentication solution.

1. Join the Windows Server 2003 computers that would participate in the network load balancing (NLB) cluster to a Windows domain (not a workgroup).

2. Set up the NLB cluster.

3. Assign a name for the cluster (this is the **cluster name**) and map it to the NLB cluster IP address on DNS/WINS. This name does not have to be the **Full Internet Name** entered on the **Cluster Parameters** tab in the **Network Load Balancing Properties** dialog box.

# Setting up Kerberos Authentication against the cluster name Service Principal Name

Updated: October 6, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

There are three phases to setting up Kerberos Authentication against the cluster name SPN, each targeted at a different entity. A sample configuration is suggested in the following procedures, but your configuration may be different.

**Phase 1: Administration of Domain Controller**
On the Windows Server 2003 domain controller, perform the following steps. You must have administrator credentials to follow this procedure.

1. Create a domain user account for IIS 6.0

   For example, on the domain controller, run net user /add <iisid> <nlb> where <*iisid*> is the user name and <*nlb*> is the password.

2. If there isn't already one, create a domain user account for the client.

   For example, on the domain controller, run net user /add <iiststt> <nlb> where <*iiststt*> is the user name and <*nlb*> is the password.

3. Register the service principal name (SPN) that will be used by the client to identify the service on the domain user account created in step 1 using the setspn.exe tool.

   For example, if Internet Explorer is the client and testweb is the cluster name, on the domain controller, run setspn -a HOST/testweb nlb.net\iisid to register the SPN of HOST/testweb on the domain user account of nlb.net\iisid.

| **Note** |
| --- |
| The SPN will be formatted as <Service-Class>/<Host>. The value of <Service-Class> depends on the client. While Internet Explorer uses the string HOST, other clients might use http or some other string for <Service-Class>. The value of <Host> is the cluster name. |

**Phase 2: Administration of Servers**
Perform each of these steps on every Windows Server 2003 computer that is part of the NLB cluster.

1. Configure IIS to run in Worker Process Isolation Mode. Start IIS Manager, expand **Local Computer**, right-click **Web Sites**, and then click **Properties**. Click the **Service** tab, clear the **Run WWW service in IIS 5.0 isolation mode** check box, and then click **OK**.

If the switch to Worker Process Isolation Mode is successful, a folder named **Application Pools** appears in IIS Manager listing for your local computer as shown in the following diagram:

2. Assign the domain user account (created in Phase 1, step one) identity to the application pool that you wish to use to run the Web site. In this example, DefaultAppPool is the application pool used. Right-click the relevant application pool folder, select **Properties**, click the **Identity** tab, then under **Application pool identity**, select **Configurable** and enter the user name and password created earlier.

3. Add the domain user account created in Phase 1, step one to the local IIS_WPG group. This is the IIS Worker Process Group. This can be accomplished using the Computer Management dialog box or by running this command: net localgroup iis_wpg add <iisid>.

4. Create your Web site. Please refer to the IIS documentation for help with this step.

5. Assign the Web site to the application pool operated on in step 2. Right-click the Web site folder, select **Properties**, click the **Home Directory** tab, and then, in **Application settings**, in the **Application pool** drop-down list, select the appropriate application pool.

6. If using host header names, right-click the Web site folder, select **Properties**, click the **Web Site** tab, and then, in **Web site identification**, click **Advanced** and enter the cluster name for the **Host header value**.

7. Right-click the Web site folder, select **Properties**, click the **Directory Security** tab, and then, in **Authentication and access control**, click **Edit**, and then under **Authenticated access**, clear the **Basic authentication** check box and select **Integrated Windows Authentication**.

8. To force precedence of Kerberos over NTLM, navigate to the Inetpub\AdminScripts directory, where there is a script called adsutil.vbs. Run the following command: adsutil set w3svc/ntauthenticationproviders Negotiate, NTLM.

**Phase 3: Administration of Client**

There are really no special steps to be performed at the client. The client computer has to use the SPN registered on the domain user account created in Phase 1, step 1. Also, if another domain user account was created in step 2, the client should use it to log on. In our sample configuration, Internet Explorer was the client and we were logged on as Administrator. So we forced Internet Explorer to accept new credentials (created in Phase 1, step 2) by selecting **Prompt for user name and password** in Tools/Internet Options/Security/Custom Level/User Authentication/Log on.

**Solution Execution and Verification**

After you have completed the three phases, the configuration is ready to be verified. The client should be able to access the Web site using Kerberos for authentication, In our sample configuration, we accessed http://testweb/test.htm using Internet Explorer. To verify the Kerberos (instead of NTLM) was indeed used for authentication, please look for an event like the following to be logged in the **Security** folder of the servers Windows Event Log.

# Server Clusters: Remote Setup, Unattended Installations and Image-based Installations

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

**In This White Paper**

Overview (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Command Line Setup

Unattended Installation of Server Clusters

Image-based Installations of Server Clusters

Configuring Your Server Clusters

Image-based Installation of the Operating System and the Cluster Service Using Automated Deployment Services (ADS)

Appendix A (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Appendix B (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Appendix C (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Appendix D (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Appendix E (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Appendix F (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Appendix G (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

# Overview (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

You can install Server clusters remotely in the following ways:

Using command line to install Server clusters

Unattended installation of Server clusters during the operating system install

Image-based installation of Server clusters during the operating system install

**Using Command Line to Install Server Clusters**
If Microsoft Windows Server 2003 Enterprise Server is already installed and configured on your cluster nodes, you can simply use the command line utility called cluster.exe to install and configure the cluster service on those nodes remotely.

**Unattended Installation of the Operating System and the Cluster Service**
To perform a clean install or to upgrade the operating system, you can either perform a hands-on installation (you must manually provide all the answers required for setup), which this document will not address, or an unattended installation using a so-called answer file. Server clusters can be installed after the operating system installation completes, by specifying certain switches in the answer file. Unattended installation of the operating system and Server clusters is discussed in details in the Unattended installation of Server Clusters section of this document.

**Image-based Installation of the Operating System and the Cluster Service**
Another way to perform a clean install of the operating system is to use image-based installations, also known as disk cloning or simply cloning. Cloning is the fastest method of deploying Windows Server 2003 Enterprise Server. Image-based installations are useful if you are deploying computers that have similar hardware and you want to perform quick installations with no or minimal manual interaction. You cannot use image-based installation to upgrade an operating system. Image-based installation is discussed in more detail in the Image-based installations of Server Clusters section of this document.

**Image-based Installation of the Operating System and the Cluster Service Using Automated Deployment Services (ADS)**
Another way to perform an operating system installation and configuration is with ADS. With ADS, you can deploy an operating system onto one or more destination devices or can repurpose those computers. ADS uses above mentioned cloning mechanism to distribute the image on to a set of servers. By automating the deployment and repurposing processes, ADS reduces the overhead of maintaining diverse systems in your data center unlike plain cloning where it is useful if you are deploying computers that have similar hardware. ADS based operating system Image installation is discussed in more detail in the ADS based Image installations of Server Clusters section of this document.

# Command Line Setup

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

You do not have to log into the cluster nodes to install the cluster service, but you must make sure that the account you use to create a cluster and add nodes to the cluster belongs to the local administrators group on all of the nodes prior to installation of the cluster service. Once you have added a cluster administrator account to the local administrators group (see section Adding a cluster administrator account to the local administrators group for details), you can run the cluster.exe (located in the **%windir%\system32** directory) command line utility to create a cluster and add nodes to the cluster. Cluster.exe automatically adds the Cluster Service Account (CSA) to the local administrators group if it is not already there.

Once you have installed a cluster, you can use cluster.exe to create and configure cluster resources as described in the Windows Server 2003 Enterprise Server help.

**Adding a Cluster Administrator Account to the Local Administrators Group**
You can add an account to the local administrators group by:

logging onto each computer and using the Local users and groups snap-in

connecting to a remote computer using the Remote Desktops snap-in or

connecting to a remote computer using telnet and running the following command:

```
net localgroup administrators /add domain\account
```

You can include this line in the answer file if you want a cluster administrator account to be added to the local administrators group automatically during the operating system setup by using the [GuiRunOnce] entry in the answer file. See sections Answer File and Required Sections and Entries below for more information about GuiRunOnce and other answer file entries.

For more information about these three options please refer to the Windows Server 2003 online help.

**Creating a Cluster**
To create a cluster from the command line, use cluster.exe utility as shown in this example:

```
%windir%\cluster /cluster: CLUSTER_NAME /CREATE /NODE: NODE_NAME1
/USER:your_domain\user /PASS:****** /IPADDR:xxx.yyy.zzz.aaa
```

**Adding Nodes to the Cluster**
To add nodes to a cluster from the command line, use cluster.exe utility as shown in this example:

```
%windir%\ cluster /cluster:CLUSTER_NAME /ADDNODES: NODE_NAME1, NODE_NAME2, NODE_NAME3
/PASSWORD:*********
```

You can combine steps Creating a Cluster and Adding nodes to the cluster into one batch file, if desired.

# Unattended Installation of Server Clusters

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

Unattended installation of Server clusters consists of the following steps:

Planning and Preparation for operating system installation

Preparing answer file for unattended installation of the Windows Server 2003 Enterprise Edition operating system

Creating a Master Installation

Running winnt32.exe

Installing the cluster service

**Planning and Preparation for Operating System Installation**
For detailed instructions on how to plan and prepare for Windows Server 2003 Enterprise Server operating system installation, please refer to the following document: *Microsoft Windows XP Preinstallation Guide*. This document is located in the Deploy.cab file on the Windows Server 2003 CD. Although the Guide contains the instructions on preparing for Windows XP installation, the same instructions apply to Windows Server 2003 Enterprise Edition as well.

**Answer File**
To automate the Windows Server 2003 installation completely, you must prepare an answer file, usually called unattend.txt that contains all of the answers for a series of graphical user interface (GUI) dialog boxes. Unattend.txt tells Setup how to interact with the distribution folders and files you create and supplies Setup with all of the information that the end user provides during a typical Windows Setup. For example, Unattend.txt contains a FullName entry in the **[UserData]** section that instructs Windows Setup to prompt the end user to provide a full name.

Although the answer file for Setup is commonly called Unattend.txt, for a network pre-installation you can name the file anything you like. For a CD-based Setup, you must name the answer file Winnt.sif.

If you are using the OPK toolkit (this toolkit is only available for OEMs), you can create or modify a Unattend.txt file by using a tool called Setup Manager. You can also use any text editor to create or modify the answer file.

**Required Sections and Entries**
A fully unattended operating system Setup requires the following sections and entries:

| Required section | Required entries in that section | Comments |
|---|---|---|
| [Unattended] | UnattendMode | |
| | TargetPath | |
| [GuiUnattended] | AdminPassword | |
| | TimeZone | |
| [Identification] | JoinWorkgroup | You may instead specify JoinDomain, DomainAdmin, and DomainAdminPassword. |
| [LicenseFilePrintData] | AutoMode | |
| | AutoUsers | Requires **AutoUsers** if AutoMode = PerServer. |
| [Networking] | | Required to configure network protocols. |
| [UserData] | ComputerName | |
| | FullName | |
| [GuiRunOnce] | | Required to install the cluster service. |

**[Unattended]**

This section contains entries for running Setup (such as whether to extend the partition on which you install the Windows operating system), and specifies location of files necessary for installation during Setup etc. You must instruct Setup to accept the EULA if you want your installation to be fully automated:

```
[Unattended]
OemSkipEula = Yes
```

**[GuiUnattended]**
This section of Sysprep.inf contains entries for preparing the graphical user interface (GUI) for unattended Setup. To completely automate operating system setup you need to include the following entries:

```
[GuiUnattended]
AutoLogon = Yes
AdminPassword = *** <replace the asterisks with the actual password>
OemSkipWelcome = 1
OemSkipRegional = 1
TimeZone = 20 <specify your time zone here>
```

**[Identification]**
This section contains entries for specifying the network identification of a computer. If these entries are not present, Setup adds the computer to the default workgroup called WORKGROUP. If there is not enough information for this entry, Setup will prompt the end user to provide this information.

Prior to adding the first node to a cluster or adding additional nodes, all nodes must have joined a domain (instead of a workgroup) and be members of the same domain. When you create a cluster or join nodes to a cluster, you specify the domain user account under which the cluster service runs. Therefore, you need to specify in this section which domain a destination computer should join, and provide the valid credentials under which to join:

```
[Identification]
DomainAdmin = your_domain\user
DomainAdminPassword = ***** <replace the asterisks with the actual password>
JoinDomain = your_domain
```

**[LicenseFilePrintData]**
This section contains entries for installing licensing information for the Windows Server 2003 family:

```
[LicenseFilePrintData]
AutoMode = PerSeat
```

**[Networking]**
This section contains no entries. However, to configure network protocols during an unattended setup, you must include the **[Networking]** section name in your answer file. In addition, you must include additional sections that describe your network adapters, protocols to be installed, and static IP address information.

To adhere to Server Clusters Best Practices, you must follow the following guidelines when configuring networking:

Use at least two interconnects. Although a server cluster can function with only one interconnect, at least two interconnects are necessary to eliminate a single point of failure and are required for the verification of original equipment manufacturer (OEM) clusters.

Reserve one network exclusively for internal node-to-node communication (the private network).

Do not use teaming network adapters on the private networks.

Use static IP addresses for each network adapter on each node.

For a complete list of instructions for Networking Best Practices, please refer to Windows Server 2003 Enterprise Server Online Help/Availability and Scalability/Cluster Servers.

Use the following entries in unattend.txt to implement the Networking Best Practices recommendations:

```
[NetAdapters]
;list your network adapters here
Adapter01 = params.Adapter01
Adapter02 = params.Adapter02
```

Next, you need to uniquely identify each network adapter. You can either use the INFID entry where you need to specify the Plug and Play IDs of your network adapters, or the NetCardAddress entry to specify MAC addresses. For computers with multiple adapters of the same type (that is, the Plug and Play ID for each is the same), you must specify the **NetCardAddress**

or PCI location information. If you do not specify the **NetCardAddress** or PCI location, only the first adapter enumerated/detected that matches the PnP ID receives the answer file entries.

If you specify the **NetCardAddress** or PCI location, Setup does not use the INFID entry because it is the least specific entry.

Therefore, we recommend that you simply identify your network cards by their MAC addresses as follows:

```
[params.Adapter01]
NetCardAddress = 0x0002A5D0510F
[params.Adapter02]
NetCardAddress = 0x000476D5F57D
;Install Client for MS Networks
[NetClients]
MS_MSClient = params.MS_MSClient
[params.MS_MSClient]
;Specify which network protocols to install
[NetProtocols]
MS_TCPIP = params.MS_TCPIP
;TCP/IP properties
[params.MS_TCPIP]
AdapterSections = params.MS_TCPIP.Adapter01, params.MS_TCPIP.Adapter02
```

Now we need to configure both network cards with static IP address information. Following Cluster Networking Best Practices recommendations, for private networks, we need to define the TCP/IP properties for static IP addresses by specifying a class A, B, or C private address and a subnet mask.

For a public cluster network, we need to specify a static IP address, subnet mask, default gateway, DNS and WINS entries.

```
;Adapter01 is used for intra-cluster communication.
[params.MS_TCPIP.Adapter01]
DHCP = No
IPAddress = 172.24.23.91
SpecificTo = Adapter01
SubnetMask = 255.255.0.0
WINS = No
;Adapter02 represents a public network
[params.MS_TCPIP.Adapter02]
DefaultGateway = 157.6.8.1
DHCP = No
IPAddress = 157.5.4.1
SpecificTo = Adapter02
SubnetMask = 255.255.252.0
DNSServerSearchOrder = 157.5.0.1,157.6.0.2
WINS = Yes
WINSServerList = 157.5.0.1,157.5.1.2
```

**[UserData]**
This section contains entries for specifying user settings during Setup:

```
[UserData]
ComputerName = SV-NODE1
FullName = User Name
OrgName = Organization Name
ProductKey = 11111-22222-33333-44444-55555
```

Of course you need to replace all of the names, passwords and the cluster IP address with real ones.

**Additional Answer File entries**
**Vendor-Specific Devices**
Sometimes you need to install vendor-specific device drivers or third-party device drivers that are not available with Windows Server 2003 Enterprise Server (for example, storage controller drivers).

To install drivers that are not shipped as a part of the Deploy.cab on the Windows Server 2003 CD, use the following key under the [Unattended] section in the unattend.txt:

```
[Unattended]
OemPnpDriversPath = folder_1_on_system_drive[;folder_2_on_system_drive]...
```

Specify this setting for the drivers for all of your secondary mass storage devices.

If you need to load drivers for bootable mass-storage devices, you need to add two additional sections to your answer file:

**[MassStorageDrivers]** and **[OEMBootFiles]**

For more information about **[MassStorageDrivers]** and **[OEMBootFiles]**, refer to the *Microsoft Windows XP Preinstallation Guide* located in the Deploy.cab file on the Windows Server 2003 CD. Although the Guide contains instructions on preparing for Windows XP installation, the same instructions apply to Windows Server 2003 Enterprise Edition as well.

**Creating a Master Installation**
There are no cluster-specific items in this step. Please refer to the *Microsoft Windows XP Preinstallation Guide* for detailed instructions on how to create a Master Installation. This document is located in Deploy.cab on the Windows Server 2003 CD.

**Running Winnt32.exe**
You can run Winnt32.exe from a command prompt to start Windows Setup.

For a complete list of the Winnt32.exe command-line options, see the Winnt32.exe Command-Line Options topic in the *Microsoft Windows XP Preinstallation Guide*. This document is located in Deploy.cab on the Windows Server 2003 CD. Although the Guide contains the instructions on preparing for Windows XP installation, the same instructions apply to Windows Server 2003 Enterprise Edition as well.

To install Windows from a network share, boot the computer using your Windows Server 2003 CD (or any other startup media) and then connect to the desired network location. Placing the distribution share and the configuration set on the network adds considerable flexibility to the pre-installation process.

To run Setup using Winnt32.exe:

Prepare an Unattend.txt file as part of building a configuration set as described above.

Start the computer where you want to install Windows.

Click **Start**, click **Run**, and then type: *path_to_winn32***\winnt32 /unattend:***filename*

where:

*path_to_winnt32*

Specifies the path to the location of Winnt32.exe. For example, \\server\share\Lang\Eng\sku\pro\x86\I386.

*filename*

Specifies the name of the answer file, which contains answers to installation questions you want to automate. The value of *filename* is usually Unattend.txt.

**Installing the Cluster Service**
To install the cluster service you must add the [GuiRunOnce] entry to your unttend.txt as follows:

**[GuiRunOnce]**
To create a cluster, add the following entry to the **GuiRunOnce** section:

```
[GuiRunOnce]
Command0 = %windir%\cluster /cluster:SV-CLUSTER /CREATE /NODE:SV-
NODE1 /USER:your_domain\user /PASS:****** /IPADDR:157.5.5.50
```

To add nodes to an existing cluster, add the following entry to the **GuiRunOnce** section:

```
[GuiRunOnce]
Command0 = %windir%\ cluster /cluster:SV-CLUSTER /ADDNODES:SV-NODE2 /PASSWORD:*********
```

# Image-based Installations of Server Clusters

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

Image-based installations, also known as disk cloning or simply cloning, are the fastest method of deploying Windows Server 2003 Enterprise Server. Image-based installations are useful if you are deploying computers that have similar hardware and you want to perform quick, clean installations with minimal end user interaction

Cloning Server clusters consists of the following steps:

Building a master installation on a master computer. Building a master installation includes installing and configuring the operating system and any software and drivers you need to include on your disk image.

Preparing the master installation with the Sysprep tool. This includes configuring and running the Sysprep tool on the master computer.

Generating a disk image of the master installation with the disk-imaging tool. This includes saving each disk image to a permanent storage location.

Loading disk images on destination computers that will make up a cluster.

You cannot clone a cluster node with cluster service installed. You must de-install the cluster service or use a specially prepared master computer without cluster services installed to create a disk image.

**Using SYSPREP to Prepare for Imaging**

**Building a Master Installation**

You need to setup a master computer which you will use to build a master installation and later to create a disk image. Make sure your master computer does not have cluster service installed and is not attached to any shared storage.

Building a master installation includes installing and configuring the operating system and any software and drivers you need to include on your disk image.

**Prepare the Master Installation**

After you have prepared a master installation on the master computer, you need to prepare a disk image for cloning. Microsoft provides a tool called sysprep that allows you to prepare an image for cloning. The tool can be found on the **Windows Server 2003 Enterprise Server CD in the \support\tools directory**. When you run sysprep on the master computer, you can supply one of the following two switches: **-factory or reseal**.

You can use Factory mode to install additional drivers and applications at the stage after the reboot that follows Sysprep. Normally, running Sysprep as the last step in the pre-installation process prepares the computer for delivery. When rebooted, the computer starts Mini-Setup. By running Sysprep with the -factory option, the computer reboots in a network-enabled state without starting Mini-Setup. In this state, Factory.exe processes its answer file, Winbom.ini, and performs the following actions:

Copies drivers from a network source to the computer

Starts Plug and Play enumeration

Stages, installs, and uninstalls applications on the computer from source files located on either the computer or a network source

Adds customer data

When finished, run Sysprep with the -reseal option to prepare the disk image for cloning.

For example, you can create a master installation that contains a minimal set of drivers, run sysprep -factory, create an image of the installation, and copy the image to multiple destination computers. If any destination computers require additional drivers, run sysprep -factory on the destination computer and load those drivers at that time.

For more information about the Factory mode and winbom.ini file, refer to the Microsoft Windows XP Preinstallation Guide which can be found on the Windows Server 2003 Enterprise Server CD in the \support\tools\deploy.cab file.

If you do not need to install any additional drivers or applications on the destination computers, run sysprep in the Reseal mode.

**Sysprep and Sysprep.inf Answer File**

To completely automate cluster server installation, you will need to use the sysprep.inf file which is an answer file used by

sysprep during and after Mini-Setup.

**Required Sections and Entries in sysprep.inf**
A fully unattended Setup requires the following sections and entries:

| Required section | Required entries in that section | Comments |
|---|---|---|
| [Unattended] | UnattendMode | |
| | TargetPath | |
| [GuiUnattended] | AdminPassword | |
| | TimeZone | |
| [Identification] | JoinWorkgroup | You may instead specify JoinDomain, DomainAdmin, and DomainAdminPassword. |
| [LicenseFilePrintData] | AutoMode | |
| | AutoUsers | Requires **AutoUsers** if AutoMode = PerServer. |
| [Networking] | | Required to configure network protocols. |
| [UserData] | ComputerName | |
| | FullName | |

Please refer to the Required Sections and Entries section of this document for an explanation of what each of these entries is used for.

**Additional sysprep.inf Entries**
**Vendor-Specific Devices**
Sometimes you need to install vendor-specific device drivers or third-party device drivers that are not available with Windows Server 2003 Enterprise Server, for example storage controller drivers.

One way to do it is to install the needed drivers on a master computer and then distribute them to destination computers as a part of a disk image if the storage controllers are identical on all cluster nodes. If the storage controllers are different on different cluster nodes, you will need to:

create separate disk images that contain those device drivers or

follow the guidelines below that describe how to use the same image for computers with different storage controllers.

**[SysprepMassStorage] Entry in sysprep.inf**
Before running Sysprep on the master installation and creating your image, identify the different mass-storage controllers that you want to install on each destination computer in the [SysprepMassStorage] section of the Sysprep.inf file. Sysprep then prepopulates the necessary driver information so that Windows can load the correct drivers when the operating system boots on a computer that uses one of the predefined mass-storage controllers.

You do not need to create the entries manually in the **[SysprepMassStorage]** section. Instead, you can use one of the following techniques:

Include the **BuildMassStorageSection** entry in the [Sysprep] section in the Sysprep.inf file. Sysprep will automatically generate the entries in **[SysprepMassStorage]** for all mass-storage controllers specified by the Plug and Play hardware IDs in Machine.inf, Scsi.inf, Pnpscsi.inf and Mshdc.inf and will install those mass-storage controllers.

--OR--

Do not include the **BuildMassStorageSection** entry in the [Sysprep] section in the Sysprep.inf file. Run the command **Sysprep -bmsd**. Sysprep will automatically generate the entries in **[SysprepMassStorage]** for all mass-storage controllers specified by the Plug and Play hardware IDs in Machine.inf, Scsi.inf, Pnpscsi.inf, and Mshdc.inf, but will not install those controllers. You can then delete items from this section before running **Sysprep -reseal** or **Sysprep -factory** on this installation. Installing a smaller number of items in the critical device database reduces the time required for this image to reboot into the operating system.

| Note |
| --- |
| When you run **Sysprep -reseal** or **Sysprep -factory**, Sysprep reads the **[SysprepMassStorage]** section of the Sysprep.inf file and writes the mass storage information into the registry before shutdown. The next time the computer is started, all mass storage controllers are available. |

**Hardware_ID**
Specifies the Plug and Play ID for the device as specified in the devices .inf file.

| **Syntax** | **path_to_device_inf[, disk_directory[, disk_description[, disk_tag]]]** |
| --- | --- |
| Values | path_to_device_inf<br><br>Specifies the path to the .inf file that contains the Plug and Play ID of the controller to install. Enclose *path_to_device_inf* in quotes if it is a long file name.<br><br>disk_directory<br><br>Specifies the name of the directory on the floppy disk provided by the third party that contains the copy of the mass-storage driver.<br><br>disk_description<br><br>Specifies the description of the floppy disk as specified in the Txtsetup.oem file provided by the third party.<br><br>disk_tag<br><br>Specifies the disk tag of the floppy disk as specified in the Txtsetup.oem file provided by the third party. |
| Example | To support a new Qlogic driver, copy the qlogic.inf file to the Sysprep folder and include the following section in the Sysprep.inf file:<br><br>[SysprepMassStorage]<br><br>PCI\VEN_1077&DEV_1080 = "C:\Sysprep\qlogic\qlogic.inf", "\nt", "Qlogic Software Disk", "\qlogic" |

For more information about sysprep, sysprep.inf or **[SysprepMassStorage]** entry refer to the *Microsoft Windows XP Preinstallation Guide* which can be found on the Windows Server 2003 Enterprise Server CD in the \support\tools\deploy.cab file.

If you are using the same image for computers with different storage controllers you will need to include the [SysprepMassStorage] and [BuildMassStorageSection] as described above.

For a complete list of sysprep.inf entries please refer to the *Microsoft Windows XP Preinstallation Guide* which can be found on the Windows Server 2003 Enterprise Server CD in the \support\tools\deploy.cab file.

Refer to Appendix A for a sample sysprep.inf file.

**Assigning Drive Letters to Shared Storage Drives (Optional)**
You may want to control how drive letters are assigned to shared storage drives. You can assign the drive letters using the diskpart.exe utility as shown in an example below. First you need to create a text file with parameters that the diskpart.exe will use as command line parameters, in the example below it is called diskpartparams.txt. The batch file itself is very short, it only calls the diskpart.exe utility with the parameters supplied in the diskpartparams.txt file.

Include the following line in sysprep.inf:

```
[GuiRunOnce]
Command1=%systemdrive%\scripts\AssisgnDriveLetters.bat
```

Make sure you create a directory called scripts (or any other name you like) on the system drive and place the following batch files there:

AssignDriveLetters.bat

```
diskpart /s diskpartparams.txt
pause
diskpartparams.txt
select volume 0
```

```
assign letter Q
select volume 1
assign letter R
select volume 2
assign letter S
select volume 3
assign letter T
exit
```

**Adding Cluster Service Account to the Local Administrators Group**
If you are not installing the cluster service on your destination computers at the time Mini-Setup runs but plan on creating a server cluster later using those nodes, you may want to add a cluster service account to the local administrators group. If you do that, you can later follow the instructions in the Command Line Setup chapter of this document to create a cluster and/or add nodes to an existing cluster.

To add a cluster service account to the Local Administrators group, include the following line in the sysprep.inf file:

```
[GuiRunOnce]
Command0=net localgroup administrators /add domain\clussvc_acct
```

**Generating and Distributing a Disk Image**
**Creating a Disk Image**
After you have prepared a disk image for cloning, you need to create a disk image of your master installation with a disk-imaging tool and save the disk image to a permanent storage location. You can either use a third-party disk imaging software or Microsoft software called iBIG.

If you are using a third-party product, refer to the accompanying documentation on how to create and distribute a disk image.

**Startup Media**
Before you can load disk images on destination computers, you need some kind of startup media to boot your computers from. Startup media contains the system files and device drivers that are necessary to start a computer so that the primary hard disk is accessible but not in use. Startup media might also contain network adapter and network drivers, CD and DVD device drivers, disk configuration tools, and scripts or batch files. You can use a floppy, CD, DVD or network boot as your startup media, depending on capabilities of your destination computers.

If you use third-party disk imaging products, they often provide tools to create different startup media. Otherwise you need to create your own.

Follow these guidelines when creating your startup media:

- Your startup media must provide network support if you are distributing disk images across a network.
- Your startup media must provide CD or DVD device support if you are distributing disk images on media and you are using a floppy disk as your startup media.
- Your startup media must support the tools you need to copy a disk image from a storage location to a destination computer. For example, if your startup media is an MS-DOS boot disk then you need to use MS-DOS tools to copy the disk image onto the destination computer.

For more information about choosing and creating startup media, refer to the Microsoft Windows Server 2003 Corporate Deployment Tools User's Guide (Deploy.chm). Deploy.chm is included in the Deploy.cab file in the support folder on the Windows Server 2003 operating CD.

**Distributing Disk Images**
After an image (or images) has been created and placed on a distribution share (or distribution media such as CD or DVD) and you have a startup media to boot your destination computers, you are ready to distribute the images to destination computers.

You need to make sure that your cluster hardware and networks are set up as described in the Windows Server 2003 Enterprise Server Online Help/Availability and Scalability/Cluster Servers. All of your cluster nodes that you will be installing already have to be connected to the shared storage.

You can load disk images to all of your cluster nodes simultaneously. Many third-party tools support multicast image distribution. You can also use BIG to distribute disk images to your cluster nodes.

When all disk images are loaded on destination computers, do not start or restart them all at once. When creating a cluster, you must be careful to install the first cluster node separately from others. Once the first node is up and running, verify that the

cluster service is up and running as well. Then you can install the rest of the cluster nodes. Since Server clusters use shared storage, corruption of data on shared storage may occur if shared storage is not protected by the cluster service.

After you have distributed disk images to destination computers, sysprep runs Mini-Setup. After Mini-Setup finishes, you should verify that all of the nodes have successfully joined the cluster. Open Cluster Administrator to see which nodes participate in the cluster, and whether everything is up and running. If it is, your cluster is ready.

# Configuring Your Server Clusters

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

After you have installed your Server clusters, most likely you will need to configure it, install additional cluster resources and applications. It is not in the scope of this document to explain how to do these tasks. Please refer to Windows Server 2003 Enterprise Server Online Help/Availability and Scalability/Cluster Servers for more information about configuring Server clusters and cluster applications.

**Using Scripts**
**Using MSClus and/or WMI to Create Resources**
Here we provide two examples of how you can further automate tasks during unattended installation of clusters.

**Using Cluster Automation Server and Windows Script Host**
By adding the following command to the sysprep.inf file, you can create a file share after you have created a cluster or added a node to an existing cluster.

```
[GuiRunOnce]
Command1 = "%systemdrive%\ClusterInstallFiles\createfs.vbs SV-
CLUSTER ClusterGroup SVFileShareResource E:\ SVFileShare"
```

When this command executes, a file share called SVFileShare will be created on the E: drive on SV-CLUSTER.

You must place a Visual Basic script called createfs.vbs in a directory ClusterInstallFiles on your system drive. Please refer to Appendix B for a sample code for such script.

In a similar fashion, you can automate the creation of various resources such as IP address resources, network name, print shares, generic resources etc. For more information about using Cluster Automation Server to create Cluster resources, refer to the Cluster Automation Server Reference in the Windows Platform SDK.

**Using the Command Line**
See Appendix C for a sample batch file that can be used to create a File Share resource with cluster.exe. Instruct Mini-Setup to run this batch file (here called createfs.bat) after Mini-Setup finishes by using the GuiRunOnce entry:

```
[GuiRunOnce]
Command2=%systemdrive%\scripts\createfs.bat
```

# Image-based Installation of the Operating System and the Cluster Service Using Automated Deployment Services (ADS)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

Automated Deployment Services (ADS) enables you to personalize the operating system image to your needs. Imaging/Cloning requires you to modify the sysprep.inf (file that contains the configuration information for operating system) every time you need to deploy the image to a different server or deploy a different configuration of the operating system. ADS reduces this complexity by allowing the user to personalize the sysperp.inf file. For more information about sysprep.inf and imaging please refer to section Image based installation of Server Cluster.

In addition, ADS enables you to use a single server to manage servers in your data center. This server, or "Controller," together with the all of the other ADS services, enables you to deploy operating system images onto devices without an operating system or to repurpose existing devices with new operating system images. In short, you can use ADS to:

Remotely purpose a device that has no operating system to a useful state or repurpose a device from one state to another state.

Operate a scale-out data center by providing ability to run extensible and configurable operations, such as scripts, on one or more systems from a single point of control.

Automated Deployment Services consists of the following three main services:

- Controller service

- Image Distribution service

- Network Boot Services

*Refer to ADS help and documentation for more information about ADS and ADS setup and installation*. This section assumes that you have ADS installed and running.

**Following are the steps to deploying Server Clusters using ADS**

1. Add devices (systems that you want to install cluster service to) to ADS Controller

2. Create a Master Image

3. Upload the image to ADS controller

4. Modify sysprep.inf to include Variables

5. Create task sequence file for Image deployment

6. Create a job template for the sequence file

7. Create and store variables associated value in ADS database for the desired device

8. Execute Job Template against the desired device

**Caution**

If you are using shared storage device then it is vital that only one node have access to the shared disk. Otherwise the shared disk can become corrupted. To prevent corruption either shutdown all but one node or use some other techinique(LUN, zoning etc) to isolate the datapath for the nodes. Once a single node cluster is formed then you can add and join other nodes to this cluster. Here are the key things you need be aware and plan accordingly before deploying clusters.

- The disks must be preformatted and ready to mount when the machine boots up in to operating system.

- No other machine should be in full operating system at the time when the first node is creating the cluster ( this is to avoid any shared disk corruption).

- Join Node(adding another node to the cluster) task sequence must be run only after a cluster has been formed . This is to avoid nodes joining simultaneously when the cluster creation is still in progress.

**1. Add Devices (Systems that You Want to Install Cluster Service to) to ADS Controller:**
After installation and configuration of ADS, you would need to add device(system where you want to deploy operating system and configure Server Cluster) to the controller. You can add the device through UI or through command line interface. *Refer to ADS Help section Manage Devices for more information*. You need to make sure the device is set to Network boot in the BIOS. Once the device boots up, it communicates with Controller and boots into deployment agent. This device will show-up in the ADS controller and you should take control of the device. You can control the device through UI (ads.msc) or through command-line interface.

To add a device through command line interface:

**adsdevice** [**/s** *controllername* [**/u** *username* **/w** *password*]] **/add** *devicename* [**/description** "*text*"] [ **/ip** *ipaddress*] [**/adminmac** *macaddress*] [**/guid** *smbiosguid*] [**/assettag** *assettag*] [**/jobtemplate** *templatename*] [**/?**]

or

**adsdevice** [**/s***controllername* [**/u***username***/w** *password*]] **/add @***filename*

E.g.

**Adsdevice** /**add** mnhp6n11 /**description** "server cluster 1st node" /**ip** 172.24.11.207 /**adminmac** 00306E1215b8 /**guid** 239d1df6-1dd6-11b2-f0e7-00306e12 /**jobtemplate** servercluster.xml

**To add a device through ADS.msc (UI interface):**

Open Automated Deployment Services.

In the console tree, right-click the **Devices** folder and click **Add**.

In the **Add Device** dialog box, type the device name in the **Name** box.

If you want to add more information to help identify the device, type the information in the remaining boxes, and then click **OK**.

**2. Create a Master Image:**

Creating Master image consists of following steps:

- Building a master installation on a master computer. Building a master installation includes installing and configuring the operating system and any software and drivers you need to include on your disk image.

- Preparing the master installation with the Sysprep tool. This includes configuring and running the Sysprep tool on the master computer.

- Generating a disk image of the master installation with the disk-imaging tool. This includes saving each disk image to a permanent storage location.

| **Note** |
| --- |
| You cannot clone a cluster node with cluster service installed. You must de-install the cluster service or use a specially prepared master computer without cluster services installed to create a disk image. |

*Refer to Image based installation of Server Cluster for more information about creating master image.*

**3. Upload the Image to ADS Controller**

After Capturing the image of the operating system you would need to add the captured image to the controller. Create directories named images imagebackup and sequences from the root of the controller. Make sure the volume where you create these directories have enough free disk space to hole at least 2 times the image size. Copy the image to images directory.

Next step is to add the image to the ADS controller database. You can add the image either through User Interface or command line. Following is the syntax for command line to add the image

**adsimage** [**/s** *controllername* [**/u** *username* **/w** *password*]] **/add** *imagename* **/path** *imagepath* [**/description**]

After adding the image, you would need to move the image to the image directory. You can check if the image is been properly added by running **adsimage.exe** again.

*Refer to managing Images section in ADS help for more information about managing image.*

**To add the image through UI Interface**

open ADS.MSC (Automated deployment service)

Right click **Images** and click **Add**

Fill out the Image File Path and Image Name, click **OK**

**4. Modify sysprep.inf to include Variables**

Sysprep.inf file is used by the mini-setup to install and configure the operating system. This files contains the configuration information details for the image that you just added to the ADS controller database. This configuration information is static to the image. ADS allows you to customize sysprep.inf file by allowing you to insert variables in the sysprep.inf file. This way, the configuration information that will change from system to system can be removed from the sysprep.inf file. Instead variable configuration is moved to the ADS controller.

Before modifying the sysprep.inf file from the image, you would need to mount the image to a drive. ADS has tools that will allow you this functionality. Change directory to the images and mount the image using below command line syntax

**imgmount** /mount /w {imagefilename} /d: driveletter

Change drive to the above drive letter and change directory to sysprep directory. There 2 ways to create or modify the sysprep.inf either through **setupmgr.exe** or through **notepad.exe**. Refer to Imaged-Base server cluster installation section for more information about sysprep.inf.

Open the sysprep.inf file in notepad.exe. Locate variables for your installation that changes from a system to system. Define them as variables instead of putting static values in sysprep.inf file. For example, In the following snippet of sysprep.inf file, items marked with * at the beginning of the line can be defined as variable. These settings differ for each system.

```
[params.MS_TCPIP.Adapter01]
*     DHCP="No"
*     IPAddress="10.11.26.11,,172.24.11.141"
    SpecificTo=Adapter01
*     SubnetMask="255.255.0.0,255.255.255.0"
*     WINS="No"
;Adapter02 is used for public network
[params.MS_TCPIP.Adapter02]
    SpecificTo=Adapter02
*     DefaultGateway="172.24.11.1"
*     DHCP="No"
*     IPAddress="172.24.11.205"
```

```
*    SubnetMask="255.255.255.0"
*    DNSServerSearchOrder="172.24.10.2,172.24.0.2"
*    WINS="Yes"
*    WINSServerList="157.55.254.201,157.55.254.203"
[GuiRunOnce]
;see section 2.2.1 in this document for a sample text of AssignDriveLetters.bat file
;see configuring cluster section and appendix B for createfs.vbs
*Command0=%systemdrive%\scripts\AssisgnDriveLetters.bat
*Command1 = "%windir%\system32\cluster.exe /cluster:SV-CLUSTER /CREATE /NODE:SV-
NODE1 /USER:domain\user /PASS:***** /IPADDR: 157.5.5.50"
*Command2 = "%systemdrive%\ClusterInstallFiles\createfs.vbs SV-
CLUSTER ClusterGroup SVFileShareResource E:\ SVFileShare"
```

After replacing these with variables, the snippets will look like the following. Notice that each variable name starts with ^ and ends with ^. They must be embedded within quotes (). If not ADS will not install and configure the operating system properly. Note: In the guirunonce section, above sample snippet replaces the cluster configuration commands to variables also. You can run your own scripts in this section also. After successful installation, Windows will run commands in guirunonce section on the first boot for configuring cluster services or any other services specified.

```
[params.MS_TCPIP.Adapter01]
    DHCP="^DHCP1^"
    IPAddress="^IPAddress1^"
    SpecificTo=Adapter01
    SubnetMask="^SubnetMask1^"
    WINS="^WINS1^"
;Adapter02 is used for public network
[params.MS_TCPIP.Adapter02]
    DefaultGateway="^DefaultGateway2^"
    SpecificTo=Adapter02
    DHCP="^DHCP2^"
    IPAddress="^IPAddress2^"
    SubnetMask="^SubnetMask2^"
    DNSServerSearchOrder="^DNSServerSearchOrder2^"
    WINS="^WINS2^"
    WINSServerList="^WINSServerList2^"
[GuiRunOnce]
    ;Mount all volumes before form/join the cluster
    Command0="^CLUSTER_COMMAND_MOUNT^"
    Command1=^AssignDriveLetters^
    Command2="^CLUSTER_COMMAND^"
    Command3=^FileShare^
```

Once you have modified the sysprep.in file, unmount image using the below command line interface.

**Imgmount** u drive:

ADS also allows you to define the variables through scripts. *Refer to ADS help on managing Images for more information.*

| **Note** |
| --- |
| Appendix F contains a modified and complete sample sysprep.inf. |

You can also use **setupmgr.exe** to create, modify unattended setup file, syspre.inf file with variables. **Run setupmgr.exe through cmd a window.**

choose create new

choose sysprep setup

choose the operating system type that you want to deploy

Above allows you to enter values for the setup. Here instead of providing the actual values, you can provide the variable names that you will define in ADS. For example ^Name^ is a variable whose value will be replaced through ADS.

After completing above, click Run Once and enter the cluster configuration command. In the above example, ^cluster_create_command^ variable is inserted in the sysprep.inf file whose actually value will be defined in ADS. Once the sysprep.inf is created with the variables, save it and copy this sysprep.inf file into the image by mounting the image to a drive.

**5. Create task sequence file for image deployment**

Next step is to create a task sequence file for ADS controller. It is a XML file containing sequence of task for controller to perform against a device or a set of devices. ADS ships with few sample sequence files. You can use any of the sample XML file and modify to your needs. In this file you will define the personalize variables for controller to replace in the sysprep.inf file. In

addition, you will define what other sequence of task controller must run against the device. For example, partition the disk, copy the image, replace the variables in the sysprep.inf file, reboot and check the state of the device etc.

You would need to modify at least the following sections in the sample XML files for it to work properly.

```
<!-- STEP 1 Create a single 4999MB partition on the disk -->
    <task description="Partition the disk">
        <command>/bmonitor/bmpart.exe</command>
        <parameters>
            <parameter>\device\harddisk0</parameter> <!-- selects harddisk0 -->
            <parameter>/init</parameter> <!-- erases all partitions on harddisk0 -->
            <parameter>/C:4999</parameter> <!-- creates a new partition (#1) of size
4999MB -->
            <parameter>/A</parameter>
                 <!-- activate the newly created partition (#1) -->
        </parameters>
    </task>
In the above section (step 1) you need to define the partition size for the disk. In
the above example it will create a partition of 4999MB on drive 0.
    <!-- STEP 2 download images -->
    <task description="Download image">
        <command>/imaging/imgbmdeploy.exe</command>
        <parameters>
            <parameter>3718Plain</parameter> <!-- name of the image to be deployed-->
            <parameter>\device\harddisk0\partition1</parameter> <!-- deploy the image
to partition1  -->
            <parameter>-r</parameter> <!-- specifies deploy mode  -->
            <parameter>-client</parameter> <!-- required parameter  -->
        </parameters>
    </task>
In the above section (step 2) you need specify the image name that you used to add to
controller. In the above 3718Plain used for the image.
    <!-- STEP 3 Personalize the sysprep.inf file -->
    <task description="Set sysprep custom info in the sysprep.inf file">
        <command>/bmonitor/bmstrrep.exe</command>
        <parameters>
            <parameter>\device\harddisk0\partition1\sysprep\sysprep.inf</parameter>
            <parameter>^ProductKey^</parameter> <!--  key(ProductKey to be searched in
sysprep.inf file
            <parameter>"$ProductKey$"</parameter> <!value to be replaced with. Make
sure to Embed it in quotes  -->
            <parameter>^OEMDuplicatorstring^</parameter>
            <parameter>"$OEMDuplicatorstring$"</parameter>
            <parameter>"$CLUSTER_COMMAND_MOUNT$"</parameter>
            <parameter>^CLUSTER_COMMAND^</parameter>
            <parameter>"$CLUSTER_COMMAND$"</parameter>
            <parameter>^AssignDriveLetters^</parameter>
            <parameter>"$AssignDriveLetters$"</parameter>
            <parameter>^FileShare^</parameter>
            <parameter>"$FileShare$"</parameter>
        </parameters>
    </task>
```

In the above section (step 3) you need to specify the variable names that you used in sysprep.inf. Notice that the variables are embedded in ^xxx^ and its accompanied value to be replaced with is in quotes ($xxxx$).

*A sample XML file for deploying a single node clusters is included in the appendix D. This sample file will also create file shares on the disk.*

**6. Create a job template for the sequence file**

Job templates in ADS provides a way to define and store instructions for task that you plan to run against a device (or set of devices) more than once. You can use either the **adsjobtemplate** command-line tool or the ADS snap-in to create a job template. You would need to associate this job template with the XML file that you just created for deploying operating system and configuring server cluster. After you create a job template, you can use it to run a job as often as you want against any device with freedom to modify the variable values. For instance, you can first create a single node cluster using the cluster command with create switch. After the cluster creation, modify this command to addnode to the next system you want to join this cluster after operating system deployment. For this you would only need to change the value associated with IPaddress and cluster command variables.

**To add the jobtemplate using ADS UI interface.** Open ADS.MSC

Right click **Job Templat**e and click **Add**. This will invoke the adding job template wizard that will guide you through the process.

**7. Create and store variables associated value in ADS database for the desired device**

Now you would need to define and store the variables for each device in controller database. These values get replaced in sysprep.inf file when the job is executed against the device. You can define variables through ADS snap-in or command-line interface. To add through ADS Snap-in, double-click the device and on the resulting pop-up click user. Click Add to add variable name that is used in the sequence file and sysprep.inf and associate it with a value.

Open ADS.MSC and double click the appropriate device

Click **User** and then click **Add .**

Enter the variable name and then enter the value for this variable and click ok.

You can also use command-line interface as listed below to add variables to the device database on the controller.

Adsdevice /edit device-name /setvar variable-name "value"

E.g.;

**Adsdevice** /edit mnhp11n3 /setvar DNSServerSearchOrder2 "172.24.10.2,172.24.0.2"

Mnhp11n3 is a device name, DNSServerSearchOrder2 is a variable.

You can create a batch script to add all the variables for a device. Appendix G includes a sample batch script file that defines values for the variables from appendix D sysprep.inf file.

**8. Execute Job Template Against the Desired Device**

Next step is to execute the job templates against the device. To assign a job template to devices manually, use either the **ADS snap-in** or **adsController** command-line tool.

Once the device is connected to the controller, right click the device and click run job. This will invoke a wizard that will take you through the steps of selecting the right jobtemplate to execute.

Once the execution starts, you can monitor the job progress by clicking on running job option on the left pane of ADS snap-in. It lists all the task that you have defined in the sequence XML file. After cluster creation you may want to configure the cluster based on your need. You can use any script to configure cluster in the [guirunonce] section of sysprep.inf file.

You can use the same sequence file, sysprep.inf, image for installing and configuring second node with little modification. You would need to modify the defined values for the variables for the second node(device). For example, cluster command to add a node to this cluster, IP address for the node etc.

# Appendix A (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This is a sample sysprep.inf file that can be used for unattended installation of a server cluster. By using this configuration file, Mini-Setup will create a cluster called SV-CLUSTER with one node SV-NODE1, will assign drive letters to shared storage drives and create a cluster file share called SVFileShare.

All computer names, cluster name, user data, passwords and IP addresses need to be replaced with real ones before you can use this file.

# Appendix C (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This is a sample batch file that can be used to create a File Share resource with cluster.exe. We assume that there is a group that already contains the Network Name, and Physical Disk resources. Below you will see an explanation of each line. The example below assumes that you have a group called "Disk Group 1" with a "Disk X:".

```
Creatfs.bat
X:
MD ClusterFS
cluster. res "ClusterFS" /create /group:"Disk Group 1" /type:"File Share"
cluster . res "ClusterFS" /priv path="X:\ClusterFS"
cluster . res "ClusterFS" /priv Sharename=ClusFileShare
cluster . res "ClusterFS" /priv Remark="This is a File Share"
cluster . res "ClusterFS" /prop Description="This is a Clustered Share"
cluster . res "ClusterFS" /priv security=Domain\User,grant,c:security
cluster . res "ClusterFS" /priv ShareSubDirs=1
cluster . res "ClusterFS" /AddDep:"Disk X:"
cluster . res "ClusterFS" /AddDep:"Network Name"
cluster . res "ClusterFS" /On
```

What each line means:

**cluster . res "ClusterFS" /Create /Group:"Disk Group 1" /Type:"File Share"**

This creates the File Share resource in the cluster group named "Disk Group 1".

| **Note** |
| --- |
| You do not want to put anything into, or out of the default Cluster Group. |

**cluster . res "ClusterFS" /priv Path="X:\ClusterFS"**

This sets the local path to the file share to X:\ClusterFS. Verify that the path exists, and that it is accessible.

**cluster . res "ClusterFS" /priv ShareName=ClusFileShare**

This sets the share name for the resource, and is the name that clients will use to connect to.

**cluster . res "ClusterFS" /priv Remark="This is a File Share"**

This sets the remarks for the file share. The remark is what the client will see when browsing the virtual server.

**cluster . res "ClusterFS" /prop Description="This is a Clustered Share"**

This gives the resource a description in Cluster Administrator. This name is only for identification in CluAdmin.

**cluster . res "ClusterFS" /priv security=Domain\User,grant,c:security**

This gives the user account "User" from domain "Domain" change share level rights to the File Share resource.

Access types are grant, deny, set, or revoke. An access mask is required for the types grant, deny, or set. Access masks are "R" for read, "C" for change, and "F" for full.

This can also be used to grant multiple users rights at the same time, here is the syntax for the security switch:

Security=Domain\User1,grant,RC,Domain\User2,revoke,everyone,set,F:security

**cluster . res "ClusterFS" /priv ShareSubDirs=1**

This sets the file share to dynamic (which translates to "share all subdirectories"). You will need to omit this line if you are creating a standard file share.

**cluster . res "ClusterFS" /AddDep:"Disk X:"**

This makes the File Share resource dependent on the Physical Disk resource for disk X:\, on which the file share resides.

**cluster . res "ClusterFS" /AddDep:"Network Name"**

This makes the File Share resource dependent on a Network Name resource. This needs to be an already existing Network Name resource.

**cluster . res "ClusterFS" /On**

This brings the newly created File Share resource online.

# Appendix D (Server Clusters: Remote Setup, Unattended Installations and Image-based Installations)

Updated: January 1, 2003

Applies To: Windows Server 2003 with SP1

This is a sample ADS Sequence file that can be used for installation of a server cluster. By using this sequence file in conjunction with [sysprep.inf] in appendix F , Mini-Setup will create a cluster called mnhp11 with one node mnhp11n3, will assign drive letters (will use Creatfs.bat from appendix C) to shared storage drives and create a cluster file share called SVFileShare (will use CreateFS.vbs from appendix B). All variables (anything that is between $xxxx$ such as Product key, domainname, computer names etc) in the <!-- STEP 3 Personalize the sysprep.inf file --> section of the below file needs to be defined as described in Appendix G. In addition, you would need to define cluster name, user data, passwords and IP addresses need to be replaced in the appendix G with real ones before you can use this file.

FileName: [da-deploy-image-form-servercluster.xml]

```
<?xml version="1.0" encoding="utf-8"?>
<!--
    This file is part of the Microsoft ADS Samples
    Copyright (c) Microsoft Corporation. All rights reserved.
    Sample sequence to purpose a device that is currently running the
    Deployment Agent and configure it connect it to a domain.
    The image to be provisioned must have been captured with a sysprep.inf
    containing the strings ^ADS_WINDOWS_PRODUCT_KEY^ , ^DomainAdminPassword^
    etc as in the personalize step below.
    Device variables must have been created for the devices as in the
    personalize step below.
    To use: boot a target into the Deployment Agent, then run this sequence
    against that device.
-->
<!-- start sequence -->
<sequence command="da-deploy-image-form-servercluster.xml" description="Deploy an image
and configure the machine to join domain and form a cluster"
    xmlns="http://schemas.microsoft.com/ads/2003/sequence" version="1">

ADS requires the user to enter these variables using the ADS snap-in. A user need to defined all the below variable for the device (system where the image will be deployed) before executing the XML sequence job template for cluster installation. You can also create a batch file to create these variables using the below listed command. Execute the batch file before running the sequence template.

```
List of Variables with their associated values:OEMDuplicatorstring= Fresh install of
Windows 2003 server with server cluster configured
ProductKey=xxxxx-yyyyy-xxxxx-yyyyy-xxxxx

# Introduction (Server Clusters: Rolling Upgrades. Upgrading to Windows Server 2003)

Updated: January 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

One of the features of Microsoft Windows Server 2003 Enterprise Edition and Datacenter Edition operating system is the ability to perform a rolling upgrade of the operating system on a server cluster. A rolling upgrade is a process of upgrading cluster nodes, one node at a time, in such a way that services and resources offered by the cluster are always available through out the upgrade process. The system downtime associated with the upgrade is reduced to a few minutesthe time needed to move resources from one node to anotheras compared to the few hours that are usually needed to upgrade a Windows based server.

An administrators can perform rolling upgrade from Windows 2000 Advance Server to Windows Server 2003 Enterprise Edition or from Windows 2000 Datacenter Sever to Windows Server 2003 Datacenter Edition. Rolling upgrade from Windows NT version 4.0 Enterprise edition directly to Windows Server 2003 Enterprise Edition is not supported. This means if you want to upgrade from Windows NT version 4.0 to Server 2003 than you have two options:

- You can maintain cluster availability by performing an rolling upgrade to Windows 2000 Advanced Server first, then to Windows Server 2003 Enterprise Edition.

- You can perform a non-rolling upgrade directly from Windows NT 4.0 to Windows Server 2003 Enterprise Edition, which will not allow you to maintain cluster availability.

A mixed-version cluster, a cluster composed of nodes running different versions of the operating system, offers the same level of availability as a homogeneous cluster. Resources that support rolling upgrades can be moved, as well as fail over and fail back, between nodes in a mixed mode cluster.

The same procedure can be used to do a rolling upgrade of system hardware or applications if they support it. However, this paper focuses only on the rolling upgrade of the operating system. If you are interested in doing a rolling upgrade of an application, check application documentation to see if the application supports rolling upgrade.

This paper assumes that the reader has a basic knowledge of clustering and is familiar with Microsoft Server Cluster in Windows 2000 operating system and in Windows Server 2003. For more information about these components, consult the Windows Server 2003 Advanced Server Online Help.

**Terminology**
The node running an older version of the operation system, application or hardware is called a *down-level* node.

The node running a newer version of the operation system, application or hardware is called an *up-level* node.

The cluster composed of nodes running different revisions of the operating system, application, or hardware, is called a *mixed-version cluster*.

# Benefits

Updated: January 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A rolling upgrade offers multiple benefits and can be an alternative for any mission-critical system that requires high availability.

Consider two examples: Jack and Jill. Jack runs a mission-critical database application on a stand-alone Windows Server 2003based server. He regularly applies Windows Server 2003 operating system service packs (every quarter), upgrades his application once a year and performs a maintenance hardware upgrade once a year as well. From past experience, he can tell that the service pack installation takes on average of 60 minutes. An application upgrade generally takes four hours. Hardware upgrades take anywhere from 30 minutes to four hours. He can also testify that once a year, something goes wrong and an upgrade takes four times as long as planned. Total downtime per year of this system averages:

4 x 60 + 240 + 240 + 240 = 16 hours, which equals 99.8 percent uptime.

Jill runs a mission critical e-mail application on a two-node cluster. She applies the same rules as Jack, but instead of upgrading both nodes at once, she performs *rolling upgrades*. She measured that it takes five minutes on average to move this application from one node to another; thus, the downtime associated with each upgrade is limited to five minutes. Total downtime per year for his system averages:

4 x 5 + 5 + 5 = 30 minutes, which equals 99.99 percent uptime.

Rolling upgrades are advantageous in that they:

- **Minimize downtime.** Rolling upgrades minimize downtime associated with software or hardware upgrades.

- **Minimize risk.** Rolling upgrades minimize the risk of losing the service in case the upgrade fails. When an upgrade of one node fails, the other node can still provide the service, giving the system administrator the choice to repair or replace a failed node without incurring any additional downtime.

- **Increase flexibility.** The nearly negligible system downtime caused by a rolling upgrade means that administrators could decide to perform a rolling upgrade during a working day instead of performing it late at night or on weekends.

Updated: January 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Rolling upgrade from Windows 2000 to Windows Server 2003**

- To perform a rolling upgrade of the operating system to Windows Server 2003 operating system on cluster nodes, you must start with Windows 2000 Advanced server (including any service packs for example SP1, SP2 etc) or Datacenter Server. Windows Server 2003 operating system does not support rolling upgrade from earlier Windows operating system, for example Windows NT 4.0.

- You can perform rolling upgrade from Windows 2000 Advanced Server to Windows Server 2003 Enterprise Edition.

- You can perform rolling upgrade from Windows 2000 Datacenter Server to Windows Server 2003 Datacenter Edition.

**Upgrade from Windows NT 4.0 to Windows Server 2003**

- Perform rolling upgrade to Windows 2000 Advanced Server first, then to Windows Server 2003 Enterprise Edition.

- Perform a non-rolling upgrade directly from Windows NT 4.0 to Windows Server 2003 Enterprise Edition, which will not allow you to maintain cluster availability.

**Upgrade from Windows NT 4.0 to Windows 2000**

- A rolling upgrade can be used to upgrade Windows NT 4.0 Server, Enterprise Edition SP4 to SP5, SP5 to SP6, and so forth. It can also be used to upgrade any Enterprise Edition service pack later than SP3 to Windows 2000 Advanced Server.

- Upgrades from Windows NT 4.0 to Windows 2000 Datacenter Server are not supported. Windows 2000 Datacenter Server can be installed in a clean install process only.

**Upgrade from Windows Server 2003 (64-bit) Enterprise Edition LE release to Windows Server 2003 (64-bit) Enterprise Edition**

- A rolling upgrade from any version of Windows Server 2003 (64-bit) Enterprise Edition LE release to Windows Server 2003 (64-bit) Enterprise Edition is not supported. You will have to perform either a fresh install or upgrade of your system to Windows Server 2003 (64-bit) Enterprise Edition. This mean the cluster will not be available during upgrade/installation.

# Limitations

Updated: January 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A rolling upgrade is not as disruptive as a regular upgrade, but you should bear in mind that it requires the applications to be moved between nodes and therefore does cause some minimal disruption in services. When an application is moved from one node to another, it must be stopped. Once the application is stopped, Cluster service moves all the resources the application uses, such as disks, Internet Protocol (IP) addresses or network names to another node, and restarts the application on another node. Any sessions between clients and the server application are cancelled during this process; database transactions are aborted and file handles are invalidated. Client applications can retry and eventually reconnect and recover once the server application is restarted on the second node. While the impact may be minimal, it should not be ignored.

The availability of a two-node cluster while one node is being upgraded is limited. Any failure of the second node while the other node is being upgraded will cause the cluster to fail.

During a rolling upgrade of a 2-node cluster, all resource groups are moved to one node. In a cluster where resources are distributed among all nodes in the cluster, this means that the node hosting all resources can run at maximum capacity while the other node is being upgraded. This can affect the application response time.

For a rolling upgrade of Windows 2000 Datacenter Server cluster with more than 2 nodes, a user will have different options to move the resources from the node that is upgrade to other nodes. Depending on the configuration and node capacity, you may want to move resources to a node that can handle the additional load from the node that is being upgraded. You can also distribute the resources from upgraded node to different nodes to reduce the performance impact. Chart out which resources will be moved to which node/nodes during each node upgrade before proceeding with rolling upgrade.

| **Note** |
| --- |
| Windows Server 2003 Datacenter Edition can only be obtained from an OEM. Please contact your OEM vendor for Windows Server 2003 Datacenter Edition availability. |

It is critical that you plan rolling upgrade of your cluster up front. You may have to plan differently if you decide to run mixed-version cluster for couple of days before upgrading the remaining downlevel nodes to Windows Server 2003. Please list out services and applications that you run on the cluster. Figure out what services or applications can be failed over (and failed back) to Windows Server 2003 from Windows 2000 operating system and vice versa. This information will be useful if you have to failover or move resources between nodes that are running different version of operating system. Check application documentation for the mixed-version cluster support requirements.

Cluster service guarantees that an up-level node can always join a cluster formed by a down-level node. It also guarantees that resources can fail over and fail back to and from a down-level node. However, it does not guarantee that applications can also support rolling upgrades of the operating system. Table 1 below summarizes the behavior of cluster-aware resources supported by Cluster service.

**Table 1 Resources supported/not supported during rolling upgrades.**

| Resource | Note |
| --- | --- |
| **File Share** | Supported during rolling upgrades. |
| **IP Address** | Supported during rolling upgrades. |
| **Network Name** | Supported during rolling upgrades. |
| **Physical Disk** | Supported during rolling upgrades. |

| | |
|---|---|
| **WINS** | WINS is not supported during rolling upgrades. You must follow the below instructions during rolling upgrade for WINS resource.<br>1. Confirm that your systems are running Windows 2000 and right Service packs if there is any.<br>2. Move WINS resource to a single node by double clicking the Groups folder in Cluster Administrator's console tree. Click the group that contains the resource and then in the **File** menu, click **Move Group**.<br>3. Upgrade the operating system on each of the nodes that is not hosting the WINS resource moved in the previous step.<br>4. Move the WINS resource that you moved in the earlier steps from the node that has not been upgraded to one of the newly upgraded nodes.<br>**Notes:**<br>● After the upgrade, the WINS resource can not failback to the Windows 2000 node.<br>● Following the procedure as described above will typically give you the highest availability of the resources that do not support rolling upgrades. |
| **DHCP** | DHCP is not supported during rolling upgrades. You must follow the below instructions during rolling upgrade for DHCP resource.<br>1. Confirm that your systems are running Windows 2000 and right Service packs if there is any.<br>2. Move DHCP resource to a single node by double clicking the Groups folder in Cluster Administrator's console tree. Click the group that contains the resource and then in the **File** menu, click **Move Group**.<br>3. Upgrade the operating system on each of the nodes that is not hosting the DHCP resource moved in the previous step.<br>4. Move the DHCP resource that you moved in the earlier steps from the node that has not been upgraded to one of the newly upgraded nodes.<br>**Notes:**<br>● After the upgrade, the DHCP resource can not failback to the Windows 2000 node.<br>● Following the procedure as described above will typically give you the highest availability of the resources that do not support rolling upgrades. |
| **Distributed Transaction Coordinator** | Supported during rolling upgrades. However, be aware that you should not create or delete the MSDTC resource while you are operating as a mixed mode (mixed version) cluster. You should instead create the MSDTC resource before starting the upgrade on any node, or wait until the upgrade is complete on all nodes. |
| **Internet Information Services** | See section Rolling upgrade Windows 2000 Internet Information Services to Windows Server 2003. |
| **NNTP Service** | NNTP Service Instance is not supported in Windows Server 2003 Enterprise Edition, therefore you must remove any NNTP Service Instance resources prior to upgrading. |

| | |
|---|---|
| **SMTP Service** | SMTP Service is not supported in Windows Server 2003 Enterprise Edition, therefore you must remove any SMTP Service resources prior to upgrading.<br>**Note**<br>This refers only to the built-in clustering resource for Windows SMTP. SMTP resources based on the Exchange 2003 resource DLL (exres.dll) are not affected by this upgrade limitation and should not be removed. |
| **Time Service** | Time Service is not supported in Windows Server 2003 Enterprise Edition, therefore you must remove any Time Service resources prior to upgrading. |
| **Local Quorum** | Supported during rolling upgrade. |
| **Message Queuing** | Primary Enterprise Services, Primary Site Services, and Backup Site Services are not supported during rolling upgrades. All other Message Queuing Services configurations are supported during rolling upgrades.<br>1. Take all of the MSMQ cluster resources offline.<br>2. For each MSMQ resource, take the Network Name resource that depends on it offline also.<br>3. Upgrade all of the nodes from Windows 2000 to Windows Server 2003 Enterprise Edition.<br>4. Bring the Network Name resources back online. Ensure that the Distributed Transaction Coordinator (DTC) resource is online, then bring the MSMQ resources online. |
| **Print Spooler** | The only Print Spooler resources supported during a rolling upgrade are those on line printer remote (LPR) ports. For more information, refer to Print documentation on Windows Server 2003 Enterprise Edition CD or Windows Server 2003 Enterprise Edition resource kit. |
| **Other resource types** | See the product documentation supplied with the application or resource. |

Before performing a rolling upgrade, identify the resources on your cluster that do not support rolling upgrades. This will help in determining which upgrade procedure you should use.

**Internet Information Services Rolling upgrade**

Windows Server 2003 provides a script that allows you to upgrade IIS. You can choose to either use the script or do the upgrade manually. In Windows Server 2003 operating system IIS is managed in a cluster using generic script resource.

Below are two methods by which you can upgrade a cluster that has IIS installed.

1. To upgrade from Windows 2000 on a cluster containing IIS using the provided script.

   a. If you do not already have a Distributed Transaction Coordinator (DTC) resource on the cluster that you are upgrading, create a DTC resource on this cluster.

   b. Upgrade or perform rolling upgrade (whichever is suitable for your needs) all nodes except the node containing the IIS instance resource from Windows 2000 to Windows Server 2003 Enterprise Edition.

   c. On an upgraded node, from command prompt navigate to the %systemroot%\system32\inetsrv directory and run

      **iis_switch** *cluster name [group name]*

| Value | Description |
|---|---|

| | |
|---|---|
| Cluster name | Cluster name or virtual server name that is hosted on an upgraded node. |
| Group name | By default the script will upgrade all IIS web and FTP resources in the cluster. A user has the option to specify a particular resource group also. |

**Note**

The script will bring the group with the newly created Generic Script resource online. However the process of bringing resource online after upgrade will fail if all resources in the group were offline or were only partially online at the time of script run.

The script will not upgrade IIS resources that are in the cluster group.

Once the script completes, using IIS, start the web site on the upgraded node. At this stage IIS can only be hosted on a Server 2003 nodes as it uses generic script that does not exist in Windows 2000 server cluster. Upgrade the final node now.

2. To upgrade from Windows 2000 on a cluster containing IIS manually.

   a. If you do not already have a Distributed Transaction Coordinator (DTC) resource on the cluster that you are upgrading, create a DTC resource on this cluster.

   b. Upgrade or perform rolling upgrade (whichever is suitable for your needs) all nodes except the node containing the IIS instance resource from Windows 2000 to Windows Server 2003 Enterprise Edition. Bring the IIS instance resource offline on Windows 2000 node after noting the dependencies of the IIS instance resource. You should note resources that depend on the IIS resource and also note what resources IIS itself is dependent on.

   c. Delete the IIS resource after removing any dependencies on the IIS instance resource.

   d. Move the group to a Windows Server 2003 Enterprise Edition node and create a Generic Script resource.

   **Note**

   From your notes of Step c, recreate the dependencies of the Generic Script resource identical to those of the now deleted IIS resource. You should make everything that was dependent on the IIS resource dependent instead on the Generic Script resource. You should also make the Generic Script resource dependent on everything that IIS was dependent on. Make sure the upgraded resource is the owner of the Generic Script Resource for IIS.

   e. Bring the group containing the new Generic Script resource online.

   f. Using IIS, start the web site on the upgraded node.

   g. Upgrade the final node.

**Application Considerations**

As stated earlier, Cluster service does not guarantee that applications can support rolling upgrades. Applications can, however, support rolling upgrades provided that they do *not*:

- Store program files on the clustered disk.
- Change the resource DLL name or location.
- Delete application registry keys either in the system registry or in the cluster configuration database.
- Change application on-disk data structures.

An application that does any of the above will not support rolling upgrades.

# How Rolling Upgrades Work (Server Clusters: Rolling Upgrades. Upgrading to Windows Server 2003)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase 1: Preliminary Configuration**
In a common scenario, each node runs Windows 2000 Advance Server, with the following software installed:

- Microsoft Server Cluster.
- File Server -- group 3 and 4
- SQL Database -- group 1 and 2

At this point, the cluster is configured as in Figure 1 below so that each node handles client requests.

**Figure 1: Configuration where both nodes handle clients**

**Phase 2: Upgrade Node 1**
Node 1 is paused, as Figure 2 below shows. All resource groups on Node 1 are moved to Node 2. Because Node 1 is paused, no new groups can be created or moved to this node by users. At this point, Node 2 handles all cluster resource groups. Node 1 is idle and can be upgraded.

**Figure 2: Node 1 idle/Node 2 active**

At this point, you can start the installation of a service pack or an upgrade to Windows Server 2003 Enterprise Edition (see Figure 3 below). Once the upgrade of Node 1 is complete, you can perform a test to verify that the operating system is fully functional.

**Figure 3: Node 1 upgrade**

Cluster service maintains each nodes version of the operating system and the Cluster service itself, as well as the aggregate version of the cluster. It uses these version numbers to determine if a node that runs a different operating system version can join a cluster.

**Phase 3: Upgrade Node 2**

Up-level Node 1 rejoins the cluster. Cluster service guarantees that the up-level node understands the down-level nodes protocols and can join a down-level cluster.

Before upgrading Node 2, confirm that the cluster operates correctly. A simple test is to:

1. Select a resource group that is not critical, and move it to Node 1. If this step succeeds, it proves that Cluster service is working.

2. Move this resource group back to Node 2. This step proves that Node 1 did not tamper with the resources in this resource group, and that they will be able to fail back in case Node 1 fails.

Node 2 is paused, as we see in Figure 4 below. All resource groups on Node 2 are moved to Node 1. Because Node 2 is paused, no new groups can be created or moved to this node by other users. At this point Node 1 handles all cluster resource groups. Node 2 is idle and can be upgraded.

**Figure 4: Node 1 upgraded/Node 2 idle**

You can now start the installation of a service pack or an upgrade to Windows Server 2003 Enterprise Edition on Node 2 (Figure 5 below). Once the upgrade of Node 2 is complete, you can perform a test to verify that the operating system is fully functional. At this point, the up-level Node 2 should successfully join the up-level Node 1.

**Figure 5: Node 2 upgraded**

**Phase 4: Final**

Node 2 rejoins the cluster, and you redistribute the resource groups back to both nodes of the cluster configuration, as represented in Figure 6 below.

**Figure 6: Windows Server 2003 upgraded Configuration where both nodes handle clients**

# Rolling Upgrade Walkthrough

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This walkthrough covers the rolling upgrade of a Windows 2000 Advanced Server based cluster to Windows Server 2003 Enterprise Edition. For the latest information about rolling upgrades, please refer to the on-line help and the release notes on the Windows Server 2003 Enterprise Edition CD.

1. Prepare a list of all resources.

2. Identify resources that do not support rolling upgrades.

   If you have a resource that does not support rolling upgrades, you have three choices:

   a. Take the resource offline and continue with the rolling upgrade. The resource will be unavailable during the entire rolling upgrade process. You will have to bring this resource online once all nodes have been upgraded.

   b. Remove the resource. The resource will be unavailable during the entire rolling upgrade process. You will have to reinstall this resource once all nodes have been upgraded.

   c. If the majority of the resources do not support rolling upgrades, you may consider upgrading all nodes at once, or performing a clean install. In both cases, all resources will be unavailable during the upgrade/install process.

3. To start Cluster Administrator (see Figure 7 below), click **Start**, point to **Programs**, point to **Administrative Tools**, and click **Cluster Administrator**.

**Figure 7: Cluster Administrator**

   All nodes and resource groups are up and online.

4. Click the first node (in our example, I4DELL1N1).

5. Click the **File** menu and click **Pause Node**. The status of I4DELL1N1 changes to **Paused**. (See Figure 8 below.)

**Figure 8: I4DELL1N1 is paused.**

6. In the left pane, click the + next to **I4DELL1N1** to expand it. Double-click **Active Groups**. All groups currently hosted on **I4DELL1N1** are displayed in the right pane (Figure 9 below).

**Figure 9: I4DELL1N1 Active groups.**

7. Click **Disk Group 1** in the right pane. Click the **File** menu and click **Move Group**. Repeat this step for each group listed.

   The services will be interrupted during the time that the services in each group are being moved to the other node and restarted. After all groups are moved, I4DELL1N2 hosts all groups and handles all client requests. I4DELL1N1 is idle (Figure 10 below).

**Figure 10: I4DELL1N2 has all groups.**

You will now need to review all resource types installed on your cluster.

8. Click **Resource Types** in the left pane (Figure 11 below).

**Figure 11: Resource types**

9. Determine which resource types do not support rolling upgrades and take offline all resources that are not supported. (Refer to Table 1 above.)

10. After ensuring that the latest released Service Pack has been applied, use Windows Server 2003 Enterprise Edition Setup to upgrade I4DELL1N1.

| **Note** |
| --- |
| To make sure that Windows Server 2003 Setup does not place temporary files on one of the clustered disks, use the installation option **/tempdrive:X**. (For more information, refer to the *Known Issues* section of this paper.) |

Setup detects Cluster Server on I4DELL1N1 and automatically installs Cluster service for Windows Server 2003

Enterprise Edition. I4DELL1N1 automatically rejoins the cluster at the end of the upgrade process, but is still paused and does not handle any cluster-related work.

You will now need to perform validation tests on I4DELL1N1 to confirm functionality.

11. Start Cluster Administrator on I4DELL1N1. You should see both nodes: I4DELL1N1 in **Paused** state, and I4DELL1N1 in **Up** state.

12. Click **I4DELL1N1** and then click **Resume Node**.

13. Repeat steps 4, 5, 6, 7, 8, 10, 11, and 12 on the second node (I4DELL1N2).

14. If necessary, upgrade any applications that do not support rolling upgrades.

15. Test the cluster by moving groups between nodes. All resources should come online on any node.

# Known Issues

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Location of Temporary Files**
The upgrade program, Winnt32.exe, selects a disk with the maximum free space for the storage of all temporary files. In a cluster, this will most likely be a clustered disk. Use the **/tempdrive:X** option to make sure that the upgrade program uses the appropriate drive (*not* a clustered disk) for the storage of temporary files.

**Print Spooler Resource**
The Print Spooler resource supports rolling upgrades but only for the LPR port and standard TCP/IP port types. Other port types are not supported on Windows 2000based server clusters.

You should not attempt to modify the printer spooler or printer configuration while running a mixed-version cluster.

**Changing Configuration in a Mixed-Version Cluster**
Changing the cluster configuration while running a mixed-version cluster is not recommended nor supported. In particular, you should not attempt to create new resources of the type that are only available on up-level Windows Server 2003based nodes.

# Troubleshooting (Server Clusters: Rolling Upgrades. Upgrading to Windows Server 2003)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resource does not support rolling upgrades.**
Follow the instructions in step 2 above.

**Resource does not come online after an upgrade of one node.**
There are a few reasons for a resource to fail to come online or fail after it was brought online on the up-level node.

1. *The resource doesn't support rolling upgrades*.

   Move the resource back to the down-level node and take it offline. You will not be able to bring it online until all nodes are upgraded

2. *The resource is not compatible with Windows Server 2003*.

3. *Another resource that your application depends on failed to come online*.

   Make sure that the other resource does not fall into categories 1 or 2 above.

**Node upgrade fails.**
When a node upgrade fails, you have the following options:

1. Repair the node.

2. Restore the node from a backup.

3. Perform a clean install of the node. In this case, you will have to evict the node from the cluster, and rejoin the cluster once the installation is complete. This process may affect other applications running on the cluster. You may need to reinstall these applications. Please refer to Windows Server 2003 Enterprise Edition or Datacenter Edition online help section on installing server cluster.

# Conclusion (Server Clusters: Rolling Upgrades. Upgrading to Windows Server 2003)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This document has presented information that should help prepare you to perform a rolling upgrade of your cluster. A rolling upgrade will save you time and money, will provide you with the comfort of knowing that even if something goes wrong you will still have a working server, and will increase the satisfaction of clients using services offered by your cluster.

# Server Clusters: Majority Node Set Quorum

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

Published: January 1, 2004

The goal of this document is to provide a plain English explanation of the new quorum type available in Windows Server 2003 clusters-majority node set (MNS) clusters. Currently, the standard quorum that is used by the Microsoft Cluster service (MSCS) in Microsoft Windows NT Server 4.0 and the Windows 2000 Server family is sufficient for the majority of situations users will encounter. With the introduction of Windows Server 2003, Microsoft has introduced the MNS quorum, which is primarily for advanced users and other software vendors to create more sophisticated end-to-end solutions.

**In This White Paper**

Motivation (Server Clusters: Majority Node Set Quorum)

What Is a Majority Node Set? (Server Clusters: Majority Node Set Quorum)

How to Set Up a Majority Node Set (Server Clusters: Majority Node Set Quorum)

Using the Cluster Command to Setup a Majority Node Set (Server Clusters: Majority Node Set Quorum)

Sizing a Majority Node Set Cluster (Server Clusters: Majority Node Set Quorum)

What to Do If You Lose Quorum (Server Clusters: Majority Node Set Quorum)

Other Considerations (Server Clusters: Majority Node Set Quorum)

# Motivation (Server Clusters: Majority Node Set Quorum)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

The Microsoft Cluster Server (MSCS) architecture requires a single quorum resource in the cluster that is used as the tie-breaker to avoid split-brain scenarios. A split-brain scenario happens when all of the network communication links between two or more cluster nodes fail. In these cases, the cluster may be split into two or more partitions[1] that cannot communicate with each other. The cluster service guarantees that even in these cases, a resource is brought online only on one node. If the different partitions of the cluster each brought a given resource online, it would violate the cluster guarantees and potentially cause data corruption. When the cluster is partitioned, the quorum resource is used as an arbiter. The partition that owns[2] the quorum resource is allowed to continue. The other partitions of the cluster are said to have lost quorum, and the cluster service and any resources hosted on the nodes not part of the partition that has quorum, are terminated.

The quorum resource is a storage-class resource and, in addition to being the arbiter in a split-brain scenario, is used to store the definitive version of the cluster configuration. To ensure that the cluster always has an up-to-date copy of the latest configuration information, the quorum resource must itself be highly available. In Windows NT Server 4.0 and Windows 2000 Server, the quorum device is typically a shared disk or physical disk resource type.[3]

This architecture limits the types of cluster configurations that can be deployed.

In Windows NT 4.0 and Windows 2000, MSCS does not support non-shared disk cluster configurations; that is, there must always be at least one shared disk in the cluster to act as the quorum resource. (Note: In this document, a shared disk is defined as any disk that is physically attached to multiple computers; it does not imply anything about how data is accessed on those disks).[4]

Although the quorum resource may be a highly available resource (such as a mirrored disk or a RAID set), there is a perception that this architecture has a single point of failure. There is a single resource and if it becomes unavailable, the cluster cannot function.

In Windows Server 2003, the goal is to enhance the types of configuration that can be deployed using MSCS. In particular, the following scenarios are addressed:

- Geographically dispersed cluster-In a cluster that spans multiple sites, the notion of quorum as a single shared-disk resource means that the storage subsystem has to interact with the cluster infrastructure to provide the illusion of a single storage device with very strict semantics.

- Clusters with no shared disks-There are some specialized configurations that need tightly consistent cluster features without having shared disks.

- Clusters that host applications that can failover, but where there is an application-specific way to keep data consistent between nodes. Two possible examples are: database log shipping for keeping database status up to date and file replication for relatively static data.

- Clusters that host applications that have no persistent data, but need to cooperate in a tightly coupled way to provide consistent volatile state.

- Clusters that want the semantic of using a persistent store for applications but do not want to add to the complexity of doing the same for the quorum device. In such cases the application data will be stored on the shared disk but the quorum information could be located a local disk of every node.

# What Is a Majority Node Set? (Server Clusters: Majority Node Set Quorum)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

A majority node set is a single quorum resource, from a server cluster perspective; however, the data is actually stored on multiple disks across the cluster. Each cluster node stores the configuration on a local disk it can have access to when it starts up. By default, the location is pointed to %systemroot%\cluster\ResourceGUID. It is recommended that users user the default location unless there is an overriding reason not to.

The cluster service ensures that the cluster configuration data stored on the majority node set is kept consistent across each cluster node. This allows cluster topologies as follows:

If the configuration of the cluster changes, that change is replicated across the different disks. The change is only considered to have been committed, that is, made persistent, if that change is made to a majority of nodes that have formed the cluster. Mathematically this equates to:

(<Number of nodes configured in the cluster>/2) + 1

This ensures that a majority of the nodes have an up-to-date copy of the data. This also means that there is a change in how the cluster service starts up on each node, since the cluster service is set to automatic startup on boot. On the first node in the cluster, the cluster service will try to join a cluster by default. Since there is no cluster available at this stage it will not be able to and will stop. The default retry period is set to one minute so the cluster service will try to restart after every minute. This will successfully happen once a majority of the cluster nodes are up and running and can talk to each other through either the public or the private network. Network priority is honored, and each node will try to talk across that network that has been flagged to be used first for network communication. This behavior is the same as in vanilla clusters (clusters that use a device on the share storage interconnect for quorum).

Once the cluster service has started up cleanly on a majority of nodes, it will then bring all the resources online. If at any point in time the cluster loses a majority of nodes, the cluster services will cleanly shut down on all nodes leading to all the resources being terminated as well. This is a very important semantic that is different from the behavior customers are used to in vanilla clusters where the cluster service is running as long as there is at least one node up and running and it can access the quorum device.

In the case of a failure or a split-brain caused by a failure in communications between cluster nodes, all resources hosted on the partition of a cluster that has lost quorum are terminated to ensure that the resources are being run on only one node in a cluster . If a cluster becomes partitioned (that is, there is a communications failure between two sets of nodes in the cluster), any partitions that do not have a majority of the configured nodes (that is, have less than (n/2) + 1 nodes) are said to have lost quorum. This will lead to the cluster service and all resources hosted on the nodes of that partition to be terminated. This ensures that if there is a partition running that contains a majority of the nodes, it can safely start up any resources that are not running on that partition, safe in the knowledge that it can be the only partition in the cluster that is running resources (since all other partitions must have lost quorum). The diagram below depicts the behavior one will see. In the diagram, Nodes 4 and 5 have lost communication with Node 1, 2, and 3. This will cause the cluster services on Nodes 4 and 5 to terminate, causing the resources they hosted to move to Nodes 1 and 3.

In a vanilla server cluster, a cluster can continue as long as **at least one of the nodes** can access and own the quorum disk.

Any node that is a cluster member and can communicate (via heartbeats) with the quorum owner are part of the cluster and can host resources. Any other nodes that are configured to be in the cluster but cannot communicate with the quorum owner are said to have lost quorum, and thus any resources that they are hosting are terminated. When a node starts up, the cluster services can join an existing cluster (if there is one up and running), or create a cluster right away (if it can access the quorum device).

A cluster running with a majority node set quorum resource, on the other hand, will only start up or continue running **if a majority of the nodes configured for the cluster are up and running** and **can all communicate with each other**. The failure semantics of the cluster are different from a vanilla MSCS cluster. Because of this difference in how the cluster survives start up and on how the cluster behaves when nodes fail or get partitioned, care must be taken when deciding to host an application on a vanilla server cluster using a physical disk as quorum resource, or on a server cluster that uses a majority node set as a quorum resource.

The following sections cover how the quorum disk resource can be setup and what happens in the event that quorum is lost.

# How to Set Up a Majority Node Set (Server Clusters: Majority Node Set Quorum)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

The majority node set resource is an optional quorum resource that we ship with the MSCS. By default, the physical disk resource is setup as a quorum resource.

Setting up a MNS cluster is no different to setting up a standard cluster. The only difference will be the location of the quorum and the fact that the user can choose not to nominate a disk located on a shared storage interconnect as a quorum disk.

If there is a shared storage, set up can be done using standard mechanisms. The quorum disk can be located on the shared interconnect or as a local quorum disk. Once installation is complete, open Cluster Administrator and create a new MNS resource in the cluster group. Bring it online. Then go to the cluster properties and change the cluster quorum to the newly created MNS resource.

If there is no shared interconnect, the cluster configuration wizard will create a single-node local quorum disk cluster by default. The procedure for creating an MNS quorum resource and using it is the same as above.

Once a single node cluster is set up, the quorum resource can be switched to the majority node set resource using cluster administrator as follows:

- Open cluster administrator and connect to the appropriate cluster.
- Create a new resource of type **Majority node set**.
- Change the cluster quorum resource to the newly created majority node set resource. The Quorum tab on the cluster properties sheet shows the current quorum resource and it can be modified by selecting the appropriate resource.

Once a single node cluster is set up using the majority node set resource, other nodes can be added to the cluster. As each node is joined, the quorum calculation is updated. In other words, if two nodes are added to build a three-node cluster, quorum is adjusted so that two out of the three nodes must be running for the cluster to be considered as having quorum.

The majority node set quorum resource ensures that the quorum data is kept consistent across all nodes of the cluster and it is responsible for making changes to the quorum data stored on all nodes in the cluster.

Each node in the cluster stores its quorum data in the following directory on the system disk:

%SystemRoot%\Cluster\MNS.%ResourceGUID%$\%ResourceGUID%$\MSCS

The contents of this directory should not be modified; this directory contains cluster configuration information. Modifying the data in this directory may mean that the cluster service cannot start on the node.

The quorum resource accesses the data on the other nodes in the cluster using a network share. When a node is added to a cluster using the majority node set resource, a file share is created to expose the cluster quorum data to the majority node set resource. The share name is defined as follows:

\\%NodeName%\%ResourceGUID%$

The share is created with local system access. Since the cluster service is running under a domain account that is also a member of the local system group, the majority node set resource has access to the share.

To avoid potential security issues and issues where the cluster service cannot access the share, the permissions or security attributes associated with this file share should not be modified. It is recommended that default setting be used and no changes be made to ACLs governing the share created to be used by the Cluster service.

Since we use SMB shares as a MNS quorum device the cluster service now have to rely on an "external" component to provide a critical infrastructure for cluster service to be functional. SMB has two components, LanManServer and LanManWorkstation, which install as separate services in Server 2003. Both these services need to be running otherwise the cluster nodes will not be able to publish shares or communicate with the shares on other cluster nodes.

# Using the Cluster Command to Setup a Majority Node Set (Server Clusters: Majority Node Set Quorum)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

Rather than using cluster administrator as described above, the cluster command can be used to change the quorum resource for a single node cluster to a majority node set resource as follows:

```
cluster resource "MyQuorum" /create /group:"Cluster Group" /type:"Majority Node Set"
cluster resource "MyQuorum" /online /wait
cluster /quorum:"MyQuorum" /path:"MSCS\"
```

# Sizing a Majority Node Set Cluster (Server Clusters: Majority Node Set Quorum)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

As described above, if a partition of a cluster loses quorum, all of the resources on that partition of the cluster are terminated. This is done to guarantee the cluster semantics that only a single instance of the resource will be brought online (and thus serving or modifying data). Loss of quorum not only happens when a cluster is partitioned, but in the event of node failures, a cluster can lose quorum simply because there are insufficient nodes up and running. The number of nodes in a majority node set cluster should be carefully considered when setting up a cluster. For example, in a two-node cluster, if either node fails for any reason, the other node cannot continue because it does not have quorum. In an eight-node cluster, up to three nodes can fail before the cluster loses quorum. The following table shows the number of node failures that a given quorums disk set cluster can tolerate and continue:

| Number of nodes configured in the cluster | Number of node failures |
|---|---|
| 1 | 0 |
| 2 | 0 |
| 3 | 1 |
| 4 | 1 |
| 5 | 2 |
| 6 | 2 |
| 7 | 3 |
| 8 | 3 |

In a situation where a cluster spans multiple sites, it is recommended that at least one site has a majority over the other. That way in case there is a site link failure you can be assured that the cluster is up and running on at least one site. If you do lose the majority site, the nodes in the minority can be restarted manually to form a cluster.

# What to Do If You Lose Quorum (Server Clusters: Majority Node Set Quorum)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

There are cases where a cluster must be allowed to continue even if it does not have quorum. Consider the case of a geographically dispersed cluster with four nodes at the "primary" site and three nodes at the "secondary" site. While there are no failures, the cluster is a 7-node cluster where resources can be hosted on any node, on any site (depending on business needs). If there is a communications failure between the sites or if the secondary site is taken offline (or fails), the primary site can continue since it will still have quorum. All resources will be re-hosted and brought online at the primary site.

In the event of a catastrophic failure of the primary site, however, the secondary site will lose quorum and therefore all resources will be terminated at that site. One of the primary purposes for having a multi-site cluster is to survive a disaster at the primary site; however, the cluster software itself cannot make a determination about the state of the primary site. The cluster software cannot differentiate between a communications failure between the sites and a disaster at the primary site. That must be done by manual intervention. In other words, the secondary site can be forced to continue even though the cluster software believes it does not have quorum. This is known as forcing quorum.

Because this mechanism is effectively breaking the semantics associated with the quorum replica set, it must only be done under controlled conditions. In the example above, if the secondary site and primary site lose communication and an administrator forces quorum at the secondary site, resources will be brought online at BOTH sites, thus allowing the potential for inconsistent data and/or data corruption in the cluster.

Forcing quorum is a manual process that requires the following steps

Stop the cluster service **ON ALL** of the remaining nodes using cluster administrator.

The cluster service must be told which nodes should be considered as having quorum. This can be done in one of two ways:

Setup ForceQuorum registry key **ON ALL** remaining nodes in the cluster under

HKLM\SYSTEM\CurrentControlSet\Services\ClusSvc\Parameters\ForceQuorum

This is a REG_SZ key that should be setup to contain a **comma separated list of the names of the nodes that are to have quorum.** The key is case insensitive. So, in the above example, if the secondary site contains "Node5", "Node6" and "Node7", then the ForceQuorum registry key should be setup as

"Node5,Node6,Node7"

| **Note** |
| --- |
| There should be no spaces in the key (except where there are spaces in the node names themselves). |

Once the registry keys are set on all nodes, the cluster service can be started on those nodes.

Setup the cluster service startup parameters **ON ALL** remaining nodes in the cluster. This is done by starting up the services control panel, selecting the cluster service and entering the following into the "start parameters" option:

/forcequorum <node list>

In the above example, if the secondary site contains "Node5", "Node6" and "Node7", then the cluster service start parameter should be set to:

/forcequorum Node5,Node6,Node7

The cluster service MUST be started by clicking the START button on the service control panel, you must not hit OK or Apply first as this does not preserve the parameters.

| **Note** |
| --- |
| Any command line parameters over-ride the registry setting, however, the command line parameters do NOT persist a reboot, and therefore, setting the registry key is the preferred mechanism for forcing quorum. |

The cluster service will now start up on those nodes that are considered part of the quorum set and resources will be brought online.

Special care must be taken if and when the primary site comes back since the nodes are configured as part of the cluster.

Do **NOT** reboot the cluster nodes at the primary site

Stop the cluster service **ON ALL** of the cluster nodes

Remove the registry key setting or the cluster service startup parameters set to force quorum

Startup the cluster service on all of the nodes at the secondary site

Boot the nodes at the primary site

| **Note** |
| --- |
| The cluster service on all nodes NOT in the force quorum node list must remain stopped until the force quorum information is removed. Failure to do so can lead to data inconsistencies OR data corruption. |

While a cluster is running in the force quorum state, it is fully functional. For example, nodes can be added or removed from the cluster; new resources, groups etc. can be defined.

# Other Considerations (Server Clusters: Majority Node Set Quorum)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP2

There is a single quorum of node resources in the cluster and it is brought online on one node at any one time, just like any other cluster resource. The majority node set resource is responsible for ensuring that the quorum data is kept consistent on all disks around the cluster. When a cluster is setup to have a majority node set quorum resource or when a node is added to a cluster with a majority node set, a file share is created on that node. As described above, each node in a majority node set cluster has a file share that exports the quorum directory, so that, regardless of where the majority node set resource is hosted, it can write to all of the members of the majority node set.

The share is NOT under cluster server control (since this would lead to a chicken and egg situation: the cluster needs the share, the share needs the cluster). In other words, the share is available and visible when the node is booted, NOT when the cluster service starts. The share will be used in quorum calculations when it is visible, NOT when the node joins the cluster, so a node that is configured to be in the cluster is contributing to the quorum calculation for the cluster even if the cluster service on that node is stopped. This is VERY important to consider and it can have an impact on operational procedures, particularly when changing the number of nodes in a cluster.

Consider the following case of a 4-node cluster:

Node 1 is booted but the cluster service is not running

Nodes 2, 3, and 4 are fully operational and running in a cluster.

The administrator then evicts nodes 2 and 3 from the cluster, thus the cluster now contains two nodes (1 and 4). Node 4 still has quorum since it has its own share and also has access to the share on Node 1 which is configured as part of the cluster but not running the cluster. If the cluster service on node 1 starts at this point, it will join the existing cluster (containing Node 4) just fine, Node 1's local quorum information stored in the registry will be updated to reflect the new membership. If on the other hand, the cluster service on Node 4 is stopped, and then the cluster service on Node 1 is started, Node 1 will NOT be able to startup and form a cluster. This is because Node 1 tries to form a cluster based on the quorum information it has in its registry (NOT the quorum database on the majority node set). It still believes that Nodes 1, 2, 3, and 4 are members and therefore it will not start until it has quorum.

This situation can be corrected by using the force quorum mechanism above. The force quorum mechanism allows the cluster service on Node 1 to startup at which point it will refresh its local registry state with that from the majority node set.

**Using MNS in single node clusters**-Using MNS as a quorum device on single node clusters is fully supported. There are some startup implications a user needs to consider when choosing this model. As explained before, MNS depends on LanManServer and LanManWorkstation to initialize. These dependencies have not been explicitly created in Service Control Manager. As such when Cluster service initializes if either of the two services are not ready Cluster services will fail and an entry denoting the same will be logged in Event Log. However the default recovery behavior for Cluster services has been set to 1 minute. This means at it will try and restart every minute and will eventually succeed when the dependant services come online. This might mean that there could be a lag time in Cluster services and clustered application to come online even after the operating system has booted successfully. This behavior is slightly different as compared to a single node cluster that has a local quorum device or a quorum device located on a share disk. This will be particularly noticed if the cluster is hosting file share resources that contain a large number of shares (2000 or more).

**Using MNS as a quorum device in File and Print clusters**-The conditions mentioned above are also applicable to larger clusters (greater than two) that choose to use MNS as a quorum device. In a cluster that hosts a large number of shares we will continue to have similar startup and failover issues. Although LanManServer has been optimized to a large extent in Windows Server 2003, it will still take some time (anywhere from two to 16 minutes) if a large number of file shares (2000 to 20,000) are hosted in the cluster. The delay will be seen on the node that will be hosting the group containing the file share resource and it the node also acts as cannon for a majority then cluster functioning could be temporarily affected.

[1] A partition is defined as a set of cluster nodes that can all communicate with each other.

[2] How a partition becomes the owner of the quorum resource is beyond the scope of this discussion.

[3] This is the only resource type supported as a quorum resource in the product shipped as part of Windows 2000. Other vendors have supplied alternative quorum resource types, but they are still typically associated with disks on a shared storage bus.

[4] MSCS does have the notion of local quorum, which can be used as a debugging tool; however, it is not recommended as a

production quorum resource (see KB article 245626).

# Using Windows Server 2003 in a Managed Environment: Controlling Communication with the Internet

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

This white paper provides information about the communication that flows between components in Windows Server 2003 and sites on the Internet, and it describes steps to take to limit, control, or prevent that communication in an organization with many users.

**In This White Paper**

Introduction to Controlling Communication with the Internet (Windows Server 2003)

Activation, Registration, and Internet Communication (Windows Server 2003)

Application Help and Internet Communication (Windows Server 2003)

Certificate Support and Internet Communication (Windows Server 2003)

Device Manager and Internet Communication (Windows Server 2003)

Driver Protection and Internet Communication (Windows Server 2003)

Dynamic Update and Internet Communication (Windows Server 2003)

Event Viewer and Internet Communication (Windows Server 2003)

File Association Web Service and Internet Communication (Windows Server 2003)

Help and Support Center: Internet Communication (Windows Server 2003)

HyperTerminal and Internet Communication (Windows Server 2003)

Internet Explorer 6.0 and Internet Communication (Windows Server 2003)

Internet Information Services and Internet Communication (Windows Server 2003)

Internet Protocol Version 6 (IPv6) and Internet Communication (Windows Server 2003)

NetMeeting and Internet Communication (Windows Server 2003)

Online Device Help and Internet Communication (Windows Server 2003)

Outlook Express 6.0 and Internet Communication (Windows Server 2003)

Plug and Play and Internet Communication (Windows Server 2003)

Program Compatibility Wizard and Internet Communication (Windows Server 2003)

Remote Assistance and Internet Communication (Windows Server 2003)

Search Companion and Internet Communication (Windows Server 2003)

Terminal Server Licensing and Internet Communication (Windows Server 2003)

Windows Error Reporting and Internet Communication (Windows Server 2003)

Windows Media Player and Internet Communication (Windows Server 2003)

Windows Media Services and Internet Communication (Windows Server 2003)

Windows Time Service and Internet Communication (Windows Server 2003)

Windows Update, Automatic Updates, and Internet Communication (Windows Server 2003)

Appendix A: Resources for Learning About Automated Installation and Deployment (Windows Server 2003)

# Introduction to Controlling Communication with the Internet (Windows Server 2003)

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

Products in the Microsoft® Windows Server™ 2003 family include a variety of technologies that communicate with the Internet to provide increased ease of use. Browser and e-mail technologies are obvious examples, but there are also technologies such as Automatic Updates that help you obtain the latest software and product information, including bug fixes and security patches. These technologies provide many benefits, but they also involve communication with Internet sites, which administrators might want to control.

Control of this communication can be achieved through a variety of options built into individual components, into the operating system as a whole, and into server components designed for managing configurations across your organization. For example, as an administrator you can use Group Policy to control the way some components communicate, or for some components, you can direct all communication to the organization's own internal Web site instead of to an external site on the Internet.

This white paper provides information about the communication that flows between components in Windows Server 2003 and sites on the Internet, and it describes steps to take to limit, control, or prevent that communication in an organization with many users. The white paper is designed to assist you, the administrator, in planning strategies for deploying and maintaining products in the Windows Server 2003 family in a way that helps provide an appropriate level of security and privacy for your organization's networked assets.

This white paper provides guidelines for controlling components in the following operating systems:

- Windows Server 2003, Web Edition
- Windows Server 2003, Standard Edition
- Windows Server 2003, Enterprise Edition
- Windows Server 2003, Datacenter Edition

The white paper is organized around individual components found in the Windows Server 2003 family, so that you can easily find detailed information for any component you are interested in.

**What This White Paper Covers and What It Does Not Cover**
The subsections that follow describe:

- Types of components covered in this white paper
- Types of components not covered in this white paper
- Security basics that are beyond the scope of this white paper, with listings of some other sources of information about these security basics

**Types of components covered in this white paper**
This white paper provides:

- Information about components that in the normal course of operation send information to or receive information from one or more sites on the Internet. An example of this type of component is Windows® Error Reporting; if you choose to use this component, it sends information to a site on the Internet.
- Information about components that routinely display buttons or links that make it easy for you to initiate communication with one or more sites on the Internet. An example of this type of component is Event Viewer; if you open an event in Event Viewer and click a link, you are prompted with a message box that says, "Event Viewer will send the following information across the Internet. Is this OK?" If you click OK, information about the event is sent to a Web site, which

replies with any additional information that might be available about that event.

- Brief descriptions of components like Microsoft Internet Explorer and Internet Information Services (IIS) that are designed to communicate with the Internet. It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization running servers that communicate across the Internet. This white paper does, however, provide basic information about how components such as Internet Information Services work, and it provides suggestions for other sources of information about balancing your organization's requirements for communication across the Internet with your organization's requirements for protection of networked assets.

**Types of components not covered in this white paper**
This white paper does not provide:

- Information about managing or working with applications, scripts, utilities, Web interfaces, Microsoft ActiveX® controls, extensible user interfaces, the .NET Framework, and application programming interfaces (APIs). These are either applications, or are layers that support applications, and as such provide extensions that go beyond the operating system itself.

  Windows Installer is not covered in this white paper, although Windows Installer includes some technology that (if you choose) you can use for installing drivers or other software from the Internet. Such Windows Installer packages are not described here because they are like a script or utility that is created specifically for communication across the Internet.

  Note that among the applications not covered in this white paper are Web-based and server-based applications, for example, server-based applications for databases, e-mail, or instant messaging. You must work with your application software provider to learn what you can do to mitigate any risks that are part of using particular applications (including Web-based or server-based applications), scripts, utilities, and other types of software that run on products in the Windows Server 2003 family.

- Information about components that store local logs that could potentially be sent to someone or could potentially be made available to support personnel. This information is similar to any other type of information that can be sent through e-mail or across the Internet in other ways. You must work with your support staff to provide guidelines about the handling of logs and any other similar information you might want to protect.

**Security basics that are beyond the scope of this white paper**
This white paper is designed to assist you, the administrator, in planning strategies for deploying and maintaining products in the Windows Server 2003 family in a way that helps provide an appropriate level of security and privacy for your organization's networked assets. The white paper does not describe security basics, that is, strategies and risk-management methods that provide a foundation for security across your organization. It is assumed you are actively evaluating and studying these security basics as a standard part of network administration.

Some of the security basics that are a standard part of network administration include:

- Monitoring. This includes using a variety of software tools, including tools to assess which ports are open on servers and clients.

- Virus-protection software.

- The principle of least privilege (for example, not logging on as an administrator if logging on as a user is just as effective).

- The principle of running only the services and software that are necessary, that is, stopping unnecessary services and keeping computers (especially servers) free of unnecessary software.

- Strong passwords, that is, requiring all users and administrators to choose passwords that are not easily deciphered.

- Risk assessment as a basic element in creating and implementing security plans.

- Software deployment and maintenance routines to help ensure that your organization's software is running with the latest security updates and patches.

- Defense-in-depth. In this context, defense-in-depth (also referred to as in-depth defense) means redundancy in security systems, for example, using firewall settings together with Group Policy to control a particular type of communication with the Internet.

**Other sources of information about security basics**

The following books and Web sites are a few of the many sources of information about the security basics described previously:

- Howard, Michael, et al. *Designing Secure Web-Based Applications for Microsoft Windows 2000*. Redmond, WA: Microsoft Press, 2000.

- Howard, Michael, and David LeBlanc. *Writing Secure Code*. Redmond, WA: Microsoft Press, 2002.

# Activation, Registration, and Internet Communication (Windows Server 2003)

Updated: July 31, 2004

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The purposes of activation and registration connected with a new installation or an upgrade
- How a computer running a product in the Microsoft Windows Server 2003 family communicates with sites on the Internet during activation and registration
- Choosing volume licensing so that product activation need not take place (to limit the flow of information to and from Internet sites)

**Purposes of Activation and Registration for a New Installation or an Upgrade**
This subsection briefly describes the differences between product activation and registration, and then describes the purpose of each.

Product registration involves the provision of personally identifiable information, such as an e-mail address, to Microsoft for the purpose of receiving information about product updates and special offers. Registration is usually done on a per-product basis and is not required. If registration is completed, all registration information is stored using a variety of security technologies and is never loaned or sold outside Microsoft.

Product activation involves the authentication with Microsoft of non-personally identifiable information, including the product identifier and a hardware hash representing the computer, for the purpose of reducing software piracy. (A hardware hash is a non-unique number generated from the computer's hardware configuration.) Activation of products in the Windows Server 2003 family is required in situations where the product is not purchased through a volume licensing program such as Microsoft Select License, Microsoft Enterprise Agreement, or Microsoft Open License. Many computer manufacturers can bypass activation on software preinstalled on a new computer by binding the software to the computer's basic input/output system (BIOS). In this situation, no activation of that software is required. Detailed information about product activation can be found on the following Web site:

http://go.microsoft.com/fwlink/?LinkId=29484

For more information about volume licensing, see "Choosing Volume Licensing So That Individual Product Activation Need Not Take Place," later in this section.

Activation is aimed at reducing software piracy as well as ensuring that Microsoft customers are receiving the product quality that they expect. Activation means that a specific product key becomes associated with the computer (the hardware) it is installed on. After that happens, that product key cannot be used for activation on other computers (unless you are enrolled in a special program that permits additional activations, for example, a program through the Microsoft Developer Network [MSDN]).

**Overview: Activation and Registration in a Managed Environment**
Product activation is an anti-piracy technology designed to verify that software products have been legitimately licensed. If you have software re-imaging rights granted under a Microsoft volume license agreement, and if you obtained a product in the Windows Server 2003 family through a retail channel or preinstalled by the computer manufacturer, you can re-image it with the product that you licensed through one of the Microsoft volume licensing programs. With volume licensing, there is no need to perform product activation.

**How a Computer Communicates with Sites on the Internet During Activation and Registration**
A product in the Windows Server 2003 family can be activated through the Internet or by phone. When it is activated through the Internet, the operating system communicates with Web sites as follows:

- **Specific information sent or received**: During activation, the following information is sent to the activation server at Microsoft:
