| Additional software | Additional software refers to installed commercial software and applications required by the applications on your server. | This additional software must be installed on the target server. This software might require modification to be compatible with Windows Server 2003 and IIS 6.0. |

# Determining Compatibility with Windows Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

At a minimum, your existing system hardware and software must be compatible with the Windows Server 2003 family before migrating the Web sites and applications to IIS 6.0. You must identify any software or hardware devices that are incompatible with Windows Server 2003.

**Compatibility of Existing Hardware**
When you select the computer that will be the target server, ensure that the computer is compatible with Windows Server 2003. The most common hardware incompatibility is a device driver that is no longer supported or is not yet supported in Windows Server 2003. When a device is no longer supported, remove the existing device and then install an equivalent device that is supported by Windows Server 2003. It is also important that you have a current system BIOS from your computer manufacturer.

For example, the target server might have a network adapter that is not included with Windows Server 2003. You can review the manufacturers Web site to obtain a driver that is compatible with Windows Server 2003.

For more information about the hardware devices supported by the Windows Server2003 operating systems, see the Hardware Compatibility List or the Windows Server Catalog.

**Compatibility of Existing Software**
Before migrating, you need to consider the compatibility of your existing applications, or other software that is installed on your server, with Windows Server 2003. This includes software and tools from manufacturers other than Microsoft, as well as Microsoft server products that do not ship with the Windows operating system. Make sure that you have the latest versions of all pre-existing software or service packs that are compatible with Windows Server 2003.

The most common software incompatibilities are caused when your application depends on software from another manufacturer that does not support Windows Server 2003. Or, you might have applications that were designed to run on Windows NT Server 4.0 or Windows 2000 Server operating systems, which reference APIs that have been changed or removed in Windows Server 2003.

To help you determine the compatibility of your existing software with Windows Server 2003, use the Windows Application Compatibility Toolkit before migrating your Web sites and applications to the target server.

# Determining Application Compatibility with IIS 6.0 Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 can run in one of two distinct modes of operation, which are called application isolation modes. *Application isolation* is the separation of applications by process boundaries that prevent the applications from affecting one another, and it is configured differently for each of the two IIS application isolation modes: IIS 5.0 isolation mode and worker process isolation mode.

*Worker process isolation mode* uses the redesigned architecture for IIS 6.0. This application isolation mode runs all application code in an isolated environment. However, unlike earlier versions of IIS, IIS 6.0 provides isolation without a performance penalty because fewer processor instructions are run when switching from one application pool to another. Worker process isolation mode is compatible with most existing Web sites and applications. Whenever possible, run IIS 6.0 in worker process isolation mode benefit from the enhanced performance and security in IIS 6.0.

*IIS 5.0 isolation mode* provides compatibility for applications that depend upon the process behavior and memory model of IIS 5.0. Run IIS in this mode only when a Web site or application cannot run in worker process isolation mode, and run it only until the compatibility issues are resolved.

| **Important** |
| --- |
| IIS 6.0 cannot run both application isolation modes simultaneously on the same server. Therefore, on a single server running IIS 6.0, you cannot run some Web applications in worker process isolation mode and others in IIS 5.0 isolation mode. If you have applications that require separate modes, you must run them on separate servers. |

During the migration process, you install Windows Server 2003 and IIS 6.0 on the target server. IIS 6.0 is configured to run in worker process isolation mode by default. Before you begin migrating your production Web sites and applications, evaluate whether your Web sites and applications are compatible with worker process isolation mode. Most of the compatibility issues with IIS 6.0 occur when configuring IIS 6.0 to run in worker process isolation mode.

One of the most common reasons for incompatibility with worker process isolation mode is that applications do not recognize custom Internet Server API (ISAPI) extensions or dynamic-link libraries (DLLs) that depend on the memory and request processing models used by earlier versions of IIS. Determine application compatibility in your lab before migrating your existing IIS Web sites and application, and if you determine that your applications are not compatible with worker process isolation mode, you can run the applications in IIS 5.0 isolation mode.

| **Note** |
| --- |
| Identifying a complete list of potential incompatibilities that applications can experience with worker process isolation mode is beyond the scope of this section. Even after following the guidelines in this section, you need to verify in a lab whether your Web sites and applications are compatible with worker process isolation mode. |

Determine the compatibility of an application with worker process isolation mode by completing the following steps:

1. Evaluate the benefits of moving to worker process isolation mode.

2. Evaluate the application changes that are required so that the applications can run in worker process isolation mode.

3. Evaluate the management and provisioning script changes that are required to set up programs and provisioning scripts in worker process isolation mode.

4. Verify the compatibility of the application with worker process isolation mode in a lab.

# Evaluating the Benefits of IIS 6.0 Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Worker process isolation mode provides higher levels of security and availability for Web sites and applications than IIS 5.0 isolation mode. Therefore, it is recommended that you configure IIS 6.0 to run in worker process isolation mode.

Worker process isolation mode provides the following improvements to IIS 6.0.

**Security Enhancements**
IIS 6.0 includes a variety of security features and technologies that help ensure the integrity of your Web site content, and of the data that is transmitted through your sites. The following security enhancement is only available when IIS 6.0 is running in worker process isolation mode.

**Default process identity for Web sites and applications is set to NetworkService**
In IIS 5.0 isolation mode, the default process identity is LocalSystem, which enables access to, and the ability to alter, nearly all of the resources on the Web server. The potential of attacks is reduced in worker process isolation mode because Web sites and applications run under the NetworkService identity. The NetworkService identity is granted less privileges, which helps prevent an attack from compromising the Web server, which is possible with the LocalSystem identity.

**Performance and Scaling Enhancements**
Future growth in the utilization of your Web sites and applications requires increased performance and scalability of Web servers. By increasing the speed at which Hypertext Transfer Protocol (HTTP) requests can be processed and by allowing more applications and sites to run on one Web server, the number of Web servers that you need to host a site is reduced. The following are a few of the performance improvements included in worker process isolation mode.

**Support for processor affinity for worker processes in an application pool**
You can configure all of the worker processes in an application pool to have affinity with specific processors in a multiprocessor or server. Processor affinity allows the worker processes to take advantage of more frequent processor caching (Level 1 or Level 2).

**Elimination of inactive worker processes and reclamation of unused resources**
You can configure application pools to have worker processes request a shutdown if they are idle for a certain amount of time. This can free unused resources for other active worker processes. New worker processes are then started only when they are needed.

**Distributing client connections across multiple worker processes**
You can configure an application pool to have more than one worker process servicing client connections, also known as a *Web garden*. Because there are multiple worker processes, the incoming client connections are distributed across the worker processes and throughput is not constrained by a single worker process.

**Ability to Isolate Web sites and applications from each other**
You can isolate Web sites and applications without incurring a performance penalty. This is because the Web site and applications, and their associated ISAPI filters, run in the same process.

**Availability Enhancements**
Because worker process boundaries isolate the applications in an application pool from the applications in other application pools, if an application fails, it does not affect the availability of other applications running on the server. Deploying applications in application pools is a primary advantage of running IIS 6.0 in worker process isolation mode.

**Reduced number of Web server restarts required when administering Web sites and applications**
Many of the common operation tasks do not force the restart of the server or the Web service restart. These tasks, such as upgrading site content or components, debugging Web applications, or dealing with faulty Web applications, can be performed without affecting service to other sites or applications on the server.

**A fault-tolerant request processing model for Web sites and applications**
In IIS 5.0 isolation mode, each Web site or application has only one worker process. However, in worker process isolation mode, you can create a *Web garden* by configuring a number of worker processes to share the processing. The benefit of a Web garden is that if one worker process stops responding, other worker processes are available to accept and process requests.

**Isolation of failed worker processes from healthy worker processes**
In worker process isolation mode, IIS can determine that a worker process is failing and start a new worker process to replace the failing worker process. Because a new worker process is created before the old worker process terminates, users requesting the Web site or application experience no interruption of service. After IIS creates the new worker process, the failed worker process can be separated, or *orphaned*, from the application pool. The advantage of orphaning a worker process rather than terminating it is that debugging can be performed on the orphaned worker process.

**Health monitoring of Web sites and applications**
In worker process isolation mode, you can configure an application pool to monitor not only the health of the entire application pool, but also individual worker processes servicing the application pool. Monitoring the health of a worker process allows IIS to detect that a worker process is unable to serve requests and to take corrective action, such as recycling the failed worker process.

In addition, worker process isolation supports other responses when a failed worker process or application pool is detected. For example, IIS can attach a debugger to an orphaned worker process or notify an administrator that an application pool has failed due to rapid-fail protection.

**Prevention of Web sites or applications that fail quickly from consuming system resources**
In some cases, availability can be affected by Web sites and applications that fail very quickly, are automatically restarted, and then fail quickly again. The endless cycle of failure and restarting can consume system resources, causing other Web sites and applications to experience denial of services because of system resource shortages.

Worker process isolation mode includes *rapid-fail protection* that stops an application pool when too many of the worker processes assigned to an application pool are found to be unhealthy within a specified period of time.

**Automatic restart of poorly performing Web sites and applications**
Some Web sites and applications have memory leaks, are poorly coded, or have other unidentified problems. In IIS 5.0 isolation mode, these applications can force you to restart the entire Web server. The recycling feature in worker process isolation mode can periodically restart the worker processes in an application pool in order to manage faulty applications. Worker processes can be scheduled to restart based on several options, such as elapsed time or the number of requests served.

# Evaluating Application Changes Required for IIS 6.0 Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In most cases, the existing Web sites and applications can be hosted in worker process isolation mode without modification. However, the following are known application issues that can create incompatibilities with worker process isolation mode and require you to run IIS 6.0 in IIS 5.0 isolation mode.

- **Requires Inetinfo.exe.** When the application must run in the same process with Inetinfo.exe, IIS must be configured to run in IIS 5.0 isolation mode because Inetinfo.exe does not process Web requests in worker process isolation mode. In worker process isolation mode, W3wp.exe processes Web requests.

- **Requires Dllhost.exe.** When the application depends on Dllhost.exe to process Web requests for the application, IIS must be configured to run in IIS 5.0 isolation mode because Dllhost.exe is not available in worker process isolation mode.

- **Requires read raw data filters.** If the application uses an ISAPI raw data filter, IIS must be configured to run in IIS 5.0 isolation mode.

- **Requires version 1.0 of the .NET Framework.** When the application requires version 1.0 of the .NET Framework, IIS must be configured to run in IIS 5.0 isolation mode because version 1.0 of the .NET Framework is only supported in IIS 5.0 isolation mode.

- **Requires ISAPI filters or extensions that are incompatible with worker process isolation mode.** When the application requires ISAPI filters or extensions that are incompatible with worker process isolation mode, IIS must be configured to run in IIS 5.0 isolation mode. ISAPI filters or extensions might be incompatible if the filter or extension has one of the following characteristics:

    - Runs in multiple instances and expects to be recycled by using the recycling provided in IIS 5.0.

    - Expects to have exclusive lock on a resource, such as a log file.

If any of the Web sites and applications running on the existing Web server has one or more of these characteristics, then do one of the following:

- Configure IIS 6.0 to run in IIS 5.0 isolation mode to ensure Web site and application compatibility. If the Web sites and applications need to be hosted in IIS 5.0 isolation mode, then the migration process is complete.

- Modify the existing applications to remove the dependencies.

# Evaluating Management and Provisioning Script Changes Required for IIS 6.0 Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When management or provisioning scripts exist for your Web sites and applications, you might need to modify them so that they properly set up the Web sites and applications for the application isolation mode that is running on the Web server — IIS 5.0 isolation mode or worker process isolation mode. If you do not modify your management and provisioning scripts as required, you will be unable to use them to install and configure your Web sites and applications on IIS 6.0.

For example, you might have a provisioning script that uses Microsoft Active Directory® Service Interfaces (ADSI) to create a Web site and configure the site for High isolation in IIS 5.0 isolation mode, which does not exist in worker process isolation mode. After migration and when the Web server is running in worker process isolation mode, you need to modify the script to create application pools instead.

Common modifications that might be necessary to your setup programs and provisioning scripts include:

- When the script installs an ISAPI extension or filter, you might need to modify the script to add an entry for the ISAPI extension or filter to the Web service extensions restriction list and set the status of the entry to **Allowed**.

  For more information about modifying your setup programs or provisioning scripts to install and enable an ISAPI extension or filter, see Configuring Web Service Extensions.

- When the script installs an application that contains dynamic content, you might need to modify the script to set the status of the appropriate Web service extensions to **Allowed**, so that IIS allows the dynamic content to run.

  For more information about modifying your setup programs or provisioning scripts to enable dynamic content, see Configuring Web Service Extensions.

- When the script installs a Web site or application that runs in High isolation in IIS 5.0, you might need to modify the script to create an application pool and configure the application pool with settings that are comparable to the original IIS 5.0 isolation settings.

  For more information about modifying your setup programs or provisioning scripts to create and configure application pools, see Configuring Application Isolation Settings in Worker Process Isolation Mode.

- When the script references metabase properties, you might need to modify the script if it references metabase properties that have changed or are no longer supported in IIS 6.0.

  For more information about modifying your setup programs or provisioning scripts to reference the proper metabase properties in IIS 6.0, see Modifying References to IIS 6.0 Metabase Properties.

# Verifying Application Compatibility with IIS 6.0 Worker Process Isolation Mode in a Lab

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After modifying your Web sites, applications, setup programs, and provisioning scripts to be compatible with worker process isolation mode, you need to test your modifications in a lab. Be sure to test for compatibility before performing the migration process on a production Web server.

Verify the compatibility of your Web sites, applications, setup programs, and provisioning scripts with worker process isolation mode in a lab by completing the following steps:

1. Make an image backup of the source server.

2. Restore the backup to a Web server in your lab, referred to hereafter as a *test source server*. Ensure that the test source server is not connected to your production network, to prevent any problems encountered during the migration from affecting your production network.

3. Perform a migration from the test source server to the test target server.

4. Configure the test target server to run in worker processor isolation mode or IIS 5.0 isolation mode.

5. Make the necessary modifications to the Web sites, applications, setup programs, and provisioning scripts so that they are compatible with worker process isolation mode.

6. Verify that the Web sites, applications, setup programs, and provisioning scripts run correctly on the test target server.

For more information about setting up a test lab, see "Designing a Test Environment" in Planning, Testing, and Piloting Deployment Projects.

# Determining Application Compatibility with .NET Framework

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For a successful migration to Windows Server 2003 and IIS 6.0, you need to determine whether your ASP.NET applications are dependent on specific versions of the .NET framework. Windows Server 2003 ships with version 1.1 of the .NET Framework, while most of the .NET applications that were developed before the release of Windows Server 2003 were designed to run on version 1.0 of the .NET framework.

| **Note** |
| --- |
| Version 1.0 of the .NET Framework is only supported in IIS 5.0 isolation mode. Therefore, you can only run version 1.0 and version 1.1 of the .NET Framework on the same server when IIS 6.0 is configured to run in IIS 5.0 isolation mode. Version 1.1 of the .NET Framework is supported in IIS 5.0 isolation mode or worker process isolation mode. |

Typically, ASP.NET applications running on version 1.0 of the .NET Framework are compatible with version 1.1 of the .NET Framework. However, there might be some incompatibilities, the majority of which are security related and can be corrected by configuring the .NET Framework to be less restrictive.

For example, in the .NET Framework version 1.0, the .NET Framework only examines the **SQLPermission.AllowBlankPassword** attribute if the user actually includes the password keyword in their connection string. If an administrator or user sets the **SQLPermision.AllowBlankPassword** attribute to **False**, it is possible to specify a connection string like "server=(localhost);uid=sam" and succeed. In the .NET Framework version 1.1, this connection string fails.

You can use both version 1.0 and version 1.1 of the .NET Framework on the same server running IIS 6.0, which is also known as *side-by-side configuration*. Side-by-side configuration allows you to run a mixture of applications that require version 1.0 or version 1.1 of the .NET Framework. During your lab testing, determine the version of the .NET Framework that is required by your applications.

For a current list of possible compatibility issues when upgrading from version 1.0 to version 1.1 of the .NET Framework, see Compatibility Considerations and Version Changes on the GotDotNet Web site. For more information about using multiple versions of the .NET Framework in side-by-side configuration, see Configuring IIS to Use the Correct Version of the .NET Framework.

| **Important** |
| --- |
| ASP.NET is not available on the following operating systems: Microsoft® Windows® XP 64-Bit Edition; the 64-bit version of Windows® Server 2003, Enterprise Edition; and the 64-bit version of Windows® Server 2003, Datacenter Edition. For more information, see "Features unavailable on 64-bit versions of the Windows Server 2003 family" in Help and Support Center for Windows Server 2003. |

# Selecting a Migration Method

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before migrating your Web sites and applications to IIS 6.0, you need to determine whether to perform the migration manually or with the IIS 6.0 Migration Tool. It is recommended that you use the migration tool to begin the migration process, except when one of the following is true:

- **You have set up programs, installation scripts, or provisioning scripts for the Web sites and applications that you are migrating.** When the Web sites and applications that you are migrating have setup programs, installation scripts, or provisioning scripts, use those programs or scripts to install the Web sites and applications on the target server. Ensure that the setup programs, installation scripts, and provisioning scripts have been properly modified to install the Web sites and applications on IIS 6.0.

- **The target server is configured to run in IIS 5.0 isolation mode.** When the Web sites and applications that you are migrating require the target server to run in IIS 5.0 isolation mode, you must perform the migration manually. To determine whether your Web sites and applications are compatible with worker process isolation mode, see Determining Application Compatibility with Worker Process Isolation Mode earlier in this section.

- **The source server has a significant number of FrontPage extended Web sites.** When the FrontPage extended Web sites make extensive use of the administrative and publishing security-related settings found in FrontPage 2000 Server Extensions, perform the migration manually. To ensure that these security-related settings are migrated properly to the target server, perform the migration manually and use FrontPage publishing to transfer the Web site to the target server.

- **You want to migrate individual virtual directories.** When you want to migrate individual virtual directories, perform the migration manually. The IIS 6.0 Migration Tool only moves Web site content and configuration settings at the Web site level, which means that all of the virtual directories beneath the Web site are migrated to the target server.

If you determine that you need to perform the migration manually, then you can proceed to the next step in the migration process — Deploying the Target Server. Otherwise, you need to know which steps in the migration process are automated by the IIS 6.0 Migration Tool, and which steps you must complete manually after running the migration Tool. Knowing the role of the IIS 6.0 Migration Tool in the migration process enables you to have the appropriate tools and resources available when you are ready to begin the migration.

# Identifying the Role of the IIS 6.0 Migration Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS 6.0 Migration Tool is a command-line utility that automates some of the steps in the process for migrating Web sites and applications hosted on IIS 4.0 or IIS 5.0 to IIS 6.0. The migration tool does not provide an end-to-end migration solution, but it automates some of the time-consuming, repetitive migration tasks. Although the migration tool is conceptually similar to the IIS 5.0 Migration Tool, the IIS 6.0 Migration Tool is a completely new tool designed specifically for Windows Server2003 and is not compatible with the previous tool.

# Migration Tasks That Are Automated by the IIS 6.0 Migration Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS 6.0 Migration Tool automates the following steps in the IIS migration process:

- Transferring the Web site content. All of the files and folders located in the home directory of the Web site and virtual directories (which can be located outside of the home directory of the Web site) are copied from the source server to the target server. The NTFS file system permissions assigned to the files and directories that make up the Web site content on the source server are granted to the corresponding files and directories on the target server. Any content referenced by the Web site or application that is not located in subdirectories of the home directory of the Web site or in virtual directories is not migrated.

- Transferring the Web site configuration in the IIS metabase. The configuration for each Web site and application, which is stored in the IIS metabase properties on the source server, is translated and then the corresponding IIS 6.0 metabase properties are appropriately configured on the target server.

- Translating the application isolation configuration. The target server is running in worker process isolation mode. The application isolation configuration for each Web site and application on the source server is translated into application pool configuration settings on the target server.

- Backing up the IIS metabase configuration to the target server. The IIS metabase configuration is backed up on the target server before migration. You can use this backup to restore the target server to a known state in the event that the migration process is not successful.

# Migration Tasks That Must Be Completed Manually

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following steps in the Web site migration process must be completed after running the IIS 6.0 Migration Tool.

**Migrating Additional Web Site and Application Content**
The IIS 6.0 Migration Tool migrates all of the content that is located in the home directory of the Web site and in any subdirectories contained in that home directory. You can migrate any Web site and application content that is not located in these directories by completing the following steps:

- **Migrate content located outside the home directory and subdirectories of the Web site.** When the Web sites and applications reference content that is located in folders outside of the home directory of the Web site or the virtual directories beneath the home directory, you must migrate this content manually.

- **Migrate content located in a virtual directory.** When the virtual directory content on the source server is stored on a disk volume, such as F:, that does not exist on the target server, you must migrate this content manually.

**Configuring Additional Web Site and Application Properties**
After running the IIS 6.0 Migration Tool, the Web sites are configured comparably to how they were configured on the source server. However, depending on the configuration of the Web sites and applications on the source server, you might need to configure additional Web site and application properties, by completing the following steps:

- **Change the IIS metabase settings to reflect where Windows is installed.** If the Windows Server 2003 systemroot path does not match the Windows systemroot path on the source server, you must modify the metabase settings on the migrated Web sites to reference the correct folder on the target server. For example, if Windows was installed on C:\WINNT on the source server, the IIS metabase entries for **ScriptMaps**, and **HTTPErrors** properties might still reference these paths, and therefore need to be updated on the target server.

- **Configure IIS properties that reference local user accounts.** There are a number of Web site configuration properties on the source server that you can configure to utilize user accounts that are local to the source server. Local user and group accounts are not migrated from the source server to the target server by the IIS 6.0 Migration Tool. As a result, the migrated Web sites reference user accounts that do not exist on the target server. In these cases, you must configure the Web sites to utilize user accounts that are domain-based or local to the target server, and then re-create the file system permissions on migrated content by completing the following steps:

    - **Configure local user NTFS permissions on content.** If NTFS permissions are granted to local user accounts on the source server, you must create new user accounts, or designate existing user accounts, for use on the target server and then grant the corresponding NTFS permissions to the user accounts on the target server.

    - **Configure anonymous account properties for Web sites and virtual directories.** If a Web site or virtual directory is configured to use a user account on the source server for anonymous access (other than the default IUSR_computername account), you must create a new user account, or designate an existing user account, for use on the target server.

    - **Configure IIS 4.0 and IIS 5.0 application isolation identities.** If the Web sites or applications are isolated and are configured to use a local user account on the source server as the application isolation identity, you must create a new user account, or designate an existing user account, for use on the target server. Then you must configure the corresponding application pool, on the target server, to use the newly created account as the identity of the application pool.

    - **Add Web service extensions for dynamic content used by the Web sites.** Any dynamic content types, including ISAPI extensions, ISAPI filters, or CGI applications, which are not automatically migrated by the IIS 6.0 Migration Tool need to be added to the Web service extensions list.

    - **Add MIME types for static content used by the Web sites.** MIME types define the types of static files that are

served by the Web server. You must identify the MIME types defined on the source Web server and then create the same associations of MIME types to file name extensions on the target Web server.

- **Configure SSL certificates.** You must export server certificates for Secure Sockets Layer (SSL)-enabled Web sites from the source server, and then install the certificates on the target server after the migration process is complete.

- **Configure FrontPage Server Extensions users and roles.** If FrontPage Server Extensions is configured to use a local user account on the source server as the FrontPage administrator, you must create a new user account, or designate an existing user account, for use on the target server. In addition, you must assign the user the same FrontPage role as the corresponding user had on the source server.

- **Configure IIS for ASP.NET applications.** If you migrate ASP.NET applications from the source server, you might need to migrate the attribute settings in the Machine.config file that are used to set process-model behavior. When the target server is configured for worker process isolation mode, the attribute settings in the Machine.config file need to be converted to corresponding application pool settings. This is because ASP.NET uses the IIS process model when IIS is running in worker process isolation mode. For more information, see Migrating Machine.config Attributes to IIS 6.0 Metabase Property Settings later in this section.

**Performing Application-Specific Migration Tasks**

In addition to the IIS 6.0 configuration changes that are required, you might need to complete any migration tasks that are specific to the applications running on the source server. The application-specific steps that you might need to perform include the following:

- **Modifying application code for compatibility with Windows Server 2003 and IIS 6.0.** When the applications on the source server are not compatible with Windows Server 2003 and IIS 6.0, you need to modify the applications. Most of these modifications are required when applications use application programming interfaces (APIs) no longer supported by Windows Server 2003 and IIS 6.0.

- **Installing additional software required by the applications.** When applications on the source server require additional software that was developed by your organization, by Microsoft, or by other organizations, you need to install that software on the target server. This software can include filters and ISAPI extensions. You must obtain a version of the software that is compatible with Windows Server 2003 and IIS 6.0.

- **Migrating MTS packages, COM objects, and COM+ applications.** When your applications include MTS packages, COM objects, or COM+ applications, you must migrate them to the target server. For MTS packages, you need to rewrite the MTS as a COM+ application.

- **Creating IP addresses that are used to uniquely identify the applications.** Web sites and applications are uniquely identified by a unique IP address, a unique combination of an IP address and a TCP port, or host headers. When Web sites and applications on the source server are uniquely identified by IP addresses, you must create corresponding IP addresses on the target server and then configure the migrated Web sites and applications to use the new IP addresses.

- **Creating users and groups that are used by the applications.** When users that access the applications on the source server have accounts that are local to the source server, you need to create new accounts on the source server and then assign the appropriate NTFS permissions on the target server to the new accounts. When the user accounts are in Active Directory, you only need to assign the appropriate NTFS permissions on the target server to the accounts in Active Directory.

- **Creating registry entries for the applications.** When your applications store configuration information in the registry, you might need to create the same registry entries for the applications on the target server.

**Note**

The IIS 6.0 Migration Tool does not migrate the IIS logs from the source server to the target server. The migration of the IIS logs is not necessary for proper operation of the Web sites and applications on the target server. However, you might want to archive the IIS logs before decommissioning the source server for historical reference to events that occurred on the source server before migration.

For information about using the IIS 6.0 Migration Tool to perform your migration, see Migrating Web Sites with the IIS 6.0 Migration Tool later in this section.

# Deploying the Target Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You must install Windows Server 2003 on the target Web server before you can migrate the Web sites and applications. In addition to installing Windows Server 2003, you must install and configure IIS 6.0 on the target server. To follow the process described in this section, install Windows Server 2003 and IIS 6.0 with the default options.

You must also configure the target server to run in worker process isolation mode or in IIS 5.0 isolation mode. Run IIS in IIS 5.0 isolation mode only when a Web site or application cannot run in worker process isolation mode. If there are no incompatibilities, configure IIS to run in worker process isolation mode to utilize the benefits of IIS 6.0 features.

Figure 6.3 illustrates the process for deploying the target server.

**Figure 6.4 Deploying the Target Server**

If you have already installed Windows Server 2003 on the target server, and you have already installed and configured IIS 6.0 on the target server, you can proceed to Migrating Web Sites with the IIS 6.0 Migration Tool or Migrating Web Sites Manually.

# Installing Server 2003

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The primary concern when installing Windows Server 2003 is to ensure that the security of the target server is maintained. When you install Windows Server 2003 as a dedicated Web server, the default components and services are configured to provide the lowest possible attack surface. You can further reduce the attack surface of the target server by enabling only the essential Windows Server 2003 components and services.

The migration process presented in this section assumes that you install Windows Server 2003 with the default options. If you use other methods for installing and configuring Windows Server 2003, such as unattended setup, your configuration settings might be different.

| **Note** |
| --- |
| When you complete the installation of Windows Server 2003, Manage Your Server automatically starts. The migration process assumes that you quit Manage Your Server and then further configure the Web server in **Add or Remove Programs**in Control Panel. |

For more information about enabling the essential Windows Server 2003 components and services required by your server, see Enabling Only Essential Windows Server 2003 Components and Services.

# Installing and Configuring IIS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Because IIS 6.0 is not installed during the default installation of Windows Server 2003, the next step in deploying the target server is to install and configure IIS 6.0. The migration process presented here assumes that you install IIS 6.0 with the default options in **Add or Remove Programs** in Control Panel. If you use other methods for installing and configuring Windows Server 2003, such as Manage Your Server, the default configuration settings might be different.

Install and configure IIS 6.0 by completing the following steps:

1. Install IIS 6.0 with only the essential components and services.

   As with installing Windows Server 2003, the primary concern when installing and configuring IIS 6.0 is to ensure that the security of the target server is maintained. Enabling unnecessary components and services increases the attack surface of the target server. You can help ensure the target server is secure by enabling only the essential components and services in IIS 6.0.

   For more information about how to install IIS 6.0, see Install IIS 6.0. For more information about the IIS 6.0 protocols and services, see Enabling Only Essential IIS Components and Services.

2. If the source server has Web sites with FrontPage Server Extensions, install FrontPage 2002 Server Extensions from Microsoft on the target server.

   For more information about how to enable FrontPage Server Extensions, see Configure Web Service Extensions.

3. Configure IIS 6.0 to run in IIS 5.0 isolation mode.

   If you determined that one or more of your Web sites or applications are incompatible with worker process isolation mode (the target server is currently configured to run in worker process isolation mode), configure IIS 6.0 to run in IIS 5.0 isolation mode in IIS Manager, or by setting the IIS metabase property **IIs5IsolationModeEnabled** to a value of **True**.

   | **Note** |
   | --- |
   | If you configure IIS 6.0 to run in IIS 5.0 isolation mode and then decide to change the configuration back to worker process isolation mode, the original worker process isolation mode settings are retained. Similarly, if you configure IIS 6.0 to run in IIS 5.0 isolation mode, change to worker process isolation mode, and then change back to IIS 5.0 isolation mode, the IIS 5.0 isolation mode settings are retained. |

   For more information about how to configure IIS 6.0 to run in worker process isolation mode or in IIS 5.0 isolation mode, see Configure Application Isolation Modes. For more information about determining compatibility with worker process isolation mode, see Evaluating Application Changes Required for Worker Process Isolation Mode.

# Migrating Web Sites with the IIS 6.0 Migration Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Earlier in the process, you determined whether to migrate your Web sites by using the IIS 6.0 Migration Tool or to migrate them manually. If you decided to use the IIS 6.0 Migration Tool to complete the migration process, perform the steps that are described in this section.

If you decided to complete the migration process manually, you can skip this step and proceed directly to Migrating Web Sites Manually later in this section. For more information about how to determine whether to perform the migration with the IIS 6.0 Migration Tool, see Selecting a Migration Method earlier in this section.

Figure 6.5 illustrates the process of performing the migration to IIS 6.0 with the IIS 6.0 Migration Tool.

**Figure 6.5 Migrating Web Sites to IIS 6.0 with the IIS 6.0 Migration Tool**

# Installing the IIS 6.0 Migration Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS 6.0 Migration Tool and its accompanying user documentation are included in the Internet Information Services (IIS) 6.0 Resource Kit Tools,which can be installed by running IIS60rkt.exe from the Microsoft Download Center. There is no setup program for the migration tool; you need only copy the IIS 6.0 Migration Tool to the target server. You do not need to install any software on the source server. To avoid installing the entire contents of the IIS 6.0 Resource Kit Tools onto your target server, install the tools onto a workstation first, and then copy the migration tool to the target server.

Install the IIS 6.0 Migration Tool by completing the following steps:

1. Install the Internet Information Services (IIS) 6.0 Resource Kit Tools by running IIS60rkt.exe from the Microsoft Download Center.

2. Create a folder on the target server to contain the migration tool.

3. Copy the IIS 6.0 Migration Tool (Iismt.exe) from Program Files\IIS Resources\IIS 6.0 Migration Tool, on the computer listed in Step 1, to the folder on the target server that you created in Step 2.

4. Verify that the migration tool operates correctly by typing **iismt** at the command prompt.

   This starts the migration tool and displays Help for the tool only. The migration process does not actually begin.

# Verifying That Clients Are Not Gaining Access to Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS 6.0 Migration Tool requires only read access to the Web site content and configuration settings on the source server. Therefore, the source server can remain online in your production environment. However, you might need to remove the source server from your production network and move it to a private network segment that has direct network connectivity to the target server under the following circumstances:

- The number of files and amount of configuration information being copied across the network generates a high volume of traffic and slows the production network.

- Firewalls that exist between the source and target servers prevent the migration tool from performing the migration. This often occurs because the migration tool uses DCOM ports that are blocked by the firewalls for communicating with the source and target servers.

- Security-related configuration settings on the source server need to be modified to allow the migration tool to work.

  Examples of these security-related configuration settings that can prevent the migration tool from working include the following:

  - Remote access to disk volumes through administrative shares is prohibited.

    The IIS 6.0 Migration Tool requires access to the disk volume that contains the Web site content to perform the migration. For example, if the Web site content is stored in D:\Inetpub\Wwwroot, the migration tool must access the administrative share (D$) of the disk volume. The administrative shares are often removed to help prevent unauthorized access to the Web server. In order to use the migration tool, you must re-create the appropriate administrative shares.

  - Remote access to the source server must be allowed for members of the local Administrators group on the source server.

    For security reasons, many organizations restrict the members of the local Administrators group so that they can only log on locally, not over the network. However, the migration tool must be able to remotely access the source server over the network, as a member of the local Administrators group.

Verify that clients are no longer accessing Web sites by completing the following steps:

1. Prevent new clients from accessing the sites by pausing the sites.

   For more information about how to pause Web sites, see Pause Web or FTP Sites.

2. Monitor the active Web connections to determine when clients are no longer accessing the source server.

   For more information about how to monitor the active Web connections, see Monitor Active Web and FTP Connections.

3. When the number of active Web counters is zero, stop the WWW service or move the source server to another network segment.

   If you elect to stop the WWW service, ensure that the IIS Admin service is running because the migration tool requires the IIS Admin service. For more information about how to stop the WWW service, see Stop the WWW Service.

# Running the IIS 6.0 Migration Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS 6.0 Migration tool is a command-line utility that is designed to run on the target server.

Before you run the IIS 6.0 Migration tool, you should test the Remote Procedure Call (RPC) connection. For information about testing RPC connections, see Rpcping.exe: RPC Ping.

To run the migration tool, type **iismt** at the command prompt, and provide the parameters, as listed in Table 2, that are appropriate to the Web sites and applications that you are migrating. For more information about each of the parameters and on how to perform the migration with the IIS 6.0 Migration Tool, see the "IIS 6.0 Migration Tool User Guide" in the IIS 6.0 Resource Kit Tools.

The IIS 6.0 Migration Tool uses the following syntax:

**iismt.exe** *Server Website*[**/user** *Username*] [**/password** *Password*] [**/path** *path*] [**/serverbindings** *ServerBindings String*] [**/siteid** *SiteID* |**Replace**][**/configonly**][**/fpse**][**/verbose**][**/overwrite**][**/noninteractive**]

Table 6.2 lists all the command-line parameters that the migration tool accepts, although not all of the parameters listed are required.

**Table 6.2 Command-Line Parameters Accepted by the IIS 6.0 Migration Tool**

| Parameter | Required or Optional | Description |
|---|---|---|
| *SourceServer* | Required | Identifies the source server by providing the following:<br>• DNS or NetBIOS name for the source server<br>• IP address of the source server |
| *WebSite* | Required | Identifies the site to be migrated by providing the following:<br>• Web site description, such as "Default Web Site"<br>• Metabase key path, such as W3SVC/1 |
| **/user** *UserName* | Optional | Specifies the user name of an account that is a member of the Administrators group on the source server. This parameter is not necessary if you log on with an account that is a member of the Administrators group on both the source server and the target server. |
| **/password** *Password* | Optional | Specifies the password that is associated with the user name. |
| **/path** *Path* | Optional | Specifies a different directory location for the home directory of the Web site on the target server. This parameter is ignored if **/configonly** is included. |
| **/serverbindings** *ServerBindingsString* | Optional | Allows a change to the IP address, host header, or port configuration of the Web site during the migration. |

| | | |
|---|---|---|
| **/siteid** *SiteID*\| **Replace** | Optional | Specifies the site ID on the target server, which can be specified as one of the following:<br>● *SiteID* - Overwrites the site ID on the target server.<br>● Replace - Overwrites the site ID on the target server with the site ID from the source server. |
| **/configonly** | Optional | Migrates only the Web site configuration and not the Web site content. |
| **/fpse** | Optional | Reapplies FrontPage Server Extensions to the migrated site on the target server. This parameter is ignored if **/configonly** is included. |
| **/verbose** | Optional | Displays metabase path copy and file copy operations to the screen during the migration process. |
| **/overwrite** | Optional | Does not display messages that prompt the user to confirm the overwriting of an existing destination folder or file when content is being copied from the source server to the target server. |
| **/noninteractive** | Optional | Does not display messages that prompt the user for input. The migration tool will exit on the first error condition. This is a useful switch for invoking the migration tool from a batch file or script program to perform an unattended migration. |

# Verifying That the IIS 6.0 Migration Tool Ran Successfully

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before continuing with the Web site migration, verify that the IIS 6.0 Migration Tool migrated the Web site content and configuration information successfully. When you run the migration tool, the output displayed by the migration tool indicates the success or failure of the migration. If the output indicates that errors occurred, you can use the IIS 6.0 Migration Tool log file to resolve any errors.

Verify that the IIS 6.0 Migration Tool ran successfully by completing the following steps:

1. Open *%systemroot%*\System32\LogFiles\IISMT\iismt_*date_time*.log in a text editor and determine if any errors occurred (where *date* is the date when the tool ran and *time* is the time the tool started).

2. Review the log file and resolve any problems that occurred during migration before proceeding to the next step in the process.

# Migrating Additional Web Site Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Some Web sites and applications have content that is not located in the home directory of the Web site or in subdirectories that are inside the home directory. The IIS 6.0 Migration Tool only migrates Web site content from the following locations:

- Within the home directory and subdirectories of the Web site.
- In virtual directories whose disk volume letter exists on both the source server and the target server.

If the code in your applications directly references content that is located outside the home directory and subdirectories of the Web site, or if a virtual directory is stored on a disk volume letter that does not exist on the target server, you must migrate this Web site content manually.

# Migrating Content Located Outside the Home Directory of the Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A Web site or application can have content that is referenced by the Web site, but is located outside the home directory and subdirectories of the Web site. This content must be migrated manually because the IIS 6.0 Migration Tool migrates content only in the home directory and subdirectories of the Web site.

**Migrating Content**

Migrate content that is located outside the home directory and subdirectories of the Web site by completing the following steps:

1. Create a folder on the target server to contain the content. Ensure that the folder is in the same relative location to the home directory of the Web site. For example, if a Web site on the source server is in D:\Wwwroot\WebSite and the content to be migrated is in D:\Program Files\SiteContent, create the same folder (D:\Program Files\SiteContent) on the target server.

2. Copy the content from the source server to the target server. Use the process of your choice for copying the content as described in Migrating Web Site Content.

3. If necessary, modify any references to the content that is located in directories that are external to the home directory of the Web site on the target server. The target server might have a different disk configuration than the source server, or you might be migrating the content to a different disk volume letter on the target server than the source server. You need to modify any references in the Web site to content that is located outside the home directory and subdirectory of the Web site.

# Migrating Content Located in Virtual Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Virtual directory content on the source server might be stored on a disk volume, such as F:, that does not exist on the target server. This content must be migrated manually because the IIS 6.0 Migration Tool migrates virtual directories only when the disk volume letter on which the virtual directory is located exists on both the source server and the target server.

Migrate content that is located in virtual directories, which are stored on a disk volume that does not exist on the target server, by completing the following steps:

1. Create a folder on the target server to contain the virtual directory and the content.

   Ensure that the folder is in the same relative location on the target servers as on the source server.

2. Copy the content from the source server to the target server.

   Use the process of your choice for copying the content as described in Migrating Web Site Content.

3. Create the virtual directory under the appropriate Web site on the target server that references the folder created in Step 1.

   For more information about how to create virtual directories on the target server, see Create a Virtual Directory in IIS 6.0.

# Modifying IIS 6.0 Metabase Properties That Reference the Systemroot Folder

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS 6.0 Migration Tool migrates metabase properties that reference the systemroot folder on the source server, but does not update the references to the systemroot folder on the target server. If the location of systemroot folder on the target server does not match the location of the systemroot folder on the source server, you must modify the metabase settings on the migrated Web sites to reference the correct systemroot folder on the target server. Because the default systemroot folder name changed from WINNT to Windows in Windows 2000 Server and later versions, you might need to manually modify the metabase properties that reference the systemroot folder on the target server.

These metabase properties that reference the location of the systemroot folder can include the following:

- **HttpErrors**. The **HttpErrors** metabase property specifies the custom error string sent to clients in response to HTTP 1.1 errors. Each string in the list specifies the HTTP error code and subcode, indicates whether the handler will be a URL or a file, and specifies which URL or file the client will be sent. Each string can be in either a URL or a file format. If you migrate the Default Web Site on Windows NT 4.0 or Windows 2000, you must reset the **HttpErrors** metabase property to contain the systemroot folder for Windows Server 2003, even if the systemroot folder exists on the same drive on both the source and target computer.

- **ScriptMaps**. The **ScriptMaps** metabase property specifies the file name extensions of applications that are used for script processor mappings.This property contains references to paths with default ISAPIs, such as C:\Windows\system32\inetsrv\asp.dll.

Compensate for the differences in the location of the systemroot folder on the target server by completing the following steps:

1. Enable the IIS 6.0 metabase edit-while-running feature.

2. Open the MetaBase.xml file in Microsoft Notepad.

3. Search for any references to the systemroot folder on the source server and replace these references with the systemroot folder path on the target server.

   For example, if the source server had been installed in C:\WINNT and the target server is installed into C:\Windows, you should replace any occurrences of "C:\WINNT" with "C:\Windows".

4. Save the MetaBase.xml file.

5. Disable the metabase edit-while-running feature.

   For more information about the edit-while-running feature, see Enabling Edit-While-Running in IIS 6.0.

# Migrating Web Sites Manually

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Earlier in the process, you decided whether to migrate your Web sites with the IIS 6.0 Migration Tool or to migrate them manually. If you are unable to use the migration tool, you must migrate manually, or use existing provisioning or setup scripts. For more information about how to determine whether you can perform the migration with the IIS 6.0 Migration Tool, see Selecting a Migration Method earlier in this section.

When there are provisioning or setup scripts for your Web sites and applications, use these scripts to install the Web sites and applications on the target server. These scripts might require modification to be compatible with worker process isolation mode, which is discussed in Evaluating Application Changes Required for IIS 6.0 Worker Process Isolation Mode earlier in this section.

Because the scripts install and configure the Web sites and applications, no migration is required. In this case, run the scripts to install and configure the Web sites and applications and then proceed to Configuring IIS 6.0 Properties later in this section to continue with the process.

Figure 6.6 illustrates the process migrating Web sites manually to IIS 6.0.

**Figure 6.6 Performing a Manual Migration to IIS 6.0**

# Verifying That Clients Are Not Accessing Web Sites Before a Manual Migration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before migrating your existing Web sites and applications, ensure that no active client sessions are running. For more information about verifying that clients are not accessing Web sites, see Verifying That Clients Are Not Accessing Web Sites earlier in this section.

# Creating Web Sites and Virtual Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For each Web site and virtual directory on the source server, you must create a corresponding Web site and virtual directory on the target server. Later in the migration process, you will copy the content into these Web sites and virtual directories.

Create the Web sites and virtual directories by completing the following steps:

1. Create the Web sites and home directories on the target server.

2. Create the virtual directories.

# Creating Web Sites and Home Directories on the Target Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Each Web site must have one home directory. The home directory is the central location for your published pages. It contains a home page or index file that welcomes visitors and contains links to other pages in your site. The home directory is mapped to the Web site's domain name or to the name of the Web server.

Create a Web site and home directory on the target server by completing the following steps:

1. Create the folder that will be the home directory for the Web site on the target server.

   The folder that is the home directory of the Web site contains all of the content and subdirectories for the Web site. The folder can be created on the Web server or on a UNC-shared folder on a separate server. At a minimum, create the folder on the following:

   - An NTFS file system partition, which helps ensure proper security.
   - A disk volume other than the system volume, which reduces the potential of an attack on a Web site bringing down the entire Web server, and improves performance.

   For more information about securing Web sites and applications see Securing Web Sites and Applications. For more information about creating directories for your Web sites see Create a Web Site.

2. Determine whether to generate the Web site identification number incrementally, or from the Web site name.

   Although site identification numbers were generated incrementally in IIS 5.1 and earlier, when you create a new site on IIS 6.0, a Web site identification number is randomly generated by using the name of the Web site. If you have administration scripts, setup programs, or provisioning scripts that depend upon the IIS 5.1 method of generating site identification numbers, you can force IIS 6.0 to use incremental site identification numbers by creating the IncrementalSiteIDCreation registry entry in the subkey HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\InetMgr\Parameters with the data type REG_DWORD and the value set to 0x1.

   For more information about configuring the Web site identification number see Configure the Web Site Identification Number.

3. Create the Web site on the target server.

   Configure the Web site to have the same configuration as the corresponding Web site on the source server. For more information about how to create a Web site, see Create a Web Site.

4. If the Web site on the source server is FrontPage extended, then configure the Web site on the target server to be FrontPage extended.

   For more information about how to configure a Web site to be FrontPage extended see Configure a Web Site to be FrontPage Extended.

# Creating Virtual Directories on the Target Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For each virtual directory within each Web site on the source server, you must create a corresponding virtual directory on the target server. A *virtual directory* is a folder name, used in an address, which corresponds to a physical directory on the Web server or a Universal Naming Convention (UNC) location. This is also sometimes referred to as *URL mapping*. Virtual directories are used to publish Web content from any folder not located in the home directory of the Web site. When clients access content in a virtual directory, the content appears to be in a subdirectory of the home directory even though it is not.

For security reasons, you might want to move the Web site content to a different disk volume during the migration process. You can move the content to another disk volume on the target server or to a shared folder on a separate server. You can use virtual directories to specify the UNC name for the location where the content is placed, and provide a user name and password for access rights.

For each virtual directory in each Web site on the source server, create a corresponding virtual directory on the target server by completing the following steps:

1. Create the folder on the target server to contain the virtual directory content.

   Create the folder in the same location on the target server unless you are placing the content on a different disk volume than the source server or you are using a UNC share to store the content. Ensure that you create the folder in a secure manner that does not compromise the security of the target server.

   For more information about securing virtual directories, see "Preventing Unauthorized Access to Web Sites and Applications" in Securing Web Sites and Applications.

2. Create the virtual directory under the appropriate Web site on the target server.

   For more information about how to create virtual directories, see Create a Virtual Directory in Appendix A: IIS Deployment Procedures.

# Migrating Web Site Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For each Web site and virtual directory on the source server, you must migrate the content to the corresponding Web site and virtual directory on the target server. You can migrate the content from the source server to the target server by using one of the following methods:

- Run the **Xcopy** command to migrate Web site content to the target server on an intranet or internal network.
- Use Windows Explorer to migrate Web site content to the target server on an intranet or internal network.
- Use the **Copy Project** command in Microsoft Visual Studio® .NET to migrate Web site content to the target server on an intranet or internal network, if the application has been developed by using Visual Studio .NET.

  | **Note** |
  | --- |
  | Front Page Server Extensions must be installed on the Web server to use the **Copy Project** command. |

- Use the **Publish Web** command in FrontPage to migrate Web site content to the target server on an intranet or over the Internet, if the Web site has been developed using FrontPage.

  For more information about how to publish Web site content on the target server by using FrontPage, see Web Site Content with FrontPage in Appendix A: IIS Deployment Procedures.

# Configuring Web Site Application Isolation Settings

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Based on the application isolation mode settings of the target server, you need to configure the application isolation settings for each migrated Web site. Configure the Web site application isolation settings so that the Web sites provide the highest possible security and availability.

Configure the Web site applications isolation settings by completing the following steps for each Web site on the source server:

1. Document the current application isolation settings for each Web site on the source server.

2. When the target server is configured for IIS 5.0 isolation mode, configure the target server to use the same the isolation settings as the source server.

3. When the target server is configured for worker process isolation mode, convert the isolation settings on the source server to application pool settings on target server.

# Documenting the Current Application Isolation Settings on the Source Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you configure the application isolation settings, document the existing application isolation settings of the Web sites and applications that are hosted on the source server. Later in the migration process, you will use these settings for configuring the application isolation mode for your Web sites and applications.

For each Web site and application currently running on the server, document the following:

**Application isolation settings**
Earlier versions of IIS can host Web sites and applications in pooled or isolated process configurations. For information about how to view the current application isolation mode, see View Application Isolation Configuration.

If you are running IIS 4.0 on Windows NT Server 4.0, your applications are isolated in one of the following ways:

- In-process (running in-process with Inetinfo.exe)
- Isolated (running under MTS)

If you are running IIS 5.0 on Windows 2000, your applications are isolated in one of the following ways:

- In-process (running in-process with Inetinfo.exe)
- Pooled (running in the pooled COM+ application)
- Isolated (running in an isolated COM+ application)

**Process identity that is used by the Web site or application**
Each Web site or application configured in High isolation, or pooled isolation, uses a configurable *identity*. An identity is a user account that provides a security context for worker process servicing the Web site or application. The identity can be used to secure content, by using NTFS permissions or data, such as data stored in Microsoft SQL Server™. For more information about how to view the identity for each Web site or application, see View Web Site and Application Process Identities.

| **Note** |
| --- |
| All Web sites and applications that are configured to run in the Inetinfo.exe process run under the security context of LocalSystem. |

# Configuring Application Isolation Settings in IIS 5.0 Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When the target Web server is configured to run in IIS 5.0 isolation mode, configure the application isolation settings on the target server identically to the settings on the source server. Web sites and applications on a Web server running in IIS 5.0 isolation mode can be configured with the following application isolation settings:

- Low (in-process).
- Medium (pooled).
- Low (isolated).

If the identity on the source server is an account local to the source server, you need to create a service account.

Configure the application isolation settings when IIS 6.0 is configured to run in IIS 5.0 isolation mode by completing the following steps:

1. Review the application isolation settings on the source server, documented earlier in the migration process.

   For more information about how the application isolation settings were documented, see Documenting the Current Application Isolation Settings on the Source Server.

2. Create any required local service accounts used for application isolation identities on the target server.

   When the application pool identity is a service account that is local to the source server, you need to create a new service account, or designate an existing service account, on the target server. Create the service account in Active Directory to:

   - Provide centralized administration of the account.
   - Provide stronger security because the account is stored in Active Directory rather than locally on the Web server.
   - Allow more than one Web server (for instance, in a Web farm) to use the same service account for the same instance of the application pool on other Web servers.

   For more information about how to create a service account to be used as an identity, see Create a Service Account.

3. Configure the application isolation settings for the Web sites on the target server to be identical to the settings in Step 1.

   For more information about how to configure the application isolation settings for a Web site, see Configure Application Isolation Settings for IIS 5.0 Isolation Mode.

4. Configure the application process identities for the Web sites on the target server to be identical to the settings in Step 1.

   For more information about how to configure the application process identities for the Web site, see Configure Application Identity for IIS 5.0 Isolation Mode.

# Configuring Application Isolation Settings in IIS 6.0 Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When the target server is configured to use worker process isolation mode, you need to configure the application isolation settings to closely approximate their configuration in IIS 5.0 isolation mode by assigning them to *application pools*. An application pool is a grouping of one or more Web sites or applications served by one or more worker processes. You might need to apply additional configurations so that the applications retain their original isolation settings.

After converting to worker process isolation mode, all applications run in the preexisting application pool named "DefaultAppPool." If all of the applications run in the same process in the previous version of IIS, then they all are assigned to the default application pool.

However, if any one of the applications in the same application pool fails, the other applications can be adversely affected. For this reason it is recommended that you isolate your applications into separate application pools whenever possible.

Configure Web sites and applications to run in their own application pool by completing the following steps:

**For each Web site or application configured in High isolation in IIS 5.0**

1. Create a new application pool to be used by the Web site or application.

   For information about how to create application pools, see Isolate Applications in Worker Process Isolation Mode.

2. If the Web site or application previously ran under an identity that is still required by the Web site or application, configure the application pool to use that same identity.

   For information about how to configure the identity for an application pool, see Configure Application Pool Identity.

3. Assign the Web site or application to the new application pool.

   For information about how to assign the Web site to the new application pool, see Isolate Applications in Worker Process Isolation Mode.

**For each Web site or application configured in Low or Medium isolation in IIS 5.0**
In earlier versions of IIS, applications ran in-process as DLLs in Inetinfo.exe (Low isolation) and the default process identity (account that the application runs under) was LocalSystem. With worker process isolation mode in IIS 6.0, applications never run in Inetinfo.exe. However, any applications that are not explicitly assigned to an application pool are assigned to the default application pool, which runs under the NetworkService process identity by default. Because LocalSystem has the same permissions and user rights as a member of the Administrators group, run Web sites and applications under the security context of the NetworkService account.

For each Web site or application that ran in Low or Medium isolation in IIS 5.0, do one of the following:

- When the Web site or application is able to function under the identity of the NetworkService account in the default application pool, continue to host the Web sites or applications in the default application pool, named "DefaultAppPool."

- When the Web site or application is unable to function under the identity of the NetworkService account in the default application pool, perform the following steps:

  1. Create a new application pool.

  2. Create a service account to be used as the identity for the application pool.

     For more information about how to create a service account to be used as an identity for an application pool, see Create a Service Account.

3. Configure the application pool identity to use the service account.

   For more information about how to configure the identity for an application pool, see Configure Application Pool Identity.

4. Place the Web site or application in the new application pool.

# Configuring IIS 6.0 Properties after Migration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Up to this point in the migration process, you have migrated the Web site content and configuration settings from the source server — either manually or with the IIS 6.0 Migration Tool. However, you might need to further configure the IIS 6.0 properties on the target server so that the Web sites run as they did before they were migrated. In addition, you should configure your target server even further to utilize the enhanced security and availability capabilities of IIS 6.0.

Figure 6.7 illustrates the process for configuring the IIS 6.0 properties on the target server.

Figure 6.7 Configuring IIS 6.0 Properties

# Configuring IIS 6.0 Properties That Reference Local User Accounts

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The configuration of IIS and the Web sites on the source server can reference user accounts that are stored in the local account database on the source server. These accounts that are stored locally on the Web server are known as *local user accounts*. Local user accounts are valid only on the Web server where they are stored, not on any other Web servers.

As a result, when IIS, or any of the Web sites on the source server, reference local user accounts you must configure IIS 6.0 and the Web sites on the target server to reference:

- Domain-based user accounts that you create
- Local user accounts that you create on the target server

For each configuration that references a local account on the source server, you need to do the following on the target server:

1. Create, or designate, a domain-based or local user account that you can use to configure IIS.

   For more information about creating a service account that is domain-based or local to the target server, see Create a Service Account.

2. Modify the IIS 6.0 properties, Web site properties, or content configuration settings, based on the type of property that you are configuring.

   The types of IIS 6.0 properties, Web site properties, or content configuration settings that can reference or use local user accounts include:

   - **NTFS permissions assigned to Web content**. Grant the same NTFS permissions to the account created in step 1on the target sever as were granted to the local user account on the source server. For more information about granting NTFS permission to content, see Configure NTFS Permissions.
   - **Anonymous accounts for Web sites**. Configure the anonymous account identity for a Web site to use the account created in Step 1 on the target server. For more information about configuring the anonymous account identity, see Configure Anonymous User Identity.
   - **Application isolation settings**. Configure the application isolation identity based on the application isolation mode configured for the server.

     When the target server is configured to run in worker processor isolation mode, configure the identity properties of the application pools. For more information about configuring the application isolation settings when the target server is configured for worker process isolation mode, see Configure Application Pool Identity.

     When the target server is configured to run in IIS 5.0 isolation mode, configure the identity properties of the COM+ applications that correspond to the Web site. For more information about configuring the application isolation settings when the target server is configured for IIS 5.0 isolation mode, see Configure Application Isolation Settings for IIS 5.0 Isolation Mode.

# Configuring IIS 6.0 Web Service Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Many Web sites and applications that are hosted on IIS 6.0 have extended functionality beyond static Web pages, including the generation of dynamic content. Providing dynamic content and other enhanced capabilities requires executable code, such as ASP, ASP.NET, and ISAPI extensions. The handlers that extend IIS functionality beyond serving static pages are known as *Web service extensions*.

If you installed IIS 6.0 as described earlier in this section, all Web service extensions are disabled by default. If you used another method to install IIS 6.0, such as using Manage Your Server, the configuration of IIS might be different.

Enabling all of the Web service extensions ensures the highest possible compatibility with your Web sites. However, enabling all of the Web service extensions creates a security risk because it increases the attack surface of IIS by enabling functionality that might be unnecessary for your server.

Web service extensions allow you to enable and disable the serving of dynamic content. *MIME types*allow you to enable and disable the serving of static content. For more information about enabling and disabling the serving of static content, see Configuring MIME Types later in this section.

| **Tip** |
| --- |
| If the appropriate Web service extension is not enabled, the Web server returns a 404 error to the client when attempting to serve the dynamic content. When the 404 error is returned as a result of a Web service extension not being enabled, a 404.2 error entry is placed in the IIS log. For more information about troubleshooting IIS 6.0, see Troubleshooting in IIS 6.0. |

Configure the Web service extensions by completing the following steps:

1. Enable the essential predefined Web service extensions based on the information in Table 6.3.

   **Table 6.3 Predefined Web Service Extensions**

   | Web Service Extension | Description |
   | --- | --- |
   | Active Server Pages | Enable this extension when one or more of the Web sites or applications contains ASP content. |
   | ASP.NET version 1.1.4322 | Enable this extension when one or more of the Web sites or applications contains ASP.NET content. |
   | FrontPage Server Extensions 2002 | Enable this extension when one or more of the Web sites are FrontPage extended. |
   | Internet Data Connector | Enable this extension when one or more of the Web sites or applications uses the Internet Data Connector (IDC) to display database information (content includes .idc and .idx files). |
   | Server-Side Includes | Enable this extension when one or more of the Web sites uses server-side include (SSI) directives to instruct the Web server to insert various types of content into a Web page. |
   | WebDAV | Enable this extension when you want to support Web Distributed Authoring and Versioning (WebDAV) on the Web server, but it is not recommended for dedicated Web servers. |

2. For each Web service extension that is used by your applications and is not a one of the default Web service extensions, add a new entry to the Web service extensions list and configure the status of the new entry to **Allowed**.

   For example, one of your applications might use an ISAPI extension to provide access to a proprietary database. Set the ISAPI extension used by the application to **Allowed** to explicitly grant it permission to run. For information about how to add a Web service extension to the list, see Configure Web Service Extensions.

3. Use a Web browser on a client computer to verify that the Web sites and applications run on the server.

# Configuring MIME Types in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 serves only the static files with extensions that are registered in the Multipurpose Internet Mail Extensions (MIME) types list. IIS 6.0 is preconfigured to recognize a default set of global MIME types, which are recognized by all configured Web sites. You can define MIME types at the Web site and directory levels, independently of one another or the types defined globally. IIS also allows you to change, remove, or configure additional MIME types. For any static content file extensions used by the Web sites hosted by IIS that are not defined in the MIME types list, you must create a corresponding MIME type entry.

Configure the MIME types after migration by completing the following steps:

1. For each static file type used by your Web site, ensure that an entry exists in the MIME types list.

   When your application uses the standard MIME types that are included in IIS 6.0, no new MIME types entry is required. For information about how to add a MIME type to the MIME types list, see Configure MIME Types.

2. Use a Web browser on a client computer to verify that the Web sites and applications run on the server.

# Migrating Server Certificates for SSL

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you use Secure Sockets Layer to encrypt confidential information exchanged between the Web server and the client, you must migrate the server certificate from the source server to the target server, install the certificate on the target server, and then configure the Web site to use the certificate.

| **Note** |
| --- |
| Server certificates are installed on the Web server and typically require no additional configuration on client servers. Server certificates allow clients to verify the identity of the server. Alternatively, some Web sites and applications might require client certificates. Client certificates are installed on the client servers and allow the server to authenticate the clients. For more information about configuring client certificates, see Certificates_IIS_SP1_Ops. |

Migrate the server certificate for Secure Sockets Layer (SSL) by completing the following steps for each Web site and application that uses SSL:

1. Export the server certificate for the Web site from the source server.

   For more information about exporting a server certificate, see Export a Server Certificate.

2. Install the server certificate to be used by the Web site on the target server.

   For more information about installing the server certificate on the Web server by using the Certificate MMC snap-in, see Install a Server Certificate.

3. Assign the server certificate to the Web site.

   For more information about assigning the server certificate to the Web site, see Assign a Server Certificate to a Web Site.

# Migrating FrontPage Users and Roles

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When the source server has Web sites that are FrontPage extended and FrontPage roles have been assigned to the Web site users, you need to migrate the FrontPage roles to the target server. The FrontPage roles control the types of access that users have on FrontPage extended Web sites. FrontPage 2002 Server Extensions are administered through the Microsoft SharePoint™ Team Services HTML administration tool, which is installed with FrontPage 2002 Server Extensions.

The predefined FrontPage roles include the following:

- Administrator. Users assigned this role can view, add, and change all server content; and manage server settings and accounts.
- Advanced author. Users assigned this role can view, add, and change pages, documents, themes, and borders; and recalculate hyperlinks.
- Author. Users assigned this role can view, add, and change pages and documents.
- Contributor. Users assigned this role can view pages and documents, and view and contribute to discussions.
- Browser. Users assigned this role can view pages and documents.

In addition to the predefined FrontPage roles, custom FrontPage roles might be defined on the source server.

Migrate FrontPage users and roles by completing the following steps:

1. Identify the FrontPage roles on the source server and compare them to the FrontPage roles on the target server.
2. Create any FrontPage roles on the target server that exist on the source server but do not exist on the target server.
3. For each FrontPage user on the source server that is local to the source server, create a corresponding user on the target server, and then assign that user the same FrontPage roles that are assigned to the corresponding user on the source server.
4. For each FrontPage user on the source server that is in Active Directory, assign the user the same FrontPage roles on the target server.

For more information about configuring the FrontPage 2002 Server Extensions users and roles, see Configure FrontPage Server Roles. For more information about administering FrontPage 2002 Server Extensions, see Installation.

# Configuring IIS 6.0 for Hosting ASP.NET Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you migrated any ASP.NET applications to the target server, you need to configure IIS 6.0 to use the correct version of the .NET Framework, and you must configure the .NET Framework to support your applications.

Configure IIS to Host ASP.NET Applications

Configure IIS 6.0 to host ASP.NET applications by completing the following steps:

1. Configure IIS 6.0 to use the correct version of the .NET Framework.

2. Configure the .NET Framework.

3. Review how ASP.NET applications run in each application isolation mode.

4. Migrate Machine.config attributes to IIS 6.0 metabase property settings.

# Configuring IIS to Use the Correct Version of the .NET Framework

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you have migrated ASP.NET applications that were developed with version 1.0 of the .NET Framework, you might have to install version 1.0 of the .NET Framework on the target server to ensure that your applications continue to function properly. After migration, version 1.1 of the .NET Framework is installed on the target server and the applications are configured to use version 1.1 of the .NET Framework. After installing version 1.0 of the .NET Framework, both version 1.0 and 1.1 of the .NET Framework are installed on the target server. This is referred to as *side-by-side support*.

Running versions 1.0 and 1.1 of the .NET Framework side-by-side is only supported when IIS is configured to run in IIS 5.0 isolation mode. If you have already configured IIS to run in worker process isolation mode, then you can only use version 1.1 of the .NET Framework on the target server. In most cases, ASP.NET applications function correctly with version 1.1 of the .NET Framework. For more information about possible application incompatibilities when migrating from version 1.0 to version 1.1 of the .NET Framework, see Determining Application Compatibility with the .NET Framework earlier in this section. When your ASP.NET application is incompatible with version 1.1 of the .NET Framework, configure the application to use version 1.0 of the .NET Framework and configure IIS to run in IIS 5.0 isolation mode.

You can configure each ASP.NET application to use a specific version of the .NET Framework by registering a *script map* in IIS for the application. A script map associates a file name extension and HTTP verb with the appropriate ISAPI for script handling. For example, when IIS receives a request for a .aspx file, the script map for the corresponding application directs IIS to forward the requested file to the appropriate version of the ASP.NET ISAPI for processing.

The script map for each ASP.NET application can be applied directly to an application, or inherited from a parent application. However, ASP.NET supports only one version of the .NET Framework for each application pool. For more information about how to configure the script map for an ASP.NET application, see Configure an ASP.NET Application for ASP.NET.

# Configuring the .NET Framework for IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The configuration method for the .NET Framework is determined by the application isolation mode that you use to configure IIS 6.0. Table 6.4 lists the methods for configuring the .NET Framework that are associated with each IIS 6.0 application isolation mode.

**Table 6.4 Methods for Configuring the .NET Framework**

| Application Isolation Mode | Configuration Method for the .NET Framework |
|---|---|
| IIS 5.0 isolation mode | Configured by making changes to the Machine.config file in the *%systemroot%*\Microsoft.NET\Framework*VersionNumber*\Config folder. |
| Worker process isolation mode | Configured by making changes to the IIS 6.0 metabase. |

When IIS 6.0 is configured to run in IIS 5.0 isolation mode, the .NET Framework uses the **<processModel>** section of the Machine.config file (in the *%systemroot%*\Microsoft.NET\Framework*versionNumber*\Config folder) for its configuration and no additional steps are required.

However, if you configured IIS 6.0 to run in worker process isolation mode, the .NET Framework ignores the **<processModel>** section of the Machine.config file, and instead gets its process configuration from the IIS 6.0 metabase. Because the migration process does not migrate the existing settings in the Machine.config file, you must manually convert any settings required by the ASP.NET applications.

For information about how to convert the Machine.config attribute settings to IIS 6.0 metabase property settings, see Migrating Machine.config Attributes to IIS 6.0 Metabase Property Settings later in this section. For more information about configuring IIS 6.0 for ASP.NET applications, see Deploying ASP.NET Applications in IIS 6.0.

# Reviewing How Applications Run in Each Application Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When running IIS 6.0 in worker process isolation mode, ASP.NET applications use the W3wp.exe worker process and application pool properties, which are stored in the IIS 6.0 metabase. When you configure IIS 6.0 to run in IIS 5.0 isolation mode, ASP.NET applications use the ASP.NET request processing model, Aspnet_wp.exe, and configuration settings. These configuration settings are stored in the Machine.config file.

Behavior of ASP.NET Applications That Are Running in IIS 5.0 Isolation Mode

By default, ASP.NET applications are configured to run in worker process isolation mode. If your application can only run in the ASP.NET process model, you must configure the server to run in IIS 5.0 isolation mode to be able to run the application on IIS 6.0. When IIS 6.0 is configured to run in IIS 5.0 isolation mode, ASP.NET applications behave as follows:

- The applications run within Aspnet_wp.exe.

  Aspnet_wp.exe is a request processing model that is similar to worker process isolation mode, and it contains worker process management capabilities similar to the WWW service in IIS 6.0. Aspnet_wp.exe includes most of the IIS application management features, such as recycling, health detection, and *processor affinity*. Processor affinity is the ability to force worker processes to run on specific microprocessors.

- The configuration settings are stored in the Machine.config file.

  When IIS 6.0 is running in IIS 5.0 isolation mode, the configuration settings for ASP.NET applications are managed by modifying the Machine.config file, not the IIS metabase file. Because there is no administrative console for the Machine.config settings, any configuration settings for ASP.NET must be made directly to the Machine.config file.

| **Important** |
| --- |
| In IIS 5.0 isolation mode, the .NET Framework ignores any configuration changes made in the IIS metabase. Administrative consoles, such as IIS Manager, make changes to the IIS 6.0 metabase, but those changes are not read by the .NET Framework. |

When IIS 6.0 is configured to run in IIS 5.0 isolation mode, your ASP.NET applications should behave as they did in IIS 5.0. However, incompatibilities can result when running version 1.1 of the .NET Framework. For more information about configuring IIS to support ASP.NET applications that use version 1.0 of the .NET Framework, see Overview of Deploying ASP.NET Applications in IIS 6.0.

Behavior of ASP.NET Applications That Are Running in Worker Process Isolation Mode

When IIS 6.0 is configured to run in worker process isolation mode, ASP.NET applications behave as follows:

- The process model within the ASP.NET ISAPI extension is disabled, and ASP.NET applications run using worker process isolation mode in IIS 6.0.

  In this configuration, the ASP.NET application runs in worker process isolation mode like any other application, such as an ASP application. In addition, IIS 6.0 provides all of the management features such as recycling, health detection, and processor affinity.

- The ASP.NET ISAPI extension is configured by a combination of configuration settings that are stored in the IIS metabase (MetaBase.xml) and configuration settings in the Machine.config file.

  When IIS 6.0 is running in worker process isolation mode, the majority of the application configuration settings are stored in the IIS metabase. You can adjust these settings directly in MetaBase.xml or from administrative consoles, such as IIS Manager, or scripts.

However, if there are existing settings in the **<processModel>** section of the Machine.config file, those configuration settings must be converted to the appropriate application pool settings when the Web server is configured to run in worker process isolation mode Additionally, there are other configuration settings that are still modified in the Machine.config file, regardless of the application isolation mode. For more information about converting Machine.config attributes to worker process isolation mode settings, see Migrating Machine.config Attributes to IIS 6.0 Metabase Property Settings.

When IIS 6.0 is configured in worker process isolation mode, your ASP.NET applications should behave as they did on IIS 5.0. Before deploying your ASP.NET applications on your production Web servers, test compatibility with IIS 6.0 running in worker process isolation mode and version 1.1 of the .NET Framework. For more information about determining application compatibility with IIS 6.0 running in worker process isolation mode, see Determining Application Compatibility with Worker Process Isolation Mode. For more information about determining compatibility with version 1.1 of the .NET Framework see Determining Application Compatibility with the .NET Framework.

If you determine that your ASP.NET applications are incompatible with worker process isolation mode, reconfigure IIS to run in IIS 5.0 isolation mode. If your ASP.NET applications are incompatible with version 1.1 of the .NET Framework, configure IIS to use version 1.0 of the .NET Framework with your ASP.NET application.

For more information about configuring IIS 6.0 to run in IIS 5.0 isolation mode, see Configure Application Isolation Modes. For more information about configuring IIS to use version 1.0 of the .NET Framework with your ASP.NET application, see Overview of Deploying ASP.NET Applications in IIS 6.0.

# Migrating Machine.config Attributes to Metabase Property Settings

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When IIS 6.0 is configured to run in IIS 5.0 isolation mode, the .NET Framework uses the **<processModel>** section of the Machine.config file (in the *%systemroot%*\Microsoft.NET\Framework*versionNumber*\Config folder) for its runtime configuration. When the target server is running in IIS 5.0 isolation mode, you do not need to convert the attribute configuration settings on the source server to their equivalent IIS 6.0 metabase property settings on the target server so you can proceed to the next step in the migration process. To proceed to the next step in the migration process, see Determining Whether to Run the IIS Lockdown Tool and UrlScan.

However, if you configured IIS 6.0 to run in worker process isolation mode, the .NET Framework ignores the **<processModel>** section of the Machine.config file, and instead gets its process configuration from the IIS 6.0 metabase. Because the migration process does not migrate the existing settings in the Machine.config file, you must manually migrate any settings that are required by your ASP.NET applications.

For information about how to migrate the Machine.config settings to IIS 6.0 metabase settings, see Migrating Machine.config Attributes to IIS 6.0 Metabase Property Settings.

# Running the IIS Lockdown Tool and UrlScan

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS Lockdown Tool and UrlScan are IIS security related programs designed for IIS 5.1 and earlier. Each tool provides different types of protection for earlier versions of IIS. The IIS migration process does not install the IIS Lockdown Tool and UrlScan on the target server.

IIS Lockdown Tool

The IIS Lockdown Tool is provided to assist administrators in configuring optimal security settings for existing IIS servers. You cannot install the IIS Lockdown Tool after migration because all of the default configuration settings in IIS 6.0 meet or exceed the security configuration settings made by the IIS Lockdown Tool.

UrlScan

UrlScan is a tool that is provided to reduce the attack surface of Web servers running earlier versions of IIS. By default, IIS 6.0 has features that significantly improve security by reducing the attack surface of the Web server. UrlScan provides flexible configuration for advanced administrators, while maintaining the improved security in IIS 6.0. When you need this flexibility in configuring your Web server, you can run UrlScan on IIS 6.0.

For more information about determining whether to run UrlScan after migrating your server to IIS 6.0, and to download the latest version of the URLScan tool, see the Knowledge Base article 307608, Using UrlScan on IIS.

# Performing Application-Specific Migration Tasks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When no setup or provisioning scripts exist for your applications, you might need to perform additional application-specific migration tasks, whether you have migrated content and metabase information manually or with the IIS 6.0 Migration Tool. Some of these tasks involve the modification of application code and might require the assistance of the application developers. Depending on your application, you might need to perform any combination of the steps in Figure 6.8.

**Figure 6.8 Performing Application-Specific Migration Tasks**

# Modifying Application Code for Compatibility with Windows Server 2003 and IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If any application code needs to be changed or recompiled to run on Windows Server 2003, you must make those changes manually. The most common application code changes include the following:

- Code that references Windows platform components or APIs no longer supported in Windows Server 2003.
- Code that references IIS metabase properties that have changed or are no longer supported in IIS 6.0.
- Code that is incompatible with worker process isolation mode.

# Modifying References to Windows Platform Components and APIs No Longer Supported in Windows Server 2003

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Applications developed to run on earlier versions of Windows server operating systems and IIS can call APIs that are not supported in Windows Server 2003 and IIS 6.0. Usually these APIs are replaced with newer APIs that provide additional functionality.

If your Web sites and applications use an API that is not supported in Windows Server 2003 and IIS 6.0, you must modify your code to use an API that provides the same functionality and is supported in Windows Server 2003 and IIS 6.0.

For example, the APIs supported by the Collaboration Data Objects for Windows NT Server 4.0 (CDONTS) DLL are not supported in Windows Server 2003. The functionality provided by CDONTS is supported by Collaboration Data Objects for Windows2000 (CDOSYS), which, in turn, is supported by Windows Server 2003. Therefore, if your applications use CDONTS, you can modify your code to use CDOSYS instead. For more information about modifying your application to use CDOSYS, see Collaboration Data Objects Roadmap.

# Modifying References to IIS Metabase Properties

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Some metabase properties that were used to configure features in earlier versions of IIS are no longer supported in IIS 6.0. Because some features are eliminated, or implemented differently in IIS 6.0, the corresponding unused metabase properties are not referenced by any code in IIS 6.0. In cases where the feature is implemented differently in IIS 6.0, new metabase properties have been created to replace the obsolete, or unused, properties.

In addition, there is one IIS 5.0 metabase property — **CPUResetInterval** — whose behavior has changed because of architectural changes made to IIS 6.0.

To determine whether any of your Web sites, applications, or setup programs reference these changed or unsupported IIS metabase properties, see Appendix B: Changes to Metabase Properties in IIS 6.0. You can then follow the recommendations associated with each changed metabase property listed in this appendix to accommodate functionality changes in IIS 6.0.

| **Tip** |
| --- |
| The metabase properties that are no longer supported in IIS 6.0 are not available in IIS 6.0, even when IIS 6.0 is configured to run in IIS 5.0 isolation mode. |

# Modifying Applications To Be Compatible with Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Most applications that were developed to run on earlier versions of IIS run in worker process isolation mode without modification. However, you might need to modify your applications to make them compatible with worker process isolation mode. For more information about the types of modifications that you might need to make to your applications, see Evaluating Application Changes Required for Worker Process Isolation Mode earlier in this section.

Your applications can require other modifications that are not described in this section because of the myriad of approaches to developing applications. For the most current information about modifying your applications to be compatible with worker process isolation mode, see IIS 6.0 Application Isolation Modes.

# Installing Additional Software Required by Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Some of your applications might require or be dependent upon additional software that is not in the same folder with the Web site content. This software can be developed by your organization, by Microsoft, or by other organizations. You must install this software on the target server by running the setup or installation program that accompanies the software.

Examples of this type of software include software that creates reports, integrates databases with dynamic content generation, or provides connectivity with applications running on other servers with non-Microsoft operating systems.

# Migrating MTS Packages, COM Objects, and COM+ Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In addition to installing any software that you installed earlier in the migration process, there can be MTS packages, COM objects, and COM+ applications that need to be migrated. Table 6.5 lists the tasks that you need to complete to migrate MTS packages, COM objects, and COM+ application from earlier version of Windows.

**Table 6.5 Migrating MTS Packages, COM Objects, and COM+ Applications**

| Source Server | Target Server | Migration Tasks |
|---|---|---|
| MTS packages on Windows NT 4.0 Server | COM+ applications | Convert the MTS package to a COM+ application. |
| COM objects | COM objects | Copy COM object files (.dll or .exe) from the source server to the target sever and register the COM object by running the regsrv32 command. |
| COM+ applications on Windows 2000 Server | COM+ applications | Create the COM+ application on the target server and use the same configuration on the target server that existed on the source server. |

For more information about migrating MTS packages, COM objects, and COM+ applications to Windows Server 2003, see the following articles: COM: Delivering on the Promises of Component Technology, and Microsoft .NET/COM Migration and Interoperability.

An example of registering a COM object that is running on the source server is CDONTS. If you decide to not modify your code to us CDOSYS instead of CDONTS, you must copy the Cdonts.dll file from the source server to the target server and then register Cdonts.dll with Windows Server2003. For more information about how to migrate CDONTS, see Migrate CDONTS.

# Modifying ODBC Data Connection Strings and DSNs

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If your application establishes database connectivity through an ODBC data connection string or through an ODBC data source name (DSN), you must do any combination of the following:

- Manually modify ODBC DSNs when the ODBC data connection string references a database that is stored on the source server and the database has not been migrated to the target server.
- Manually create a system ODBC DSN on the target server for each system ODBC DSN on the source server.

**Modifying ODBC DSNs**

ODBC data connection strings might need to be modified if they reference the database or are migrated to a different location. For more information about modifying ODBC data connection strings, see Connecting to a Data Source or Driver.

**Creating System ODBC DSNs**

In addition, if you have system ODBC DSNs that are defined on the source server, you need to create corresponding ODBC DSNs on the target server. Table 6.6 lists methods for administering ODBC DSNs on different Windows server operating systems. You can administer ODBC DSNs on the source server and the target server by using the methods listed in this table.

**Table 6.6 Administering ODBC DSNs on Source Servers and Target Servers**

| Operating System | Administered Through | Additional Information |
|---|---|---|
| Windows Server 2003 | Data Sources (ODBC) in Administrative Tools | For more information about using Data Sources (ODBC) in Windows Server 2003, see Help and Support Center for Windows Server 2003. |
| Windows 2000 Server | Data Sources (ODBC) in Administrative Tools | For more information about using Data Sources (ODBC) in Windows 2000 Server, see Windows 2000 Server Help. |
| Windows NT 4.0 Server | ODBC Data Sources in Control Panel | For more information about using ODBC Data Sources in Windows NT 4.0 Server, see Help in the ODBC Data Source Administrator in the ODBC Data Sources, in Control Panel. |

# Creating IP Addresses That Are Used by Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can uniquely identify a Web site or application by associating the Web site or application with a unique IP address, a unique combination of an IP address and a TCP port number, or host headers. For Web sites and applications on the source server that are uniquely identified by IP addresses, you must create corresponding IP addresses on the target server and then configure the Web sites and applications to use the newly created IP addresses.

To create IP addresses that are used by applications, complete the following steps:

1. Determine which Web sites and applications on the source server are uniquely identified by IP addresses.

   For more information about how to determine which Web sites and applications on the source server are uniquely identified by IP addresses see Determine Web Sites Uniquely Identified by IP Addresses.

2. For each Web site and application identified in Step 1, assign new a new IP address to the TCP/IP properties of the network adapter in the target server that the clients use to access the Web sites and applications.

   For more information about how to assign a new IP addresses to the network adapter in the target server that the clients use to access the Web sites and applications see Assign Additional IP Addresses to a Network Adapter.

3. Configure the migrated Web sites and applications on the target server to use the IP addresses assigned in Step 2.

   For more information about how to configure the IP addresses assigned to Web sites and applications see Configure IP Address Assigned to Web Sites.

# Creating Users and Groups That Are Used by Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Web sites and applications on the source server might be accessed by accounts that are local to the source server. The local user and group accounts need to be created on the target server so that the accounts can access the Web sites and applications on the target server.

In cases where the users and groups that are used by the applications exist in Active Directory, no steps are required and you can continue to the next migration step. To continue to the next step in the migration process, see Creating Registry Entries for Applications.

Create the users and groups that are used by applications and are local to the source server by completing the following steps:

1. Identify the users and groups that are local to the source server.

2. For each group on the source server, create a corresponding group on the target server.

3. For each user on the source server, create a corresponding user on the target server.

4. For each user created in Step 3, assign the user to the same groups as the corresponding user on the source server.

   For more information about viewing the users and groups on the source server, see "Creating user and group accounts" in Windows 2000 Server Help and Windows NT Server 4.0 Help. For more information about creating users and groups in Windows Server 2003, see Create a Service Account.

5. For each user created in Step 3, assign the same user rights assigned to the corresponding user on the source server.

   For more information about assigning user rights to a user, see Grant User Rights to a Service Account.

6. Assign the same NTFS permissions for the content on the target server as the NTFS permissions for the content on the source server.

   For more information about configuring NTFS permissions on the target server, see Configure NTFS Permissions.

# Creating Registry Entries for Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Some applications save configuration information in the Windows registry. If the setup program or provisioning script creates the registry entries, run the setup program or provisioning script on the target server. Otherwise, you must manually identify the registry entries and then re-create them on the target server.

| **Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and then use the Registry Reference directly or connect to it on the Web at http://www.microsoft.com/reskit. |

Create application registry entries on the target server manually by completing the following steps:

1. Identify the registry entries required by the applications that are currently running on the source server.

   Earlier in the migration process, you identified the registry entries required by the applications on the source server. For more information about identifying registry entries, see Identifying Which Web Site and Application Components to Migrate earlier in this section.

2. Back up the registry entries on the source server that you identified in the previous step by using the registry editor Regedit.exe.

   For more information about backing up copies of registry entries, see Back Up and Restore Registry Entries.

3. Copy the .reg backup file, created in Step 2, to the target server.

4. Modify the .reg backup file created in the previous step to accommodate for changes in disk volume letters, such a F:, or paths to folders by completing the following steps:

   a. In Notepad, open the .reg backup file created in Step 2.

   b. Search for specific references to disk volume letters or paths that you want to change, and update them to reflect the disk volume letters or paths on the target server.

   c. Save the .reg file.

5. Restore the registry backup on the target server.

   For more information about restoring registry entries, see Back Up and Restore Registry Entries.

# Completing the Migration_IIS_SP1_Dep

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

At this point in the process, you have migrated your Web sites and applications to the target server and configured the IIS 6.0 properties to settings on the source server. Now you need to verify that the migration completed successfully, capture the current configuration of the target server, and enable client access to the target server. After you complete these last steps, your migration is complete. Figure 6.9 illustrates the process for completing the migration to IIS 6.0.

**Figure 6.9 Completing the Migration to IIS 6.0**

# Verifying That the Web Sites and Applications Migrated Successfully

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before deploying the target server to a production environment, verify that the Web site content and configuration information migrated successfully by completing the following steps:

1. Review the system log in Windows Server 2003 on the target server to determine whether any of the Web sites did not start.

   IIS 6.0 creates entries in the system log when a Web site fails to start for any reason. Search the System log on the target server for to determine if any errors occurred. For more information about how to troubleshoot Web sites that fail to start, see Troubleshooting in IIS 6.0.

2. Verify that the Web site content migrated to the target server.

   Compare the files and folders for each Web site on the target server with the original files and folders on the source server to determine whether the Web site content has been migrated correctly. Ensure that the number and size of the files and folders on the target server approximates the number and size of the same files on the source server.

3. Verify that the Web site configuration migrated to the target server.

   View the Web site configuration information for a random sampling of the Web sites that were migrated. Compare the Web site configuration on the target server with the corresponding Web site configuration on the source server. Ensure that the configuration for the Web sites has been migrated correctly.

4. Perform functional testing of the migrated Web sites and applications to ensure that the Web sites and applications behave as expected.

   You can find possible causes of application failure by reviewing the Windows Server 2003 and IIS 6.0 Migration Tool logs and application configuration, but the only way to accurately assess whether your Web sites and applications migrated successfully is to perform functional testing. Functional testing is designed to ensure that Web sites and applications are functioning correctly in the most common usage scenarios (for example URLs and inputs).

   Procedures for performing functional testing of Web sites and applications are beyond the scope of this section. For more complete information about general testing, go to the MSDN Library and search for "testing".

# Backing Up the Target Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you enable client access to the target server, perform a complete image backup of the target server. Performing this image backup provides you with a point-in-time snapshot of the Web server. If you need to restore the target server in the event of a failure, you can use this backup to restore the Web server to a known configuration.

| **Important** |
| --- |
| Do not proceed further unless you have a successful backup of the entire target server. Otherwise, you can lose Web sites, applications, or data that you migrated to the target server. |

For more information about how to back up the Web server, see Back Up and Restore the Web Server to a File or Tape.

# Enabling Client Access to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you have migrated your Web sites from the source server to the target server, you are ready to enable client access to the Web sites on the target server while maintaining the DNS entries to the source servers. After a period of time that meets your business needs, you can remove the DNS entries that point to the Web sites on the source server.

Enabling Client Access

Enable client access to the Web sites that are on the target server by completing the following steps:

1. Create the appropriate DNS entries for the Web sites and applications running on the target server. For more information about how to create DNS entries for your Web sites and applications see “Managing resource records” in Help and Support Center for Windows Server 2003.

2. Monitor client traffic to determine whether clients are successfully accessing the target server. For more information about how to monitor client traffic to Web sites on the target server, see Monitor Active Web and FTP Connections.

3. Establish a monitoring period, such as a few hours or a day, to confirm that clients accessing Web sites on the target server are experiencing response times and application responses that meet or exceed your requirements.

4. Remove the DNS entries that are pointing to the Web sites and applications on the source server. For more information about how to remove DNS entries for your Web sites and applications, see “Managing resource records” in Help and Support Center for Windows Server 2003.

5. Prevent new clients from accessing the Web sites on the source server by pausing the Web sites on the source server. For more information about how to pause Web sites on the source server, see Pause Web or FTP Sites.

6. Monitor client traffic to the Web sites on the source server to determine when clients are no longer accessing the source server. For more information about how to monitor client traffic to Web sites on the source server, see Monitor Active Web and FTP Connections.

7. When clients are no longer accessing the Web sites on the source server, decommission the hardware for the source server.

# Additional Resources About Migrating IIS Web Sites to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to this section.

# Migrating Apache Web Sites to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Migration* is the process of installing a Microsoft® Windows® Server 2003 operating system and Internet Information Services (IIS) 6.0 on a server and then moving or reinstalling existing Apache Web sites and applications to that server. Migrating Apache Web sites and applications to IIS 6.0 allows you to take advantage of the improved security, performance, and management provided by Windows Server 2003 and IIS 6.0. The migration process provides minimal outage of service to the users accessing the Web sites and applications, while ensuring that the existing configuration and content of the Web sites and applications are maintained.

**In This Section**

For information about migrating Web sites on earlier versions of IIS to IIS 6.0, see Migrating IIS Web Sites to IIS 6.0.

# Overview of Migrating Apache Web Sites to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache Web site migration process is completed with the *Apache to IIS 6.0 Migration Tool*. This tool is a set of configurable modules to migrate Apache Web sites — including FrontPage® Server Extensions from Microsoft, .htaccess files, and user directories — to servers running IIS 6.0 on Microsoft Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Datacenter Edition; and Windows® Server 2003, Web Edition. The tool is a Perl-based command-line utility that migrates both Web content and configuration settings.

The Apache to IIS 6.0 Migration Tool supports Apache versions 1.3.0–1.3.22, as well as the following Linux distributions:

- Red Hat software (Linux versions 6.0, 6.2, 7.0, 7.1, and 7.2)
- Mandrake Linux (versions 8.0, 8.1, and 8.2)
- SuSE (versions 7.3 and 8.0)

You can use the Apache to IIS 6.0 Migration Tool to migrate site content and configuration settings from a *source server* (a server running a supported version of Linux and Apache) to a *target server* (a server running a Windows Server 2003 operating system and IIS 6.0). You can perform the migration from the source server, the target server, or on an *intermediate computer*. The intermediate computer must have File Transfer Protocol (FTP) access to the source and target servers.

The Apache to IIS 6.0 Migration Tool migrates only the Apache Web site content and configuration. If the Apache Web site is made up of only static content, such as Hypertext Markup Language (HTML) pages, the migration can most likely be completed with a few simple steps. However, Apache Web sites containing dynamic content, such as PHP: Hypertext Preprocessor (PHP) or Common Gateway Interface (CGI) scripts, might need modifications to the code in the dynamic content after migration. In addition, any existing provisioning scripts or setup programs for the existing Apache Web sites typically require modifications after the migration process is complete. Because each organization has different provisioning scripts and setup programs, you need to review and make modifications based on input from your developers, and then test the Web site after completing the modifications. For more information about possible necessary modifications to dynamic content, see Determining Web Site Compatibility with IIS 6.0 later in this section.

For more information about the Apache to IIS 6.0 Migration Tool, including how to install it, see Preparing to Migrate to IIS 6.0 later in this section. For more information about the additional migration tasks that you must perform after running the Apache to IIS 6.0 Migration Tool, see Migrating Apache-Specific Extensions later in this section.

# Process for Migrating Apache Web Sites to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In addition to migrating the existing Web site content, the migration process automatically migrates the Web site configuration including FrontPage Server Extensions. Before performing the migration of the Web site, you need to evaluate the compatibility of the Apache Web sites with the software installed on your existing server, including dynamic content, database connections, and *external modules*. External modules are software components that are not shipped as a part of the Linux operating system.

If your Apache Web sites contain dynamic content or you want to further secure the Web sites, you can use the Apache to IIS 6.0 Migration Tool to customize the configuration of IIS 6.0 and migrate the dynamic content. Figure 7.1 illustrates the process for migrating existing Apache Web sites to IIS 6.0.

**Figure 7.1 Migrating Apache Web Sites to IIS 6.0**

| **Tip** |
| --- |
| To upgrade a Web farm, use the process described in this section to upgrade each server in the Web farm. |

Depending on your familiarity with Linux, Windows Server 2003, Apache, IIS 6.0, and the migration process, you might require less guidance through the migration process. The following quick-start guide provides a detailed overview of the Apache to IIS migration process described in this section. You can use this guide to help identify the steps of the migration process where you need additional information and skip the information with which you are already familiar. In addition, all of the procedures required to complete the migration process are documented in Appendix A: IIS Deployment Procedures.

**Prepare for Migration**

1. Determine Web site compatibility with IIS 6.0.
2. Determine application compatibility with worker process isolation mode by evaluating the differences between application isolation modes.
3. Identify the role of the Apache to IIS 6.0 Migration Tool in the migration process.
4. Select one of the following Apache to IIS 6.0 Migration Tool installation options:
    - The source server installation option
    - The target server installation option
    - The intermediate computer installation option

**Deploy the Target Sever**

1. Install Windows Server 2003.
2. Install IIS 6.0.
3. Configure the FTP service.

**Perform the Migration**

1. Install the Apache to IIS 6.0 Migration Tool:
    - Install the migration tool on computers running Linux.
    - Install the migration tool on computers running Windows.
    - Configure the target server for migration.
2. Verify that clients are not accessing the Web sites.
3. Migrate the Web site content.
4. Migrate the Web site configuration.
5. Recover from an interruption in the migration process:
    - Determine the cause of resolve any errors.
    - Restart the migration tool in recovery mode.

**Migrate Apache-Specific Extensions**

1. Migrate dynamic content.
2. Migrate database content and connectivity:
    - Migrate the database content.
    - Migrate the database connectivity.
3. Migrate external modules.

**Configure IIS 6.0 After Migration**

1. Configure Web service extensions.
2. Configure Multipurpose Internet Mail Extensions (MIME) types.
3. Configure Web site properties.
4. Configure server certificates for Secure Sockets Layer (SSL).
5. Back up the target server.

**Enable Client Access After Migration**

Enable client access to the Web sites on the target server.

# Preparing to Migrate to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before initiating the migration, ensure that existing Apache Web sites are compatible with IIS 6.0 and Windows Server 2003. In addition, determine if the existing Web sites are compatible with worker process isolation mode in IIS 6.0. Then, you must identify which steps in the migration process are automated by the Apache to IIS 6.0 Migration Tool and which steps you need to complete after running the tool. Finally, you must decide which option to use to install the tool.

**Figure 7.2 Preparing for Migration of Apache Web Sites to IIS 6.0**

# Determining Web Site Compatibility with IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you migrate to IIS, you must determine the compatibility of the Apache Web site with IIS 6.0. Because of architectural differences, Web sites hosted on Apache have different dependencies than Web sites hosted on IIS. For example, some PHP applications running on Apache use MySQL to connect to databases, whereas IIS Web sites use Microsoft ActiveX® Data Objects (ADO) or Open Database Connectivity (ODBC) to connect to databases. After you migrate an Apache Web site that uses MySQL for database connectivity, you must modify the Web site content to use ADO database connectivity.

Table 7.1 lists the Apache Web site components that you must consider before migrating the Apache Web site to IIS 6.0, along with brief descriptions of the compatibility issues, if any, that can result after migration.

**Table 7.1 Apache Web Site Component Migration Compatibility Issues**

| Web Site Component | Description | Compatibility Issues |
|---|---|---|
| Static content | Static content contains no executable code. Examples of static content include HTML, .jpg, and .gif files. | Static content should migrate to IIS 6.0 without any modifications. However, IIS 6.0 MIME types might need to be configured to enable static content file types that are not well known.<br><br>For more information about MIME types, see Configuring File MIME Types on IIS 6.0 later in this section. |
| Dynamic content | Dynamic content contains executable code. Examples of dynamic content include CGI and PHP files. | To run Apache dynamic content on IIS, you must do one of the following:<br>• Run the executable code on an appropriate environment that is compatible with IIS 6.0.<br>• Convert the executable code to an environment that is supported by IIS 6.0.<br><br>For more information, see Migrating Apache-Specific Extensions later in this section. |
| Database connectivity | Database connectivity provides a standardized method of connecting to various database systems. MySQL is the most common database connectivity standard used in Apache Web sites. | To provide database connectivity on IIS 6.0, you must do one of the following:<br>• Obtain a version of MySQL that is compatible with IIS 6.0.<br>• Convert the executable code so that it uses ADO. ADO is the database connectivity standard supported by IIS 6.0.<br><br>For more information, see Migrating Apache-Specific Extensions later in this section. |

| | | |
|---|---|---|
| External modules | External modules provide extended features to Apache Web sites. These components include Cold Fusion and Wpoison. | To use the features provided by these external modules, you must do one of the following:<br>• Obtain a version of the external module that is compatible with IIS 6.0.<br>• Convert the external module to IIS 6.0. For example, Wpoison is written in CGI and can be converted to run on IIS 6.0.<br><br>For more information, see Migrating Apache-Specific Extensions later in this section. |

# Determining Web Site Compatibility with Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 can run in one of two distinct modes of operation, which are called application isolation modes. *Application isolation* is the separation of applications by process boundaries that prevent the applications from affecting one another, and is configured differently for each of the two IIS isolation modes: IIS 5.0 isolation mode and worker process isolation mode.

*Worker process isolation mode* takes advantage of the redesigned architecture for IIS 6.0. This isolation mode runs all application code in an isolated environment; however, unlike earlier versions of IIS, IIS 6.0 provides isolation without a performance penalty because there are no added process hops. Worker process isolation mode is compatible with most existing Web sites and applications. Whenever possible, run IIS 6.0 in worker process isolation mode to take advantage of the enhanced performance and security in IIS 6.0. When IIS 6.0 is configured to use worker process isolation mode, the metabase property **IIs5IsolationModeEnabled** contains a value of **False**.

*IIS 5.0 isolation mode* provides compatibility for applications that depend upon the process behavior and memory model of IIS 5.0. Run IIS in this mode only when a Web site or application has compatibility issues when running in worker process isolation mode and you cannot resolve the problem. When IIS 6.0 is configured to use IIS 5.0 isolation mode, the metabase property **IIs5IsolationModeEnabled** contains a value of **True**.

**Important**

IIS 6.0 cannot run both application isolation modes simultaneously on the same server. Therefore, on a single server running IIS 6.0, you cannot run some Web applications in worker process isolation mode and others in IIS 5.0 isolation mode. If you have applications that require separate modes, you must run them on separate servers.

After you install the target server, IIS is configured to use worker process isolation mode by default. The only reason for configuring IIS to use IIS 5.0 isolation mode is if there are Apache extensions that run only in IIS 5.0 isolation mode. For example, if the preprocessor for the dynamic content in an Apache Web site is incompatible with worker process isolation mode, you must configure IIS to use IIS 5.0 isolation mode. Determine Web site compatibility, in particular Apache-specific extensions to the Web sites, with IIS in your lab before migrating your existing Apache Web sites. In most cases, IIS hosts the Web sites in worker process isolation mode without any problems.

For more information about how to migrate Apache-specific extensions and how to determine compatibility of these extensions with worker process isolation mode, see Migrating Apache-Specific Extensions.

**Note**

Identifying a complete list of potential incompatibilities that Web sites can experience with worker process isolation mode is beyond the scope of the content in this section. Even after following the guidelines in this section, you need to verify in your lab whether your Web sites are compatible with worker process isolation mode.

# Identifying the Role of the Migration Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you migrate Apache Web sites to IIS 6.0, you must know which steps of the migration process are automated by the Apache to IIS 6.0 Migration Tool and which steps you must complete manually. This will allow you to have the appropriate tools and resources available when you are ready to start the migration. In addition, you need to determine the configuration and placement of your Web site after running the tool. The automation provided by the Apache to IIS 6.0 Migration Tool is the same for static and dynamic content. However, depending on the content in your Apache Web site, further configuration might be required after running the tool.

The following steps in the Apache Web site migration process are automated by the Apache to IIS 6.0 Migration Tool:

**Copying of Web site content**
The migration tool creates a copy of the files and folders containing Web site content. The copied files are converted from standard UNIX text file format (end-of-line denoted by carriage return) on the server running Apache to standard Windows text file format (end-of-line denoted by carriage return and line feed characters) on the server running IIS. The Web site content is placed on the server running IIS in a location selected while running the tool.

**Translation of Web site configuration**
The configuration of the Apache Web server and individual Web sites is translated to the corresponding IIS Web server and Web site configuration settings in the IIS metabase.

**Migration of ~user directories**
~user directories are private virtual Web directories that contain individual user Web sites. The tool migrates the contents of these directories, creates corresponding users, and converts permissions found in these virtual Web directories.

**Translation of .htaccess permissions**
The .htaccess file sets permissions for access for the virtual Web directories on an Apache Web server. The permissions in this file are translated by the tool into the corresponding directory permissions in the NTFS file system.

**Migration of MIME types and port numbers**
MIME types define the types of *static* files that are served by the Web server. The tool automatically determines the MIME types defined on the Web server running Apache and then creates the associations of MIME types to extensions on the Web server running IIS.

**Migration of FrontPage Server Extensions**
The tool detects the presence of FrontPage 2000 Server Extensions and FrontPage 2002 Server Extensions on the Apache Web server; enumerates the Web sites and subweb sites; enumerates the FrontPage Server Extensions settings, users, and roles; creates the Web sites and subweb sites; and recalculates the links for each Web site and subweb site.

**Creation of status file**
The tool creates a file that contains the status of the migration steps completed by the tool. The status file can be used for confirming that the migration completed successfully or for troubleshooting any problems encountered while performing the migration with the tool.

The following steps in the Apache Web site migration process need to be completed after running the Apache to IIS 6.0 Migration Tool:

**Convert code within dynamic content**
Dynamic content, such as PHP or CGI, on Apache needs to be modified to run on IIS 6.0.

**Modify database connectivity within dynamic content**
For the Web sites and applications that have database connectivity, the content needs to be modified to use database connectivity provided by IIS 6.0 and Windows Server 2003.

**Migrate external modules used by Web sites**
After migration, you need to migrate external modules that are used by the Web sites and applications.

**Add Web service extensions used by the Web sites**
Any dynamic content types that are not automatically migrated by the tool must be added as Web service extensions. These new Web service extensions might be necessary for any modifications or conversions of dynamic code.

**Configure advanced Web site properties**

After the tool completes its migration tasks, the Web sites are configured comparably to how they were on Apache. You might want to configure the Web site to take advantages of the advanced security and availability features in IIS 6.0.

**Obtain server certificates for SSL**

For each Web site on the Apache Web server that uses SSL, you must either renew the existing server certificates in a format that is compatible with IIS 6.0 or you must request new server certificates in a format that is compatible with IIS 6.0. This is because the server certificates on the Apache Web server are in a format that is incompatible with IIS. Once you have the server certificates, you must import the certificates into IIS and configure your Web sites to use the appropriate certificates.

# Selecting a Migration Tool Installation Option

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool supports four options you can choose from when determining how you want to migrate Apache Web sites to IIS. Your familiarity with the Linux or Windows operating systems and the access that you have to the Web servers involved in the migration will determine the process you should follow to install and then run the tool. In some cases, you might not have unrestricted access to the Web servers because another group manages the Apache servers or the Web servers are behind firewalls that prevent FTP traffic.

To install and run the Apache to IIS 6.0 Migration Tool for any of the installation options, you must be able to:

- Log on to the source server with an account that has root-level or super-user access.
- Log on to the target server with an account that is a member of the local Administrators group.

In addition, when you select the intermediate computer installation option, you must be able to:

- Log on to the intermediate computer running Linux with an account that has root-level or super-user access.
- Log on to the intermediate computer running Windows with an account that is a member of the local Administrators group.

Table 7.2 lists and describes the installation options for the Apache to IIS 6.0 Migration Tool. Read this table to select the installation option that best fits your needs.

**Table 7.2 Apache to IIS 6.0 Migration Tool Installation Options**

| Installation Option | Installation Details |
|---|---|
| The source server (See Figure 7.3) | • Install and run the Apache to IIS 6.0 Migration Tool on your Linux-based source server (you do not need to physically access the Windows-based target server).<br>• Install Perl on both the Linux-based source server and the Windows-based target server.<br>• Enable the FTP service on the Windows-based target server only. |
| The target server (See Figure 7.4) | • Install and run the migration Apache to IIS 6.0 Migration Tool on the Windows-based target server (you do not need to physically access the Linux-based source server).<br>• Install Perl on the Windows-based target server only.<br>• Enable the FTP service on the Linux-based source server only. |
| An intermediate computer running Microsoft Windows 2000 or later (See Figure 7.5) | • Install and run the Apache to IIS 6.0 Migration Tool on a Windows-based intermediate computer (you do not need to physically access either the Linux-based source server or the Windows-based target server).<br>• Install Perl on both the Windows-based intermediate computer and the Windows-based target server.<br>• Enable the FTP service on both the Windows-based target server and the Linux-based source server. |

| | |
|---|---|
| An intermediate computer running a supported version of Linux (See Figure 7.5) | • Install and run the Apache to IIS 6.0 Migration Tool on a Linux-based intermediate computer (you do not need to physically access either the Linux-based source server or the Windows-based target server).<br>• Install Perl on both the Linux-based intermediate computer and the Windows-based target server.<br>• Enable the FTP service on both the Windows-based target server and the Linux-based source server. |

The Apache to IIS 6.0 Migration Tool must be installed on the source server, target server, or intermediate computer. The high-level process for installing the tool includes the following:

1. Copying the compressed distribution files (.tar for Linux or .zip for Windows) to the appropriate computer based on the installation option selected.

2. Expanding the compressed distribution files.

3. Installing the Perl interpreter, if it is not already installed.

For more detailed information about the installation option that you have selected for the Apache to IIS 6.0 Migration Tool, see Installing the Migration Tool later in this section.

# Source Server Installation Option

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you select the source server installation option, you install and run the Apache to IIS 6.0 Migration Tool on the source server, which runs Apache. In addition, you must install and configure the FTP service on the target server.

Figure 7.3 illustrates the migration process for the source server installation option.

**Figure 7.3 Migrating from Apache to IIS 6.0 with the Source Server Installation Option**

The process for migrating Apache Web sites when you select the source server installation option is as follows:

1. The Apache to IIS 6.0 Migration Tool prompts you for the appropriate user credentials for the source server and target servers.

2. The tool then transfers the Apache-based Web site content and the configuration information from the source server to the target server by way of FTP.

3. The tool applies the Web site configuration settings to the IIS Web sites on the target server.

# Target Server Installation Option

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you select the target server installation option, you install and run the Apache to IIS 6.0 Migration Tool on the target server, which runs Windows Server 2003 and IIS 6.0. In addition, you must install and configure the FTP service on the source server.

Figure 7.4 illustrates the migration process for the target server installation option.

**Figure 7.4 Migrating from Apache to IIS 6.0 with the Target Server Installation Option**

The process for migrating Apache Web sites when you select the target server installation option is as follows:

1. The Apache to IIS 6.0 Migration Tool prompts you for the appropriate user credentials for the source and target servers.

2. The tool then transfers the Apache-based Web site content and the configuration information from the source server to the target server by way of FTP.

3. The tool applies the Web site configuration settings to the IIS 6.0 Web sites on the target server.

# Intermediate Computer Installation Option

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you select the intermediate computer installation option, you install and run the Apache to IIS 6.0 Migration Tool on the intermediate computer, which runs either Windows or Linux. In addition, you must install and configure the FTP service on the source and target servers.

Figure 7.5 illustrates the migration process for the intermediate computer installation option.

**Figure 7.5 Migrating from Apache to IIS 6.0 with the Intermediate Computer Installation Option**

The process for migrating Apache Web sites when you select the intermediate computer installation option is as follows:

1. The Apache to IIS 6.0 Migration Tool prompts you for the appropriate user credentials for the source and target servers.

2. The tool transfers the Apache-based Web site content and the configuration information from the source server to the intermediate computer by way of FTP.

3. The tool applies the site configuration settings to the IIS Web sites on the target server.

# Deploying the Target IIS 6.0 Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Web server running IIS 6.0 must be installed and configured before you can migrate the Apache Web sites. In addition to installing Windows Server 2003, you must install and configure IIS 6.0 and, based on the installation option you selected, install and configure the FTP service on the target server. The tool uses FTP to transfer Web site content between the source and target servers.

**Figure 7.6 Deploying the Target Server**

If the target server is already installed and configured, you can proceed to Performing the Migration later in this section.

# Installing Windows Server 2003 Before Migrating

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The primary concern when installing Windows Server 2003 is to ensure that the security of the target server is maintained. When you install Windows Server 2003 as a dedicated Web server, the default components and services are configured to provide the lowest possible attack surface. You can further reduce the attack surface of the target server by enabling only the essential Windows Server 2003 components and services.

The migration process presented here assumes that you install Windows Server 2003 with the default options. If you use other methods for installing and configuring Windows Server 2003, such as unattended setup, the default configuration settings might be different.

| **Note** |
| --- |
| When you complete the installation of Windows Server 2003, Manage Your Server automatically starts. The migration process assumes that you close Manage Your Server, and then further configure the Web server in **Add or Remove Programs** in Control Panel. |

For more information about the essential components and services to enable in Windows Server 2003, see Enabling Only Essential Windows Server 2003 Components and Services.

# Installing IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Because IIS 6.0 is not installed during the default installation of Windows Server 2003, the next step in deploying the target server is to install and configure IIS 6.0. The migration process presented here assumes that you install IIS 6.0 with the default options in **Add or Remove Programs** in Control Panel. If you use other methods for installing and configuring Windows Server 2003, such as Manage Your Server, the default configuration settings might be different.

Install and configure IIS 6.0 by completing the following steps:

1. Install IIS 6.0 with only the essential components and services.

   As with installing Windows Server 2003, the primary concern when installing and configuring IIS 6.0 is to ensure that the security of the target server is maintained. Enabling unnecessary components and services increases the attack surface of the target server. You can help ensure that the target server is secure by enabling only the necessary components and services in IIS 6.0.

   For more information about how to install IIS 6.0, see Install IIS 6.0. For more information about the necessary IIS 6.0 components and services, see Enabling Only Essential IIS Components and Services.

2. In addition to the necessary components and services recommendations in step 1, enable the File Transfer Protocol (FTP) Service.

   The FTP service migrates content to the target server when you install and run the Apache to IIS 6.0 Migration Tool on the source server or on an intermediate computer.

   For more information about how to enable the FTP service, see Configure IIS Components and Services.

3. If the source server has Web sites that are FrontPage extended, enable FrontPage 2002 Server Extensions on the target server.

   For more information about how to enable FrontPage Server Extensions, see Configure a Web Site to be FrontPage Extended.

# Configuring the FTP Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool requires the FTP service to migrate Apache Web sites to the target server. The installation option you previously selected will determine on which computers you need to enable the FTP service. Table 7.3 lists the FTP service requirements for each installation option.

**Table 7.3 Methods for Installing and Configuring the FTP Service**

| If You Install and Run the Migration Tool On | Install and Configure FTP Service On |
|---|---|
| The source server | The target server |
| The target server | The source server |
| An intermediate computer | Both the target and source server |

**Configure the FTP service on the target server**

After you install the FTP service on the target server, no additional configuration is required. The Apache to IIS 6.0 Migration Tool works with the FTP service in the default configuration. Later in the deployment process, the tool creates a default FTP site to be used for Web site migration.

**Configure the FTP service on the source server**

Configuring the FTP service on the source server requires installing and configuring the FTP package from the Linux distribution disc. After the FTP service is installed, you must configure it to allow access to the Web sites.

For more information about how to install and configure the FTP service on the source computer, see the FTP documentation that accompanies the version of Linux that is installed on the source server.

# Performing the Migration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In the next step of the migration process, the Apache to IIS 6.0 Migration Tool copies the Web site content from the source server to the target server. Then, the tool transfers the Apache Web site settings to the corresponding IIS 6.0 metabase properties.

**Figure 7.7 Performing the Migration from Apache to IIS 6.0**

# Installing the Migration Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Now you are ready to install the Apache to IIS 6.0 Migration Tool based on the method you selected in Selecting a Migration Tool Installation Option. You can install the tool on one of the following:

- Source server, which is running Linux
- Target server, which is running Windows Server 2003
- Intermediate computer, which can be running either Linux or Windows

The installation process is dependent on the operating system. So, for example, you can use the same procedure for installing the Apache to IIS 6.0 Migration Tool on the source server or for an intermediate computer running Linux.

Install the Apache to IIS 6.0 Migration Tool by completing the following steps:

1. Install the tool on a computer running Linux. Or, install the tool on a computer running Windows.
2. Configure the target server for migration.

# Installing the Migration Tool on Computers Running Linux

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool installation process on the source server and on an intermediate computer running Linux is identical. The versions of Linux supported by the tool are listed in Overview of Migrating Apache Web Sites to IIS 6.0.

Install the Apache to IIS 6.0 Migration Tool on the computer running Linux by completing the following steps:

1. Install the Internet Information Services 6.0 Resource Kit Tools from the Microsoft Download Center onto a computer other than the target server.

2. Install Perl on the computer running Linux.

   Because the Apache to IIS 6.0 Migration Tool is written in Perl, you must install a Perl interpreter before you can run the tool. Install Perl on the computer running Linux and verify that the Perl interpreter is configured properly before installing the tool. To obtain a free copy of Perl, see ActivePerl.

3. Create a folder to contain the Apache to IIS 6.0 Migration Tool on the computer running Linux.

4. Change to the folder created in Step 3 so that the folder is the current working folder.

Copy the file AIISMT_linux.tar.gz from the *systemroot*\Program Files\AIISMT folder on the computer in Step 1 to the folder created in Step 3.

1. At a Linux command line type **tar -zxvf AIISMT_linux.tar.gz.**

   The compressed files are extracted to the folder created in step 3.

# Installing the Migration Tool on Computers Running Windows

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool installation process on the target server and on an intermediate computer running Windows is identical. The target server must be running Windows Server 2003. The intermediate computer can be running Microsoft Windows 2000 Professional, Microsoft Windows 2000 Server, Windows 2000 Advanced Server, or Microsoft Windows Server 2003.

Install the Apache to IIS 6.0 Migration Tool on the computer running Windows by completing the following steps:

1. Install the Internet Information Services 6.0 Resource Kit Tools from the Microsoft Download Center onto a computer other than the target server.

2. Install Perl on the computer running Windows.

   Because the Apache to IIS 6.0 Migration Tool is written in Perl, you must install a Perl interpreter before you can run the tool. Install Perl on the computer running Windows and verify that the Perl interpreter is configured properly before installing the tool. To obtain a free copy of Perl, see ActivePerl.

3. Copy the AIISMT_windows.exe from the *systemroot*\Program Files\AIISMT folder on the computer in step 1 to the desktop of the target server.

4. Double-click AIISMT_windows.exe.

   The **WinZip Self-Extractor** dialog box appears.

5. In the **Unzip to folder** box, type the path of the folder where you want to extract the tool or click **Browse**to browse to the folder.

6. Click **Unzip**.

   The WinZip Self-Extractor extracts the Apache to IIS 6.0 Migration Tool into the folder selected in step 5.

# Configuring the Target Server for Migration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You must configure the target server before you can perform the migration process. The configuration process creates virtual directories in the FTP root mapped to the physical drives of the server.

Configure the target server for migration by completing the following steps:

1. At the command line, type **cd ***installation_path*, where *installation_path* is the fully qualified path where you installed the Apache to IIS 6.0 Migration Tool, and then press ENTER.

   This changes the default folder to the folder where you installed the tool. For more information about how the Apache to IIS 6.0 Migration Tool was installed, see Installing the Migration Tool on Computers Running Windows.

2. At the command line, type **aiismt_setup**, and then press ENTER.

3. When prompted to create a virtual directory, type **y** to create a virtual directory on the disk volume you want to use for migration.

   You must select at least one disk volume and create a virtual directory.

   | **Important** |
   | --- |
   | You cannot create a virtual directory on a drive formatted with the FAT file system because access rights to directories on that drive cannot be set. |

The aiismt_setup program creates the virtual directories in the FTP site root and configures FTP to listen on TCP port 21.

# Verifying that Clients Are Not Accessing Web Sites Before Migrating

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool requires only read access to the Web site content and configuration settings on the source server; therefore, the source server can remain online in your production environment. However, you might need to remove the source server from your production network and move it to a private network segment that has direct network connectivity to the target server when:

- The amount of files and configuration information being copied across the network can generate a high volume of traffic and slow the production network.
- Firewalls that reside between the source and target servers prevent the migration tool from performing the migration. This is most commonly caused because the migration tool uses FTP for communicating with the source and target servers, and the FTP protocol is blocked by the firewalls.
- Security-related configuration settings on the source server need to be changed to allow the migration tool to work. This can include enabling FTP on production Web servers that are directly connected to the Internet.

# Migrating Web Site Content to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The migration of your Apache Web site involves migrating both the Web site content and its configuration. Based on the installation option you selected, the Apache to IIS 6.0 Migration Tool prompts you for the information required to perform the migration of the Web site content.

To run the tool, do one of the following, depending on the operating system on the computer:

- On Linux-based computers: From the Linux shell, change the current folder to the folder where you installed the tool, and then type **perl aiismt_main.pl**.
- On Windows-based computers: At the command line, change the current folder to the folder where you installed the tool, and then type **aiismt**.

After the Apache to IIS 6.0 Migration Tool starts, it prompts you for information. Table 7.4 lists the information that the migration tool requires to migrate the Web site content.

**Table 7.4 Information Required by Migration Tool During Web Site Content Migration**

| Information Required | Do the Following |
|---|---|
| Session name | Type a:<br>• Unique session name to indicate that the tool should begin a new migration process.<br>• Previous session name if you want to resume a previous migration. Supplying a previous session name causes the tool to run in recovery mode. |
| Source server IP address | If you run the tool on the:<br>• Target server or on an intermediate computer, type the IP address of the source server.<br>• Source server, press ENTER to see the default IP address displayed. If the tool cannot detect the source server's IP address, it will prompt you to confirm that the source server is running on a supported operating system. |
| Root user password | If you run the Apache to IIS 6.0 Migration Tool on the:<br>• Target server or on an intermediate computer, type the root user password to gain access to the Linux-based source server's system files and FTP service.<br>• Source server, you do not need to type the root user password. |
| Target server IP address | If you run the Apache to IIS 6.0 Migration Tool on the:<br>• Source server or on an intermediate computer, type the IP address of the source server.<br>• Target server, type the IP address of the target server or press ENTER to use the default (LocalHost) IP address. |

| | |
|---|---|
| User name and password for the target server | If you run the Apache to IIS 6.0 Migration Tool on the:<br>• Source server or on an intermediate computer, type a user name that is a member of the local Administrators group on the target server, and the associated password.<br>• Target server, you do not need to type a user name and password. |
| Configuration file path | Type the complete path to the httpd.conf file, which is a file that contains configuration and settings for Apache on the source server. You can also press ENTER to see the default path (/Etc/Httpd/Conf/Httpd.conf). |
| Web site directory on target server | Type the path of the directory on the target server where you want the Web site content to be migrated. You must supply a path for each Web site migrated.<br>When a Web site has SSL certificates associated with it, the Apache to IIS 6.0 Migration Tool prompts you to indicate whether you want the certificates to be migrated as well. |
| Listening IP address and port number | When you want to change the listening IP address and port number, type the new values. The new IP address and port numbers are applied to all the sites you selected for migration. |
| Web site IP address | When you want to change the IP address at the site level, type the new IP address, or type to use all unassigned IP addresses. |

**Note**

If you run the Apache to IIS 6.0 Migration Tool on the source server, the target server credentials are authenticated. If you run the tool on the target server, the source server credentials are authenticated.

For more information about how to migrate Web sites from Apache to IIS 6.0, see the "Apache to IIS 6.0 Migration Tool User Guide" in the IIS 6.0 Resource Kit Tools.

If the migration tool is interrupted or fails at any point during the process, you can run it in recovery mode. For more information about the recovery process, see Recovering from an Interruption in the Migration Process.

# Migrating Web Site Configuration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After migrating the Web site content, you must migrate the Web site configuration. Before you continue in the migration process, check the Apache to IIS 6.0 Migration Tool status file, Aiismt_Status.html in the session directory, to ensure that the migration has completed successfully up to this point.

To start Web site configuration migration on the target server, at the command line, change the current folder to the folder where you installed the Apache to IIS 6.0 Migration Tool, and then type **aiismt**.

During the migration of the Web site configuration, the tool prompts you to supply the session name. The files with the configuration settings are located in a folder under the FTP root. The folder uses the name of the current migration session, which you specified when you migrated the Web site content in Migrating Web Site Content to IIS 6.0 earlier in this section.

During the Web site configuration process on the target server, the Apache to IIS 6.0 Migration Tool does the following:

- Migrates Apache Web site directives and maps them to corresponding IIS configuration settings, including security settings.
- Migrates the FrontPage Server Extensions settings, users, and roles if any of the Apache Web sites are FrontPage extended.
- Sets the security settings on the sites by assigning user rights to the directories that contain site-related content.
- Verifies that settings have been correctly applied to the Web sites on the target server when the Web site configuration migration is complete.

# Recovering from an Interruption in the Migration Process

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you received no error messages while migrating the Web site content and configuration, you can proceed to one of the following sections in this section:

- Migrating Apache-Specific Extensions if any of your Web sites contain dynamic content.
- Configuring IIS 6.0 if all of your Web sites contain static content.

If you received an error message while running the Apache to IIS 6.0 Migration Tool, do the following:

1. Determine the cause of the error and resolve the problem.
2. Restart the Apache to IIS 6.0 Migration Tool in recovery mode.

In addition to resolving migration errors, you can use the tool in recovery mode to:

- Perform another migration if the majority of the settings are the same.

  For example, you might run the tool to migrate a specific Web site on a Web server that hosts multiple Web sites. You can migrate subsequent Web sites by running the tool in recovery mode and change only the name of the Web site to be migrated. The remainder of the settings remain unchanged.

- Perform the actual migration of Web site content and configuration after a trial migration.

  You can perform a *trial migration* of the Web site and content by supplying all information except the Web sites to migrate. You can use this method to validate the majority of the migration settings. You can subsequently run the tool in recovery mode.

- Provide a scripted environment for automating the Apache to IIS 6.0 Migration Tool migration process.

  The tool creates an answer file that is used by the recovery process, which you can edit to automate the tool. The answer file has the naming convention of AIISMT_*session name*_Recovery.txt, where *session_name* is the session name for the migration.

# Determining Cause of and Resolving Errors

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool automatically creates a status file for each migration session in the session folder, located in the FTP root on the target server. The name of the session folder is identical to the migration tool session name. The status file, Aiismt_Status.html, contains information about every phase of the migration process.

If an interruption occurs while the tool is running:

1. Refer to the status file to determine the cause of the failure.

2. Resolve any errors before proceeding with the upgrade process.

# Restarting the Migration Tool in Recovery Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the Apache to IIS 6.0 Migration Tool is interrupted or fails at any point during the process, you can run it again in recovery mode. Recovery mode allows you to pick up the migration process from the point at which the tool was interrupted, rather than starting over from the beginning. Any of the following events can cause a failure or interruption in the migration tool:

- System failure.
- Network connection terminated.
- FTP access denied.

You can restart the migration tool in recovery mode when:

- An interruption occurs during data entry.

  If the tool terminates as you are entering information about the migration (such as IP addresses or file paths) you can restart it in recovery mode. The migration tool validates your user credentials, and the migration process proceeds from the point where the tool was interrupted. You do not need to retype the information you have already entered.

- An interruption occurs during file transfer.

  If the migration tool terminates during the process of transferring files from the source server to the target server, you can restart it in recovery mode. The tool resumes migration with the file that was being transferred during the interruption.

# Migrating Apache-Specific Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the Apache Web site contains dynamic content, requires database connectivity, or includes external modules, you must separately migrate these Apache-specific extensions to complete the migration process.

Figure 7.8 illustrates the process for migrating Apache-specific extensions to IIS 6.0.

**Figure 7.8 Migrating Apache Specific Extensions to IIS 6.0**

The Apache-specific extensions on Linux commonly include MySQL and PHP. The combination of Linux, Apache, MySQL, and PHP are often referred to as LAMP. LAMP is the application platform used for Linux systems. The migration of the Apache Web sites must include the migration of LAMP.

For more information about migrating Apache Web sites to IIS, see Migrating from Linux-Apache-MySQL-PHP. Although the white paper refers to IIS 5.0 and Windows 2000 Server, the processes and methods are applicable for IIS 6.0 and Windows Server 2003.

| **Important** |
| --- |
| Test the migration of Apache-specific extensions in your lab environment before starting the Web site migration. |

The Apache-specific extensions that you might need to migrate include:

- Dynamic content.
- Database content and connectivity.
- External modules.

# Migrating Dynamic Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool transfers the files that make up the dynamic content to the target server during the Web site content migration. However, the dynamic content typically cannot run on IIS and requires further tailoring. Table 7.5 describes the advantages and disadvantages of the methods for migrating dynamic content.

**Table 7.5 Comparison of Methods for Migrating Dynamic Content**

| Migration Method | Advantages | Disadvantages |
|---|---|---|
| Run dynamic content on a preprocessor that ships with IIS and Windows Server 2003. | • Requires minimal migration effort, depending on the extent of changes to the dynamic content.<br>• Requires no purchase of additional preprocessor. | • Might not run as efficiently as dynamic content written in ASP or ASP.NET. |
| Run dynamic content on a preprocessor external to IIS and Windows Sever 2003. | • Requires minimal migration effort, depending on the extent of changes to the dynamic content. | • Might not run as efficiently as dynamic content written in ASP or ASP.NET.<br>• Requires purchase of an additional preprocessor. |
| Rewrite the dynamic content in ASP or ASP.NET. | • Runs the dynamic content more efficiently than the other methods.<br>• Requires no purchase of additional preprocessor. | • Requires the most migration effort because the dynamic content must be completely rewritten. |

**Important**

When you run dynamic content written in preprocessors, you need to enable the *Web service extensions* (request handlers, such as Perl and CGI, that extend IIS functionality beyond serving static pages) for the preprocessor. For more information, see Configuring Web Service Extensions in IIS 6.0.

**Run Dynamic Content on a Preprocessor that Ships with IIS**

When you select this method for migrating the dynamic content, you must have the source code to the dynamic content and you must use a preprocessor that ships with IIS 6.0 and Windows Server 2003, such as CGI or Perl. You might have to adjust the code to accommodate any differences between preprocessors on Apache and IIS and between Linux and Windows.

Ensure that the version of the preprocessor supported on IIS 6.0 and Windows Server 2003 is compatible with the version of the code in the dynamic content. You will most likely need to modify the code in the dynamic content to compensate for version and platform differences. For example, CGI scripts migrated from Apache Web sites typically require modification to run on IIS 6.0 and Windows Server 2003.

**Run Dynamic Content on a Preprocessor External to IIS**

This method for migrating the external module assumes that you have the source code to the dynamic content and you can purchase or obtain a version of the preprocessor that runs with IIS, such as PHP. You might have to adjust the code to accommodate any differences between preprocessors on Apache and IIS 6.0.

For example, if the dynamic content is written in PHP, you must obtain a version of a PHP preprocessor for IIS to install and configure the PHP preprocessor on IIS 6.0. You must then adjust the PHP code to accommodate any differences between the PHP preprocessors on Apache and IIS 6.0.

**Rewrite the Dynamic Content in ASP or ASP.NET**

When you select this method for migrating the dynamic content, you need to evaluate the function of the original dynamic content, draft a functional specification for the dynamic content, and then develop a version of the dynamic content in ASP or ASP.NET.

For more information about selecting either ASP or ASP.NET, see Active Server Pages and ASP.NET.

# Migrating Database Content and Connectivity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Database connectivity provides a standardized method of connecting to various database systems. Although the Apache to IIS 6.0 Migration Tool migrated the Web site content and configuration, any database content and database connectivity must be migrated separately. Many Apache Web sites and applications use a database server, such as MySQL, the most common database connectivity standard used in Apache Web sites. Dynamic and static content can make requests to databases through MySQL.

For more information about how to migrate database content and connectivity to IIS, see Migrating from Linux-Apache-MySQL-PHP. Although the white paper refers to IIS 5.0 and Windows 2000 Server, the processes and methods are applicable for IIS 6.0 and Windows Server 2003.

# Migrating the Database Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Apache to IIS 6.0 Migration Tool does not transfer the database content to the target computer. You must migrate the database content by other methods, whose advantages and disadvantages are described in Table 7.6.

**Table 7.6 Comparison of Methods for Migrating Database Content**

| Migration Method | Advantages | Disadvantages |
|---|---|---|
| Obtain a copy of the database that is compatible with IIS 6.0 and Windows Server 2003. | • Requires minimal migration effort.<br>• Administrators are familiar with administering the database engine. | • Might not run as efficiently as Microsoft Data Engine (MSDE) or Microsoft SQL Server™ 2003.<br>• Requires purchase of an additional preprocessor. |
| Convert the database to MSDE or SQL Server 2000. | • Might run more efficiently than the original database engine on IIS 6.0 and Windows Server 2003.<br>• Requires no purchase of additional database when using MSDE. | • Requires more extensive conversion.<br>• Administrators might not be familiar with administering MSDE or SQL Server 2000. |

**Obtain a Copy of the Database Engine that is Compatible with IIS**

Most database engines on Linux have compatible versions that are designed for Windows. The easiest method of converting the database is to run the same database engine because little or no modification to the dynamic content is required. For more information, see the Web site or product documentation for the database engine used by the source server to determine if there is a version for Windows.

**Convert the Database to MSDE or SQL Server 2000**

Microsoft SQL Server supports the importing of data stored in other databases into SQL Server 2000. For example, you can import MySQL data directly into SQL Server 2000. You can use ODBC connectivity between MySQL and MSDE or SQL Server 2000 to import data as well. Client applications, such as Microsoft Access XP, can be used to import data through ODBC to MSDE or SQL Server 2000.

For more information about importing data into SQL Server 2000, see SQL Server. You can use the same methods for migrating data into MSDE as SQL Server 2000 because MSDE is based on SQL Server 2000.

# Migrating the Database Connectivity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You need to ensure that the dynamic content migrated to the target computer by the Apache to IIS 6.0 Migration Tool can use a database connectivity supported on IIS 6.0 and Windows Server 2003. Table 7.7 describes the advantages and disadvantages of the methods for migrating database connectivity.

**Table 7.7 Comparison of Methods for Migrating Database Connectivity**

| Migration Method | Advantages | Disadvantages |
|---|---|---|
| Obtain a version of the database that runs on IIS 6.0 and Windows Server 2003. | • Requires minimal migration effort. | • Requires purchase of the database that is compatible with IIS 6.0 and Windows Server 2003. |
| Convert the dynamic content to use ADO or ODBC. | • Requires no purchase of additional database. | • Requires more extensive conversion. |

**Obtain a Version of the Database Connectivity that Runs on IIS 6.0**

The database connectivity for dynamic content is implemented on Apache as libraries that are called by the dynamic content. When you install a version of the database connectivity on IIS 6.0 and Windows Server 2003, the appropriate libraries are also installed. There should be minimal changes to the dynamic content.

| Note |
|---|
| This method assumes that you are installing a version of the database, such as MySQL, on the target server. |

**Convert the Dynamic Content to use Windows Database Connectivity**

When you use this method, the assumption is that you are connecting to MSDE or SQL Server 2000 as the database engine through ODBC or ADO. If you are installing a version of the database engine on IIS 6.0 and Windows Server 2003, use the database connectivity libraries that accompany the database engine to reduce the effort required in the migration.

For example, there are ODBC drivers for MySQL; however, if you install MySQL on the target server, there is little or no conversion if you continue to use the MySQL libraries. In this case, converting your dynamic content to use ODBC has no long-term advantage unless you are planning to migrate to another database engine.

For more information about selecting ODBC, see Open Database Connectivity (ODBC). For more information about selecting ADO, see ActiveX Data Objects.

# Migrating External Modules

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

External modules, such as Cold Fusion and Wpoison, provide extended features to Apache Web sites. The Apache to IIS 6.0 Migration Tool transfers external modules to the target computer if they are in the same directory with the other Web site content. When the external modules are stored in other directories, you must manually transfer the external modules to the target server. After the external modules are transferred to the target server, you must complete additional steps so that the external modules run on IIS and Windows Server 2003. Table 7.8 describes the advantages and disadvantages of the methods for migrating external modules.

**Table 7.8 Comparison of Methods for Migrating External Modules**

| Migration Method | Advantages | Disadvantages |
|---|---|---|
| Obtain a version of the external module that runs on IIS 6.0 and Windows Server 2003. | • Requires minimal migration effort.<br>• Source code for the external module is not required. | • Might not run as efficiently as external modules written in ASP or ASP.<br>• Requires purchase of another version of the external module.<br>• Might require minor modifications to the Web site content to accommodate version differences. |
| Convert the external modules to run on the same preprocessor as IIS 6.0 and Windows Sever 2003. | • Can require minimal migration effort, depending on the extent of changes to the code for the external module. | • Might not run as efficiently as external modules written in ASP or ASP.NET.<br>• Might require the purchase of an additional preprocessor.<br>• Requires the source code of the external module so that the module can be converted. |
| Rewrite the external module in ASP or ASP.NET. | • Runs the dynamic content produced by the original external module more efficiently.<br>• Requires no additional purchases. | • Requires the most migration effort because the external module must be completely rewritten. |

**Obtain Version of External Module that Runs on IIS 6.0 and Windows Server 2003**

When you select this method for migrating the external module, you need to purchase a version of the external module for Windows. Install and configure the external module on the target server using the documentation that accompanies the external module.

For example, if an Apache Web site uses Cold Fusion, you would purchase a version of Cold Fusion for IIS 6.0 and Windows Server 2003. After installing and configuring Cold Fusion on the target server, you might have to adjust the code, such as PHP, CGI, or Perl, that calls the external module to accommodate any difference between Cold Fusion on Apache and IIS.

**Convert External Modules to Run on Same Preprocessor as IIS 6.0 and Windows Sever 2003**

This method for migrating the external module assumes you have the source code to the external modules. In addition, you must have a preprocessor on IIS that supports the code in which the external module is written, such as PHP, CGI, or Perl. You might have to adjust the code to accommodate any differences between preprocessors on Apache and IIS.

| **Important** |
| --- |
| When you run external modules written in preprocessors, you need to enable the Web service extensions for the preprocessor. For more information, see Configuring Web Service Extensions in IIS 6.0. |

**Rewrite the External Module in ASP or ASP.NET**

Select this method if no version of the external module exists for IIS 6.0 and Windows Server 2003 and you do not have the source code to the external module, or if you want to rewrite the external module to take advantage of the enhanced performance offered by ASP or ASP.NET. You need to evaluate the functions of the external module, draft a functional specification for the external module, and then develop a version of the external module in ASP or ASP.NET.

For more information about selecting either ASP or ASP.NET, see Active Server Pages and Microsoft® ASP.NET Developer Center.

| **Important** |
| --- |
| When you write ASP or ASP.NET applications, you must enable Web service extensions for ASP or ASP.NET. For more information, see Configuring Web Service Extensions in IIS 6.0. |

# Configuring IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After migrating the Web site content, configuration, and Apache-specific extensions, you must further configure IIS to allow proper operation of the Web sites. This post-migration configuration of IIS ensures that your Web sites run as they did on Apache before they were migrated to IIS 6.0.

Figure 7.9 illustrates the process for configuring IIS 6.0 after completing the migration of the Web sites from Apache.

**Figure 7.9 Configuring IIS 6.0 After Migration**

# Configuring Web Service Extensions in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Many Web sites and applications that you migrate have extended functionality beyond static pages, including the ability to generate dynamic content. Any request handlers, such as Perl and CGI, that extend IIS functionality beyond serving static pages are known as *Web service extensions*. Web service extensions allow you to enable and disable the serving of dynamic content and easily determine the content types on the Web server that can initiate code.

If you installed IIS 6.0 as described in Installing IIS 6.0, all Web service extensions are disabled by default. If you used another method, such as using Manage Your Server, the configuration of IIS might be different.

Enabling all Web service extensions ensures the highest possible compatibility with your Web sites. However, enabling all Web service extensions creates a security risk because it increases the attack surface of IIS by enabling functionality that might be unnecessary for your server.

Web service extensions allow you to enable and disable the serving of dynamic content. *MIME types* allow you to enable and disable the serving of static content. For more information about enabling and disabling the serving of static content, see Configuring File MIME Types on IIS 6.0.

| **Tip** |
| --- |
| If the appropriate Web service extension is not enabled, the Web server returns a 404 error when attempting to serve the dynamic content. |

Configure the Web service extensions by completing the following steps:

1. Enable the essential predefined Web service extensions based on the information in Table 7.9.

   Table 7.9 Predefined Web Service Extensions

   | Web Service Extension | Enable When |
   | --- | --- |
   | Active Server Pages | Enable this extension when one or more of the Web sites or applications contains ASP content. |
   | ASP.NET version 1.1.4322 | Enable this extension when one or more of the Web sites or applications contains ASP.NET content. |
   | FrontPage Server Extensions 2002 | Enable this extension when one or more of the Web sites are FrontPage extended. |
   | Internet Data Connector | Enable this extension when one or more of the Web sites or applications uses the Internet Data Connector (IDC) to display database information (content includes .idc and .idx files). |
   | Server-Side Includes | Enable this extension when one or more of the Web sites uses server-side include (SSI) directives to instruct the Web server to insert various types of content into a Web page. |
   | WebDav | Enable this extension when you want to support Web Distributed Authoring and Versioning (WebDAV) on the Web server, but it is not recommended for dedicated Web servers. |

   | **Important** |
   | --- |
   | Enable only the Web service extensions that are required by the migrated Apache Web sites. |

2. For each Web service extension used by your applications that is not one of the default Web service extensions, add a new entry to the Web service extensions list and configure the status of the new entry to **Allowed**.

For information about how to add a Web server extension to the list, see Configure Web Service Extensions.

3. Use a Web browser on a client computer to verify that the Web sites and applications run on the server.

# Configuring File MIME Types on IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS serves only static files with extensions registered in the Multipurpose Internet Mail Extensions (MIME) types list. IIS is preconfigured to recognize a default set of global MIME types, which are recognized by all configured Web sites. You can define MIME types at the Web site and directory levels independent of one another or of the types defined globally. IIS also allows you to change, remove, or configure additional MIME types. For any static content file extensions used by the Web sites hosted by IIS that are not defined in the MIME types list, you must create a corresponding MIME type entry.

The Apache to IIS 6.0 Migration Tool migrates the MIME types for the Apache Web sites; however, you must add any MIME types for content that was added earlier in the Apache migration process by completing the following steps:

1. For each static type used by your Web site, ensure that an entry exists in the MIME types list.

   When your application uses the standard MIME types included in IIS 6.0 or the MIME types migrated by the Apache to IIS 6.0 Migration Tool, no new MIME type entries are required. However, if you add new static content earlier in the Apache migration process, you must add the new MIME types. For information about adding a MIME type to the MIME types list, see Configure MIME Types.

2. Use a Web browser on a client computer to verify that the Web sites and applications run on the server.

# Configuring Web Site Properties

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After the Apache Web sites are migrated, they run in a configuration that approximates their configuration on the Apache Web server. All of the Web sites run in the default application pool with the default security identity, NetworkService. In this configuration, the Web sites do not take advantage of the enhanced security and availability of IIS 6.0.

You can further configure the Web sites to provide the following:

- Improved security. In many cases, you can improve the security of the Web sites by isolating and running each one with unique identities. For more information about improving the security of the Web sites, see Securing Web Sites and Applications.

- Enhanced availability. In many cases, you can improve the availability of your Web sites. For more information about improving the availability of your Web sites, see Ensuring Application Availability.

# Configuring Server Certificates for SSL

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Some of the Web sites on the source server might use Secure Sockets Layer (SSL) to encrypt confidential information exchanged between the Web server and the client. For each SSL-encrypted Web site that you migrated from the source server, you need to ensure that you have a certificate for that Web site installed on the target server. You can either renew the existing certificates on the source server in a format that is compatible with IIS 6.0 or you can request new certificates. After you have installed the server certificates on the target server, you can import the certificates into the certificate store on the target server, and then configure your Web sites to use the appropriate certificates.

| **Note** |
| --- |
| *Server certificates* are installed on the Web server and typically require no additional configuration on the client servers. Server certificates allow the clients to verify the identity of the server. Alternatively, some Web sites and applications might require *client certificates*. Client certificates are installed on the client servers and allow the server to authenticate the clients. For more information about configuring client certificates, see Certificates_IIS_SP1_Ops. |

For each Web site and application that uses SSL, configure the server certificate for SSL by completing the following steps:

1. Obtain an SSL server certificate that is compatible with IIS 6.0 by doing one of the following:

   - Renew an existing certificate in a format that is compatible with IIS 6.0.

     The format of the SSL server certificate on the source server is in a format that is incompatible with IIS. You can renew an existing certificate with your certification authority in a format that is compatible with IIS 6.0.

     For more information about renewing existing server certificates in a format that is compatible with IIS 6.0, contact your certification authority.

   - Request a new certificate from a certification authority in a format that is compatible with IIS 6.0.

     You can use the Web Server Certificate Wizard either to generate a certificate request file (Certreq.txt, by default) that you send to a certification authority, or to generate a request for an online certification authority, such as Microsoft Certificate Services in Windows Server 2003. Depending on the level of identification assurance offered by your server certificate, you can expect to wait several days to several months for the certification authority to approve your request and send you a certificate file.

     For more information about requesting a server certificate by using the Web Server Certificate Wizard, see Request a Server Certificate.

2. Install the SSL server certificate to be used by the Web site on the target server.

   After you obtain an SSL server certificate, you need to install the certificate on the target server. Install the SSL server certificate on the target server by using the Certificate MMC snap-in.

   For more information about installing the SSL server certificate on the Web server, see Install a Server Certificate.

3. Assign the SSL server certificate to the Web site.

   For more information about assigning the SSL server certificate to the Web site, see Assign a Server Certificate to a Web Site.

# Backing Up the Target IIS 6.0 Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you enable client access to the target server, perform a complete image backup of the target server. Performing this image backup provides you with a point-in-time snapshot of the Web server. If you need to restore the target server in the event of a failure, you can use this backup to restore the Web server to a known configuration.

| **Important** |
| --- |
| Do not continue with the migration process unless you have a successful backup of the entire target server. Otherwise, you can lose Web sites, applications, or data that you migrated to the target server. |

For more information about how to back up the Web server, see Back Up and Restore the Web Server to a File or Tape.

# Enabling Client Access After Migration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you have migrated your Web sites from the source server to the target server, you are ready to enable client access to the Web sites on the target server, while maintaining the DNS entries to the source servers. After a period of time that meets your business needs, you can remove the DNS entries that point to the Web sites on the source server.

Figure 7.10 illustrates the final step of the process for migrating Web sites from Apache to IIS 6.0.

**Figure 7.10 Enabling Client Access After Migration to IIS 6.0**

Enable client access to the Web sites on the target server by completing the following steps:

1. Create the appropriate DNS entries for the Web sites and applications running on the target server.

   For more information about how to create DNS entries for your Web sites and applications, see "Managing resource records" in Help and Support Center for Windows Server 2003.

2. Monitor client traffic to determine whether clients are successfully accessing the target server.

   For more information about how to monitor client traffic to Web sites on the target server, see Monitor Active Web and FTP Connections.

3. Establish a monitoring period, such as a few hours or a day, to confirm that clients accessing Web sites on the target server are experiencing response times and application responses that meet or exceed your requirements.

4. Remove the DNS entries pointing to the Web sites and applications on the source server.

   For more information about how to remove DNS entries for your applications, see "Managing resource records" in Help and Support Center for Windows Server 2003.

5. Monitor client traffic to the Web sites on the source server to determine when clients are no longer accessing the source server.

   For more information about how to monitor client traffic to Web sites on the source server, see Monitor Active Web and FTP Connections.

6. When clients are no longer accessing the Web sites on the source server, decommission the hardware for the source server.

# Additional Resources About Migrating Apache Web Sites to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to migrating Apache Web sites to IIS 6.0.

**Related Information**

- Securing Web Sites and Applications
- Ensuring Application Availability
- Upgrading an IIS Server to IIS 6.0
- Migrating IIS Web Sites to IIS 6.0
- Appendix A: IIS Deployment Procedures
- Active Server Pages and Microsoft ASP.NET Developer Center for more information about selecting either ASP or ASP.NET to rewrite dynamic content.
- Migrating from Linux-Apache-MySQL-PHP for more information about migrating Apache Web sites to IIS.
- SQL Server for more information about importing data into SQL Server 2000.

**Related topics in the IIS 6.0 Operations Guide**
For more information about configuring client certificates, see Certificates_IIS_SP1_Ops.

**Related Windows Server 2003 Help topics**
For best results in identifying Help topics by title, in Help and Support Center, under the **Search** box, click **Set search options**. Under **Help Topics**, select the **Search in title only** check box.

- "Managing resource records" in Help and Support Center for Windows Server 2003 for more information about how to create DNS entries for your applications.

# Appendix A: IIS Deployment Procedures

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

**In This Appendix**

Assign Additional IP Addresses to a Network Adapter

Assign a Server Certificate to a Web Site

Back Up and Restore Registry Entries

Back Up and Restore the IIS Metabase

Back Up and Restore the Web Server to a File or Tape

Configure an ASP.NET Application for ASP.NET

Configure Anonymous User Identity

Configure a Web Site to be FrontPage Extended

Configure Application Identity for IIS 5.0 Isolation Mode

Configure Application Isolation Modes

Configure Application Isolation Settings for IIS 5.0 Isolation Mode

Configure Application Pool Health

Configure Application Pool Identity

Configure Application Pool Performance

Configure Application Pool Recycling

Configure FrontPage Server Roles

Configure Compression

Configure FTP Server Authentication

Configure IIS Components and Services

Configure IP Address Assigned to Web Sites

Configure IP Address and Domain Name Restrictions

Configure MIME Types

Configure NTFS Permissions

Configure the State Service on the ASP.NET State Server

Configure the Registry

Configure the Web Site Identification Number

Configure Web Server Authentication

Configure Web Service Extensions

Configure Web Site Permissions

Configure Windows Server 2003 Services

Convert Existing Disk Volumes to NTFS

Create a Service Account

Create A SQL Server Database for Storing ASP.NET Session State

Create a Virtual Directory in IIS 6.0

Create a Web Site

Debug Application Pool Failures

Determine Web Sites Uniquely Identified by IP Addresses

Disable Network Adapters

Enable ASP.NET

Enable Buffering on the Administrative Web Site

Enable Logging_IIS_SP1_Dep

Enable Network Adapters

Enable Security Auditing

Enable the WWW Service After Upgrade

Enable Web Site Content Auditing

Export a Server Certificate

Gather and Display WWW Service Uptime Data

Grant User Rights to a Service Account

Install a Server Certificate

Install IIS 6.0

Install Subauthentication

Isolate Applications in Worker Process Isolation Mode

Make a Service Account a Member of the Local Administrators Group

Migrate CDONTS

Modify the IIS Metabase Directly

Monitor Active Web and FTP Connections

Obtain a Server Certificate for an NLB Cluster

Pause Web or FTP Sites

Publish Web Site Content with FrontPage

Remove Virtual Directories

Request a Server Certificate

Secure the Root Folder of Each Disk Volume

Secure Windows Server 2003 Built-in Accounts

Set Processor Affinity

Stop the WWW Service

Upgrade FrontPage Extended Web Sites

View Application Isolation Configuration

View Web Site and Application Process Identities

# Assign Additional IP Addresses to a Network Adapter

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can configure a network adapter to have additional IP addresses. When you assign a specific IP address to a network adapter, you can uniquely identify a Web site or application by associating the Web site or application with that unique IP address.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc.**

**Procedures**

**To assign additional IP addresses to a network adapter**

1. In Control Panel, click **Network Connections**, right-click the network adapter that connects to the client computers, and then click **Properties**.
2. On the **General** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
3. On the **General** tab, click **Advanced**.
4. On the **Advanced TCP/IP Settings** dialog box, click **Add**.
5. On the **TCP/IP Address** dialog box, enter the **IP address** and the **Subnet mask**, and then click **Add**.
6. Click **OK** twice, and then click **Close**.

# Assign a Server Certificate to a Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Server certificates contain information about the server that allows the client to positively identify the server before sharing sensitive information. After you obtain a server certificate from a trusted certification authority and install the server certificate on the Web server, you need to assign the server certificate to the Web site.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc.**

**Procedures**
**To assign a server certificate to a Web site**

1. In IIS Manager, expand the local computer, and then expand the **Web Sites** folder.
2. Right-click the Web site or file that you want, and then click **Properties**.

   Depending on whether you are configuring a Web site or a file, select either the **Directory Security** or **File Security** tab, and under **Secure communications**, click **Server Certificate**.
3. In the Web Server Certificate Wizard, click **Assign an existing certificate**.
4. Follow the steps in the Web Server Certificate Wizard, which guides you through the process of installing a server certificate.
5. You can view the information about the certificate by clicking the **View Certificate** button on the **Directory Security** or **File Security** tab of the Web sites **Properties** page.

# Back Up and Restore Registry Entries

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Some COM objects, COM+ objects, Internet Server API (ISAPI) extensions, and other components save configuration information in the Windows registry. If no setup program or provisioning script exists to make the appropriate registry updates during migration, you must manually identify the registry entries and then recreate them on the target server. To accomplish this, once you have identified the registry entries required by the applications currently running on the source server, back up the registry entries on the source server by using the registry editor Regedit.exe. Modify the registry entries in the backup files created by the registry editor to reflect changes in disk volume drive letters or paths to directories, and then restore the updated registry backups to the target server. Restoring the registry entries is accomplished by merging the backup files into the registry on the target server.

| **Caution** |
| --- |
| The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the registry reference. |

**Procedures**

**To back up registry entries by using the registry editor**

1. In the **Run** dialog box, type **regedit**, and then click **OK**.
2. In the registry editor, right-click the registry key or subkey that contains the registry entries that you want to back up, and then click **Export**.
3. In the **Export Registry File** dialog box, select a location for the backup registry file. Click **Save** to save the registry file to that location.
4. Close the Registry Editor.

**To restore registry entries**

1. Copy the backup registry file to any location on the target server.
2. In Windows Explorer, navigate to the backup registry file on the target server, and right-click the file name.
3. Click **Merge**. In the **Registry Editor** message box, click **Yes** to add the information in the file to the registry.
4. Click **OK** to finish.

**Related Information**

For more information about the registry, see the Registry Reference in the Windows Server 2003 Deployment Kit.

# Back Up and Restore the IIS Metabase

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Metabase backup files are copies of the metabase configuration file (MetaBase.xml) and the matching metabase schema file (MBSchema.xml). The metabase can be restored from the backup files by using the metabase configuration backup and restore feature. You can create backup files by using IIS Manager or the command-line script **iisback.vbs**, which is stored in *systemroot*\System32.

The administrator can create a *portable backup* by providing a password that is used by IIS to encrypt the secure metabase properties in the backup files. Encrypting the secure properties in this way allows the backup files to be restored to another computer by using the password. Once a backup is created, the password within the backup file cannot be changed.

When creating a *non-portable backup*, the administrator does not provide a password. Instead, the machine key is used to encrypt secure metabase properties. Because a machine key is unique to the computer it belongs to, a backup created this way can only be restored to the original computer.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc, Iisback.vbs

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc.**

**Procedures**

**To create a portable backup (password required)**

1. In IIS Manager, right-click the local computer, click **All Tasks**, and then click **Backup/Restore Configuration**.
2. Click **Create Backup**.
3. In the **Configuration backup name** box, type a name for the backup file.
4. Select the **Encrypt backup using password** check box, type a password into the **Password** box, and then type the same password in the **Confirm password** box.
5. Click **OK**, and then click **Close**.

   The IIS metabase is created in the *systemroot***\system32\inetsrv\MetaBack** folder.

**To create a non-portable backup (password not required)**

1. In IIS Manager, right-click the local computer, click **All Tasks**, and click **Backup/Restore Configuration**.
2. Click **Create Backup**.
3. In the **Configuration backup name** box, type a name for the backup file.
4. Click **OK**, and then click **Close**.

   The IIS metabase is created in the *systemroot***\system32\inetsrv\MetaBack** folder.

**To restore the metabase backup**

1. In IIS Manager, right-click the local computer, click **All Tasks**, and click **Backup/Restore Configuration**.
2. In the **Backups** list box, click the version of the **Automatic Backup** file that you want to restore, and click **Restore**. If prompted for a password, type the password you chose to secure the backup.

The IIS metabase is restored to the location from which it was backed up.

# Back Up and Restore the Web Server to a File or Tape

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You should back up a Web server before upgrading it or making configuration changes to it. A complete Web server backup includes all Web sites, applications, and data stored on the Web server. For example, before an upgrade, or before you enable client access to a target Web server, perform a complete image backup before you change any of the configuration settings on the existing Web server. The image backup provides a point-in-time snapshot of the Web server. If unforeseen problems occur during the upgrade or configuration process, you can use this backup to restore the Web server to a known configuration.

A backup file can be saved to a hard disk, a floppy disk, or to any other nonremovable or removable media on which you can save a file. Backup files usually have the extension .bkf, but you can change it to any extension you prefer.

You should back up all boot and system volumes, including the System State, when you back up the Web server.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: ntbackup.exe

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc.**

**Procedures**

### To back up to a file or tape

1. Open **Accessories**, click **System Tools**, and then click **Backup**.
2. Click the **Advanced Mode** link on the Backup or Restore Wizard.
3. Click the **Backup** tab, and then on the **Job** menu, click **New**.
4. In the **Click to select the check box for any drive, folder, or file that you want to back up** text box, click the box next to **System State** and any other items you would like to backup. You should back up all boot and system volumes along with the System State.
5. In **Backup destination**, do one of the following:
   - Choose **File** if you want to back up files and folders to a file. This is selected by default. You will not be able to choose any other option if you do not have a tape drive on your system.

     -or-

   - Click a tape device from the drop-down list if you want to back up files and folders to a tape. You cannot use this option if you do not have a tape device on your system.
6. In **Backup media or file name**, do one of the following:
   - If you are backing up files and folders to a file, type a path and file name for the backup (.bkf) file, or click the **Browse** button to find a file.
   - If you are backing up files and folders to a tape, select the tape you want to use from the drop-down list box.
7. Click **Tools**, and then click **Options** to select any backup options you want, such as the backup type and the log file type. When you have finished selecting backup options in the **Options** dialog box, click **OK**.

8. Click **Start Backup**, and then make any necessary changes to the **Backup Job Information** dialog box.
9. Click the **Advanced** tab if you want to set advanced backup options such as data verification or hardware compression. When you have finished setting advanced backup options, click **OK**.
10. Click **Start Backup** to start the backup operation.

**To restore the Web server from a file or tape**

1. Open **Accessories**, point to **System Tools**, and then click **Backup**.
2. Click the **Advanced Mode** link on the Backup or Restore Wizard.
3. Click the **Restore and Manage Media** tab, and then in **Expand the desired media item, then check the box for the items to restore**, expand the media item that contains the backup file you wish to use, and select the check box next to **System State** for that file. This will restore the System State data along with any other data you have selected for the current restore operation.
4. In **Restore files to**, do one of the following:
   - Click **Original location** if you want the backed up files and folders to be restored to the folder or folders they were in when they were backed up. Skip to step 6.

     -or-

   - Click **Alternate location** if you want the backed up files and folders to be restored to a folder that you designate. This option will preserve the folder structure of the backed up data; all folders and subfolders will appear in the alternate folder you designate.

     -or-

   - Click **Single folder** if you want the backed up files and folders to be restored to a folder that you designate. This option will not preserve the folder structure of the backed up data; the files will appear only in the folder that you designate.
5. If you selected **Alternate location** or **Single folder**, type a path for the folder under **Alternate location**, or click the **Browse** button to find the folder.
6. On the **Tools** menu, click **Options**, click the **Restore** tab, and then do one of the following:
   - Click **Do not replace the file on my computer** if you do not want the restore operation to copy over files that are already on your hard disk.

     -or-

   - Click **Replace the file on disk only if the file on disk is older** if you want the restore operation to replace older files on your disk with newer files from your backup.

     -or-

   - Click **Always replace the file on my computer** if you want the restore operation to replace files on your disk regardless of whether the backup files are newer or older.
7. Click **OK** to accept the restore options you have set.
8. Click **Start Restore**.
9. Click the **Advanced** tab if you want to change any advanced restore options, such as restoring security settings and junction point data. When you are done setting advanced restore options, click **OK**.
10. Click **OK** to start the restore operation.

# Configure an ASP.NET Application for ASP.NET

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

By default, when the Microsoft® .NET Framework is installed on a computer with an existing .NET Framework installation, most Microsoft ASP.NET applications are automatically updated to use the newly installed version. The exceptions are applications that are bound to an incompatible or later version of the .NET Framework. Although later versions of the .NET Framework are designed to be backward compatible, you might need to configure an ASP.NET application to use an earlier version, if it cannot run successfully on a later version of the .NET Framework.

When multiple versions of the .NET Framework are executing side-by-side on a single computer, the ASP.NET ISAPI version script that is mapped to an ASP.NET application determines which version of the common language .NET Framework is used for the application. The following sections describe the process for configuring an ASP.NET application to target a specific version of the .NET Framework.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type:

**runas /user:** *administrative_accountname* **"mmc %systemroot%\system32\inetsrv\iis.msc".**

**Procedures**

**Viewing the Script Map for an ASP.NET Application**

When managing a computer with multiple versions of the .NET Framework installed, it is often useful to view the script map for an ASP.NET application to determine which version is used by the application.

**To view the script map for an ASP.NET application**

1. Open IIS Manager, expand the local computer, and navigate to the Web site folder that contains the ASP.NET application.
2. Right-click the Web site folder, and then click **Properties**.
3. In the **Properties** dialog box, on the **Home Directory** tab, click the **Configuration** button.
4. In the **Application Configuration** dialog box, on the **Mappings** tab, select an ASP.NET application extension, such as .asmx or .aspx.

   The **Executable Path** column of the dialog box lists the path to the ASP.NET ISAPI version used by the selected application type. By default, the ASP.NET ISAPI is installed in the following location: *systemroot*\Microsoft.NET\Framework*versionNumber*

   The version number shown in the path indicates the version number of the ASP.NET ISAPI used by the application type. The first two digits of the ASP.NET ISAPI version number are the same as the first two digits of the version number of the .NET Framework used by the application.

**Configuring an ASP.NET Application for ASP.NET**

When the .NET Framework is installed on a computer with an existing .NET Framework installation, by default all ASP.NET application script maps are automatically updated to use the newly installed version. To make it easier to reconfigure the script map for an ASP.NET application, each installation of the .NET Framework comes with an associated version of the ASP.NET IIS Registration tool (Aspnet_regiis.exe). Administrators can use Aspnet_regiis.exe to remap an ASP.NET application to the correct version of ASP.NET.

| **Note** |
| --- |
| Because Aspnet_regiis.exe is linked to a specific version of the .NET Framework, administrators must use the appropriate version of Aspnet_regiis.exe to reconfigure the script map for an ASP.NET application. |

Aspnet_regiis.exe can also be used to display the status of all installed versions of ASP.NET, register the associated version of ASP.NET, create client-script directories, and perform other configuration operations.

**To use Aspnet_regiis.exe to update a script map for an ASP.NET application**

1. In the **Run** dialog box, type **cmd**, and then click **OK**.
2. At the command prompt, use the **cd** command to change the directory of the Aspnet_regiis.exe version you want to use. Remember that each version of the .NET Framework comes with its own version of Aspnet_regiis.exe. By default, Aspnet_regiis.exe is located in the following directory: *systemroot*\Microsoft.NET\Framework*versionNumber*

   You can check to see which version you are running by using the procedure "To view the script map for an ASP.NET application" earlier in this section.
3. Run **Aspnet_regiis.exe** using the **-s** or **-sn** option along with the path to the application to set up the script maps. The following command-line example updates the script maps for an application called SampleApp1.

   **Aspnet_regiis.exe -s W3SVC/1/ROOT/SampleApp1**

| **Note** |
| --- |
| The **-s** and **-sn** options allow you to install script maps for ASP.NET at the specified path recursively (-s), which copies the script maps to the subfolders, or nonrecursively (-sn), which does not copy the script maps to the subfolders. |

**To get a list of the options available for Aspnet_regiis.exe**

- At the command prompt in the folder where Aspnet_regiis.exe is installed, type: **Aspnet_regiis ?**.

  A list of options available for use with Aspnet_regiis.exe displays.

# Configure Anonymous User Identity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When the Web sites and applications running on the Web server require anonymous access, IIS must be configured with a user account specifically for anonymous access. This user account can be stored in the local account database on the Web server or in a domain.

If, prior to upgrade, the anonymous user identity is configured to use an account stored in a domain you must configure the anonymous user identity to use the same domain-based account after the upgrade. This is necessary because the upgrade process automatically configures IIS to use the default anonymous user account IUSR_*computername*, where *computername* is the name of the computer on which IIS is running. You can configure the anonymous user identity to use the domain-based user account through IIS Manager. If the anonymous user identity does not use an account stored in a domain, it can be configured to use an account stored in the local account database on the Web server.

**Procedures**

**To configure the account used for Anonymous authentication**

1. In IIS Manager, expand the local computer, right-click the site, directory, or file that you want to configure, and then click **Properties**.
2. Click the **Directory Security** or **File Security** tab, depending on the level for which you are changing the security settings.
3. In the **Authentication and access control** section, click **Edit**.
4. Select the **Enable anonymous access** check box.
5. Type the valid Windows user account you want to use for Anonymous access, or click **Browse** to locate it.
6. Click **OK** twice.

# Configure a Web Site to be FrontPage Extended

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions from Microsoft provides Web-based and command-line administration for extending Web sites. *Extending* a Web site means enabling various FrontPage 2002 Server Extensions features to improve how you manage the content development and security of your site. Extending Web sites with FrontPage 2002 Server Extensions enables the Web site owner to author the site in the Microsoft® FrontPage® web site creation and management tool and delegate Web site ownership and administration credentials. After a Web site is extended, a FrontPage client can open the Web site and author it in FrontPage.

Before you can use FrontPage 2002 Server Extensions, you must create one or more Web sites to contain them. An extended Web site, formerly known as a virtual server, is an IIS Web site that receives additional functionality when it is extended by FrontPage Server Extensions. By default, IIS provides a working extended Web site called **Default Web Site**. This extended Web site points to the content directory *systemroot*\Inetpub\wwwroot.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc.**

**Procedures**
Before extending a site, check to make sure that the FrontPage 2002 Server Extensions optional component is installed. In Control Panel, click **Add or Remove Programs**, and then click **Windows Components Wizard**. If the FrontPage 2002 Server Extensions component is not installed, add it by using the following procedure.

**To add the FrontPage 2002 Server Extensions component**

1. In the **Windows Components Wizard** select **Application Server**, and then click **Details**.
2. In the **Application Server** subcomponents list, select **Internet Information Services**, and then click **Details**.
3. In the IIS subcomponents list, select the check box for **FrontPage 2002 Server Extensions**, and then click **OK** to complete the Windows Components Wizard and install FrontPage 2002 Server Extensions. You might need your Windows Server 2003 installation CD to complete the installation.

**To extend a site by using the FrontPage Server Extensions 2002 Server Administration tool**

1. Open Administrative Tools, and then click **Microsoft SharePoint Administrator**.
2. If the FrontPage 2002 Server Extensions optional component is not installed IIS returns error 404, "The page cannot be found." In this case, add the FrontPage 2002 Server Extensions component by using the procedure described earlier in this section.
3. On the **FrontPage Server Extensions 2002 Server Administration** site, verify that the extended Web site you created is listed in the **Virtual Servers section**.
4. To extend the Web site, click the **Extend** link next to the extended Web site name.
5. Click **Submit**. The **FrontPage Server Extensions 2002 Server Administration** tool adds FrontPage 2002 Server Extensions template directories to the content directory of your extended Web site, and adds other files that contain metadata.

# Configure Application Identity for IIS 5.0 Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you are running Internet Information Services (IIS) 6.0 in IIS 5.0 isolation mode, you also need to configure application identities for IIS 5.0 isolation mode. On your Microsoft® Windows® Server 2003–based server running in IIS 5.0 isolation mode, configure the application identity to the same settings as were set up on your server running IIS 5.0. You can do this by modifying the identity property of the COM+ object created for the Web site.

**Procedures**

**To configure Web site and application process identities in IIS 5.0**

1. In the **Run** dialog box, type **mmc**, and then click **OK** to start the Microsoft Management Console (MMC).
2. If the Component Services Snap-in is not already loaded, on the **File** menu, click **Add/Remove Snap-in**, and then click **Add**. Under **Available Standalone Snap-ins**, click **Component Services**, and then click **Add**. Click **Close** and then click **OK**.
3. In MMC, in the console tree, expand **Component Services**, expand **Computers**, expand **My Computer**, and then expand **COM+ Applications**.
4. Right-click **IIS Out-of-Process Pooled Applications** and then click **Properties**.
5. Click the **Identity** tab.
6. In **User**, type the user name. In the **Password** and **Confirm password** text boxes, enter the password for the user account. To look up a valid user name, click **Browse**.
7. Click **OK**.

# Configure Application Isolation Modes

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can run Internet Information Services (IIS) 6.0 in one of two modes: *worker process isolation mode* or *IIS 5.0 isolation mode*. Worker process isolation mode is the default mode the Web server runs in after a clean installation of the Microsoft® Windows® Server 2003 operating system. IIS 5.0 isolation mode is the default mode when you upgrade to IIS 6.0 from a previous version of IIS. Administrators should only run IIS in IIS 5.0 isolation mode when applications on the server are determined to be incompatible with worker process isolation mode.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: lis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname***mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**Configuring IIS for Worker Process Isolation Mode**
To complete the following procedure, you must restart IIS, which will temporarily interrupt the World Wide Web Publishing Service (WWW service).

### To configure IIS for worker process isolation mode

1. In IIS Manager, expand the local computer, right-click **Web Sites**, and then click **Properties**.
2. Click the **Service** tab, clear the **Run WWW service in IIS 5.0 isolation mode** check box, and then click **OK**.
3. To start the WWW service, click **Yes** when asked if you want to restart IIS now.

If the switch to worker process isolation mode is successful, a folder named Application Pools appears in the IIS Manager listing for your local computer. You can quickly determine which isolation mode IIS is running because the Application Pools folder is present in worker process isolation mode and absent in IIS 5.0 isolation mode.

**Configuring IIS for IIS 5.0 Isolation Mode**
After you complete the following procedure, you must restart the WWW service, which will temporarily interrupt the service.

### To configure IIS for IIS 5.0 isolation mode

1. In IIS Manager, expand the local computer, right-click **Web Sites**, and then click **Properties**.
2. Click the **Service** tab, select the **Run WWW service in IIS 5.0 isolation mode** check box, and then click **OK**.
3. To start the WWW Service, click **Yes** when asked if you want to restart IIS now.

# Configure Application Isolation Settings for IIS 5.0 Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Isolating* applications means configuring them to run in a process (memory space) that is separate from the Web server core (the core components required to run Internet Information Services (IIS), such as IISAdmin, the metabase, and so on) and other applications. You can configure applications into one of three levels of application protection:

- Low (IIS process)
- Medium (pooled)
- High (isolated)

Note that server-side includes (SSI), Internet Database Connector (IDC), and other InProcessISAPIApps applications (special applications that must be run in process) cannot be run in medium or high isolation.

**Requirements**

- Mode: This feature of IIS 6.0 is available only when IIS is running in IIS 5.0 isolation mode.
- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc.**

**Procedures**
**To set or change the level of application protection**

1. In IIS Manager, expand the local computer, right-click the Web site or the starting-point directory for the application you want to configure, and then click **Properties**.
2. Click the **Home Directory**, **Virtual Directory**, or **Directory** tab, depending on whether you are configuring a Web site, a virtual directory, or an application.
3. In the **Application protection** box, click the appropriate level of protection, and then click **OK**.

The Web server finishes processing any current requests for the application before it creates a separate process. At the next request for the application, the application will run in the appropriate memory space.

# Configure Application Pool Health

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Monitoring the health of a worker process includes detecting whether the worker process is able to serve requests and then taking appropriate action. For example, if a worker process fails to respond to a ping request by the World Wide Web Publishing Service (WWW service), the worker process probably does not have threads available for processing incoming requests. You can monitor the health condition of an application pool by pinging the worker processes assigned to it at regular intervals. When a configurable unhealthy condition occurs, you can also set the following features to take corrective action:

- Rapid-fail protection
- Startup time limit
- Shutdown time limit

**Requirements**

- Mode: This feature of Internet Information Services (IIS) 6.0 is available only when IIS is running in worker process isolation mode.
- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

Consider the following when setting the configuration for recycling the worker processes assigned to an application pool:

- Worker process pinging is enabled by default. Adjust the ping interval to get timely information about application pool health without triggering false unhealthy conditions.
- When the WWW service detects that a worker process fails more than a set maximum number of times in a set time period, it places the worker process in a rapid-fail protection state. Placing application pools in rapid-fail protection state protects the availability of other applications on the server.
- When the WWW service detects that a worker process is unhealthy, it marks the worker process for termination. Within configured time limits, IIS terminates the worker process. It is important to tune the shutdown time period to fit the load characteristics of the applications that are being processed.
- After IIS terminates an unhealthy worker process, it starts a new worker process to replace the unhealthy one. It is important to tune the startup time period to fit the overlap desired between the unhealthy worker process and the new worker process.

**To configure worker process pinging**

1. In IIS Manager, expand the local computer, right-click the application pool you want to configure, and then click **Properties**.
2. On the **Health** tab, select the **Enable pinging** check box.
3. In the text box to the right of **Ping worker process every (frequency in seconds)**, type the number of seconds to

elapse before the worker process is pinged, and then click **OK**.

**To configure rapid-fail protection**

1. In IIS Manager, expand the local computer, right-click the application pool you want to configure, and then click **Properties**.
2. On the **Health** tab, select the **Enable rapid-fail protection** check box.
3. In the text box to the right of **Failures**, type the maximum number of failures allowed.
4. In the box to the right of **Time period (in minutes)**, type the elapsed time, in minutes, during which the number of failures is counted, and then click **OK**.

**To configure startup and shutdown time limits**

1. In IIS Manager, expand the local computer, right-click the application pool you want to configure, and then click **Properties**.
2. On the **Health** tab, under **Startup time limit**, in the text box to the right of **Worker process must startup within (time in seconds)**, type the time, in seconds, to elapse before starting up a new worker process.
3. On the **Health** tab, under **Shutdown time limit**, in the text box to the right of **Worker process must shutdown within (time in seconds)**, type the time, in seconds, to elapse before shutting down a failing worker process, and then click **OK**.

# Configure Application Pool Identity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The identity of an application pool is the name of the service account under which the application pools worker process runs. By default, application pools operate under the Network Service user account, which has low-level user access rights. You can configure application pools to run under the Local System user account, which is an account with more user rights than the Network Service or Local Service user accounts. However, be mindful that running an application pool under an account with increased user rights presents a high security risk.

**Requirements**

- Mode: This feature of Internet Information Services (IIS) 6.0 is available only when IIS is running in worker process isolation mode.
- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc.**

**Procedures**
By default, application pools operate under the Network Service user account, which has low-level user access rights. Consequently, this account provides better security against attackers or malicious users who might attempt to take over the computer on which the World Wide Web Publishing Service (WWW service) is running. The Local Service user account has low access rights as well, and is useful for situations that do not require access to resources on remote computers. You can, however, configure application pools to run under the Local System user account, which is an account with more user rights than the Network Service or Local Service user accounts.

### To change the service account that an application pool runs under

1. In IIS Manager, expand the local computer, and expand **Application Pools**.
2. Right-click the application pool you want to configure, and then click **Properties**.
3. Click the **Identity** tab, and click either **Predefined** or **Configurable**.

   **Predefined** refers to standard service accounts, such as Network Service (the default), which has low-level user access rights that can be used for access to resources on remote computers, Local Service, which has low-level access rights, and is used for situations that do not require access to resources on remote computers, or, Local System, which is an account with more user rights than the Network Service or Local Service account.

   **Configurable** refers to registered user names.
4. If you click **Predefined**, click a predefined account in the list box.
5. If you click **Configurable**, in the **User name** and **Password** boxes, type the user name and password of the account under which you want the worker process to operate.
6. Click **OK**.

# Configure Application Pool Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In worker process isolation mode, Internet Information Services (IIS) 6.0 can be configured to optimize the performance of an application pool, allowing you optimize the performance of your Web applications. Some of the ways to accomplish this include configuring an application pool to limit the size of its request queue, enabling CPU monitoring to allow the server to take action when CPU usage exceeds maximum CPU use, configuring the server to shut down a worker process after being idle for a specified number of minutes, and creating a Web garden, which is an application pools with more than one worker process assigned. Setting these configurations helps you manage the resources on a Web server.

**Requirements**

- Mode: This feature of IIS 6.0 is available only when IIS is running in worker process isolation mode.
- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
When performance is degraded by too many requests or by problem applications, and you want to configure the application pool to improve the performance of the worker processes assigned to the pool, consider the following:

- When an application pool receives requests faster than it can handle them, the requests might consume all of the application pools memory. This could happen when the requests queue size limit is large and legitimate requests are coming in at a rapid rate, or during a denial of service attack. To prevent requests from consuming all of an application pools memory, limit the size of the request queue for the application pool.
- When problem applications consume excessive CPU resources, you need a way to manage them. In worker process isolation mode, you can enable CPU monitoring, configure CPU limits, and direct IIS to take action when a worker process exceeds the CPU limit set for it.
- Web gardens are application pools with more than one worker process assigned. Create a Web garden to achieve more robust performance when resources often get tied up with a single worker process, or when you need to smooth out the handling of a workload.

### To configure idle timeout

1. In IIS Manager, expand the local computer, right-click the application pool you want to configure, and then click **Properties**.
2. On the **Performance** tab, under **Idle Timeout**, select the **Shutdown worker process after being idle for (time in minutes)** check box.
3. In the text box to the right of **Shutdown worker process after being idle for (time in minutes)**, type the number of minutes to elapse before the worker process is recycled, and then click **OK**.

### To configure a request queue limit

1. In IIS Manager, expand the local computer, right-click the application pool you want to configure, and then click **Properties**.
2. On the **Performance** tab, select the **Limit the kernel request queue (number of requests)** check box.

3. In the text box to the right of **Limit the kernel request queue (number of requests)**, type the maximum number of requests to allow in the request queue, and then click **OK**.

**To configure CPU monitoring**

1. In IIS Manager, expand the local computer, right-click the application pool you want to configure, and then click **Properties**.
2. On the **Performance** tab, select the **Enable CPU monitoring** check box.
3. In the box to the right of **Maximum CPU use (percentage)**, type the percent maximum CPU threshold.
4. In the text box to the right of **Refresh CPU usage numbers (in minutes)**, type the number of minutes before the CPU usage numbers are refreshed.
5. In the drop-down list box below **Action performed when CPU usage exceeds maximum CPU use**, select the action to take, and then click **OK**.

**To configure a Web garden**

1. In IIS Manager, expand the local computer, right-click the application pool you want to configure, and then click **Properties**.
2. On the **Performance** tab, under **Web garden**, in the **Maximum number of worker processes** textbox, type the number of worker processes to assign to the application pool, and then click **OK**.

# Configure Application Pool Recycling

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) can be configured to periodically restart worker processes assigned to an application pool, which recycles faulty Web applications. Recycling keeps problematic applications running smoothly, especially when it is not feasible to modify the application code. Recycling helps ensure that problematic applications do not cause other applications to fail, and that system resources can be recovered from unhealthy applications. Use the Configure Application Pool Health procedure earlier in this appendix to configure worker process shutdown and startup times to ensure that applications do not experience downtime.

**Requirements**

- Mode: This feature of IIS 6.0 is available only when IIS is running in worker process isolation mode.
- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To recycle a worker process immediately on demand**

1. In IIS Manager, expand the local computer.
2. Expand **Application Pools**.
3. Right-click the appropriate application pool you want to recycle, and then click **Recycle**.

**To configure a worker process to be recycled after a set elapsed time**

1. In IIS Manager, expand the local computer, and expand **Application Pools**.
2. Right-click the application pool you want to configure, and then click **Properties**.
3. On the Recycling tab, select the **Recycle worker processes (in minutes)** check box.
4. In the text box to the right of the **Recycle worker processes (in minutes)**, type the number of minutes that you want to elapse before the worker process is recycled, and then click **OK**.

**To configure a worker process to be recycled after a set number of processing requests**

1. In IIS Manager, expand the local computer, and expand **Application Pools**
2. Right-click the application pool you want to configure, and then click **Properties**.
3. On the **Recycling** tab, select the **Recycle worker process (number of requests)** check box.
4. In the text box to the right of the **Recycle worker process (number of requests)**, type the number of requests to be processed before the worker process is recycled, and then click **OK**.

**To configure a worker process to be recycled at scheduled times**

1. In IIS Manager, expand the local computer, expand **Application Pools**.
2. Right-click the application pool you want to configure, and then click Properties.
3. On the Recycling tab, select the Recycle worker processes at the following times check box.

4. Click **Add to add a time to the list, Remove to delete a time**, or **Edit to change an existing time when the worker process is recycled**, and then click **OK**.

| **Note** |
| --- |
| When recycling is set to occur at scheduled times, it may occur off-schedule if the system time is manually altered. To avoid unintended changes in the time that recycling occurs, recycle the scheduled worker processes soon after the system time is changed. |

**To configure a worker process to be recycled after consuming a set amount of memory**

1. In IIS Manager, expand the local computer, and expand **Application Pools**.
2. Right-click the application pool you want to configure, and then click **Properties**.
3. On the Recycling tab, under Memory recycling, select the Maximum virtual memory (in megabytes) check box.
4. In the text box to the right of **Maximum virtual memory (in megabytes)**, type the maximum amount of virtual memory allowed before the worker process is recycled.
5. Select the Maximum used memory (in megabytes) check box.
6. In the text box to the right of **Maximum used memory (in megabytes)**, type the maximum amount of memory allowed before the worker process is recycled, and then click **OK**.

# Configure Compression

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To more efficiently use available bandwidth, it is advisable to enable IIS's HTTP compression feature. HTTP compression provides faster transmission time between compression-enabled browsers and IIS regardless of whether your content is served from local storage or a UNC resource. You can compress static files only, application response files only, or both static files and application response files. Compressing application response files is usually called dynamic compression.

By default, enabling static file compression compresses .htm, .html, and .txt files. Enabling dynamic compression compresses .asp, .dll, and .exe files. You can customize the file types that are compressed. See Customizing the File Types IIS Compresses for more information.

Enabling compression of static files in IIS always results in more efficient utilization of bandwidth and faster Web site performance. Enabling dynamic compression always results in more efficient utilization of bandwidth, but if your server's processor utilization is already extremely high, the CPU load imposed by dynamic compression might make your site perform more slowly.

If you already have a network-based compression solution installed, enabling compression in IIS might not result in bandwidth utilization or performance improvements, depending on whether the network-based compression and IIS-based compression are redundant. See Optimizing IIS 6.0 Performance for detailed information about the many compression configuration options available.

Requirements

- Mode: This feature of IIS 6.0 is available whether IIS is running in worker process isolation mode or IIS 5 compatibility mode.
- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

Procedures

**To enable server-wide HTTP compression**

1. In IIS Manager, expand the local computer, right-click the Web Sites folder, and then click **Properties**.
2. Click the Service tab, and in the HTTP compression section, select the **Compress application files** check box to enable dynamic compression.
3. Select the **Compress static files** check box to compress static files.
4. In the **Temporary directory** box, type the path to a local directory or click **Browse** to locate a directory. Once a static file is compressed, it is cached in this temporary directory until it expires, or the content changes. The temporary directory must be on a local drive on an NTFS-formatted partition. The directory cannot be compressed, and should not be shared.
5. Under **Maximum temporary directory size**, click a folder size option. If you click the **Limited to (in megabytes)** option and enter a number in the text box next to it, IIS automatically cleans up the temporary directory according to a least recently used rule when the set limit is reached.
6. Click **Apply**, and then click **OK**.

| **Note** |
| --- |
| If you notice a performance loss specific to serving dynamic content, disable compression of dynamic content. |

# Configure FrontPage Server Roles

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The configuration of Internet Information Services (IIS) and the Web sites on the source server might reference user accounts that are stored in the local account database on the source server. These accounts stored locally on the Web server are known as *local user accounts*. Local user accounts are only valid on the Web server where they exist, not on other Web servers. When you migrate your Web site to another server, these local user accounts must be recreated on the target server. Once the user accounts have been created, the roles that were assigned to the user accounts on the source server must be assigned to the user accounts on the target server.

You can manage roles from the Site Administration page for your Web site. On this page you can view a list of roles, change which rights are included in a role, add a new role, and delete a role.

**Procedures**

**To add a user account and assign FrontPage server roles to it**

1. Open **Administrative Tools**, and click **Microsoft SharePoint Administrator**.
2. On the **Server Administration** page, click the name of the extended Web site for which you want to assign user roles.
3. On the **Site Administration** page for the Web site, click **Manage users**.
4. On the **Manage Users** page, click **Add a user**.
5. On the **Add a User** page, in the **User** section, click **Add user or group name (For example, DOMAIN\name)**, and enter a user name in the format *LocalComputerName**UserAccountName*.
6. In the **User Role** section, select the check boxes for all roles that apply to this user account, and then click **Add User**.

**To assign FrontPage server roles to an existing user account**

1. Open **Administrative Tools**, and click **Microsoft SharePoint Administrator**.
2. On the **Server Administration** page, click the name of the extended Web site for which you want to assign user roles.
3. On the **Site Administration** page for the Web site, click **Manage users**.
4. On the **Manage Users** page, click the name of the user for which you need to change the roles.
5. On the **Edit User Role Membership** page, next to **User Role**, select the check box for every role that applies to this user, and then click **Submit**.

# Configure FTP Server Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) supports the following File Transfer Protocol (FTP) authentication methods:

- Anonymous FTP authentication
- Basic FTP authentication

Available authentication settings must be set at the site level for FTP sites. FTP service is not enabled by default in IIS 6.0.

| **Important** |
| --- |
| If you change the security settings for your FTP site or virtual directory, your Web server prompts you for permission to reset the security settings for the child nodes of that site or directory. If you choose to accept these settings, the child nodes inherit the security settings from the parent site or directory. |

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**Enable Anonymous FTP Authentication**
If you select Anonymous FTP authentication to secure FTP resources, all requests for that resource are accepted without prompting the user for a user name or password. For Anonymous authentication, IIS automatically creates a Windows user account called IUSR_*computername*, where *computername* is the name of the server on which IIS is running. If you have both Anonymous FTP authentication and Basic FTP authentication enabled, IIS tries to use the Anonymous FTP authentication user account first.

### To enable the Anonymous FTP authentication method

1. In IIS Manager, right-click the FTP site, directory, virtual directory, or file you want to configure, and click **Properties**.
2. Click the **Security Accounts** tab.
3. Select the **Allow anonymous connections** check box.
4. To allow your users to gain access by Anonymous authentication only, select the **Allow only anonymous connections** check box.
5. In the **User name** and **Password** boxes, enter the Anonymous logon user name and password you want to use, and then click OK

   The user name is the name of the anonymous user account, which is typically designated as **IUSR**_*computername*.

   **Note** If the default **IUSR**_*computername* account will not be used for Anonymous FTP authentication, you must create a Windows user account appropriate for the authentication method. For more information about creating a new user account, see the procedure Create a Service Account in this section.
6. Set the appropriate NTFS permissions for the anonymous account.
7. For more information about setting NTFS permissions, see the procedure Configure NTFS Permissions earlier in this

appendix.

**Enable Basic FTP Authentication**

If you select the Basic FTP authentication method to secure your FTP resources, users must log on with a user name and password corresponding to a valid Windows user account. If the FTP server cannot verify a user's identity, the server returns an error message. Basic FTP authentication provides only low security because the user transmits the user name and password across the network in an unencrypted form.

**To enable the Basic FTP authentication method**

1. Create a Windows user account appropriate for the authentication method. If appropriate, add the account to a Windows user group.

   For more information about creating a new user account, see the procedure Create a Service Account earlier in this appendix.

2. Configure NTFS permissions for the directory or file for which you want to control access.

   For more information about setting NTFS permissions, see the procedure Configure NTFS Permissions earlier in this appendix.

3. In IIS Manager, right-click the FTP site, directory, virtual directory, or file you want to configure, and click **Properties**.

4. Click the **Security Accounts** tab.

5. Clear the **Allow anonymous connections** check box, and then click **OK**.

# Configure IIS Components and Services

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

**Add or Remove Programs** helps you manage programs and components on Microsoft® Windows® Server 2003 and Internet Information Services (IIS) 6.0. As you enable and disable the IIS protocols and services, you correspondingly increase and decrease the attack surface of the Web server.

| **Tip** |
| --- |
| You can also add Windows components by using the Configure Your Server Wizard. |

**Procedures**

**To configure IIS components and services**

1. In Control Panel, open **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. On the Windows Components Wizard page, under **Components**, click **Application Server**, and then click **Details**.
4. Click **Internet Information Services (IIS)**, and then click **Details**.
5. Enable or disable the appropriate IIS components and services by selecting the check box to add the component or clearing the check box to remove the component.
6. Complete the Windows Components Wizard by following the instructions in the wizard.

# Configure IP Address Assigned to Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can configure your Web site to use a unique IP address that uniquely identifies the Web site.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

### To configure the IP address assigned to a Web site

1. In IIS Manager, expand the local computer, right-click the Web site you want to configure, and then click **Properties**.
2. Click the **Web Site** tab, and then click the drop-down arrow next to **IP Address**.
3. Click the IP address you want to use from the drop-down list of IP addresses, and then click **OK**.

# Configure IP Address and Domain Name Restrictions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can configure your Web site to grant or deny specific computers, groups of computers, or domains access to Web sites, directories, or files.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**Configure Restrictions Based on IP Address**
You can use IIS Manager to grant or deny access to Web sites or applications for a computer or group of computers.

**Grant or deny access to resources for a single computer**
You can either deny or grant access for a single computer based upon its IP address.

**To grant access to resources for a computer**

1. In IIS Manager, expand the local computer, right-click a Web site, directory, or file you want to configure, and click **Properties**.
2. Click the **Directory Security** or **File Security** tab. In the IP address and domain name restrictions section, click **Edit**.
3. Click **Granted access**.
4. When you select **Granted access**, you grant access to all computers and domains, except to those that you specifically deny access.
5. Click **Add**.
6. Click **Single computer**.
7. Click **DNS Lookup** to search for computers or domains by name, rather than by IP address.
8. Type the DNS name for the computer. IIS searches on the current domain for the computer, and if found, enters its IP address in the IP address box.

   The following information is important to remember when using the **DNS Lookup** feature:

   - Server performance decreases while DNS addresses are being looked up.
   - A user accessing your Web server through a proxy server will appear to have the IP address of the proxy server.
   - Some user server access problems can be corrected by using the "*.domainname.com" syntax rather than the "domainname.com" syntax.

9. Click **OK** three times.

**To deny access to resources for a computer**

1. In IIS Manager, expand the local computer, right-click a Web site, directory, or file you want to configure, and click **Properties**.

2. Click the **Directory Security** or **File Security** tab. In the **IP address and domain name restrictions** section, click **Edit**.
3. Click **Denied access**.

   When you select **Denied access**, you deny access to all computers and domains, except to those that you specifically grant access.
4. Click **Add**.
5. Click **Single computer**.
6. Click **DNS Lookup** to search for computers or domains by name, rather than by IP address.
7. Type the DNS name for the computer. IIS searches on the current domain for the computer, and if found, enters its IP address in the **IP address** box.

   The following information is important to remember when using the **DNS Lookup** feature:

   - Server performance decreases while DNS addresses are being looked up.
   - A user accessing your Web server through a proxy server will appear to have the IP address of the proxy server.
   - Some user server access problems can be corrected by using the "*.domainname.com" syntax rather than the "domainname.com" syntax.
8. Click **OK** three times.

**Grant or deny access to resources for a group of computers**

A group of computers can be either denied or granted access based upon their network ID and a subnet mask. The network ID is the IP address of a host computer, usually a router for the *subnet*. The subnet mask determines which part of the IP address is a subnet ID, and which part is a host ID. All computers in a subnet have the same subnet ID, but have their own unique host ID. By specifying a network ID and a subnet mask, you can select a group of computers.

**To grant access to resources for a group of computers**

1. In IIS Manager, expand the local computer, right-click a Web site, directory, or file you want to configure, and click **Properties**.
2. Click the **Directory Security** or **File Security** tab. In the **IP address and domain name restrictions** section, click **Edit**.
3. Click **Granted access**.

   When you select **Granted access**, you grant access to all computers and domains, except to those that you specifically deny access.
4. Click **Add**.
5. Click **Group of computers**.
6. In the **Network ID** box, type the IP address of the host computer.
7. In the **Subnet mask** box, type the subnet ID for the computer you want grant or deny access to.
8. Click **OK** three times.

**To deny access to resources for a group of computers**

1. In IIS Manager, expand the local computer, right-click a Web site, directory, or file you want to configure, and click **Properties**.
2. Click the **Directory Security** or **File Security** tab. In the **IP address and domain name restrictions** section, click **Edit**.
3. Click **Denied access**.

   When you select **Denied access**, you deny access to all computers and domains, except to those that you specifically grant access.

4. Click **Add**.
5. Click **Group of computers**.
6. In the **Network ID** box, type the IP address of the host computer.
7. In the **Subnet mask** box, type the subnet ID for the computer you want grant or deny access to.
8. Click **OK** three times.

#### Configure Restrictions Based on Domain

Access to resources for a domain can be granted or denied by using IIS Manager.

**To grant access to resources for a domain**

1. In IIS Manager, expand the local computer, right-click a Web site, directory, or file you want to configure, and click **Properties**.
2. Click the **Directory Security** or **File Security** tab. In the **IP address and domain name restrictions** section, click **Edit**.
3. Click **Granted access**.

   When you select **Granted access**, you grant access for all computers and domains, except for those that you specifically deny access.
4. Click **Add**.
5. Click **Domain name**. You will see a warning message saying that "Restricting access by domain name requires a DNS reverse lookup on each connection. This is a very expensive operation and will dramatically affect server performance." Click **OK** to close the message dialog box.
6. In the **Domain name** box, type the domain name.
7. Click **OK** three times.

**To deny access to resources for a domain**

1. In IIS Manager, expand the local computer, right-click a Web site, directory, or file you want to configure, and click **Properties**.
2. Click the **Directory Security** or **File Security** tab. In the **IP address and domain name restrictions** section, click **Edit**.
3. Click **Denied access**.

   When you select **Denied access**, you deny access for all computers and domains, except for those that you specifically grant access.
4. Click **Add**.
5. Click **Domain name**.
6. In the **Domain name** box, type the domain name.
7. Click **OK** three times.

# Configure MIME Types

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) serves only static files with extensions registered in the Multipurpose Internet Mail Exchange (MIME) types list. IIS is preconfigured to recognize a default set of global MIME types, and also allows you to configure additional MIME types and change or remove MIME types. These MIME types are recognized by all Web sites you create in IIS.

MIME types can also be defined at the Web site and directory levels, independent of one another or the types defined globally. When you view MIME types at the Web site or directory level, only the types unique to that level are displayed, not all types inherited from the next level up. If you apply a MIME type at the global level after modifying the same MIME type at a lower level, the global-level MIME type overrides the modified MIME type at the lower level.

When IIS delivers a mail message to a mail application, or a Web page to a client Web browser, it also sends the MIME type of the data it is sending. If there is an attached or embedded file in a specific format, IIS tells the client application the MIME type of the embedded or attached file. The client application then knows how to process or display the data being received from IIS. IIS returns error 404.3 if a client request refers to a file name extension that is not defined in the MIME types.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

### To add a global MIME type

1. In IIS Manager, right-click the local computer, and click **Properties**.
2. Click the **MIME Types** button.
3. Click **New**.
4. In the **Extension** box, type the file name extension.
5. In the **MIME type** box, type a description that exactly matches the file type defined on the computer.

| **Note** |
| --- |
| You can also create a MIME type for files without an extension or for undefined MIME types. This is not recommended. |

6. Click **OK**.

### To add a MIME type to a Web site or directory

1. In IIS Manager, right-click the Web site or Web site directory for which you want to add a MIME type, and click **Properties**.
2. Click the **HTTP Headers** tab.
3. Click **Mime Types**.
4. Click **New**.
5. In the **Extension** box, type the file name extension.
6. In the **MIME type** box, type a description that exactly matches the file type defined on the computer. If you define a

MIME type that has already been defined at a higher level, you are prompted to select the level where the MIME type should reside.

7. Click **OK**.

**To remove a MIME type from a Web site or directory**

1. In IIS Manager, right-click the Web site or Web site directory from which you want to remove a MIME type, and click **Properties**.
2. Click the **HTTP Headers** tab.
3. Click **Mime Types**.
4. From the **Registered MIME types** list, click the MIME type you want to remove, and then click **Remove**.
5. Click **OK** three times.

# Configure NTFS Permissions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use NTFS permissions to define the level of access to your directories and files that you want to grant to specific users and groups of users. Proper configuration of file and directory permissions is crucial for preventing unauthorized access to your resources.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**To secure a Web site by using NTFS permissions**

1. In IIS Manager, expand the local computer, right-click the Web site or file you want to configure, and click **Permissions**.
   - To add a group or user that does not appear in the **Group or user names** list box, click **Add**, and in the **Enter the object names to select** text box, type the name of the user or group. Click **OK**.

     -OR-

   - To change or remove permissions from an existing group or user, click the name of the group or user in the **Group or user names** list box.
2. To allow or deny a permission such as **Read & Execute**, **List Folder Contents**, **Read**, or **Write**, in the **Permissions for group or user name** list box, select the **Allow** or **Deny** check box next to the appropriate permission, and then click **OK**.

| **Important** |
| --- |
| Inherited Deny permissions do not prevent access to an object if the object has an explicit Allow permission entry. Explicit permissions take precedence over inherited permissions, including inherited Deny permissions. |

With NTFS permissions, you also have the choice of assigning special permissions to groups or users. Special permissions are permissions on a more detailed level. For better management, you should assign broad-level permissions to users or groups, where it is applicable. For descriptions of permissions, see "Permissions for files and folders" in Help and Support Center for Windows Server 2003.

**To secure a Web site using NTFS special permissions**

1. In IIS Manager, expand the local computer, right-click a Web site or file you want to configure, and click **Permissions**.
2. Click **Advanced**, and then do one of the following on the **Permissions** tab:
   - To set special permissions for an additional group or user, click **Add**, and in the **Enter the object name to select** text box, type the name of the user or group. Click **OK**.
   - To view or change special permissions for an existing group or user, click the name of the group or user, and then click **Edit**.

- To remove an existing group or user and its special permissions, click the name of the group or user and then click **Remove**. If the **Remove** button is unavailable, clear the **Allow inheritable permissions from the parent to propagate to this object and all child objects. Include these with entries exclusively defined here.** check box, and then click **Remove**. Click **OK** and skip steps 3-6 below.

3. To allow or deny a permission such as **Read & Execute**, **List Folder Contents**, **Read**, or **Write**, in the **Permissions** list box, select the **Allow** or **Deny** check box next to the appropriate permission.
4. In the **Apply onto** list box, click the folders or subfolders you want these permissions to be applied to.
5. To prevent the subfolders and files from inheriting these permissions, clear the **Apply these permissions to objects and/or containers within this container only** check box, and then click **OK** three times.

| **Important** |
| --- |
| It is recommended that you assign permissions to the highest-level folders as possible and then apply inheritance to propagate the settings to lower-level subfolders and files. For more information on inheritance, see "How inheritance affects file and folder permissions" in Help and Support Center for Windows Server 2003. |

# Configure the State Service on the ASP.NET State Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The ASP.NET state service is used to manage session state on a computer. The ASP.NET state service is installed by default when Microsoft® Windows® Server 2003 is installed. The file aspnet_state.exe is installed on the remote server that will store session state information; the default location is *systemroot***Microsoft.NET\Framework****version***aspnet_state.exe**.

**Procedures**

**To configure the ASP.NET state service**

1. On the remote server that will store session state information, open **Administrative Tools**, and then click **Services**.
2. In the details pane, right-click **ASP.NET State Service**, and then click **Properties**.
3. On the **General** tab, in the **Startup type** list box, click **Automatic**.
4. Under **Service status**, click **Start**, and then click **OK**. The state service starts automatically when the Web server is restarted.

# Configure the Registry

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If a registry entry must be created or modified to correctly configure the server, you can edit the entry directly using the registry editor Regedit.exe.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Regedit.exe.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

| ⚠Caution |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the registry reference. |

**To create a new registry entry by using the registry editor**

1. In the **Run** dialog box, type **regedit**, and then click **OK**.
2. In the registry editor, navigate to the key or subkey under which you wish to add an entry and select the name of the key or subkey by clicking on it.
3. On the **Edit** Menu, point to **New** and then click the data type for the entry, such as **String Value**, **Binary Value**, or **DWORD Value**.
4. In the details pane, type the name of the registry entry, and then press ENTER to create the entry.
5. To assign a value to the registry entry, right-click the entry and then click **Modify**. If the entry has been defined as **Binary Value**, click **Modify Binary Data** instead.
6. In the **Edit ValueType Value** dialog box, type an appropriate value in the **Value data** text box. Type or select the value of other options, such as the base (hexadecimal or decimal) for DWORD values, and then click **OK**.

**To configure an existing registry entry by using the registry editor**

1. In the **Run** dialog box, type **regedit**, and then click **OK**.
2. In the registry editor, navigate to the registry entry that you want to modify.
3. In the details pane, right-click the entry, and click **Modify**. If the entry has been defined as **Binary Value**, then click **Modify Binary Data** instead.
4. In the **Edit ValueType Value** dialog box, type an appropriate value in **Value data**. Type or select the value of other options, such as the base (hexadecimal or decimal) for DWORD values, and then click **OK**.

**Related Information**

For more information about the registry, see the Registry Reference in the Windows Server 2003 Deployment Kit.

# Configure the Web Site Identification Number

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When a new site is created on Internet Information Services (IIS) 6.0, a Web site identification number is randomly generated based on the name of the Web site. In this way, Web sites of the same name usually generate the same Web site identification for IIS 6.0 servers in a Web farm. With IIS 5.0 and earlier versions, Web site identification numbers were incremental. For example, because the default Web site is created first, its site identification number is 1, and the next site to be created is identified as 2.

If you have administrative scripts that depend upon the IIS 5.0 method of generating Web site identification numbers, you can edit the registry entry IncrementalSiteIDCreation in the Windows registry to force IIS to use the incremental method of generating Web site identification numbers.

| **Note** |
| --- |
| When you remotely administer a server running IIS, the value of the IncrementalSiteIDCreation registry entry on the local server is used to determine the generation of Web site identification numbers on the remote server. |

**Requirements**

- Credentials: Membership in the Administrators group on the local and on the remote computer is required to make changes to the remote computers registry. Network policy settings might prevent you from completing this procedure.
- Tools: Regedit.exe.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

| **Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the registry reference. |

### To configure the IncrementalSiteIDCreation registry entry

1. To open the registry editor, in the **Run** dialog box, type **regedit**, and then click **OK**.
2. Expand **HKEY_LOCAL_MACHINE**, expand **SOFTWARE**, expand **Microsoft**, expand the **InetMGR** subkey, and then click **Parameters**.
3. Under **Parameters**, in the details pane, click **IncrementalSiteIDCreation**. If the entry does not exist, create it by doing the following:
4. Select **Parameters** by clicking on it.
5. On the **Edit** Menu, point to **New**, and then click **DWORD Value**.
6. Type **IncrementalSiteIDCreation** and press ENTER to create the entry.
7. With the entry **IncrementalSiteIDCreation** selected, on the **Edit** menu, click **Modify**.
8. In the **Value data** box, type **1** to force IIS to use the incremental method of generating Web site identification numbers, and then click **OK**.

**Related Information**

For more information about the registry, see the Registry Reference in the Windows Server 2003 Deployment Kit.

# Configure Web Server Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can set the authentication method for your Web resources with property sheets at the Web site, directory, or file level by using IIS Manager.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To configure Web server authentication**

1. In IIS Manager, right-click the **Web Sites** folder, Web site, directory, virtual directory, or file and click **Properties**.

   | **Note** |
   | --- |
   | Configuration settings made at the Web Sites folder level can be inherited by all Web sites |

2. Click the **Directory Security** or **File Security** tab, depending upon the level at which you are configuring security settings.
3. In **Authentication and access control**, click **Edit**.
4. To configure Integrated Windows authentication, in **Authenticated access**, select the **Integrated Windows authentication** check box.
5. To configure Digest authentication, in **Authenticated access**, select the **Digest authentication for Windows domain servers** check box.
6. To configure **Advanced Digest authentication**, in the **Realm** text box, type the realm name, or click **Select** to browse for a domain.

   | **Note** |
   | --- |
   | If Basic authentication is enabled for the site, virtual directory, or folder you are configuring, the **Default domain** text box will also be available. However, Realm is only meaningful for Advanced Digest authentication. |

   To configure Basic authentication, In the **Authenticated access** section, select the **Basic authentication (password is sent in clear text)** check box. Because Basic authentication sends passwords over the network unencrypted, a dialog box appears asking if you want to proceed. Click **Yes** to proceed. In the **Default domain** box, either type the domain name you want to use, or click **Select** to browse to a new default logon domain.

7. To configure .NET Passport authentication, select the **.NET Passport Authentication** check box. When .NET Passport authentication is selected, all other authentication methods are unavailable. .NET Passport cannot be used with other authentication methods because it validates user credentials in a fundamentally different way.
8. Click **OK** twice.

# Configure Web Service Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In order to take a more proactive stance against malicious users and attackers, Internet Information Services (IIS) is not installed on members of the Microsoft® Windows® Server 2003 family by default. Furthermore, when you initially install IIS, it is installed in a highly secure mode. By default, IIS serves only static content — features such as ASP, ASP.NET, server-side includes, WebDAV publishing, and FrontPage 2002 Server Extensions from Microsoft do not work unless they are specifically enabled. You can configure these features, also called Web service extensions, through the Web Service Extensions node in IIS Manager.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type: **runas /user:***administrative_accountname* **"mmc %systemroot%\system32\inetsrv\iis.msc"**.

**Procedures**

### To enable and disable a Web service extension

1. In IIS Manager, expand the local computer, and then click **Web Service Extensions**.
2. In the details pane, click the Web service extension that you want to enable or disable.
3. To enable a disabled Web service extension, click **Allow**.
4. To disable an enabled Web service extension, click **Prohibit**.

   A message box with a list of applications that will be prevented from running on the IIS Web server displays.
5. Click **OK** to disable the Web service extension.

To use, or to deny the use of, an HTTP request handler that is not in the list of Web service extensions, you must first register it by adding the HTTP request handler to the list of Web service extensions.

### To add new Web service extensions

1. In IIS Manager, expand the computer name, and then click **Web Service Extensions**.
2. In the details pane, click **Add a new Web service extension**.
3. In the **Extension name** text box, type the name of the new Web service extension, and then click **Add**.
4. In the **Path to file** text box, type the path or click **Browse** to navigate to any files that the new Web service extension requires, and then click **OK**.
5. Optionally, select the **Set extension status to Allowed** check box to automatically set the status of the new Web service extension to **Allowed**.
6. Click **OK** to add the new Web service extension.

You cannot delete built-in extensions. You can delete only extensions that you have added to the Web extension list.

### To delete Web service extensions

1. In IIS Manager, expand the computer name, and then click **Web Service Extensions**.
2. In the details pane, right click the Web Service Extension you want to delete, and then click **Delete**.

3. Click **Yes** to confirm the deletion.

You can also use IIS Manager to specify the applications that are allowed to call Web service extensions.

**To allow an application to call Web service extensions**

1. In IIS Manager, expand the local computer, and then click **Web Service Extensions**.
2. In the details pane, click **Allow all Web service extensions for a specific application**.
3. From the **Application** list box, click the name of the application.

   The Web service extension that the application is allowed to call appears in the **Extensions to be allowed** box.
4. Click **OK** to allow the application to call Web service extensions.

You can disable all Web service extensions that are registered on the local computer with one setting in the Web Service Extension node of IIS Manager.

**To disable all Web service extensions**

1. In IIS Manager, expand the local computer, and then **click Web Service Extensions**.
2. Click **Prohibit all Web service extensions**. The following message appears:

   If you prohibit all extensions, all Web service extensions in the list will be prohibited. This may prevent applications from running on your IIS Web server. Do you want to prohibit all extensions?
3. To disable all extensions, click **Yes**. To cancel the action, click **No**. For more information, click **Help**.
4. If you click **Yes**, the status of each Web service extension is **Prohibited**.

# Configure Web Site Permissions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can configure access permissions for specific Web sites, directories, and files. Unlike NTFS permissions, Web permissions affect everyone who tries to access your Web site. Web site permissions are not meant to be used in place of NTFS permissions, but are used in conjunction with them.

| **Note** |
| --- |
| If Web site permissions conflict with NTFS permissions for a directory or file, the more restrictive settings are applied. |

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To set permissions for Web content**

1. In IIS Manager, right-click the **Web Sites** folder, Web site, directory, virtual directory, or file you want to configure, and click **Properties**.
2. On the **Home Directory**, **Virtual Directory**, or **File** property sheet, select or clear any of the following check boxes (if available), depending on the type of access you want to grant or deny:
   - **Script Source Access**. Users can access source files. If **Read** is selected, source can be read, if **Write** is selected, source can be written to. **Script Source Access** includes the source code for scripts. This option is not available if neither **Read** nor **Write** is selected.
   - **Read** (selected by default). Users can view directory or file content and properties.
   - **Write**. Users can change directory or file content and properties.
   - **Directory browsing**. Users can view file lists and collections.
   - **Log visits**. A log entry is created for each visit to the Web site.
   - **Index this resource**. Allows Indexing Service to index this resource. This allows searches to be performed on the resource.
3. In the **Execute Permissions** list box, select the appropriate level of script execution:
   - **None** Do not run scripts or executables on the server.
   - **Scripts only** Run only scripts on the server.
   - **Scripts and Executables** Run both scripts and executables on the server.

4. Click **OK**. If child nodes for a directory have different Web site permissions configured, the **Inheritance Overrides** box appears.

   If a child node belonging to the directory whose Web site permissions you have changed has also set the Web site permissions for a particular option, the permissions in the child node will override those you have set for the directory. If you want the Web site permissions at the directory level to apply to the child nodes, you must select those child nodes in the **Inheritance Overrides** box.

5. If the **Inheritance Overrides** box appears, select the child nodes in the **Child Nodes** list to which you want the directory's Web permissions to apply. You can also click **Select All** to set the property to apply the Web permissions to all child nodes.

6. You might see more than one **Inheritance Overrides** box if more than one property has been defined in the child nodes of the directory. Select the child nodes from the **Child Nodes** list or click **Select All**, and then click **OK** to apply the Web permissions for this property to the child nodes.

# Configure Windows Server 2003 Services

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can use Add or Remove Programs in Control Panel to add or remove Microsoft® Windows® Server 2003 services, and you can use the Services console to enable or disable services. As you add and remove Windows Server 2003 services and enable and disable services, you increase and decrease the attack surface of the Web server correspondingly.

| **Note** |
| --- |
| You can also add Windows Server2003 services by using the Configure Your Server Wizard. |

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To add or remove Windows Server 2003 services**

1. From Control Panel, click **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. On the Windows Components Wizard page, in the **Components** box, select or clear the check box next to the component to enable or disable the appropriate Windows Server 2003 services. You may need to select a higher level component and then click **Details** to locate the component you wish to add or remove.
4. Click **Next** to run the Windows Components Wizard.
5. Follow the instructions in the Windows Components Wizard to complete the addition or removal of the component.

| **Note** |
| --- |
| You may need to have your Windows Server2003 CD-ROM available to complete the installation of the component. |

**To enable or disable Windows Server 2003 services**

1. Open Administrative Tools, and then click **Services**.
2. In the details pane, right-click the Windows Server 2003 service that you want to change, and then click **Properties**.
3. On the **General** tab, in the **Startup type** list box, click one of the following:
4. **Automatic**. The service starts automatically when the Web server is restarted.
5. **Manual**. The service can be started manually by an administrator or by another service.
6. **Disabled**. The service cannot be started by an administrator or by another service unless the startup type is changed to **Automatic** or **Manual**.
7. Click **OK** to save the changes.

# Convert Existing Disk Volumes to NTFS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The command-line tool **Convert.exe** converts FAT and FAT32 volumes to the NTFS file system, leaving existing files and folder intact. Volumes converted to the NTFS file system cannot be converted back to FAT or FAT32.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Convert.exe

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

### To convert FAT and FAT32 volumes to NTFS

1. In the **Run** dialog box, type **convert** followed by the appropriate syntax, and then click **OK**.

**Syntax**

```
convert [Volume] /fs:ntfs
```

**Parameters**

`Volume`

Specify the drive letter (followed by a colon), mount point, or volume name to convert to NTFS. Required if the volume to be converted is not the current volume.

`/fs:ntfs`

Required. Converts the volume to NTFS.

# Create a Service Account

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A service account is a user account that is created explicitly to provide a security context for services running on Microsoft® Windows® Server 2003. Application pools use service accounts to assign permissions to Web sites and applications running on Internet Information Services (IIS). Administrators can manage service accounts individually to determine the level of access for each application pool in a distributed environment.

Use Active Directory Users and Computers to create service accounts in the Active Directory® directory service. Use Computer Management to create local service accounts on a local computer.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Active Directory Users and Computers; Computer Management.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**To create a service account in Active Directory**

1. Open **Administrative Tools**, and then click **Active Directory Users and Computers**.
2. In the console tree, double-click the **Domain** node.
3. In the **Details** pane, right-click the organizational unit where you want to add the service account, point to **New**, and then click **User**.
4. In **First name**, type a first name for the service account.
5. In **Last name**, type a last name for the service account.
6. Modify **Full name** as desired.
7. In **User logon name**, type the name that the service account will log on with and, from the drop-down list, click the UPN suffix that must be appended to the service account logon name (following the @ symbol). Click **Next**.
8. In **Password** and **Confirm password**, type a password for the service account.
9. Select the appropriate password options, and then click **Next**.
10. Click **Finish** to complete creating a service account.

**To create a service account on the local Web server**

1. Open **Administrative Tools**, and then click **Computer Management**.
2. In the console tree, expand **System Tools**, expand **Local Users and Groups**, and then click **Users**.
3. On the **Action** menu, click **New User**.
4. Type a **User name**, **Full name**, and a **Description** of the user account.
5. In **Password** and **Confirm password**, type a password for the user account.
6. Set the user account access by selecting the check box to set the option or clearing the check boxes to remove the option for:

- **User must change password at next logon**
- **User cannot change password**
- **Password never expires**
- **Account is disabled**

7. Click **Create**, and then click **Close**.

**To create a service account for IIS_WPG Group**

1. Open Administrative Tools, and then click **Computer Management**.
2. In the console tree, expand **System Tools**, expand **Local Users and Groups**, and click **Groups**.
3. Click the IIS_WPG group and, on the **Action** menu, click **Add to Group**.
4. Under **Description**, type the name of the account and click **Add**.
5. In the **Select Users** dialog box, click the **Object Types** button, and select or clear the check box for the object types you want to find. Click **OK**.
6. Click the **Locations** button to select the location of the service account. Click **OK**.
7. Enter the name of the object under **Enter the object names to select**.
8. Click **OK**, and then click **OK** again.

# Create A SQL Server Database for Storing ASP.NET Session State

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ASP.NET SQL state server is used to manage session state on a computer running Microsoft® SQL Server™. All versions of Microsoft ASP.NET that are installed on the same computer share the same SQL state server. The SQL state server version of session state that is used is always the one that is installed with the latest version of ASP.NET. When this version of ASP.NET is uninstalled, the latest remaining version on the computer is then registered and used in its place.

**Requirements**

- Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Create an ASP.NET session state database with SQL Server Enterprise Manager**

1. On the **Start** menu, point to **Programs**, point to **Microsoft SQL Server**, and then click **Enterprise Manager**.
2. In **SQL Server Enterprise Manager**, connect to the server running SQL Server that will store the session state.
3. On the **Tools** menu, click **SQL Query Analyzer**.
4. In SQL Query Analyzer, on the **File** menu, click **Open**, and navigate to **InstallSqlState.sql** (the SQL script that builds the ASP.NET session state database).

   The InstallSqlState.sql file is located on the Web server in *systemroot***\Microsoft.NET\Framework***version* (where *version* is the most recent version number of the .NET Framework installed on the Web server).
5. On the **Query** menu, click **Execute**.
6. Ensure the query completed with no errors by reviewing the status in the lower window of the SQL Query Analyzer.
7. Close SQL Query Analyzer.
8. In **SQL Server Enterprise Manager**, in the console tree, expand the server node, and then click **Databases**.
9. In the details pane, verify that **ASPState** is listed.
10. Close SQL Server Enterprise Manager.

# Create a Virtual Directory in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In most cases, the content you publish to your Web site is located in a home directory on your computer, such as C:\Inetpub\Wwwroot\. However, there might be instances when the content is located in another directory, or even on a remote computer.

To be able to publish content from any directory not contained within your home directory, you must create a *virtual directory*. A virtual directory is a directory that is not contained in the home directory but appears to client browsers as though it were. You can create a virtual directory by using IIS Manager or by using Windows Explorer.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **"mmc %systemroot%\system32\inetsrv\iis.msc"**.

**Procedures**
**To create a virtual directory by using IIS Manager**

1. In IIS Manager, expand the **Web Sites** folder, and expand the Web site to which you want to add a virtual directory.
2. Right-click the Web site or folder within which you wish to create the virtual directory, select **New**, and then click **Virtual Directory**. The Virtual Directory Creation Wizard appears.
3. Click **Next**.
4. In the **Alias** box, type a name for the virtual directory. This is the name the user types, and should be short and easy to type.
5. Click **Next**.
6. In the **Path** box, type the name of the physical directory or click **Browse** to navigate to the physical directory in which the content for the virtual directory resides.
7. Click **Next**.
8. Under **Allow the following permissions**, select the check boxes for the access permissions you want to assign to your users, and then click **Next**.

| **Note** |
| --- |
| For security purposes, when selecting access permissions, consider allowing only the default **Read** permission. By restricting permissions in this way, you can mitigate potential attacks against your Web site by malicious users. |

1. Click **Finish**. The virtual directory is created below the currently selected folder level.

**To create a virtual directory by using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the folder you want to be a virtual directory, and select **Sharing and Security**.
3. On the **Web Sharing** tab, click **Share this folder**.

4. On the **Edit Alias** dialog box, in the **Alias** box, type the name for the virtual directory.
5. Under **Access permissions**, select the check boxes for the type of access you want to assign to the virtual directory.
6. Under **Application permissions**, select the check boxes for the type of application access you want to assign to the virtual directory.
7. Click **OK**, and then click **OK** again.

# Create a Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

During installation of Internet Information Services (IIS), a default home directory and Web site configuration are created on your hard disk. Similarly, creating a Web site by using IIS Manager does not create content, but merely creates a directory structure and configuration files from which to publish the content. To publish your Web content, you can place content in the default home directory, or you can create a different home directory or virtual directory and place content there.

**Important** If you install ASP.NET with IIS 6.0, structure the content of your Web site so that requests for Web site content do not need to contain /bin in the request URL. As a security measure, ASP .NET returns a 404 error for all requests containing /bin in the requested URL.

**Requirements**

- Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To use the default Web site**

1. In IIS Manager, expand the local computer, and expand the **Web Sites** folder.
2. Right-click **Default Web Site**, and select **Properties**.
3. On the **Web Site** tab, under **Web site identification**, type the name of your Web site in the **Description** box.
4. Click **OK**. The new name of the site appears in IIS Manager.

**To create a new Web site**

1. In IIS Manager, expand the local computer, and right-click the **Web Sites** folder.
2. Select **New**, and then click **Web Site**. The Web Site Creation Wizard appears.
3. Click **Next**.
4. In the **Description** box, type a name for your site, and then click **Next**.
5. Type or select the IP address (the default is **All Unassigned**), TCP port, and host header (for example, *www.mysite.com*) for your site.
6. Click **Next**.
7. In the **Path** box, type the name of the directory or click **Browse** to navigate to the directory that contains, or will contain, the site content.
8. Click **Next**.
9. Select the check boxes for the Web site access permissions you want to assign to your users, and then click **Next**.
10. Click **Finish**.
11. To change these and other settings later, right-click the Web site, and select **Properties**.

# Debug Application Pool Failures

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To enable *orphaning* of a worker process serving an application pool (which keeps failed applications running while your diagnostic tools monitor them), and to attach a debugger to the worker process, you must change the values of three metabase properties. The values of these metabase properties, which are set by running a script, must specified as follows:

- Set the **OrphanWorkerProcess** metabase property to **TRUE** to notify the WWW service to orphan the worker process when it fails.
- Set the **OrphanActionExe** metabase property to specify an executable to run when the worker process is orphaned.
- Set the **OrphanActionParams** metabase property to configure command-line parameters for attaching the debugger to the worker process.

Consider the following guidelines when you enable debugging of application pool failures:

- Debugging requires that you set all three metabase properties outlined above; enabling debugging is ineffective until you attach a debugger.
- When you no longer want to use the debugging feature, disable it. Putting an application in orphan state wastes resources if the diagnostics are not running or will not be used.

**Requirements**

- Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To enable and configure debugging on a worker process**

1. Copy the following ADSI script (written in VBScript) into a text editor or word processor.

```
set appPoolObj=GetObject("IIS://localhost/W3svc/AppPools/app pool name")
' Set the application pool properties:
appPoolObj.Put "OrphanWorkerProcess", TRUE
appPoolObj.Put "OrphanActionExe", "full path\ntsd.exe"
appPoolObj.Put "OrphanActionParams", "-g -p %1%"
' Save the property changes in the metabase:
appPoolObj.SetInfo
WScript.Echo "After: " & appPoolObj.OrphanWorkerProcess & ", " &
appPoolObj.OrphanActionExe & ", " & OrphanActionParams
```

2. Save the file with the extension .vbs.
3. In the **Run** dialog box, type **cmd**, and then click **OK**.
4. At the command prompt, run the script by typing the following command:

   **cscript //nologo** *filename*

   where *filename* is the fully qualified path of the script file.

– or –

You can call the script by using a batch file that contains the following command:

```
"cscript //nologo filename"
```

where *filename* is the fully qualified path of the script file.

# Determine Web Sites Uniquely Identified by IP Addresses

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can determine whether you have any Web sites that are uniquely identified with an IP address by viewing the Properties sheet of the Web sites on your source server.

**Requirements**

- Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To determine Web sites that are uniquely identified by an IP address in IIS 5.0**

1. Open Administrative Tools, and then click **Internet Service Manager**.
2. In IIS Manager, expand the server, right-click the Web site, and then click **Properties**.
3. On the **Web Site** tab, under **IP Address**, note whether there is a specific IP address assigned to this Web site. A specific IP address entry in this box denotes a uniquely identified Web site.

**To determine Web sites that are uniquely identified by an IP address in IIS 4.0**

1. Click **Start**, click **Programs**, click **Windows NT 4.0 Option Pack**, click **Microsoft Internet Information Server**, and then click **Internet Service Manager**.
2. In Internet Service Manager, expand the server, right-click the Web site, and then click **Properties**.
3. On the **Web Site** tab, under **IP Address**, note whether there is a specific IP address assigned to this Web site. A specific IP address entry in this box denotes a uniquely identified Web site.

# Disable Network Adapters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To ensure that clients cannot connect to the Web server while it is being upgraded, disable the network adapter that connects the Web server to the clients before taking it offline for the upgrade.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: none.

**Procedures**

**To disable the network adapter for IIS 5 0**

1. Click **Start**, click **Settings**, and then click **Network Connections**.
2. Locate the network adapter that connects the Web server to the clients.
3. Right-click the network adapter, and then click **Disable**.

**To disable the network adapter for IIS 4 0**

1. In Control Panel, double-click **Network**.
2. On the **Bindings** tab, click the network adapter, click **Disable**, and then click **OK**.

# Enable ASP.NET

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A server running a member of the Microsoft® Windows® Server 2003 family supports application server functionality, with Microsoft ASP.NET as an option that you can enable when configuring the application server role. To deploy ASP.NET Web applications to a production server, you must be sure to enable the ASP.NET and Internet Information Services (IIS) roles on the production server before you distribute the application.

| **Note** |
| --- |
| If you want to install ASP.NET on a domain controller, there are special steps you must take to make the installation work properly. For more information, see Knowledge Base article 315158, Fix: ASP.NET does not work with the Default ASPNET Account on a Domain Controller. |

**Procedures**

ASP.NET, along with the .NET Framework version 1.1, is included with Windows Server 2003. You need to install it by using Add or Remove Programs, or enable it by using the Configure Your Server Wizard.

| **Note** |
| --- |
| When you use the Configure Your Server Wizard or the **Add or Remove Programs** dialog box to install ASP.NET on a server running Windows Server 2003, ASP.NET is automatically enabled in IIS Manager. However, if you install ASP.NET from a Web download or as part of an application such as Microsoft® Visual Studio®.NET, you must enable ASP.NET manually, as described later in this section. |

**To enable ASP.NET on a server running Windows Server 2003 by using the Configure Your Server wizard**

1. Click **Start**, and then click **Manage Your Server**.
2. In the **Manage Your Server** window, click **Add or remove a role**.
3. In the Configure Your Server wizard, click **Next**.
4. In the **Server Role** dialog box, click **Application Server (IIS, ASP.NET)** and then click **Next**.
5. In the **Application Server Options** dialog box, select the **Enable ASP.NET** check box.
6. Click **Next**, and then click **Next** again.
7. If you are prompted to do so, insert your Windows Server 2003 installation CD in the CD-ROM drive, and then click **Next**.
8. When the installation is complete, click **Finish**.

**To enable ASP.NET on a server running Windows Server 2003 by using Add or Remove Programs**

1. In Control Panel, click **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. In the **Components** box in the Windows Components Wizard, select the **Application Server** check box, and then click **Details**.
4. In the **Application Server** dialog box, select the **ASP.NET** check box, and then click **OK**.
5. In the Windows Components Wizard, click **Next** to begin installing ASP.NET.
6. When the Windows Components Wizard has finished configuring Windows Server 2003, click **Finish**.

# Enable Buffering on the Administrative Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you install the Remote Administration (HTML) Tool for IIS 6.0 on a server that has been upgraded to Windows Server 2003 from Microsoft Windows NT 4.0, you may receive an error when you try to view the administrative Web site. This error occurs because, by default, buffering is set to **False** in IIS 4.0. However, in IIS 6.0, buffering is set to **True** by default, and this setting is not changed during upgrade. To view the administrative Web site in IIS 6.0, you must enable buffering.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: lis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **"mmc %systemroot%\system32\inetsrv\iis.msc"**.

**How To**

**To enable buffering on the administrative Web site (for upgrades from Windows NT 4.0)**

1. In IIS Manager, double-click *servername* (local computer).
2. Double-click **Web Sites**.
3. Right-click the Administration Web site and then click **Properties**.
4. Click **Home Directory**, click **Configuration**, and then click **Options**.
5. Check the **Enable buffering** check box, and then click **OK** twice.

# Enable Logging_IIS_SP1_Dep

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can enable logging for individual Web and File Transfer Protocol (FTP) sites. After you enable logging for a Web or FTP site, all traffic to the site (including virtual directories) is written to the corresponding file for each site. You can also enable logging for specific virtual directories.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: lis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To enable logging on a Web or FTP site**

1. In IIS Manager, expand the local computer, expand the **Web or FTP Sites** directory, right-click the Web or FTP Site for which you want to enable logging, and then click **Properties**.
2. On the **Web Site** or **FTP Site** tab, click the **Enable logging** check box.
3. In the **Active log format** list box, click a format. By default, the format is **W3C Extended Log File Format**.

   | **Note** |
   | --- |
   | If you select Open Database Connectivity (ODBC) logging, click **Properties** and type the ODBC Data Source Name (DSN) and the name of the table within the database into the text boxes. If a user name and password are required to access the database, type the necessary credentials, and click **OK**. |

4. Click **Apply**, and then click **OK**.

**To enable logging for a specific virtual directory on a site**

1. In IIS Manager, expand the local computer, expand the **Web Sites** directory, right-click the virtual directory, and click **Properties**.
2. On the **Virtual Directory** or **Directory** tab, select the **Log visits** check box if it is not selected. By default, the check box is selected.
3. Click **Apply**, and then click **OK**.

# Enable Network Adapters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you have upgraded the Web server, you are ready to enable client access to the Web sites. During the upgrade process, you disabled the network adapter on the Web server to prevent users from accessing the Web server during the upgrade process. Now that you know the upgrade completed successfully, you can enable the network adapters.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: none.

**To enable the network adapter for IIS 6.0**

1. In Control Panel, click **Network Connections**, and then click **Local Area Connection**.
2. The network adapter is automatically enabled.

# Enable Security Auditing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Microsoft® Windows® Server 2003 uses security and system logs to store collected security events. Before enabling the system and security logs, you need to enable auditing for the system log and establish the number of events you want recorded in the security log. You customize system log events by configuring *auditing*. Auditing is the process that tracks the activities of users and processes by recording selected types of events in the security log of the Web server. You can enable auditing based on categories of security events such as:

- Any changes to user account and resource permissions.
- Any failed attempts for user logon.
- Any failed attempts for resource access.
- Any modification to the system files.

The most common security events recorded by the Web server are associated with user accounts and resource permissions.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Microsoft Management Console (MMC); Local Security Policy

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **"mmc %systemroot%\system32\inetsrv\iis.msc"**.

**Procedures**
**To define or modify auditing policy settings for an event category on the local Web server**

1. Open Administrative Tools, and then click **Local Security Policy**.
2. In the console tree, click **Local Policies**, and then click **Audit Policy**.
3. In the details pane, double-click an event category for which you want to change the auditing policy settings.
4. On the **Properties** page for the event category, do one or both of the following:
    - To audit successful attempts, select the **Success** check box.
    - To audit unsuccessful attempts, select the **Failure** check box.
5. Click **OK**.

Perform the following procedure on the domain controller.

**To define or modify auditing policy settings for an event category within a domain or organizational unit, when the Web server is joined to a domain**

1. Open Administrative Tools, and then click **Active Directory Users and Computers**.
2. Right-click the appropriate domain, site, or organizational unit and then click **Properties**.
3. On the **Group Policy** tab, select an existing Group Policy object to edit the policy.

4. In **Group Policy Object Editor**, in the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policy**, and then click **Audit Policy**.
5. In the details pane, double-click an event category for which you want to change the auditing policy settings.
6. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
7. Do one or both of the following:
    - To audit successful attempts, select the **Success** check box.
    - To audit unsuccessful attempts, select the **Failure** check box.
8. Click **OK**.

# Enable the WWW Service After Upgrade

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you upgrade a Web server running Internet Information Services (IIS) 5.0 and the Microsoft® Windows® 2000 operating system, the World Wide Web Publishing Service (WWW service) is disabled unless, prior to upgrade, you elected to run the IIS Lockdown Tool or you added the entry RetainW3SVCStatus to the registry. However, if neither of those was done, then you need to enable the WWW service after the upgrade.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Microsoft Management Console (MMC); Local Security Policy.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To enable the WWW Service after upgrade**

1. Open Administrative Tools, and then click **Services**.
2. In the **Services** pane, double-click **World Wide Web Publishing Service**.
3. On the **Properties** page, on the **General** tab, select **Automatic** from the **Startup Type** drop-down box.
4. Under **Service Status**, click the **Start** button.
5. Click **OK**.

# Enable Web Site Content Auditing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Once you have enabled security auditing, you must also enable auditing on the Web site content (files and folders) in order to track any modification or deletion of the content.

Before you set up auditing for files and folders, you must first enable object access auditing. This security setting determines whether to audit the event of a user accessing an object, such as a file, folder, or printer. Enabling object access auditing is accomplished by defining auditing policy settings for the object access event category of the Audit Policies in Local Security Settings. If you do not enable object access auditing, you receive an error message when you set up auditing for files and folders, and no files or folders are audited. After object access auditing is enabled, you can view the security log in Event Viewer to review the results of your changes. You can then set up Web site content auditing.

| **Tip** |
| --- |
| Because the security log is limited in size, carefully select the files and folders to be audited. In addition, consider the amount of disk space that you want to devote to the security log. The maximum size for the security log is defined in Event Viewer. |

If file or folder auditing has been inherited from the parent folder, you will see the following.

- In the **Auditing Entry for File or Folder** dialog box, in the **Access** box, the check boxes are unavailable.

-or-

- In the **Advanced Security Settings for File or Folder** dialog box, the **Remove** button is unavailable.

**Requirements**

- Credentials: You must be logged on as a member of the Administrators group or you must have been granted the Manage auditing and security log right in Group Policy to perform this procedure.
- Tools: Windows Explorer
- File system: To enable auditing of Web site content, the disk volumes on which the Web site is stored must use the NTFS file system.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

### To enable object access auditing

1. Open Administrative Tools, and then click **Local Security Policy**.
2. Expand **Local Policies**, and then click **Audit Policy**.
3. Right-click **Audit object access**, and then click **Properties**.
4. Enable auditing by clicking one of the following:
    - Click **Success** to generate an audit entry when a user successfully accesses an object.
    - Click **Failure** to generate an audit entry when a user unsuccessfully attempts to access an object.
    - If you clear both check boxes, object access auditing is turned off.

5. Click **OK**.

**To apply or modify auditing policy settings for a local file or folder**

1. Open Accessories, and then click **Windows Explorer**.
2. Right-click the file or folder for which you want to set audit policy settings, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, and then click the **Auditing** tab.
4. Do one of the following:
   - To set up auditing for a new user or group, click **Add**. In **Enter the object name to select**, type the name of the user or group that you want to audit, and then click **OK**.
   - To remove auditing for an existing group or user, click the group or user name, click **Remove**, click **OK**, and then skip the rest of this procedure.
   - To view or change auditing for an existing group or user, click the name of the group or user, and then click **Edit**.
5. In the **Apply onto** box, click the location where you want auditing to take place.
6. In the **Access** box, indicate what actions you want to audit by selecting the appropriate check boxes:
   - To audit successful events, select the **Successful** check box.
   - To stop auditing successful events, clear the **Successful** check box.
   - To audit unsuccessful events, select the **Failed** check box.
   - To stop auditing unsuccessful events, clear the **Failed** check box.
   - To stop auditing all events, click **Clear All**.
7. If you want to prevent subsequent files and subfolders of the original object from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.

# Export a Server Certificate

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Web server certificates contain information about the server that allows the client to positively identify the server over a network before sharing sensitive information, in a process called *authentication*. Secure Sockets Layer (SSL) uses these certificates for authentication, and uses encryption for message integrity and confidentiality. SSL is a public key–based security protocol that is used by Internet services and clients to authenticate each other and to establish message integrity and confidentiality.

If you use SSL to protect confidential information exchanged between the Web server and the client, you must migrate or export the certificates and the associated private keys from the source server to the target server.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

### To export a server certificate

1. In the **Run** dialog box, type **mmc**, and then click **OK**. The Microsoft Management Console (MMC) appears.
2. If you do not have **Certificate Manager** installed in MMC, you need to install it.

   For more information on how to add the Certificate snap-in to an MMC console, see the procedure "To add the Certificates Snap-in to MMC" in Install a Server Certificate this appendix.
3. In the console tree, click the logical store where the certificate you want to export exists. Usually this is in the **Certificates** folder in the **Personal** directory under **Certificates (Local Computer)** on the Console Root.
4. Right-click the certificate you want to export, click **All Tasks**, and click **Export** to start the Certificate Export Wizard.
5. Click **Next**.
6. On **Export Private Key**, click **Yes** to export the private key.

   | **Important** |
   | --- |
   | You must export the private key along with your certificate for it to be valid on your target server. Otherwise, you will have to request a new certificate for the target server. |

7. In the **Export File Format** dialog box, click the format you want for the certificate. If the certificate has already been formatted, that format is selected as the default. Click **Next**.

   Do not select **Delete the private key if export is successful**, because this will disable the SSL site that corresponds to that private key.
8. Continue to follow steps in the wizard, and enter a password for the certificate backup file when prompted. Using a strong password is highly recommended because it ensures that the private key is well protected.
9. Type the name of the file you want to export, or click **Browse** to search for the file. Click **Next**.
10. Click **Finish** to complete the Certificate Export Wizard.

# Gather and Display WWW Service Uptime Data

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can use Internet Information Services (IIS) 6.0 Performance Monitor to record and display data about the uptime of World Wide Web Publishing Service (WWW service) and Web sites by using the Service Uptime performance counter. These procedures support the task of determining the availability of the WWW service and Web sites running on IIS.

Use the following procedures to:

- Create a log file to record WWW service uptime data.
- Select a performance counter to generate uptime data for the WWW service and your Web sites.
- Start the Service Uptime performance counter.
- Connect System Monitor to the data in the log file you are using to gather WWW service and Web site uptime data.
- Read the display window in the details panel of System Monitor to display WWW service and Web site uptime data.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Perfmon.msc; Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**Gathering WWW Service Uptime Data**
You can use IIS 6.0 Performance Monitor to create a log file, and to select and start the Service Uptime performance counter.

### To gather uptime data on the WWW service and Web sites

1. Open Administrative Tools, and then click **Performance**.
2. In the console pane, click **Performance Logs and Alerts**, and then click **Counter Logs**.
3. Right-click in the details pane, and select **New Log Settings** from the menu.
4. Enter the name you want to use for the new log, for example, *WWWServiceUptime*, and then click **OK**.

   The property sheets for the new counter log open.
5. On the **General** tab, click **Add Counters**.
6. In the **Add Counters** window, if the performance counters you want to monitor are on the local computer, click **Use local computer counters**. If the performance counters you want to monitor are on a remote computer, click **Select counters from computer**, and then click the remote computer in the drop-down list.
7. Under **Performance object**, click **Web Service** in the drop-down list.
8. Click **Select counters from list**, and then click the **Service Uptime** counter.
9. Click **All instances**.
10. Click **Add**, and then click **Close**.

The **Service Uptime** counter for the computer you selected displays in the **Counters** window on the **General** tab.

11. Click **OK**.
12. To start logging data, select the log file on the **Performance** detail pane and, on the **Action** menu, click **Start**.
13. The counter log you created displays in green on the **Computer Logs** detail pane.
14. To manually stop logging data, select the log file and, on the **Action** menu, click **Stop**.
15. To start logging data again, select the log file and, on the **Action** menu, click **Start**.

**Displaying WWW Service Uptime Data**

Consider the following guidelines for displaying WWW service uptime data:

- This procedure reads a log file that gathers WWW service uptime data. Before you can read the log file, you must create the file and connect it to the performance counter, as described earlier in this section.
- The file logs data for all instances of the Service Uptime performance counter. One instance, named the Total instance, accumulates WWW service data. Each of the other instances accumulates data about a Web site. Each Web site is recorded by a separate instance.

**To display data for WWW service uptime and Web site uptime**

1. Open Administrative Tools, and click **Performance**.
2. In the console pane, click **System Monitor**.
3. Right-click in the details pane, and then click **Properties**.
4. On the **Source** tab, under **Data Source**, click **Log files**, and then click **Add**.
5. In the **Select Log File** window, navigate to the log file that you created to gather WWW service and Web sites uptime data.
6. Select the log file name from the list, and then click **Open**.
7. Click the **Data** tab, and then click the **Add** button. Under **Performance object**, select **Web Service** from the drop-down list.
8. Click the **Select counter from list** button and click **Service Uptime**.
9. Click the **All instances** button.
10. Click **Add**, and then click **Close**.
11. On the **System Monitor Properties** window, click **OK**.

    The Service Uptime counter instances appear in the list in the **Performance** detail pane.
12. Select the instance desired to view the graph and statistics for WWW Service ("_Total"), or for each Web site.

# Grant User Rights to a Service Account

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Typically, the user rights assigned to the IIS_WPG group is sufficient for most Web sites or applications. However, when a Web site or application requires additional user rights to run properly, you must assign the required rights to the service account that is used as the identity for the Web sites and applications.

You grant user rights based on where the account is stored. If the service account is created locally on the Web server, you make changes in user rights through Local Computer Policy by using the Group Policy Object Editor MMC snap-in. When the service account is created in Active Directory, make the changes on the appropriate Group Policy object in Active Directory.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**To add the Group Policy Object Editor to MMC**

1. In the **Run** dialog box, type **mmc**, and then click **OK**.

   The Microsoft Management Console appears.

2. On the **File** menu, click **Add/Remove Snap-in**.
3. On the **Standalone** tab, click **Add**.
4. In the **Available Standalone Snap-ins** list box, click **Group Policy Object Editor**, and then click **Add**.
5. In the **Select Group Policy Object** dialog box, in **Group Policy Object**, select **Local Computer**, and then click **Finish**.
6. Click **Close**, and then click **OK**.

**To grant user rights to a service account when the service account is stored locally on the Web server**

1. In MMC, open the **Group Policy Object Editor**.
2. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **User Rights Assignment**.
3. In the details pane, double-click the **user right** that you want to grant to the service account.
4. In the **user_right Properties** dialog box (where **user_right** is the user right you selected in Step 3), click **Add User or Group**.
5. In the **Select Users, Computers, or Group** dialog box, type the name of the service account, and then click **OK**.
6. In the **user_right Properties** dialog box (where **user_right** is the user right you selected in Step 3), click **OK**.

**To grant user rights to a service account when the service account is stored in Active Directory**

1. In MMC, open **Active Directory Users and Computers**.
2. In the console tree, browse to the organizational unit that contains the Group Policy object that you want to modify, right click the organizational unit, and then click **Properties**.

3. In the **organizational_unit Properties** dialog box (where **organizational_unit** is the organizational unit you selected in Step 2), click the **Group Policy** tab.
4. Select the Group Policy object that you want to modify, and then click **Edit**.

   The Group Policy Object Editor appears.
5. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **User Rights Assignment**.
6. In the details pane, double-click the user right that you want to grant to the service account.
7. In the **user_right Properties** dialog box (where **user_right** is the user right you selected in Step 3), click **Add User or Group**.
8. In the **Select Users, Computers, or Group** dialog box, type the name of the service account, and then click **OK**.
9. In the **user_right Properties** dialog box (where **user_right** is the user right you selected in Step 3), click **OK**.
10. Close the Group Policy Object Editor.
11. Click **OK**.

# Install a Server Certificate

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Web server certificates contain information about the server that allows the client to positively identify the server over a network before sharing sensitive information. This process is called *authentication*. If you use Secure Sockets Layer (SSL) to protect confidential information exchanged between the Web server and the client and you have exported the certificates from the source server to the target server, the server certificate needs to be installed on the Web server before you can assign the server certificate to Web sites for use with SSL

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Certificates MMC snap-in.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

### To add the Certificates Snap-in to MMC

1. In the **Run** dialog box, type **mmc**, and then click **OK**.

   The Microsoft Management Console appears.

2. On the **File** menu, click **Add/Remove Snap-in**.
3. On the **Standalone** tab, click **Add**.
4. In the **Available Standalone Snap-ins** list box, click **Certificates**, and then click **Add**.
5. Click the **Computer account** option, and then click **Next**.
6. Click the **Local computer (the computer this console is running on)** option, and then click **Finish**.
7. Click **Close**, and then click **OK**.

### To install a server certificate on a Web server

1. In MMC, open the **Certificates** snap-in.
2. In the console tree, click the logical store where you want to import the certificate.

   The default location of the logical store for certificates is on the Console Root in the **Certificates (Local Computer)/ Personal/Certificates** folder.

3. On the **Action** menu, point to **All Tasks**, and then click **Import** to start the Certificate Import Wizard.

   | **Important** |
   | --- |
   | You should only import certificates obtained from trusted sources. Importing an altered or unreliable certificate could compromise the security of any system component that uses the imported certificate. |

4. Click **Next**.
5. Type the name of the file that contains the certificate to be imported, or click **Browse** and navigate to the file.

   Certificates can be stored in several different file formats. The most secure format is Public-Key Cryptography Standard (PKCS) #12, an encryption format that requires a password to encrypt the private key. It is recommended that you send

certificates using this format for optimum security.

If the certificate file is in a format other than PKCS #12, skip to step 8.

If the certificate file is in the PKCS #12 format, do the following:

- In the **Password** box, type the password used to encrypt the private key. You must have access to the password that was originally used to secure the file.

- (Optional) If you want to be able to use strong private key protection, select the **Enable strong private key protection** check box, if available.

- (Optional) If you want to back up or transport your keys at a later time, select the **Mark key as exportable** check box.

6. Click **Next**.
7. In the **Certificate Store** dialog box, do one of the following:

   - If the certificate should be automatically placed in a certificate store based on the type of certificate, select **Automatically select the certificate store based on the type of certificate**.

   - If you want to specify where the certificate is stored, select **Place all certificates in the following store**, click **Browse**, and select the certificate store to use.

8. Click **Next**, and then click **Finish**.

The file from which you import certificates remains intact after you have completed importing the certificates. You can use Windows Explorer to delete the file if it is no longer needed.

# Install IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can install Internet Information Services (IIS) 6.0 by using **Add/Remove Windows Components** from Add or Remove Programs in Control Panel.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**To install IIS 6.0 using Control Panel**

1. In Control Panel, double-click **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. In the **Components** list box, click **Application Server**, and then click **Details**.
4. In the **Subcomponents of Application Server** box, click **Internet Information Services (IIS)**.
5. Click **OK** to start the installation of IIS 6.0.

# Install Subauthentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To use Digest authentication in Internet Information Services (IIS) 6.0 when the domain controller is running Microsoft® Windows® 2000, you must enable subauthentication, which is not installed by default on IIS 6.0. There are three requirements for enabling subauthentication:

- Install the subauthentication component, Iissuba.dll.
- Set the **UseDigestSSP** metabase property to **False**.
- Set the identity of the application pool to **Local System**. For more information about setting application pool identity, see Ensuring Application Availability.

Consider the following guidelines for enabling subauthentication:

- The requirement to use subauthentication applies to Digest authentication only. Using Advanced Digest authentication does not require subauthentication.
- When you no longer want to use subauthentication, unregister the sub-authentication component and set the identity of the application pool to Local System.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname***mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To install and register the subauthentication component**

1. In the **Run** dialog box, type **cmd**, and click **OK**.
2. At the command prompt type:

   ```
   rundll32 systemroot\system32\iissuba.dll, RegisterIISSUBA.
   ```

3. Press ENTER.
4. For any application pools that use Digest authentication, set the application pool identity to Local System.

   For more information about Digest authentication, see Configure Web Server Authentication.

   For more information on configuring application pool identity, see Configure Application Pool Identity.

**To unregister the subauthentication component**

1. In the **Run** dialog box, type **cmd**, and click **OK**.
2. At the command prompt, type:

   ```
   rundll32 systemroot\system32\iissuba.dll,UnregisterIISSUBA.
   ```

3. Press ENTER.

# Isolate Applications in Worker Process Isolation Mode

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

An *application pool* is a configuration that links one or more applications to a set of one or more worker processes. Because applications in an application pool are separated from other applications by worker process boundaries, an application in one application pool is not affected by problems caused by applications in other application pools.

By creating application pools and assigning Web sites and applications to them, you can improve the availability and reliability of your Web sites and applications.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To create a new application pool**

1. In IIS Manager, expand the local computer, right-click **Application Pools**, click **New**, and then click **Application Pool**.
2. If the ID that appears in the **Application pool ID** box is not the ID that you want, type a new ID.
3. Under **Application pool settings**, click one of the following options:
   - **Use default settings for the new application pool**

   -or-

   - **Use existing application pool as a template**.
4. If you click the **Use existing application pool as template** option, in the drop-down box, click the **Application pool name** of the application pool you want to use as a template.
5. Click **OK**.

**To assign a Web site or application to an application pool**

1. In IIS Manager, right-click the application that you want to assign to an application pool, and then click **Properties**.
2. Click the **Virtual Directory**, **Directory**, or **Home Directory** tab, depending on the type of application you have selected.
3. If you are assigning a directory or virtual directory, verify that **Application name** is filled in. If the **Application name** box is not filled in, click **Create**, and then type a name.
4. In the **Application pool** list box, click the name of the application pool to which you want to assign the Web site.
5. Click **OK**.

# Make a Service Account a Member of the Local Administrators Group

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If an application requires specific user rights to run successfully, but the service account for the application cannot be assigned the appropriate permissions, make the service account a member of the local administrators group. This should give the service account sufficient user rights to allow the application to run successfully.

**Procedures**

**To add a service account to the local administrators group**

1. In Administrative Tools, click **Computer Management**.
2. In the console tree, expand **Local Users and Groups**, and then click **Groups**.
3. Right-click the **Administrators** group, and then click **Add to Group**.
4. Click **Add**.
5. Click **Look in** to display a list of domains from which users and groups can be added to the group.
6. In **Location**, click the domain containing the users and computers you want to add, and then click **OK**.
7. In **Enter the object names to select**, type the name of the user or group you want to add to the group, and then click **OK**.
8. If you want to validate the user or group names that you are adding, click **Check Names**.

# Migrate CDONTS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Collaboration Data Objects (CDO) for Microsoft® Windows NT® Server (CDONTS) has been removed from Microsoft® Windows® Server 2003. However, if you upgrade to Windows Server 2003, CDONTS remains on your server, because Cdonts.dll is not removed during an upgrade to Windows Server 2003. CDONTS is not installed when you perform a clean installation of Windows Server 2003, but if necessary, you can copy it to the computer running Windows Server 2003 and register it.

Note: If your Web applications use CDONTS, you can modify your code to use Collaboration Data Objects for Windows 2000 (CDOSYS), which is supported by Windows Server 2003.

**Procedures**

**To copy CDONTS to a computer running Windows Server 2003**

1. On the source server, copy Cdonts.dll from the *systemroot***\system32** folder to a floppy disk.
2. On the target server, copy Cdonts.dll from the floppy disk to the folder *systemroot***\system32**.
3. To register CDONTS, on the target server, in the **Run** dialog box, type **cmd**, and then click **OK**.
4. At the command prompt, change to the *systemroot***\system32** directory and then type:

   **regsvr32** *%windir%* **\system32\cdonts.dll**.

   If the process is successful, the following message displays:

   **DllRegisterServer in cdonts.dll succeeded.**
5. Click **OK**.

# Modify the IIS Metabase Directly

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you need to modify the Internet Information Services (IIS) metabase, you can do so directly in the Metabase.xml file by using a text editor. Before you can modify the Metabase .xml file, you must enable the edit-while-running feature of the metabase by using IIS Manager. Once you have made your changes and saved the Metabase.xml file, disable the edit-while-running feature of the metabase. To implement changes to some metabase properties, you might need to restart the server.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

### To enable the edit-while running feature of the metabase by using IIS Manager

1. In IIS Manager, right-click the local computer, and then click **Properties**.
2. Select the **Enable Direct Metabase Edit** check box, and then click **OK**.

### To modify the IIS metabase

1. Open the Metabase.xml file in a text editor. The default path to this file is *systemroot***\system32\inetserv\metabase.xml**
2. Modify the metabase properties that you wish to change in the Metabase.xml file.
3. Save the changes to the file, and close the text editor.

Most changes to metabase properties are automatically recognized by IIS; in some cases, you must restart IIS for the metabase property changes to go into effect.

### To disable the Edit-while running feature of the metabase by using IIS Manager

1. In IIS Manager, right-click the local computer, and then click **Properties**.
2. Clear the **Enable Direct Metabase Edit** check box, and then click **OK**.

# Monitor Active Web and FTP Connections

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To ensure that service to clients is not interrupted; monitor the Web server for any active Web and File Transfer Protocol (FTP) connections before taking the Web server offline. Internet Information Services (IIS) 4.0, IIS 5.0, and IIS 6.0 include performance monitor counters that can be used to monitor the active Web and FTP connections. Monitor the active Web and FTP connections to ensure one of the following is true:

- The number of active Web and FTP connections is zero.
- All active Web or FTP sessions can be accounted for and can be terminated.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Perfmon.msc, Perfmon.exe.

**Procedures**

**To monitor active Web and FTP connections in IIS 6.0**

1. Open Administrative Tools, and then click **Performance**.
2. Right-click the **System Monitor details** pane, and then click **Add Counters**.
3. Do one of the following:
   - To monitor any computer on which the monitoring console is run, click **Use local computer counters**.

   -or-

   - To monitor a specific computer, regardless of where the monitoring console is run, click **Select counters from computer**, and specify a computer name or IP address.
4. In **Performance object**, click:
   - **Web Service** to monitor active Web connections.

   -or-

   - **FTP Service** to monitor active FTP connections.
5. Click **Select counters from list**, and select **Current Connections**.
6. Click **All instances**.
7. Click **Add**, and then click **Close**.

**To monitor active Web and FTP connections in IIS 5.0**

1. Open Administrative Tools, and then click **Performance**.
2. Right-click the **System Monitor details** pane and then click **Add Counters**.
3. Do one of the following:

- To monitor any computer on which the monitoring console is run, click **Use local computer counters**.

-or-

- To monitor a specific computer, regardless of where the monitoring console is run, click **Select counters from computer**, and specify a computer name or IP address.

4. In **Performance object**, click:

   - **Web Service** to monitor active Web connections.

   -or-

   - **FTP Service** to monitor active FTP connections.

5. Click **Select counters from list**, and then click **Current Connections**.
6. Click **All instances**.
7. Click **Add**, and then click **Close**.

**To monitor active Web and FTP connections in IIS 4.0**

1. Open Administrative Tools, and then click **Performance Monitor**.
2. Click **Edit**, and then click **Add to Chart**.
3. The local computer is listed in the Computers box. To monitor any other computer on which the monitoring console is run, click the button to the right of **Computers** and select a computer from the **Select Computer** list, and then click **OK**.
4. In **Performance object**, click:

   - **Web Service** to monitor active Web connections.

   -or-

   - **FTP Service** to monitor active FTP connections.

5. In **Counters**, click **Current Connections**.

| **Note** |
| --- |
| The performance counters are not installed when IIS 4.0 is installed on Microsoft® Windows NT® version 4.0. In this case, if the performance counters have not been manually enabled, they do not appear in the Counters list. For more information about enabling the performance counters, see Knowledge Base article 226512, HOW TO: Reinstall IIS 4.0 Performance Monitor Counters. |

6. Click **Add**, and then click **Done**.

# Obtain a Server Certificate for an NLB Cluster

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can use the Web Server Certificate Wizard to obtain a server certificate to be used with all Web servers in a Network Load Balancing (NLB) cluster. To ensure that the name on the certificate matches the name of the server, specify the virtual name of the NLB cluster as the common name on the certificate. After you receive the server certificate, install it on all machines in the NLB cluster.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc, Web Server Certificate Wizard.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **"mmc %systemroot%\system32\inetsrv\iis.msc"**.

**Procedures**
**To obtain a server certificate for an NLB cluster**

1. In IIS Manager, double-click the local computer, and then double-click the **Web Sites** folder.
2. Right-click the Web site for which you want to obtain a certificate, and then click **Properties**.
3. On the **Directory Security** or **File Security** tab, under **Secure communications**, click **Server Certificate**.
4. In the Web Server Certificate Wizard, click **Create a new certificate**.
5. Follow the steps in the Web Server Certificate Wizard. On the **Your Site's Common Name** page, type the virtual name of the NLB cluster in the **Common name** box, and then click **Next** to continue following the steps in the wizard.

By default, the certificate request file is saved as C:\Certreq.txt, but the wizard allows you to specify a different location.

# Pause Web or FTP Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To ensure that service to clients is not interrupted, pause all Web and File Transfer Protocol (FTP) sites on the Web server before taking the server offline. Pausing a site prevents the site from accepting new connections, but does not affect requests that are already being processed. Stopping a site does not interfere with other Internet services that are running.

You can pause a Web or FTP site by using either IIS Manager or a command-line script.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**Pausing Web Sites**
If you pause a Web site, you can temporarily reduce the load on the computer that hosts the site, and can make changes to the folder or document structure of the Web site.

**To pause a Web site by using Internet Services Manager in IIS 4.0**

1. Click **Start**, click **Programs**, click **Windows NT 4.0 Option Pack**, click **Microsoft Internet Information Server**, and then click **Internet Services Manager**.
2. In Internet Services Manager, right-click the Web site you want to pause, and then click **Pause**.

**To pause a Web site by using Internet Services Manager in IIS 5.0**

1. Open Administrative Tools, and then click **Internet Services Manager**.
2. In Internet Services Manager, right-click the Web site you want to pause, and then click **Pause**.

| **Note** |
| --- |
| If a site stops unexpectedly, Internet Services Manager might not correctly indicate the state of the site. In IIS, right-click the **Web Sites** folder and then click **Refresh** to see the current state of all Web sites. |

**Pausing FTP Sites**
**To pause an FTP site by using Internet Services Manager in IIS 4.0**

1. Click **Start**, click **Programs**, click **Windows NT 4.0 Option Pack**, click **Microsoft Internet Information Server**, and then click **Internet Services Manager**.
2. In Internet Services Manager, right-click the FTP site you want to pause; and then click **Pause**.

**To pause an FTP site by using Internet Services Manager in IIS 5.0**

1. Open Administrative Tools, and then click **Internet Services Manager**.
2. In Internet Services Manager, right-click the FTP site you want to pause, and click **Pause**.

| **Note** |
| --- |

If a site stops unexpectedly, Internet Services Manager might not correctly indicate the state of the site. In IIS, right-click the **FTP Sites** folder and click **Refresh** to see the current state of all FTP sites.

# Publish Web Site Content with FrontPage

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage Server Extensions from Microsoft provides a Web-based administration tool for extending Web sites. *Extending* a Web site means implementing features of FrontPage Server Extensions that enable the site owner to author the site in Microsoft® FrontPage® and delegate Web site ownership and Web site administration credentials. Making content available on an extended Web site is called *publishing* the Web site. A Web site that is not extended cannot be opened or authored in FrontPage.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**Extending a Web site**
You can use the FrontPage 2002 Server Administration tool to extend a Web site.

### To extend a Web site by using the FrontPage 2002 Server Administration tool

1. Open Administrative Tools, and then click **Microsoft SharePoint Administrator**.

| **Note** |
| --- |
| If IIS returns error 404, "The page cannot be found," check to make sure FrontPage 2002 Server Extensions is enabled by using **Add or Remove Programs** in Control Panel. |

1. On the **FrontPage Server Extensions 2002 Server Administration** site, check to see that the Web site you created is listed in the **Virtual Servers** section.
2. To extend the Web site, click the **Extend** link next to the name of the Web site.
3. To specify an administrator account for the extended Web site, type the administrator name in **Administrator user name**.
4. Click **Submit**.
5. The **FrontPage 2002 Server Administration** tool adds FrontPage Server Extensions template directories to the content directory of your extended Web site, and adds other files that contain metadata.

**Publishing a Web site**
If your Internet service provider (ISP) has FrontPage Server Extensions from Microsoft installed, you can publish to the Web server by using HTTP. Otherwise, you can use FrontPage to publish your Web site to a File Transfer Protocol (FTP) server.

| **Note** |
| --- |
| If you publish to a location on your local computer, your Web site will not have the full FrontPage functionality unless your computer is a server that has FrontPage Server Extensions or SharePoint Team Services from Microsoft installed. |

### To publish to a Web server by using HTTP

1. In Microsoft FrontPage, on the **File** menu, click **Publish Web**.
2. In the **Publish Destination** dialog box, do one of the following:
   - Type the location of a Web server.

     -or-

   - Click the drop-down arrow to select a location to which you have already published another Web site.

     -or-

   - Click **Browse** to find the publishing location.

| **Note** |
| --- |
| If you have previously chosen a publishing destination for this Web site, the **Publish Destination** dialog box will not appear; proceed to step 4. |

3. Click **OK**.
4. Specify the pages you want to publish by clicking **Options** in the **Publish Web** dialog.
5. Click the **Publish** tab, and do one or more of the following:
   - Under **Publish**, specify whether you want to publish only pages that have changed, or all pages.
   - Under **Changes**, specify how you want FrontPage to determine which pages have been changed.
   - If you want to create a log file for the changes made during publishing, select that check box.
6. Click **OK**.
7. To publish subwebs, select the **Include subwebs** check box.
8. Click **Publish**.

| **Note** |
| --- |
| If you cancel publishing in the middle of the operation, files that have already been published remain on the destination Web server. |

FrontPage publishes your Web site to the Web server you specified. If you want to verify that your Web site was successfully published, click the hyperlink that is displayed after the Web has been published — your Web browser will open to the Web site you just published.

**To publish to an FTP site**

1. In FrontPage, on the **File** menu, click **Publish Web**.
2. In the **Publish Destination** dialog box, type the location of the FTP server, or click the drop-down arrow to select a location to which you have already published another Web site.

| **Note** |
| --- |
| If you have previously chosen a publishing destination for this Web site, the **Publish Destination** dialog box will not appear; proceed to step 4. |

3. Click **OK**.

4. Specify the pages you want to publish by clicking **Options** in the **Publish Web** dialog.
5. Click the **Publish** tab, and do one or more of the following:
6. Under **Publish**, specify whether you want to publish only pages that have changed, or all pages.
7. Under **Changes**, specify how you want FrontPage to determine which pages have been changed.
8. If you want to create a log file for changes made during publishing, select that check box.
9. Click **OK**.
10. To publish subwebs, select the **Include subwebs** check box.
11. Click **Publish**.

| **Note** |
| --- |
| If you cancel publishing in the middle of the operation, files that have already been published remain on the destination FTP server. |

12. FrontPage publishes your Web site to the FTP server you specified.

# Remove Virtual Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Internet Information Services (IIS) Lockdown Tool works by turning off unnecessary IIS features and components to reduce the attack surface of the Web server. To assist in mitigating these potential risks, remove any unnecessary virtual directories.

**Procedures**

**To remove a virtual directory using IIS Manager**

1. In IIS Manager, expand the site containing the virtual directory you want to remove, right-click the virtual directory, and then click **Delete**.
2. Click **Yes**.

**To remove a virtual directory using Windows Explorer**

1. In Windows Explorer, browse to the folder containing the virtual directory you want to remove, right-click the directory, and then click **Sharing and Security**.
2. Click the **Web Sharing** tab, click **Remove**, and then click **Yes**.
3. Click **OK**.

   You can verify that the virtual directory was deleted by starting IIS Manager and expanding the Web site.

| **Note** |
| --- |
| The following method does not work for root virtual directories |

**To delete a virtual directory using the Iisvdir.vbs administration script**

1. In the **Run** dialog box, type **cmd**, and then click **OK**.
2. At the command prompt, use the **cd** command to change to the directory where the Iisvdir.vbs script is installed. The default location for this file is *systemroot***/system32/iisvdir.vbs**.
3. At the command prompt, type:

   ```
   cscript iisvdir.vbs /delete "Sample Web Site" VirtualDirectoryName.
   ```

   Substitute your Web site name and virtual directory name as appropriate. If there are spaces in the Web site name, use quotation marks around the Web site name, as shown in the preceding example.
4. Click **OK**.

# Request a Server Certificate

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To enable Secure Sockets Layer (SSL) on a Web site, you must first request a server certificate from a trusted certification authority. After you obtain the certificate, you need to install it on the Web server, and then assign it to one or more Web sites.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**To request a server certificate**

1. In IIS Manager, expand the local computer, and then expand the **Web Sites** folder.
2. Right-click the Web site or file that you want, and then click **Properties**.
3. On the **Directory Security** or **File Security** tab, under **Secure communications**, click **Server Certificate**.
4. In the Web Server Certificate Wizard, click **Next**, and then click **Create a new certificate**.
5. Follow the steps in the Web Server Certificate Wizard, which guides you through the process of requesting a new server certificate.

# Secure the Root Folder of Each Disk Volume

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Immediately after a new installation of Microsoft® Windows® Server 2003, the special group Everyone has Read and Execute permissions on the root of the *system volume*, which is the disk volume where Windows Server 2003 is installed.

Any folders created beneath the root of the system volume automatically inherit the permissions assigned to the root of the system volume. This means that the Everyone group will have Read and Execute permissions on any new folders created immediately beneath the root of the system volume. To prevent an accidental breach in security, remove the permissions assigned to the special group "Everyone" on dedicated Web servers.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.
- File System: The system volume must use the NTFS file system if you want to set file and folder permissions.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To secure the root of the system volume by removing permissions**

1. Open Accessories, and then click **Windows Explorer**.
2. In Windows Explorer, locate the root of the system volume.
3. Right-click the root of the system volume, click **Properties**, and then click the **Security** tab.
4. In the **Group or user names** list box, click **Everyone**, and then click **Remove**.
5. Click **OK**.

# Secure Windows Server 2003 Built-in Accounts

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After the installation of Microsoft® Windows® Server 2003, the built-in accounts Administrator and Guest exist on the Web server. In some instances, potential attackers can exploit these well known accounts unless they are renamed or disabled.

The Administrator account can be renamed, but cannot be disabled. The Guest account can be renamed and disabled. To help prevent potential attackers from exploiting these accounts, do the following:

- Rename the Administrator account.
- Rename and disable the Guest account.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: lis.msc.

**Recommendation**

As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**

**To rename the Administrator user account**

1. In Control Panel, click **Administrative Tools**, and then click **Computer Management**.
2. In the console tree, expand **Local Users and Groups**, and then click **Users**.
3. In the details pane, right-click **Administrator**, and then click **Rename**.
4. Type the new user name, and then press ENTER.

**To disable and rename the Guest user account**

1. In Control Panel, click **Administrative Tools**, and then click **Computer Management**.
2. In the console tree, expand **Local Users and Groups**, and then click **Users**.
3. In the details pane, right-click **Guest**, and then click **Properties**.
4. In the **Guest Properties** dialog box, on the **General** tab, click the **Account is disabled** check box, and then click **OK**.
5. In the **Details** pane, right-click **Guest**, and then click **Rename**.
6. Type the new user name, and then press ENTER.

# Set Processor Affinity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

On a multi-CPU server, you can configure application pools to establish affinity between worker processes and CPUs in order to take advantage of more frequent CPU cache hits. You can use processor affinity to control processors when applications place demands on system resources.

Processor affinity is used when it is necessary to continue processing an application that is tied to a subset of the hardware, so that transitions from one processor to another are minimized. You can establish affinity on a server that is supporting multiple applications so that a processor is dedicated to each application.

Consider the following when setting processor affinity to enable debugging of application pool failures:

- By default, processor affinity is off, and the load is distributed across all available CPUs.
- Processor affinity is used in conjunction with the processor affinity mask setting that is used to specify the CPUs.
- The metabase property **SMPProcessorAffinityMask** is a hexadecimal number. The maximum value, FFFFFFFF, is equivalent to decimal 32, the largest number of processors currently allowed. The hexadecimal value, translated to binary, gives the processors that are connected to the worker process in the application pool. For example, the hexadecimal number FFFFFFFF translates to the binary number 1111 1111 1111 1111 1111 1111 11111111 . This means that all 32 processors are available to the worker processes in the application pool. If the hexadecimal value is 00000005, the binary value is 0000 0000 0000 0000 0000 0000 0000 0101, which means that processor 0 and processor 2 are connected to the worker processes in the application pool (processors are numbered from the right, beginning with 0).

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.
- Mode: The processor affinity feature of IIS 6.0 is available only when running in worker process isolation mode.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**To set processor affinity**

1. Copy the following ADSI script into a text editor or word processor. The script (written in VBScript) enables and configures processor affinity.

```
set appPoolObj=GetObject("IIS://localhost/W3svc/AppPools/app pool name")
' Set the properties. Enable processor affinity for processors 0,1,2,3:
appPoolObj.Put "SMPAffinitized", TRUE
appPoolObj.Put "SMPProcessorAffinityMask", &H0000000F
' Save the property changes in the metabase:
appPoolObj.SetInfo
WScript.Echo "After: " & appPoolObj.SMPAffinitized & ", " &
appPoolObj.SMPProcessorAffinityMask
```

2. In the text editor, change the value of the metabase property **SMPProcessorAffinityMask** to the hexadecimal value that corresponds to the CPU numbers of the CPUs that are used by the worker processes in the application pool.

3. Save the file with extension **.vbs**.
4. In the **Run** dialog box, type **cmd** and then click **OK**.
5. At the command prompt, run the script by typing: **cscript //nologo** *filename***.vbs** where *filename* is the fully qualified path of the script file.
6. To ascertain that the metabase properties have changed, view the metabase properties in the Metabase.xml file to see if the values have been correctly set. To do so, open the Metabase.xml file in Notepad or another text editor. The default path to this file is *systemroot***\system32\inetserv\metabase.xml**.

# Stop the WWW Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Once you have verified that no users are accessing your Web site, you can stop the World Wide Web Publishing Service (WWW service) on your source computer. You can then migrate your Web sites to the target server.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Recommendation**
As a security best practice, log on to your computer using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At the command prompt, type **runas /user:***administrative_accountname* **mmc %systemroot%\system32\inetsrv\iis.msc**.

**Procedures**
**To stop the WWW Service in IIS 5.0**

1. Open Administrative Tools, and then click **Services**.
2. In the **Services** pane, double-click **World Wide Web Publishing Service**.
3. On the **Properties** page, on the **General** tab under **Service Status**, click the **Stop** button, and then click **OK**.

**To stop the WWW Service in IIS 4.0**

1. Open Control Panel, and then double-click **Services**.
2. On the **Services** page, click **World Wide Web Publishing Service**, and then click the **Stop** button, and then click **Close**.

# Upgrade FrontPage Extended Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can upgrade Web sites to FrontPage 2002 Server Extensions from Microsoft from any previous version of FrontPage Server Extensions. During the upgrade process, changes are made to your Web site metadata and background structure, and some content is added to your Web site to enable it to work with FrontPage 2002 Server Extensions.

After you have installed FrontPage 2002 Server Extensions, you can upgrade your extended Web sites from the command-line, or by using Microsoft® SharePoint™ Administrator. To upgrade an extended Web site from the command-line, use the upgrade command.

**Procedures**

**To upgrade an extended Web site from the command line**

1. In the **Run** dialog box, type **cmd**, and then click **OK**.
2. At the command prompt, change to the FrontPage Extensions directory by typing:

   ```
   cd %CommonProgramFiles%\Microsoft Shared\Web Server Extensions\50\bin.
   ```

3. Then, at the command prompt, type:

   ```
   cwsadm -o upgrade -p Port -m WebSiteURL
   ```

   where *Port* is the optional port number of the site to be upgraded (defaults to port 80), and *WebSiteURL* is the URL for the Web site you are upgrading.

**To upgrade an extended Web site by using SharePoint Administrator**

1. On the server, open **Administrative Tools**, and then click **Microsoft SharePoint Administrator**.
2. In the list of extended Web sites, next to the extended Web site you want to upgrade, click **Upgrade**.
3. In the **Administrator user name** box, type the user name for the administrator of the extended Web site.
4. Click **Submit**.

# View Application Isolation Configuration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before configuring Internet Information Services (IIS) 6.0 to run in worker process isolation mode, you need to document the configuration for existing Web sites and applications running on the source server so you can transfer the settings to the target server.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Iis.msc.

**Procedures**

**To view application isolation settings in IIS 5.0**

1. Open Administrative Tools, and then click **Internet Services Manager**.
2. Expand the local computer, right-click the Web site for which you are documenting the settings, and then click **Properties**.
3. Click the **Home Directory** tab.
4. Under **Application Settings**, note the settings for **Application Protection**. Available settings are:
   - Low (IIS Process)
   - Medium (Pooled)
   - High (Isolated)
5. Click **OK**.

**To view application isolation settings in IIS 4.0**

1. Click **Start**, click **Programs**, click **Windows NT 4.0 Option Pack**, click **Microsoft Internet Information Server**, and then click **Internet Services Manager**.
2. In Internet Services Manager, expand **Internet Information Server**, expand the local computer, right-click the Web site for which you are documenting the settings, and then click **Properties**.
3. On the **Home Directory** tab, under **Application Settings**, note whether the check box **Run in separate memory space (isolated process)** is selected.
4. Click **OK**.

# View Web Site and Application Process Identities

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before configuring Internet Information Services (IIS) 6.0 to run in worker process isolation mode, you need to document the process identity used by the Web site and application. After configuring IIS 6.0 to run in worker process isolation mode, you will use the documented process identities to configure the application pools in worker process isolation mode.

**Requirements**

- Credentials: Membership in the Administrators group on the local computer.
- Tools: Internet Service Manager (ISM) for IIS 4.0 and IIS 5.0, and IIS Manager for IIS 6.0.

**Procedures**

**To view Web site and application process identities in IIS 6.0 running in IIS 5.0 Isolation Mode**

1. In the **Run** dialog box, type **mmc**, and then click **OK**.
2. If you do not have the Component Services Snap-in installed, in MMC, on the **File** menu, click **Add/Remove Snap-ins**, and then click **Add**. Under **Available Standalone Snap-ins**, click **Component Services**, and then click **Add**.
3. In MMC, in the console tree, expand **Component Services**, expand **Computers**, expand **My Computer**, and then click **COM+ Applications**.
4. Right-click *WebSiteName* and then click **Properties** (where *WebSiteName* is the name of the Web site or application).
5. Click the **Identity** tab.
6. Document the identity for the Web site or application found in the **User** text box.

**To view Web site and application process identities in IIS 5.0**

1. In the **Run** dialog box, type **mmc**, and then click **OK**.
2. If you do not have the Component Services Snap-in installed, in the **File** menu click **Add/Remove Snap-ins**, and then click **Add**. Under **Add Standalone Snap-ins**, click **Component Services**, and then click **Add**. Click **Close** and then click **OK**.
3. In MMC, in the console tree, expand **Computers**, expand **My Computer** and expand **COM+ Applications**.
4. Right-click **IIS-{***WebSiteName***//Root}** and then click **Properties** (where *WebSiteName* is the name of the Web site or application).
5. Click the **Identity** tab.
6. Document the identity for the Web site or application found in the **User** text box.

**To view Web site and application process identities in IIS 4.0**

1. Click **Start**, click **Programs**, click **Windows NT 4.0 Option Pack**, click **Microsoft Internet Information Server**, and then click **Internet Services Manager**.
2. In the console tree, expand **Microsoft Transaction Server**, expand **Computers**, expand **My Computer**, expand **Packages installed**, right-click *WebSiteName* and then click **Properties** (where *WebSiteName* is the name of the Web site or application).
3. Click the **Identity** tab.
4. Document the identity for the Web site or application found in the **User** text box.

# Appendix B: Changes to Metabase Properties in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

There are IIS 5.0 metabase properties that are no longer supported in IIS 6.0. When upgrading or migrating from an earlier version of IIS, these properties are still in the metabase, but IIS 6.0 ignores the settings. On a new installation of IIS 6.0, these properties have been removed from the metabase, and they are not available even when IIS 6.0 is running in IIS 5.0 isolation mode.

There is one IIS 5.0 metabase property — **CPUResetInterval** — that still exists in the IIS 6.0 metabase, but it behaves differently in IIS 6.0.

Table 1.1 lists metabase properties that have changed in IIS 6.0. If your Web sites, applications, or setup programs refer to any of these IIS metabase properties, follow the recommendations described in the table to accommodate these changes and ensure compatibility with IIS 6.0.

**Table 1.1 IIS Metabase Properties That Have Changed Since IIS 5.0**

| IIS Metabase Properties | Recommendation |
|---|---|
| • **AspThreadGateEnabled**<br>• **AspThreadGateLoadHigh**<br>• **AspThreadGateLoadLow**<br>• **AspThreadGateSleepMax**<br>• **AspThreadGateTimeSlice** | In IIS 5.0, these metabase properties are provided for the configuration of performance features.<br>In IIS 6.0, these performance features are provided by other means. As a result, IIS 6.0 no longer uses these metabase properties.<br>Remove any references to these metabase properties from Web sites, applications, or setup programs.<br>For more information about improving performance in IIS 6.0, see Web Server Scalability. |

| | |
|---|---|
| • **CPUAppEnabled**<br>• **CPUCGIEnabled**<br>• **CPUCGILimit**<br>• **CPUEnableActiveProcs**<br>• **CPUEnableAllProcLogging**<br>• **CPUEnableAppLogging**<br>• **CPUEnableCGILogging**<br>• **CPUEnableEvent**<br>• **CPUEnableKernelTime**<br>• **CPUEnablePageFaults**<br>• **CPUEnableProcType**<br>• **CPUEnableTerminatedProcs**<br>• **CPUEnableTotalProcs**<br>• **CPUEnableUserTime**<br>• **CPULimitLogEvent**<br>• **CPULimitPause**<br>• **CPULimitPriority**<br>• **CPULimitProcStop**<br>• **CPULimitsEnabled**<br>• **CPULoggingInterval**<br>• **CPULoggingMask**<br>• **CPULoggingOptions** | In IIS 5.0, these metabase properties are provided for the configuration of processor (CPU) management features.<br><br>In IIS 6.0, processor management (CPU throttling) is provided by other means. As a result, IIS 6.0 no longer uses these metabase properties.<br><br>Remove any references to these IIS metabase properties from Web sites, applications, or setup programs.<br><br>The following metabase properties reference and implement CPU throttling in IIS 6.0:<br>• **CPULimit**<br>• **CPUResetInterval**<br>• **CPUAction**<br><br>For more information about CPU throttling in IIS 6.0, see the CPULimit Metabase Property, CPUResetInterval Metabase Property, and CPUAction Metabase Property metabase properties. |
| **CPUResetInterval** | In IIS 5.0, this property enables the monitoring of processor utilization at the Web site level. IIS 5.0 was unable to monitor individual processes for a Web site, such as multiple processes in an ASP.NET Web garden.<br><br>In IIS 6.0, this property enables the monitoring of processor utilization at the worker process level. You cannot monitor the processor utilization for individual Web sites unless there is only one Web site in the application pool.<br><br>For more information about how to configure this value for worker processes in an application pool, see the CPUResetInterval Metabase Property metabase property. |

| | |
|---|---|
| **DisableSocketPooling** | In IIS 4.0 and IIS 5.0, Windows Sockets (WinSock) listens for HTTP requests that use Transmission Control Protocol (TCP). WinSock uses the concept of *sockets* to provide TCP connectivity. As a result, IIS 4.0 and IIS 5.0 are bound to the scalability constraints of using sockets through WinSock. In IIS 5.0, socket pooling addresses these scalability problems, in cases where a large number of Web sites were configured with individual IP addresses.<br><br>In IIS 5.0, socket pooling allows for socket resources to be shared between multiple Web sites and thus provides significant improvements — up to two to three times the scaling capacity of earlier versions of IIS.<br><br>In IIS 6.0, HTTP.sys is responsible for listening for HTTP requests and provides similar functionality to the **DisableSocketPooling** metabase property.<br><br>To configure HTTP.sys, use Httpcfg.exe.<br><br>**Note**<br>On new installations of Windows Server 2003 and IIS 6.0, the **DisableSocketPooling** metabase property still exists; however, IIS 6.0 ignores the property. |
| **HcMimeType** | In IIS 5.0, this metabase property indicates which Multipurpose Internet Mail Extensions (MIME) types are supported by the compression scheme.<br><br>IIS 6.0, HTTP compression is performed in a different way, and this metabase property is no longer used.<br><br>Remove any references to this metabase property from Web sites, applications, or setup programs. |
| **PutReadSize** | In IIS 5.0, this metabase property is provided to support the Web Distributed Authoring and Versioning (WebDAV) component, but is untested and unsupported.<br><br>In IIS 6.0, this functionality is integrated with the WebDAV component. As a result, IIS 6.0 no longer uses this metabase property.<br><br>Remove any references to this metabase property from Web sites, applications, or setup programs.<br><br>For more information about WebDAV in IIS 6.0, see About WebDAV. |
| **UNCAuthenticationPassthrough** | In IIS 5.0, this metabase property enables pass-through user authentication for Universal Naming Convention (UNC) virtual root access, which is for authentication schemes that support delegation.<br><br>In IIS 6.0, pass-through authentication occurs automatically when the **UNCUserName** and **UNCPassword** metabase properties are not specified. As a result, IIS 6.0 no longer uses this metabase property.<br><br>Remove any references to this metabase property from Web sites, applications, or setup programs.<br><br>For more information, see the UNCUserName Metabase Property and UNCPassword Metabase Property metabase properties. |

# Appendix C: Choosing a Cluster Technology for IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Windows Server 2003 supports three different cluster technologies: Server cluster, which is the Windows Server 2003 name for the Microsoft technology first made available as Microsoft Cluster Server (MSCS) in Windows NT Server 4.0, Enterprise Edition; Network Load Balancing (NLB); and Component Load Balancing (CLB). These Microsoft clustering technologies can be key ingredients in improving availability, reliability and scalability. The following table compares the purposes and uses of the three cluster technologies.

**Table 1.1 Cluster Technologies Supported in Windows Server 2003**

| Cluster technology | Purpose | Suitable applications |
|---|---|---|
| Server cluster | Provide high availability by making application software and data available on several servers linked together in a cluster configuration. If one server stops functioning, a process called *failover* automatically shifts the workload of the failed server to another server in the cluster. The failover process is designed to ensure continuous availability of critical applications and data. | • *Stateful* applications have long-running in-memory state, or they have large, frequently updated data states. A database such as Microsoft® SQL Server™ is an example of a stateful application. |
| NLB | • Address bottlenecks caused by front-end Web services and Web servers.<br>• Support load balancing of Transmission Control Protocol (TCP), User Datagram Protocol (UDP), and Generic Routing Encapsulation (GRE) traffic requests. | *Stateless* applications do not have long-running in-memory state. A stateless application treats each client request as an independent operation, and therefore it can load-balance each request independently. Stateless applications often have read-only data or data that changes infrequently. Web front-end servers, virtual private networks (VPNs), and File Transfer Protocol (FTP) servers typically use NLB. Microsoft recommends using NLB with IIS 6.0. |
| CLB | Perform dynamic load balancing, over multiple nodes, of middle-tier application components that use COM+. | Applications that use COM+ components. |

**Limitations of clusters**

While a well-designed solution can guard against application failure, system failure and site failure, cluster technologies do have the following limitations:

- Cluster technologies depend on compatible applications and services to respond appropriately when failure occurs.
- Clusters can be designed to handle failure, but they are not meant to protect user data. The cluster by itself does not guard against loss of a user's work. Typically, the recovery of lost work is handled by the application software; the application software must be designed to recover the user's work, or it must be designed in such a way that the user's session state can be maintained if a failure occurs.
- Cluster technology cannot protect against failures caused by viruses, software corruption or human error. To protect against these types of problems, organizations need solid data protection and recovery plans.

For more information on cluster technologies available in Window Server 2003, see An Overview of Windows Clustering Technologies: Server Clusters and Network Load Balancing.

# Clustering IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 Web servers can be made highly available by failover using a Server cluster; however, Microsoft recommends that you use Network Load Balancing (NLB). In addition to providing high availability for IIS, NLB is a good cluster solution for a Web farm scenario because it also offers load balancing capabilities. NLB is generally less expensive to implement than Server cluster, which has additional hardware requirements. Windows Server 2003 Web Edition supports NLB.

**Upgrading to IIS 60 from an IIS 5.0 Cluster**
In Windows 2000, IIS 5.0 Web sites and FTP services used the IIS Server Instance resource type to achieve high availability with Microsoft Cluster Service (MSCS).

In Windows Server 2003, the IIS Server Instance resource type is now a *Generic Script* resource.This new resource type allows you to implement start/stop and health monitoring functions as scripts rather than as C or C++ programs. To manage IIS in a Windows Server 2003 cluster, you must use this Generic Script resource.

Windows Server 2003 provides a script called Iis_switch.vbs, which is located by default in the *systemroot*\system32\inetsrv directory. Iis_switch.vbs allows you to upgrade to IIS 6.0 from a Windows 2000 Server cluster with IIS 5.0 installed. First, upgrade all nodes except the node containing the IIS instance resource from Windows 2000 to Windows Server 2003, Enterprise Edition. Then, you can either use the script or perform the upgrade manually.

For step-by-step instructions about upgrading IIS from a clustered Windows 2000 Server configuration, see Server Clusters: Rolling Upgrades—Upgrading to Windows Server 2003.

# FTP Cluster Deployments

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Depending on the environment in which the FTP servers reside, you can use either Server clusters or NLB clusters to provide highly available FTP servers. The following table compares Server clusters and NLB.

| Server cluster | NLB |
| --- | --- |
| • Appropriate for FTP sites with high update rates, or in situations where you want to have a single copy of the FTP content.<br>• Uses a shared disk; does not require replication.<br>• Can be configured as active/passive only, which provides high availability but does not provide load balancing. | • Appropriate for FTP sites that are mainly read-only and used mostly for downloading content.<br>• Requires replication.<br>• Single-affinity mode is strongly recommended.<br>• Recommended for clustering FTP servers, instead of Server cluster. |

For more information about the process of implementing FTP in a Server cluster, see Checklist: Creating a clustered IIS Web or FTP service in the Windows Server 2003 Operations Guide. For an example of an FTP cluster configuration, see Example: Controlling the Distribution of Client Traffic within the Cluster.

# Additional Resources for Clustering IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following additional resources can help you configure Network Load Balancing (NLB) for IIS 6.0.

- For an introduction to NLB, see What is Network Load Balancing?
- For comprehensive information about deploying IIS in an NLB configuration, see Designing Network Load Balancing and Deploying Network Load Balancing in the Windows Server 2003 Deployment Kit.
- For information about scalability and performance issues for IIS 6.0 in an NLB configuration, see Improving IIS 6.0 Scalability and Availability with Network Load Balancing.
- For information about using Kerberos authentication with load-balanced Web sites, see Kerberos Authentication for load-balanced Web sites.

# Appendix D: Running 32-bit Applications on 64-bit Windows

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Windows Server 2003™, Service Pack 1 enables IIS 6.0 to run 32-bit Web applications on 64-bit Windows using the Windows-32-on-Windows-64 (WOW64) compatibility layer. IIS 6.0 using WOW64 is intended to run 32-bit personal productivity applications needed by software developers and administrators, including 32-bit Internet Information Services (IIS) Web applications.

On 64-bit Windows, 32-bit processes cannot load 64-bit DLLs, and 64-bit processes cannot load 32-bit DLLs. If you plan to run 32-bit applications on 64-bit Windows, you must configure IIS to create 32-bit worker processes. Once you have configured IIS to create 32-bit worker processes, you can run the following types of IIS applications on 64-bit Windows:

- Internet Server API (ISAPI) extensions
- ISAPI filters
- Active Server Page (ASP) applications (specifically, scripts calling COM objects where the COM object can be 32-bit or 64-bit)
- ASP.NET applications

IIS can, by default, launch Common Gateway Interface (CGI) applications on 64-bit Windows, because CGI applications run in a separate process.

**Configuring IIS to run 32-bit Web applications on 64-bit Windows**
Before you configure IIS to run 32-bit applications on 64-bit Windows, note the following:

- IIS only supports 32bit worker processes in Worker Process Isolation mode on 64-bit Windows.
- On 64-bit Windows, the World Wide Web Publishing service can run 32-bit and 64-bit worker processes. Other IIS services like the IIS Admin service, the SMTP service, the NNTP service, and the FTP service run 64-bit processes only.
- On 64-bit Windows, the World Wide Web Publishing service does not support running 32-bit and 64-bit worker processes concurrently on the same server.

**To enable IIS 6.0 to run 32-bit Web applications on 64-bit Windows**

1. Open a command prompt and navigate to the *%windir%*\Inetpub\AdminScripts directory.
2. Type the following:

```
cscript.exe adsutil.vbs set W3SVC/AppPools/Enable32BitAppOnWin64 1
```

3. Press ENTER.

# Appendix E: Unattended Setup

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) 6.0 is not installed by default when you install the Microsoft® Windows® Server 2003 operating system. To simplify the setup process on multiple computers, you can set up IIS 6.0 while the server is unattended. To do so, you can either create an answer file that you can use to install IIS 6.0 at the same time you install Windows Server 2003, or you can perform an unattended installation of IIS 6.0 after you install Windows Server 2003.

In This Appendix

Creating an Answer File

Installing IIS 6.0 with the Operating System

Installing IIS 6.0 After the Operating System

Related Resources

- For information about configuring Web, File Transfer Protocol (FTP), Network News Transfer Protocol (NNTP), and Simple Mail Transfer Protocol (SMTP) sites and services, see Configuring Internet Sites and Services.

# Creating an Answer File

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To set up unattended installation for IIS 6.0, you must create an answer file containing parameters with appropriate settings, depending on how you want to customize your installation of IIS. You have two options for unattended installation of IIS 6.0:

- Install and set up IIS 6.0 at the same time that you install the Windows Server 2003 operating system.
- Install IIS 6.0 after the Windows Server 2003 operating system has been installed.

If you install IIS 6.0 simultaneously with the operating system, you need to create a complete answer file and include a [Components] section, as well as an optional [InternetServer] section that contains IIS–related parameters. Use the Winnt32.exe command-line utility to run your answer file. For more information about using Winnt32.exe, see Installing IIS 6.0 with the Operating System. For more information about creating and using a Windows unattended setup answer file, see Planning for Unattended Setup in Help and Support Center for Microsoft Windows Server 2003.

If you install IIS 6.0 after the Windows Server 2003 operating system has been installed, you can create an answer file containing only the [Components] and optional [InternetServer] sections. Use the Sysocmgr.exe command-line utility to run this answer file. For more information about using Sysocmgr.exe, see Installing IIS 6.0 After the Operating System.

Table B.1 lists the unattended installation parameters for IIS that you include in the [Components] section of the answer file. The default setting for all of the following parameters is **off** unless a component is required by some other component that you are installing. For example, if you are installing the World Wide Web Publishing Service (WWW service), then Common Files, IIS Manager, and network COM+ access are turned on by default.

**Table B.1 IIS Unattended Installation Parameters**

| Parameter | Description |
|---|---|
| *aspnet*= on/off | Enable ASP.NET . |
| *complusnetwork* = on/off | Enable network COM+ access. |
| *dtcnetwork* = on/off | Enable network Distributed Transaction Coordinator (DTC) network access. |
| *bitsserverextensionsisapi* = on/off | Enable the BITS Server Extensions ISAPI. |
| *bitsserverextensionsmanager* = on/off | Enable the BITS Server Extensions snap-in. |
| *iis_common* = on/off | Enable Common Files. |
| *iis_ftp* = on/off | Enable the File Transfer Protocol (FTP) service. |
| *fp_extensions* = on/off | Enable FrontPage® 2002 Server Extensions from Microsoft. |
| *iis_inetmgr* = on/off | Enable IIS Manager. |
| *iis_nntp* = on/off | Enable the Network News Transfer Protocol (NNTP) service. |
| *iis_smtp* = on/off | Enable the Simple Mail Transfer Protocol (SMTP) service. |
| *iis_asp* = on/off | Enable Active Server Pages (ASP). |

| | |
|---|---|
| *iis_internetdataconnector* = on/off | Enable Internet Data Connector (IDC). |
| *sakit_web* = on/off | Enable Remote Administration (HTML).<br>You cannot perform an unattended installation of this feature simultaneously with performing an unattended installation of the operating system.<br>You can perform an unattended installation of this feature if you install IIS after you have installed the operating system by using the Sysocmgr.exe command-line utility.<br>This feature is not available on Itanium-based computers running Windows XP 64-Bit Edition; the 64-bit version of Windows Server 2003, Enterprise Edition; or the 64-bit version of Windows Server 2003, Datacenter Edition. |
| *tswebclient* = on/off | Enable remote desktop Web connection. |
| *iis_serversideincludes* = on/off | Enable server-side includes (SSI). |
| *iis_webdav* = on/off | Enable WebDAV publishing. |
| *iis_www* = on/off | Enable the WWW service. |
| *appsrv_console* = on/off | Enable Application Server Console.<br>This feature is not available on Itanium-based computers running Windows XP 64-Bit Edition. |
| *inetprint* = on/off | Enable Internet printing. |

Table B.2 lists the optional IIS unattended installation parameters. You include these parameters in the [InternetServer] section.

**Table B.2 Optional IIS Unattended Installation Parameters**

| Parameter | Description |
|---|---|
| *SvcManualStart* = **www** and/or **ftp** | If WWW or FTP is present, those services will be set to manual start. If you specify both **www** and **ftp**, separate them with a comma (**,**). When installed, the default service state is to automatically start. |
| *PathFTPRoot* = path to FTProot | Alternate path to which the FTP service is installed. The default is *systemroot*\Inetpub\Ftproot. |
| *PathWWWRoot* = path to WWWroot | Alternate path to which the WWW service is installed. The default is *systemroot*\Inetpub\Wwwroot. |
| *ApplicationDependency* = *ApplicationName, GroupID, GroupID* | Adds application and dependencies.<br>For example:<br>ApplicationDependency = CommerceServer, ASP, IndexingService<br>ApplicationDependency = ExchangeServer, ASP60<br>ApplicationDependency = MyApp, ASP.NET v1.1.4322<br>This example makes Commerce Server dependent on ASP and the Indexing Service, Exchange Server dependent on ASP, and MyApp dependent on ASP.NET v1.1.4322. |

| | |
|---|---|
| *ExtensionFile* = <*Enabled Flag*>, <*File Path*>[ ,<*UI Deletable Flag*> [ , <*Group ID*> [ ,<*Description*> ] ] ] | Specifies an extension file. The *UI Deletable Flag*, *Group ID*, and *Description* settings are all optional. However, if you specify any of the optional settings, you must include all of the previous settings.<br><br>The parameters represent the following:<br><br>*Enabled Flag* is set to **0** (zero) for disabled and **1** for enabled.<br><br>*File Path*is the path to the file, and it can contain environment variables.<br><br>*UI Deletable Flag* specifies whether the item can be deleted using IIS Manager. Set to **0** for not deletable and **1** for deletable.<br><br>*Group ID* allows you to group different dynamic-link libraries (DLLs) and Common Gateway Interfaces (CGIs) and have dependencies for the applications.<br><br>*Description* is the description of the extension file.<br><br>For example:<br><br>ExtensionFile = 1, windir\MyISAPIS\Myisapi.dll, 1, MyGroup, My Custom ISAPI<br><br>–Or–<br><br>ExtensionFile = 1, windir\MyCGIs\Mycgi.cgi, 1, MyGroup, My Custom CGI |
| *DisableWebServiceOnUpgrade* = True/False | The default for this parameter is **True** for upgrades from the Microsoft® Windows® 2000 Server operating system, unless you have run the IIS Lockdown Tool or added the registry entry RetainW3SVCStatus to the registry. Please see Caution below.<br><br>For more information about when the WWW service is disabled after an upgrade has been performed, see Upgrading an IIS Server to IIS 6.0. |

**Caution**

Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference in the Microsoft Windows Server 2003 Deployment Kit.

Related Information

For more information about the registry, see the Registry Reference in the Microsoft Windows Server 2003 Deployment Kit.

# Installing IIS 6.0 with the Operating System

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use the Winnt32.exe command-line utility to install IIS 6.0 by using an unattended answer file that includes a [Components] section with the unattended setup parameters listed in Table B.1 and — optionally — an [InternetServer] section with the parameters listed in Table B.2.

| **Important** |
| --- |
| You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /User:***MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters). |

**To use the Winnt32.exe command-line utility**

1. At a command prompt, type:

   ```
   winnt32 /unattend:AnsweFile /s:InstallSource
   ```

   where *AnswerFile* is a file that contains answers to questions that should be automated during installation, and *InstallSource* is the location of the Windows 2003 installation files.

**To use an x86-based computer to view the command options available for Winnt32.exe**

1. On a computer running Microsoft® Windows® 95, Windows® 98, Windows® Millennium Edition, Microsoft® Windows NT® , Windows 2000, Windows XP, or Windows Server 2003 operating systems, insert the Setup CD for Windows Server 2003 in the CD-ROM drive.
2. On the **Start** menu, click **Run**.
3. In the **Open** box, type

   ```
   cmd
   ```

4. Click **OK**.
5. At the command prompt, change to the CD-ROM drive, change to the I386 directory, type

   ```
   winnt32 /?
   ```

   and then press ENTER.

**To use an Itanium-based computer to view the command options available for Winnt32.exe**

1. On an Itanium-based computer running Windows XP 64-Bit Edition; the 64-bit version of Windows Server 2003, Enterprise Edition; or the 64-bit version of Windows Server 2003, Datacenter Edition, insert the Setup CD for the 64-bit version of the product into the CD-ROM drive.
2. On the **Start** menu, click **Run**.
3. In the **Open** box, type

   ```
   cmd
   ```

4. Click **OK**.
5. At the command prompt, change to the CD-ROM drive, change to the IA64 directory, type

   ```
   winnt32 /?
   ```

   and then press ENTER.

# Installing IIS 6.0 After the Operating System

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To install IIS by using scripts after you have installed and set up Windows Server 2003, use the Sysocmgr.exe command-line utility with an unattended answer file that includes a [Components] section with the unattended setup parameters listed in Table B.1 and, optionally, an [InternetServer] section with the parameters listed in Table B.2.

| **Important** |
| --- |
| You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /***User***:***MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters). |

**To install IIS 6.0 by using scripts after the operating system has been installed**

1. On the **Start** menu, click **Run**.
2. In the **Open** box, type

   `cmd`

3. Click **OK**.
4. At the command prompt, type

   **Sysocmgr.exe /i:sysoc.inf /u:%** *PathToUnattendFile* **%**

   and then press ENTER.

To view Sysocmgr.exe Help, type `Sysocmgr.exe/?` at the command prompt.

and then press ENTER .

# Additional Resources_IIS_SP1_Dep

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

# Windows Server 2003 Operations

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Microsoft® Windows Server™ 2003 Operations documentation provides step-by-step, task-oriented information for Windows Server 2003 technologies. This set of Operations documentation is designed to assist information technology (IT) operators and administrators with prescriptive guidance for how to operate, manage, and troubleshoot Windows Server 2003 technologies.

# Active Directory Operations Guide

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Active Directory Operations Guide provides administering and troubleshooting information for Active Directory™ directory service technologies in the Microsoft® Windows Server™ 2003 and Windows Server 2003 with Service Pack 1 (SP1) operating systems.

You cannot install Active Directory on a server running Windows Server 2003, Web Edition, but you can join the server to an Active Directory domain as a member server. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition, on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=9253).

| **Note** |
| --- |
| The Windows Server 2003 Active Directory Operations Guide is also available as a downloadable document on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=63079). |

**In this guide**

- Administering Active Directory Operations
- Troubleshooting Active Directory Operations

# Troubleshooting Active Directory Operations

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This Active Directory Troubleshooting guide provides troubleshooting information for Active Directory in the Microsoft Windows Server 2003 and Windows Server 2003 with Service Pack 1 (SP1) operating systems.

**In this guide**

- Configuring a Computer for Troubleshooting Active Directory
- Troubleshooting Active Directory Replication Problems
- Additional Resources for Troubleshooting Active Directory

This initial release of the Active Directory Troubleshooting guide includes troubleshooting recommendations and procedures for diagnosing and fixing problems that may occur with Active Directory replication in a Windows Server 2003 forest. This content focuses primarily on responses to Directory Service event log messages and tool-based error messages that might be reported by the Repadmin.exe and Dcdiag.exe tools, which are available in Windows Support Tools.

Installation of Windows Server 2003 with SP1 is encouraged for improved diagnostic support in both Windows Support Tools, which you must install separately, and the Ntdsutil.exe administrative command-line tool, which is included with the operating system.

**Acknowledgments**

Key Technical Reviewers: Arren Conner, Gregory Johnson, Rob Kochman, Ajit Krishnan, Dave Tesar

# Configuring a Computer for Troubleshooting Active Directory

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you can use advanced troubleshooting techniques to identify and fix Active Directory problems, you must configure your computer for troubleshooting and have a basic understanding of Windows Server 2003 troubleshooting concepts, procedures, and tools. For information about monitoring tools for Windows Server 2003, see Monitoring and Status Tools on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=59526).

**Configuration Tasks for Troubleshooting**
To configure your computer for troubleshooting, perform the following tasks:

Install Windows Server 2003 SP1

Install Windows Support Tools

Install Network Monitor

Set logging levels

**Install Windows Server 2003 SP1**
If possible, upgrade domain controllers to Windows Server 2003 Service Pack 1 (SP1). To install this service pack, go to the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=9999) and follow instructions for downloading the service pack.

The advantages of running Windows Server 2003 with SP1 with regard to troubleshooting include enhancements to the Ntdsutil command-line tool. Ntdsutil.exe has new functionality that makes it easier to remove domain controller metadata and to authoritatively restore directory objects.

**Install Windows Support Tools**
For improved diagnostic support, install Windows Support Tools that ship with Windows Server 2003 SP1. The SP1 version of Windows Support Tools includes enhanced versions of the Dcdiag.exe and Repadmin.exe tools. The Dcdiag.exe command-line tool now provides new reporting on the overall health of replication with respect to Active Directory security, as well as new Domain Name System (DNS) diagnostic tests. You can use Repadmin.exe to manage replication consistency settings on multiple domain controllers instead of editing the registry on individual computers.

Make sure that the SP1 version of Windows Support Tools is installed on all domain controllers that are running Windows Server 2003 with SP1.

**Options for Running SP1 Windows Support Tools**
You can run Windows Support Tools that ship with Windows Server 2003 SP1 on computers running the following operating systems:

- Windows Server 2003 with SP1
- Windows Server 2003 without SP1

You can also run some tools, such as Repadmin.exe and Dcdiag.exe, on computers running Windows XP Professional, Windows XP Professional with SP1, or Windows XP Professional with Service Pack 2 (SP2). Options for other tools vary by tool. In this guide, the operating system that is required for running a tool is specified as a prerequisite for each procedure.

**Options for Installing SP1 Windows Support Tools**
The SP1 version of Windows Support Tools can be installed as an .msi package only on computers running Windows Server 2003 with SP1. To run Repadmin and Dcdiag from computers running Windows Server 2003 without SP1 or from computers running Windows XP Professional, you must copy the respective executable files to those computers.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Builtin Administrators group.
- Operating system: Windows Server 2003 with SP1. You cannot use suptools.msi to install the SP1 version of Windows Support Tools on a computer that is not running Windows Server 2003 with SP1.

**To install Windows Support Tools**

1. Insert the Windows CD into your CD-ROM drive.
2. If you are prompted to reinstall Windows, click **No**.
3. When the **Welcome** screen appears, click **Perform additional tasks**, and then click **Browse this CD**.
4. Go to the \Support\Tools folder. For complete setup information, see the Readme.htm file in this folder.
5. Double-click **suptools.msi**.
6. Follow the instructions that appear on your screen.

**Install Network Monitor**

Use Network Monitor to troubleshoot connectivity issues by tracing network traffic between computers. For information about installing and using Network Monitor, see Network Monitor on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42987).

**Set Logging Levels**

If the information that you receive in the Directory Service log in Event Viewer is not sufficient for troubleshooting, raise the logging levels by using the appropriate registry entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Diagnostics**.

By default, the logging levels for all entries are set to **0**, which provides the minimum amount of information. The highest logging level is **5**. Increasing the level for an entry causes additional events to be logged in the Directory Service event log. The following diagram shows the diagnostic entries that are available.

Use the following procedure to change the logging level for a diagnostic entry.

| **Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the domain of the domain controller on which you are setting the logging level.

- Tools: Regedit.exe

**To change the logging level for a diagnostic entry**

1. Click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Navigate to the entry for which you want to set logging in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Diagnostics**.
3. Double-click the entry, and for the **Base** click **Decimal**.
4. In the **Value** data box, type an integer from **0** through **5**, and then click **OK**.

# Troubleshooting Active Directory Replication Problems

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Active Directory replication problems can have several different sources. For example, Domain Name System (DNS) problems, networking issues, or security problems can all cause Active Directory replication to fail.

Inbound or outbound replication failure causes Active Directory objects that represent the replication topology, replication schedule, domain controllers, users, computers, passwords, security groups, group memberships, and Group Policy to be inconsistent between domain controllers. Directory inconsistency causes either operational failures or inconsistent results, depending on the domain controller that is contacted for the operation at hand. Active Directory depends on network connectivity, name resolution, authentication and authorization, the directory database, the replication topology, and the replication engine. When the root cause of a replication problem is not immediately obvious, determining the cause among the many possible causes requires systematic elimination of probable causes.

**Event and Tool Solution Recommendations**
Ideally, the red (Error) and yellow (Warning) events in the Directory Service event log suggest the specific constraint that is causing replication failure on the source or destination domain controller. If the event message suggests steps for a solution, try the steps listed in the event. The Repadmin tool and other diagnostic tools also provide information that can help you resolve replication failures.

**Ruling Out the Obvious**
Sometimes replication errors occur because of intentional disruptions. For example, when you troubleshoot Active Directory replication problems, rule out intentional disconnections and hardware failures or upgrades first.

**Intentional Disconnections**
If replication errors are reported by a domain controller that is attempting replication with a domain controller that has been built in a staging site and is currently offline awaiting its deployment in the final production site (remote), you can account for those errors. To avoid separating a domain controller from the replication topology for extended periods, which causes continuous errors until the domain controller is reconnected, consider adding such computers initially as member servers and using the install-from-media method to install Active Directory. You can back up an up-to-date domain controller to removable media (CD/DVD or other media) and ship the media to the destination site. Then, you can use the media to promote the domain controllers at the site, without requiring replication. For more information about installing from media, see Installing a Domain Controller in an Existing Domain Using Restored Backup Media.

**Hardware Failures or Upgrades**
If replication problems occur as a result of hardware failure (for example, failure of the motherboard, disk subsystem, or hard drive), notify the server owner so that the hardware problem can be resolved.

Periodic hardware upgrades can also cause domain controllers to be out of service. Ensure that your server owners have a good system of communicating such outages in advance.

**Correct Response to Any Outdated Server Running Windows 2000 Server**
If a domain controller running Windows 2000 Server has failed for longer than the number of days in the tombstone lifetime, the solution is always the same:

1. Move the server from the corporate network to a private network.
2. Either forcefully remove Active Directory or reinstall the operating system.
3. Remove the server metadata from Active Directory so that the server object cannot be revived.

| **Note** |
| --- |
| By default, NTDS Settings objects that are deleted are revived automatically for a period of 14 days. Therefore, if you do not remove server metadata (use Ntdsutil to perform metadata cleanup), the server metadata is reinstated in the directory, which prompts replication attempts to occur. In this case, errors will be logged persistently as a result of the inability to replicate with the missing domain controller. |

**Root Causes**
If you rule out intentional disconnections, hardware failures, and outdated Windows 2000 domain controllers, the remainder of replication problems almost always have one of the following root causes:

- Network connectivity: The network connection might be unavailable or network settings are not configured properly.
- Name resolution: DNS misconfigurations are a common cause for replication failures.
- Authentication and authorization: Authentication and authorization problems cause "Access denied" errors when a domain controller tries to connect to its replication partner.
- Directory database (store): The directory database might not be able to process transactions fast enough to keep up with replication timeouts.
- Replication engine: If intersite replication schedules are too short, replication queues might be too large to process in the time that is required by the outbound replication schedule. In this case, replication of some changes can be stalled indefinitely — potentially, long enough to exceed the tombstone lifetime.
- Replication topology: Domain controllers must have intersite links in Active Directory that map to real wide area network (WAN) or virtual private network (VPN) connections. If you create objects in Active Directory for the replication topology that are not supported by the actual site topology of your network, replication that requires the misconfigured topology fails.

**General Approach to Fixing Problems**
Use the following general approach to fixing replication problems:

1. Monitor replication health daily, or use Repadmin.exe to retrieve replication status daily.
2. Attempt to resolve any reported failure in a timely manner by using the methods described in event messages and this guide. If software might be causing the problem, uninstall the software before you continue with other solutions.
3. If the problem that is causing replication to fail cannot be resolved by any known methods, remove Active Directory from the server and then reinstall Active Directory. For more information about reinstalling Active Directory, see Decommissioning a Domain Controller.
4. If Active Directory cannot be removed normally while connected to the network, use one of the following methods to resolve the problem:

   - Force Active Directory removal in Directory Services Restore Mode, clean up server metadata, and then reinstall Active Directory.
   - Reinstall the operating system, and rebuild the domain controller.

   For more information about forcing Active Directory removal, see Forcing the Removal of a Domain Controller.

**Monitoring Replication Health**
Monitoring for replication failures is critical to being able to solve replication problems quickly and effectively. Use one of the following methods to monitor replication health:

| **Note** |
| --- |
| For detailed information on how to use Repadmin, see Monitoring and Troubleshooting Active Directory Replication Using Repadmin (http://go.microsoft.com/fwlink/?LinkId=122830). |

- Use a monitoring application that you set to capture and report specific errors and events on a daily basis.

- Use the Repadmin tool to retrieve replication status daily.

**Using a Monitoring Application to Monitor Replication Health**

For all domain controllers in a forest, monitor replication health on a daily basis by using Microsoft Operations Manager (MOM) or an equivalent monitoring application. For information about using MOM to monitor Active Directory, see Active Directory Management Pack Technical Reference for MOM 2005 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41369).

**Using Repadmin to Retrieve Replication Status**

Replication status is an important way for you to evaluate the status of the directory service. If replication is working without errors, you know the domain controllers that are online. You also know that the following systems and services are working:

- DNS infrastructure
- Kerberos
- Windows Time service (W32time)
- Remote procedure call (RPC)
- Network connectivity

Use Repadmin (Windows Support Tools) to monitor replication status daily by running a command that assesses the replication status of all domain controllers in your forest. The procedure generates a .csv file that you can open in Excel and filter for replication failures.

Use the following procedure to retrieve the replication status of all domain controllers in the forest.

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the forest root domain or the Enterprise Admins group in the forest.
- Tools:

  Repadmin.exe (Windows Support Tools)

  Excel (Microsoft Office)

**To retrieve replication status**

1. Open a command prompt, type the following command, and then press ENTER:

   **repadmin /showrepl * /csv >showrepl.csv**

2. In Excel, on the **File** menu, click **Open.**
3. In **Files of type**, click **Text Files (*.prn;*.txt;*.csv)**.
4. In **Look in**, navigate to showrepl.csv, and then click **Open**.
5. In the Excel spreadsheet, right-click the column heading for **showrepl_COLUMNS** (column A) and then click **Hide**. Repeat for the column labeled **Transport Type**.
6. Select the row just under the column headings, and then, on the **Windows** menu, click **Freeze Pane**.
7. Click the upper-left corner of the spreadsheet to highlight the entire spreadsheet. On the **Data** menu, point to **Filter,** and then click **AutoFilte**r.
8. In the heading of the **Last Success** column, click the down arrow, and then click **Sort Ascending**.

9. In the heading of the **Source DC** column, click the down arrow, and then click **Custom**. In the **Custom AutoFilter** dialog box, complete the custom filter as follows:

    a. Under **Source D**C, click **does not contain**.

    b. In the corresponding text box, type **del** to filter deleted domain controllers from the spreadsheet.

10. In the heading of the **Last Failure** column, click the down arrow, and then click **Custom**. In the **Custom AutoFilter** dialog box, complete the custom filter as follows:

    a. Under **Last Failure**, click **does not equal**.

    b. In the corresponding text box, type **0** to filter for only domain controllers that are experiencing failures.

For every domain controller in the forest, the spreadsheet shows the source replication partner, the time that replication last occurred, and the time that the last replication failure occurred for each naming context (directory partition). By using **Autofilter** in Excel, you can view the replication health for working domain controllers only, failing domain controllers only, or domain controllers that are the least or most current, and you can see the replication partners that are replicating successfully.

**Attempting to Resolve Problems**

Replication problems are reported in event messages and in various error messages that occur when an application or service attempts an operation. Ideally, these messages are collected by your monitoring application or when you retrieve replication status.

Most replication problems are identified in the event messages that are logged in the Directory Service event log. Replication problems might also be identified in the form of error messages in the output of the **repadmin /showrepl** command.

**repadmin /showrepl Error Messages That Indicate Replication Problems**

To identify Active Directory replication problems, use the **repadmin /showrepl** command as described in the previous section. The following table shows error messages that are generated by this command, along with the root causes of the errors and links to topics that provide solutions for the errors.

**repadmin /showrepl Error Messages**

| Repadmin error | Root cause | Solution |
|---|---|---|
| The time since last replication with this server has exceeded the tombstone lifetime. | A domain controller has failed inbound replication with the named source domain controller long enough for a deletion to have been tombstoned, replicated, and garbage-collected from Active Directory. | Event ID 2042: It has been too long since this machine replicated |
| No inbound neighbors. | If no items appear in the "Inbound Neighbors" section of the output that is generated by **repadmin /showrepl**, the domain controller was not able to establish replication links with another domain controller. | Fixing Replication Connectivity Problems (Event ID 1925) |
| Access is denied. | A replication link exists between two domain controllers, but replication cannot be performed properly due to an authentication failure. | Fixing Replication Security Problems |
| Last attempt at <date - time> failed with the "Target account name is incorrect." | This problem can be related to connectivity, DNS, or authentication issues.<br><br>If this is a DNS error, the local domain controller could not resolve the globally unique identifier (GUID)–based DNS name of its replication partner. | Fixing Replication DNS Lookup Problems (Event IDs 1925, 2087, 2088)<br><br>Fixing Replication Security Problems<br><br>Fixing Replication Connectivity Problems (Event ID 1925) |
| LDAP Error 49. | The domain controller computer account might not be synchronized with the Key Distribution Center (KDC). | Fixing Replication Security Problems |

| | | |
|---|---|---|
| Cannot open LDAP connection to local host | The administration tool could not contact Active Directory. | Fixing Replication DNS Lookup Problems (Event IDs 1925, 2087, 2088) |
| Active Directory replication has been preempted. | The progress of inbound replication was interrupted by a higher priority replication request, such as a request generated manually with the **repadmin /sync** command. | Wait for replication to complete. This informational message indicates normal operation. |
| Replication posted, waiting. | The domain controller posted a replication request and is waiting for an answer. Replication is in progress from this source. | Wait for replication to complete. This informational message indicates normal operation. |

**Event Messages That Indicate Active Directory Replication Problems**

The following table lists common events that might indicate problems with Active Directory replication, along with root causes of the problems and links to topics that provide solutions for the problems.

**Events That Indicate Active Directory Replication Problems**

| Event ID and source | Root cause | Solution |
|---|---|---|
| 1311 — NTDS KCC | The replication configuration information in Active Directory does not accurately reflect the physical topology of the network. | Fixing Replication Topology Problems (Event ID 1311) |
| 1388 — NTDS Replication | Strict replication consistency is not in effect, and a lingering object has been replicated to the domain controller. | Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042) |
| 1925 — NTDS KCC | The attempt to establish a replication link for a writable directory partition failed. This event can have different causes, depending on the error. | Fixing Replication Connectivity Problems (Event ID 1925)<br><br>Fixing Replication DNS Lookup Problems (Event IDs 1925, 2087, 2088) |
| 1988 — NTDS Replication | The local domain controller has attempted to replicate an object from a source domain controller that is not present on the local domain controller because it may have been deleted and already garbage-collected. Replication will not proceed for this directory partition with this partner until the situation is resolved. | Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042) |
| 2042 — NTDS Replication | Replication has not occurred with this partner for a tombstone lifetime, and replication cannot proceed. | Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042) |
| 2087 — NTDS Replication | Active Directory could not resolve the DNS host name of the source domain controller to an Internet Protocol (IP) address, and replication failed. | Fixing Replication DNS Lookup Problems (Event IDs 1925, 2087, 2088) |
| 2088 — NTDS Replication | Active Directory could not resolve the DNS host name of the source domain controller to an IP address, but replication succeeded. | Fixing Replication DNS Lookup Problems (Event IDs 1925, 2087, 2088) |
| 2095 — NTDS Replication | Update sequence number (USN) rollback has occurred and replication has been stopped. This error indicates an improper Active Directory restore, possibly of a virtual machine file (.vhd). | For an explanation of this problem and recommendations for solutions, see Running Domain Controllers in Virtual Server 2005 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=38330). |
| 5805 — Net Logon | A machine account failed to authenticate, which is usually caused by either multiple instances of the same computer name or the computer name not replicating to every domain controller. | Fixing Replication Security Problems |

For more information about replication concepts, see “Active Directory Replication Technologies” in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41950).

# Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042)

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If a domain controller does not replicate for a period of time that is longer than the tombstone lifetime and the domain controller is then reconnected to the replication topology, objects that were deleted from Active Directory while the domain controller was offline can remain on the domain controller as lingering objects.

**Tombstone Lifetime and Replication of Deletions**
When an object is deleted, Active Directory replicates the deletion as a tombstone object, which consists of a small subset of the attributes of the deleted object. By inbound-replicating this object, other domain controllers in the domain and forest become aware of the deletion. The tombstone is retained in Active Directory for a specified period called the tombstone lifetime. At the end of the tombstone lifetime, the tombstone is deleted from the directory permanently.

The default value of the tombstone lifetime depends on the version of the operating system that is running on the first domain controller that is installed in a forest, as follows:

- Windows 2000 Server or Windows Server 2003: The default value is 60 days.
- Windows Server 2003 with Service Pack 1 (SP1): The default value is 180 days.

| **Note** |
| --- |
| The tombstone lifetime value that is in effect when a domain controller is upgraded to Windows Server 2003 SP1 is not changed by upgrading. The existing value is maintained until you change it manually. |

After the tombstone is removed permanently, the object deletion can no longer be replicated. Therefore, the tombstone lifetime defines how long domain controllers in the forest retain knowledge of a deleted object and thus the time during which a unique deletion must be received by all direct and transitive replication partners of the originating domain controller.

**How Lingering Objects Occur**
When conditions beyond your control cause a domain controller to be disconnected for a period that is longer than the tombstone lifetime, one or more objects that are deleted from Active Directory on all other domain controllers might remain on the disconnected domain controller. Such objects are called lingering objects. Because the domain controller is offline during the entire time that the tombstone is alive, the domain controller never receives replication of the tombstone.

When it is reconnected to the replication topology, this domain controller acts as a source replication partner that has an object that its destination partner does not have.

Replication problems occur when the object on the source domain controller is updated. In this case, when the destination attempts to inbound-replicate the update, one of the following happens:

- If the destination domain controller has strict replication consistency enabled, it recognizes that it cannot update the object and locally halts inbound replication of the directory partition from that source domain controller.
- If the destination domain controller has strict replication consistency disabled, it requests the full replica of the updated object. In this case, the object is reintroduced into the directory.

Lingering objects can reside in writable or read-only partitions that are potentially replicated between domain controllers in the same or different domains in the same forest.

**Causes of Long Disconnections**
Unexpectedly long disconnections can be caused by the following conditions:

- A domain controller is left in a storage room and forgotten, or shipment of a prestaged domain controller to its remote location takes longer than a tombstone lifetime.

- Replication fails and monitoring is not in place. Failures can occur as follows:

    - A domain controller is started and connected to the corporate intranet but experiences inbound replication failure as a result of an underlying network connectivity failure, name resolution failure, or authentication failure that prevents replication from occurring.

    - A bridgehead server is overloaded, and replication becomes backlogged. Excessively high replication load on a global catalog server, in combination with a short intersite replication interval, can result in updates not being replicated.

| **Note** |
| --- |
| Global catalog servers replicate read-only replicas of all domain directory partitions in the forest. The replication of read-only replicas has a lower priority than the replication of writable replicas. In addition, global catalog servers are often bridgehead servers, which adds to the replication load. If the replication load on global catalog servers acting as bridgehead servers is too high as a result of an extremely short replication interval, excessive numbers of concurrent outbound replication partners, or a combination of both, the replication queue can become backlogged. If the condition persists, read-only replicas can remain in the queue indefinitely. These conditions can result in lingering objects on a global catalog server. |

- Wide area network (WAN) connections are unavailable for long periods. For example, a domain controller onboard a cruise ship might be unable to replicate because the ship is at sea for longer than the tombstone lifetime.

- The reported event is a false positive because an administrator shortened the tombstone lifetime to force tombstone deletion (garbage collection).

- The reported event is a false positive because the system clock on the source or destination domain controller is improperly rolled forward or back in time. Clock skews are most common following a system reboot and can have the following causes:

    - System clock battery or motherboard problems.

    - The time source for a computer is improperly configured, including a time source server configured with Windows Time service (W32time), third-party time servers, and network routers.

    - The system clock is advanced or rolled back by an administrator attempting to extend the useful life of a system state backup or accelerate the garbage collection of deleted objects. Make sure that the system clock reflects the actual time and that event logs do not contain events from the future or invalid past.

**Indications That a Domain Controller Has Lingering Objects**

An outdated domain controller can store lingering objects with no noticeable effect as long as an administrator, application, or service does not update the lingering object or attempt to create an object with the same name in the domain or with the same user principal name (UPN) in the forest. However, the existence of lingering objects can cause problems, especially if the object is a security principal.

**Symptoms Associated with Lingering Objects**

The following symptoms indicate that a domain controller has lingering objects:

- A deleted user or group account remains in the global address list (GAL) on Exchange servers. Therefore, although the account name appears in the GAL, attempts to send e-mail messages result in errors.

- Multiple copies of an object appear in the object picker or GAL for an object that should be unique in the forest. Duplicate objects sometimes appear with altered names, causing confusion on directory searches. For example, if the relative distinguished name of two objects cannot be resolved, conflict resolution appends "*CNF:*GUID*" to the name, where * represents a reserved character, CNF is a constant that indicates a conflict resolution, and *GUID* represents the **objectGUID** attribute value.

- E-mail messages are not delivered to a user whose Active Directory account appears to be current. After an outdated

domain controller or global catalog server becomes reconnected, both instances of the user object appear in the global catalog. Because both objects have the same e-mail address, e-mail messages cannot be delivered.

- A universal group that no longer exists continues to appear in a user's access token. Although the group no longer exists, if a user account still has the group in its security token, the user might have access to a resource that you intended to be unavailable to that user.

- A new object or Exchange mailbox cannot be created, but you do not see the object in Active Directory. An error message reports that the object already exists.

- Searches that use attributes of an existing object incorrectly find multiple copies of an object of the same name. One object has been deleted from the domain, but it remains in an isolated global catalog server.

If an attempt is made to update a lingering object that resides in a writable directory partition, events are logged on the destination domain controller. However, if the only version of a lingering object exists in a read-only directory partition on a global catalog server, the object cannot be updated and this type of event will never be triggered.

**Registry Setting That Determines Whether Lingering Objects Are Replicated**

If a writable lingering object exists in your environment and an attempt is made to update the object, the value in the **strict replication consistency** registry entry (type **REG_DWORD**) in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters** determines whether replication proceeds or is stopped, as follows:

- **1** (enabled): Inbound replication of the specified directory partition from the source is stopped on the destination.

- **0** (disabled): The destination requests the full object from the source domain controller, and the lingering object is revived in the directory as a new object.

**Default Settings for Strict Replication Consistency**

The default value for the **strict replication consistency** registry entry is determined by the conditions under which the domain controller was installed into the forest.

| **Note** |
| --- |
| Raising the domain or forest functional level does not change the replication consistency setting on any domain controller. |

**Strict replication consistency enabled**

The value of **strict replication consistency** on domain controllers that are installed into a forest defaults to enabled (**1**) under the following conditions:

- The forest root domain of a new forest is created by upgrading the Windows NT 4.0 primary domain controller (PDC) to Windows Server 2003 by using the Windows Server 2003 version of Winnt32.exe.

- The forest root domain of a new forest is created by installing Active Directory on a server running Windows Server 2003.

**Strict replication consistency disabled**

The value of **strict replication consistency** on domain controllers defaults to disabled (**0**) under the following conditions:

- A domain controller running Windows 2000 Server is upgraded to Windows Server 2003.

- A server running Windows 2000 Server is promoted into a Windows Server 2003 forest.

If you have a domain controller that is running Windows Server 2003 with SP1, you do not need to edit the registry to set strict replication consistency. Instead, you can use Repadmin to set the value for one or all domain controllers in the forest. To set strict replication consistency for specific domain controllers or for all domain controllers, see Event ID 1388 or 1988: A lingering object is detected.

For more information about strict replication consistency, see "How the Active Directory Replication Model Works" in the Windows Server 2003 Technical Reference on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=27636.

**Tool for Removing Lingering Objects**

On domain controllers running Windows Server 2003 or Windows Server 2003 with SP1, use Repadmin.exe (in Windows Support Tools) to remove the lingering object or objects. Windows Support Tools are available on the operating system CD in the Support\Tools folder. The version of Repadmin that ships with Windows Server 2003 provides the option **/removelingeringobjects**, which safely removes instances of lingering objects from both writable directory partitions and read-only directory partitions.

The **repadmin /removelingeringobjects** command does the following:

1. Compares the directory database objects on a reference domain controller with the objects on the target domain controller, which contains (or is suspected to contain) lingering objects. There must be connectivity between the reference domain controller and the target domain controller.

2. Either removes the lingering objects or logs the potential deletions to the Directory Service event log, as follows:

    - If you use the **/advisory_mode** parameter, events are logged in the Directory Service event log for the objects that are found.

    - If you do not use the **/advisory_mode** parameter, the found objects are deleted without replicating the deletions; that is, the deletions occur only on the target domain controller.

Choose the problem that best describes your situation from the following list, and then step through the suggested fix:

- Event ID 1388 or 1988: A lingering object is detected

- A deleted account remains in the Address Book, e-mail is not received, or a duplicate account exists

- Event ID 2042: It has been too long since this machine replicated

Configuring a Computer for Troubleshooting Active Directory

# Event ID 1388 or 1988: A lingering object is detected

Updated: November 19, 2012

Applies To: Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012

If a destination domain controller logs Event ID 1388 or Event ID 1988, a lingering object has been detected and one of two conditions exists on the destination domain controller:

- Event ID 1388: Inbound replication of the lingering object has occurred on the destination domain controller.
- Event ID 1988: Inbound replication of the directory partition of the lingering object has been blocked on the destination domain controller.

**In this topic**

- Event ID 1388
- Event ID 1988
- Diagnosis
- Resolution
  - Use Repadmin to identify the GUID of an authoritative domain controller
  - Use Repadmin to remove lingering objects
- Enable strict replication consistency
  - Use Repadmin to enable strict replication consistency
  - Use Regedit to enable strict replication consistency
- Ensure that strict replication consistency is enabled for newly promoted domain controllers

**Event ID 1388**

This event indicates that a destination domain controller that does not have strict replication consistency enabled received a request to update an object that does not reside in the local copy of the Active Directory database. In response, the destination domain controller requested the full object from the source replication partner. In this way, a lingering object was replicated to the destination domain controller. Therefore, the lingering object was reintroduced into the directory.

| **Important** |
| --- |
| When Event ID 1388 occurs, if either the source domain controller (the replication partner that is outbound-replicating the lingering object) or the destination domain controller (the inbound replication partner that reports Event ID 1388) is running Windows 2000 Server, you cannot use the Repadmin tool to remove lingering objects. For information about how to remove lingering objects in this case, see article 314282 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=41410). The procedures and information in this article apply to the removal of lingering objects from global catalog servers as well as from domain controllers that are not global catalog servers. |

The event text identifies the source domain controller and the outdated (lingering) object. The following is an example of the event text:

```
Log Name: Directory Service
Source: Microsoft-Windows-ActiveDirectory_DomainService
Date: 5/3/2008  3:34:01 PM
```

```
Event ID: 1388
Task Category: Replication
Level: Error
Keywords: Classic
User: ANONYMOUS LOGON
Computer: DC3.contoso.com
Description:
Another domain controller (DC) has attempted to replicate into this DC an
object which is not present in the local Active Directory Domain Services database.
The
object may have been deleted and already garbage collected (a tombstone
lifetime or more has past since the object was deleted) on this DC. The
attribute set included in the update request is not sufficient to create
the object. The object will be re-requested with a full attribute set
and re-created on this DC.

Source DC (Transport-specific network address):
4a8717eb-8e58-456c-995a-c92e4add7e8e._msdcs.contoso.com
Object:
CN=InternalApps,CN=Users,DC=contoso,DC=com
Object GUID:
a21aa6d9-7e8a-4a8f-bebf-c3e38d0b733a
Directory partition:
DC=contoso,DC=com
Destination highest property USN:
20510
User Action:
Verify the continued desire for the existence of this object. To
discontinue re-creation of future similar objects, the following
registry key should be created.

Registry Key:
HKLM\System\CurrentControlSet\Services\NTDS\Parameters\Strict Replication Consistency
```

**Event ID 1988**

This event indicates that a destination domain controller that has strict replication consistency enabled has received a request to update an object that does not exist in its local copy of the Active Directory database. In response, the destination domain controller blocked replication of the directory partition containing that object from that source domain controller. The event text identifies the source domain controller and the outdated (lingering) object. The following is an example of the event text:

```
Log Name: Directory Service
Source: Microsoft-Windows-ActiveDirectory_DomainService
Date: 2/7/2008  8:20:11 AM
Event ID: 1988
Task Category: Replication
Level: Error
Keywords: Classic
User: ANONYMOUS LOGON
Computer: DC5.contoso.com
Description:
Active Directory Domain Services Replication encountered the existence of objects
in the following partition that have been deleted from the local
domain controllers (DCs) Active Directory Domain Services database. Not all direct
or transitive replication partners replicated in the deletion
before the tombstone lifetime number of days passed. Objects that
have been deleted and garbage collected from an Active Directory Domain Services
partition but still exist in the writable partitions of other DCs
in the same domain, or read-only partitions of global catalog servers
in other domains in the forest are known as "lingering objects".

This event is being logged because the source DC contains a lingering
object which does not exist on the local DCs Active Directory Domain Services database.
This replication attempt has been blocked.

The best solution to this problem is to identify and remove all
lingering objects in the forest.

Source DC (Transport-specific network address):
4a8717eb-8e58-456c-995a-c92e4add7e8e._msdcs.contoso.com
Object:
CN=InternalApps,CN=Users,DC=contoso,DC=com
Object GUID:
```

a21aa6d9-7e8a-4a8f-bebf-c3e38d0b733a

**Diagnosis**
An object that has been permanently deleted from AD DS (that is, its tombstone has been garbage-collected on all connected domain controllers) remains on a disconnected domain controller. The domain controller failed to receive direct or transitive replication of the object deletion because it was disconnected (it is offline or experiencing an inbound replication failure) from the replication topology for a period that exceeded a tombstone lifetime. The domain controller is now reconnected to the topology and that object has been updated on the domain controller, causing a replication notification to the replication partner that an update is ready for replication. The replication partner responded according to its replication consistency setting. This notification applies to attempted replication of a writable object. A copy of the writable lingering object might also exist on a global catalog server.

**Resolution**
If replication of a lingering object is detected, you can remove the object from AD DS, along with any read-only replicas of the object, by identifying the domain controllers that might store this object (including global catalog servers) and running a **repadmin** command to remove lingering objects on these servers (**repadmin /removelingeringobjects**). This command is available on domain controllers that are running Windows Server 2008. It is also available on domain controllers that are not running Windows Server 2008 but are running the version of Repadmin.exe that is included with Windows Support Tools in Windows Server 2003.

To remove lingering objects, do the following:

1. Use the event text to identify the following:

    a. The directory partition of the object

    b. The source domain controller that attempted replication of the lingering object

2. Use Repadmin to identify the GUID of an authoritative domain controller

3. Use Repadmin to remove lingering objects

4. Enable strict replication consistency, if necessary

5. Ensure that strict replication consistency is enabled for newly promoted domain controllers, if necessary

**Use Repadmin to identify the GUID of an authoritative domain controller**
To perform the procedure that removes lingering objects, you must identify the globally unique identifier (GUID) of an up-to-date domain controller that has a writable replica of the directory partition that contains the lingering object that has been reported. The directory partition is identified in the event message.

The object GUID of a domain controller is stored in the **objectGUID** attribute of the NTDS Settings object.

### Requirements

- Membership in **Domain Admins** in the domain of the domain controller whose GUID you want to identify is the minimum required to complete this procedure. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

- Tool: Repadmin.exe

**To identify the GUID of a domain controller**

1. At a command prompt, type the following command, and then press ENTER:

    ```
    repadmin /showrepl <ServerName>
    ```

| Parameter | Description |
|---|---|

| | |
|---|---|
| /showrepl | Displays the replication status, including when the domain controller that is specified by <ServerName> last attempted inbound replication of Active Directory partitions. Also displays the GUID of the specified domain controller. |
| <ServerName> | The name of the domain controller whose GUID you want to display. |

2. In the first section of the output, locate the **objectGuid** entry. Select and copy the GUID value into a text file so that you can use it elsewhere.

**Use Repadmin to remove lingering objects**

If the destination domain controller and source domain controller are running either Windows Server 2003 or Windows Server 2008, you can use this procedure to remove lingering objects with Repadmin. If either domain controller is running Windows 2000 Server, follow the instructions in article 314282 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=41410).

### Requirements

- Membership in **Domain Admins** in the domain of the domain controller that has lingering objects, or **Enterprise Admins** if the directory partition that has lingering objects is the configuration or schema directory partition, is the minimum required to complete this procedure. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

- Operating system: Windows Server 2003 or Windows Server 2008 for <ServerName> and <ServerGUID>

- Tool: Repadmin.exe

**To use Repadmin to remove lingering objects**

1. Open a Command Prompt as an administrator: On the **Start** menu, right-click **Command Prompt**, and then click **Run as administrator**. If the **User Account Control** dialog box appears, provide Domain Admins or Enterprise Admins credentials, if required, and then click **Continue**.

2. At the command prompt, type the following command, and then press ENTER:

```
repadmin /removelingeringobjects <ServerName> <ServerGUID> <DirectoryPartition> /advisory_mode
```

| Parameter | Description |
|---|---|
| /removelingeringobjects | Removes lingering objects from the domain controller that is specified by <ServerName> for the directory partition that is specified by <DirectoryPartition>. |
| <ServerName> | The name of the domain controller that has lingering objects, as identified in the event message (Event ID 1388 or Event ID 1988). You can use the Domain Name System (DNS) name or the distinguished name, for example, the distinguished name CN=DC5,OU=Domain Controllers,DC=contoso,DC=com or the DNS name DC5.contoso.com. |
| <ServerGUID> | The GUID of a domain controller that has an up-to-date, writable replica of the directory partition that contains the lingering object |
| <DirectoryPartition> | The distinguished name of the directory partition that is identified in the event message, for example:<br>• For the Sales domain directory partition in the contoso.com forest: DC=sales,DC=contoso,DC=com<br>• For the configuration directory partition in the contoso.com forest: CN=configuration,DC=contoso,DC=com<br>• For the schema directory partition in the contoso.com forest: CN=schema,CN=configuration,DC=contoso,DC=com |

| | |
|---|---|
| /advisory_mode | Logs the lingering objects that will be removed so that you can review them, but does not remove them. |

3. Repeat step 2 without `/advisory_mode` to delete the identified lingering objects from the directory partition.

4. Repeat steps 2 and 3 for every domain controller that might have lingering objects.

**Note**

The <ServerName> parameter uses the `DC_LIST` syntax for `repadmin`, which allows the use of `*` for all domain controllers in the forest and `gc:` for all global catalog servers in the forest. To see the `DC_LIST` syntax, type `repadmin /listhelp`. For information about the syntax of the `/regkey` and `/removelingeringobjects` parameters, type `repadmin /experthelp`.

**Enable strict replication consistency**

To ensure that lingering objects cannot be replicated if they occur, enable strict replication consistency on all domain controllers. The setting for replication consistency is stored in the registry on each domain controller. However, on domain controllers that are running Windows Server 2003 with Service Pack 1 (SP1), Windows Server 2003 with Service Pack 2 (SP2), Windows Server 2003 R2, or Windows Server 2008, you can use Repadmin to enable strict replication consistency on one or all domain controllers.

On domain controllers running Windows Server 2003 without SP1 or running any version of Windows 2000 Server, you must edit the registry to enable the setting.

**Use Repadmin to enable strict replication consistency**

Use this procedure to remove lingering objects on a domain controller that is running Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2003 R2, or Windows Server 2008.

Membership in **Domain Admins**, or equivalent, is the minimum required to complete this procedure on a single domain controller. Membership in **Enterprise Admins**, or equivalent, is the minimum required to complete this procedure on all domain controllers in the forest. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

**To use Repadmin to enable strict replication consistency**

1. Open a Command Prompt as an administrator: On the **Start** menu, right-click **Command Prompt**, and then click **Run as administrator**. If the **User Account Control** dialog box appears, provide Domain Admins or Enterprise Admins credentials, if required, and then click **Continue**.

2. At the command prompt, type the following command, and then press ENTER:

```
repadmin /regkey <DC_LIST> +strict
```

| Parameter | Description |
|---|---|
| /regkey | Enables (+) and disables (-) the value for the **Strict Replication Consistency** registry entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters** |
| <DC_LIST> | The name of a single domain controller, or* to apply the change to all domain controllers in the forest. For the domain controller name, you can use the DNS name, the distinguished name of the domain controller computer object, or the distinguished name of the domain controller server object, for example, the distinguished name CN=DC5,OU=Domain Controllers,DC=contoso,DC=com or the DNS name DC5.contoso.com. |
| +strict | Enables the **Strict Replication Consistency** registry entry. |

3. If you do not use `*` to apply the change to all domain controllers, repeat step 2 for every domain controller on which you want to enable strict replication consistency.

**Note**

For more naming options and information about the syntax of the <DC_LIST> parameter, at the command prompt type `repadmin /listhelp`. For information about the syntax of the `/regkey` and `/removelingeringobjects` parameters, type `repadmin /experthelp`.

#### Use Regedit to enable strict replication consistency

As an alternative to using Repadmin, you can enable strict replication consistency by editing the registry directly. The registry method is required for a domain controller that is running a version of Windows Server that is earlier than Windows Server 2003 with SP1. The setting for replication consistency is stored in the **Strict Replication Consistency** entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters**.

The values for the **Strict Replication Consistency** registry entry are as follows:

- Value: **1** (**0** to disable)
- Default: **1** (enabled) in a new Windows Server 2003 or Windows Server 2008 forest; otherwise **0**.
- Data type: **REG_DWORD**

**Requirements:**

- Membership in **Domain Admins**, or equivalent, is the minimum required to complete this procedure. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).
- Tool: Regedit.exe

| ⚠Caution |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

##### To use Regedit to enable strict replication consistency

1. Open Regedit as an administrator: Click **Start** and then, in **Start Search**, type **regedit**. At the top of the **Start** menu, right-click **regedit.exe**, and then click **Run as administrator**. In the **User Account Control** dialog box, provide Domain Admins credentials, and then click **OK**.
2. Navigate to the **Strict Replication Consistency** entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters**.
3. Set the value in the **Strict Replication Consistency** entry to **1.**

#### Ensure that strict replication consistency is enabled for newly promoted domain controllers

If you are upgrading a forest that was originally created using a computer running Windows 2000 Server, you should ensure that the forest is configured to enable strict replication consistency on newly promoted domain controllers to help avoid lingering objects. After you update the forest as described in Upgrading Active Directory Domains to Windows Server 2008 AD DS Domains (http://go.microsoft.com/fwlink/?LinkId=89032), all new domain controllers that you subsequently add to the forest are created with strict replication consistency disabled. However, you can implement a forest configuration change that causes new domain controllers to have strict replication consistency enabled. To ensure that new domain controllers that you add to the forest have strict replication consistency enabled, you can use the Ldifde.exe tool to create an object in the configuration directory partition of the forest. This object is responsible for enabling strict replication consistency on any Windows Server 2003 or Windows Server 2008 domain controller that is promoted into the forest.

The object that you create is an operational GUID with the following name:

CN=94fdebc6-8eeb-4640-80de-ec52b9ca17fa,CN=Operations,CN=ForestUpdates,CN=Configuration,DC=<ForestRootDomain>

You can use the following procedure on any domain controller in the forest to add this object to the configuration directory partition.

Membership in **Enterprise Admins**, or equivalent, is the minimum required to complete this procedure. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups

(http://go.microsoft.com/fwlink/?LinkId=83477).

**To create the object that ensures strict replication consistency on new domain controllers**

1. In a text editor, such as Notepad, create the following text file:

   ```
   dn:
   CN=94fdebc6-8eeb-4640-80de-
   ec52b9ca17fa,CN=Operations,CN=ForestUpdates,CN=Configuration,DC=<ForestRootDomain>
   changetype: add
   objectClass: container
   showInAdvancedViewOnly: TRUE
   name: 94fdebc6-8eeb-4640-80de-ec52b9ca17fa
   objectCategory: CN=Container,CN=Schema,CN=Configuration,DC=<ForestRootDomain>
   ```

   Where <ForestRootDomain> contains all domain components (DC=) of the forest root domain, for example, for the contoso.com forest, DC=contoso,DC=com; for the fineartschool.net forest, DC=fineartschool,DC=net.

2. Open a Command Prompt as an administrator: On the **Start** menu, right-click **Command Prompt**, and then click **Run as administrator**. If the **User Account Control** dialog box appears, provide Enterprise Admins credentials, if required, and then click **Continue**.

3. At the command prompt, type the following command, and then press ENTER:

   ```
   ldifde -i -f <Path>\<FileName>
   ```

| Parameter | Description |
|---|---|
| -i | Specifies the import mode. If the import mode is not specified, the default mode is export. |
| -f | Identifies the import or export file name. |
| <Path>\<FileName> | The path and name of the import file that you created in step 1, for example, C:\ldifde.txt. |

For information about using Ldifde, see LDIFDE (http://go.microsoft.com/fwlink/?LinkId=42656).

# A deleted account remains in the Address Book, e-mail is not received, or a duplicate account exists

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Deleted accounts remaining in the global address list (GAL), e-mail messages for existing accounts not being received, or duplicate objects existing in Active Directory are all symptoms that can indicate a lingering object problem. If you have no error or event that identifies the lingering object and its directory partition (for example, event ID 1388 or event ID 1988), you must search the global catalog for an object that you believe might be causing the problem. When you identify the lingering object and the directory partition of the object, you can perform the procedures to remove it.

**Solution**

Based on these symptoms of a lingering object, you usually have a good idea of the name of the object and you can use the following steps to solve the problem:

- Use this name to identify the object in the global catalog.
- Identify the directory partition of the object.
- Remove all lingering objects from that directory partition on all global catalog servers in the forest.

**Identify the Duplicate (Lingering) Object**

Use the following procedure to identify the duplicate (lingering) object by searching the global catalog for its distinguished name. Use an attribute that uniquely identifies the object for the account that is not receiving e-mail, cannot be created because it already exists, or appears in the Address Book or in access control lists (ACLs) when it has already been deleted.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Users group.
- Tool: Ldp.exe (Windows Support Tools)

**To establish the distinguished name of an object**

1. Click **Start**, click **Run**, type **Ldp**, and then click **OK**.
2. On the **Connection** menu, click **Connect**.
3. In **Port**, type **3268**, and then click **OK**.
4. On the **Connection** menu, click **Bind**.
5. In the **Bind** dialog box, provide credentials for a user account in the forest, and then click **OK**.
6. On the **View** menu, click **Tree**.
7. In the **Tree View** dialog box, in **BaseDN**, type the distinguished name of the forest root domain, and then click **OK**.
8. In the console tree, right-click the forest root domain, and then click **Search**.
9. In the **Search** dialog box, in **Filter**, replace the default filter (objectClass=*) to create a filter of the following form:

   (*attribute*=*value*)

   where *attribute* is the Lightweight Directory Access Protocol (LDAP) name of an attribute and *value* is the value that you know or suspect to be associated with the object that you are searching for. For example, use (userPrincipalName=JanD@contoso.com), (sAMAccountName=JanD), or (sn=Dryml) to locate the duplicate user object Jan Dryml. You can use the asterisk (*) in the *value* field if you want to search all objects.
10. In the **Scope** box, click **Subtree**, and then click **Run**.

11. Click **Close**, and then view the results. You must identify which of the displayed objects should be removed from Active Directory. An indication that you have found a lingering object that exists only on a global catalog server is that the object does not exist in a writable replica of the directory partition.

12. If necessary, repeat steps 8 through 10 to rephrase the query, and then run it again.

**Identify the Directory Partition of the Object**

After you identify the distinguished name of the object that is causing problems, if it is a domain object, identify the domain in which it is located by looking at the DC= part of the distinguished name. For example, if the object you find has the distinguished name CN=Jan Dryml,CN=Users,DC=Region1,DC=Contoso,DC=com, the directory partition name for the user account is DC=Region1,DC=Contoso,DC=com.

**Remove the Lingering Object**

Use the directory partition name in the procedure "To use Repadmin to remove lingering objects" to remove the lingering object from all domain controllers and global catalog servers in the forest as described in "Event ID 1388 or 1988: A lingering object is detected."

# Event ID 2042: It has been too long since this machine replicated

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If a domain controller has not replicated with its partner for longer than a tombstone lifetime, it is possible that a lingering object problem exists on one or both domain controllers. When this condition occurs, inbound replication with the source partner is stopped on the destination domain controller and event ID 2042 is logged in the Directory Services event log. The event identifies the source domain controller and the appropriate steps to take to either remove the outdated domain controller or remove lingering objects and restore replication from the source domain controller.

An example of the event text is as follows:

```
Event Type:Error
Event Source:NTDS Replication
Event Category:Replication
Event ID:2042
Date:3/22/2005
Time:7:28:49 AM
User:NT AUTHORITY\ANONYMOUS LOGON
Computer:DC3
Description:
It has been too long since this machine last replicated with the
named source machine. The time between replications with this source
has exceeded the tombstone lifetime. Replication has been stopped
with this source.
The reason that replication is not allowed to continue is that
the two machine's views of deleted objects may now be different.
The source machine may still have copies of objects that have
been deleted (and garbage collected) on this machine. If they
were allowed to replicate, the source machine might return
objects which have already been deleted.
Time of last successful replication:
2005-01-21 07:16:03
Invocation ID of source:
0397f6c8-f6b8-0397-0100-000000000000
Name of source:
4a8717eb-8e58-456c-995a-c92e4add7e8e._msdcs.contoso.com
Tombstone lifetime (days):
60

The replication operation has failed.

User Action:

Determine which of the two machines was disconnected from the
forest and is now out of date. You have three options:

1. Demote or reinstall the machine(s) that were disconnected.
2. Use the "repadmin /removelingeringobjects" tool to remove
inconsistent deleted objects and then resume replication.
3. Resume replication. Inconsistent deleted objects may be introduced.
You can continue replication by using the following registry key.
Once the systems replicate once, it is recommended that you remove
the key to reinstate the protection.
Registry Key:
HKLM\System\CurrentControlSet\Services\NTDS\Parameters\Allow Replication With Divergent
and Corrupt Partner
```

The **repadmin /showrepl** command also reports error 8614:

```
Source: Default-First-Site-Name\DC1
******* 1502 CONSECUTIVE FAILURES since 2005-01-21 07:16:00
Last error: 8614 (0x21a6):
            The Active Directory cannot replicate with this server
because the time since the last replication with this server has
exceeded the tombstone lifetime.
```

**Solution**
Treat this occurrence as a lingering object condition, and do the following:

- Run the **repadmin /showrepl** command on the domain controller that received the error to determine which domain controller has been disconnected for longer than a tombstone lifetime.

- Check the system time on both the source and destination domain controllers. If there is a time difference, ensure that you correct the time issue before proceeding. You may have to wait a couple of hours to see ensure that a time skew does not occur. If a time skew does occur, you must diagnose why and solve the issue. For example, there could be hardware issues, like system battery failure, or a firmware update might be required, or the forest root PDC might not be configured to use an external time source (as described in Configure the Time Source for the Forest).

- Remove lingering objects. Follow the instructions for removing lingering objects from the source and destination domain controllers as described in Event ID 1388 or 1988: A lingering object is detected.

- Restart replication on the destination domain controller. After you remove lingering objects, you must restart replication on the domain controller that logged the event by editing the registry setting that allows replication with a potentially out-of-date domain controller. You can also perform this procedure if you do not want to wait to remove lingering objects and you want to start replication immediately.

- Reset the registry to protect the domain controller against outdated replication. After replication has resumed on the domain controller that logged the event, reset the registry so that this domain controller continues to log events if replication is attempted with a domain controller where the last successful replication occurred longer than a tombstone lifetime ago.

**Restart Replication Following Event ID 2042**
To restart inbound replication on the destination domain controller following event ID 2042, you must edit the **Allow Replication With Divergent and Corrupt Partner** registry entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters**.

Use the following procedure to change the registry entry value. This procedure does not require a restart of the domain controller to take effect.

| ⚠**Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the domain of the domain controller.

- Tool: Regedit.exe

**To restart replication following event ID 2042**

1. Click **Start**, click **Run**, type **regedit**, and then click **OK**.

2. Navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters**

3. In the details pane, create or edit the registry entry as follows:

   If the registry entry exists in the details pane, modify the entry as follows:

   a. In the details pane, right-click **Allow Replication With Divergent and Corrupt Partner**, and then click **Modify**.

b. In the **Value data** box, type **1**, and then click **OK**.

If the registry entry does not exist, create the entry as follows:

a. Right-click **Parameters**, click **New**, and then click **DWORD Value**.

b. Type the name **Allow Replication With Divergent and Corrupt Partner**, and then press ENTER.

c. Double-click the entry. In the **Value data** box, type **1**, and then click **OK**.

**Reset the Registry to Protect Against Outdated Replication**

When you are satisfied that lingering objects have been removed and replication has occurred successfully from the source domain controller, edit the registry to return the value in **Allow Replication With Divergent and Corrupt Partner** to **0**.

| **Note** |
| --- |
| If you did not remove the lingering objects, attempting replication might result in replication of a lingering object. If strict replication consistency is enabled on the destination domain controller, replication with the source domain controller will be blocked again. |

# Fixing Replication Security Problems

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When security problems cause replication to fail, various event log messages and Repadmin messages contain error codes that identify the problems.

The version of Dcdiag.exe that is included with Windows Support Tools in Windows Server 2003 Service Pack 1 (SP1) provides new functionality that reports on the overall health of replication with respect to Active Directory. Dcdiag is modified to detect common causes of "Access denied" events, "Account unknown" events, and similar events.

The error codes that Dcdiag detects are described in the following table. Error codes that are marked with an asterisk (*) are not always caused by a security problem.

| Error code | Description |
|---|---|
| 5 | Access is denied. |
| 1314* | A required privilege is not held by the client. |
| 1326 | Logon failure: unknown user name or bad password. |
| 1396 | Logon failure: The target account name is incorrect. |
| 1908 | Could not find the domain controller for this domain. |
| 1397* | Mutual authentication failed. The server's password is out of date at the domain controller. |
| 1398* | There is a time and/or date difference between the client and server. |
| 1722* | The remote procedure call (RPC) server is unavailable. |
| 2202* | The specified username is invalid. |
| 8453 | Replication access was denied. |

Use the procedures in An "Access denied" or other security error has caused replication problems to diagnose and fix replication security problems.

# An "Access denied" or other security error has caused replication problems

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Replication problems that have security causes can be tested and diagnosed by using the version of Dcdiag.exe that is included with Windows Support Tools in Windows Server 2003 Service Pack 1 (SP1).

**Cause**
A replication destination domain controller cannot contact its source replication partner to get Active Directory updates as a result of one or more security errors occurring on the connection between the two domain controllers.

**Solution**
Run the replication security error diagnostic test that is available in the version of Dcdiag in Windows Support Tools that is included in Windows Server 2003 SP1.

**Test a Domain Controller for Replication Security Errors**
You can test any or all domain controllers in your forest for security errors.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group to test a domain controller in your domain or a member of the Enterprise Admins group to test a domain controller in another domain.

- Tool: Dcdiag.exe (Windows Support Tools) in Windows Server 2003 SP1

- Operating system:

  - Although you can run the enhanced version of Dcdiag on computers running Windows XP Professional and Windows Server 2003 with no service pack installed, to run the new replication security test (**/test:CheckSecurityError**), you must run Dcdiag on a domain controller running Windows Server 2003 with SP1.

  - You can run the new Dcdiag replication security tests against domain controllers that are running the following operating systems:

    Windows 2000 Server with Service Pack 3 (SP3)

    Windows 2000 Server with Service Pack 4 (SP4)

    Windows Server 2003

    Windows Server 2003 with SP1

**To test a domain controller for replication security errors**

1. At a command prompt, type the following command, and then press ENTER:

   **dcdiag /test:CheckSecurityError /s:** *DomainControllerName*

   where *DomainControllerName* is the Domain Name System (DNS) name, network basic input/output system (NetBIOS) name, or distinguished name of the domain controller on which you want to test.

   If you do not use the **/s:** switch, the test is run against the local domain controller. You can also test all domain controllers in the forest by using **/e:** instead of **/s:**.

2. Copy the report into Notepad or an equivalent text editor

3. Scroll to the Summary table near the bottom of the Dcdiag log file.
4. Note the names of all domain controllers that reported "Warn" or "Fail" status in the Summary table.
5. Find the detailed breakout section for the problem domain controller by searching on the string "DC: *DomainControllerName*".
6. Make the required configuration changes on the domain controllers.

   Rerun **Dcdiag /test:CheckSecurityError** with the **/e:** or **/s:** switch to validate the configuration changes.

**Test the Connection Between Two Domain Controllers for Replication Security Errors**
You can test the connection between two domain controllers in your forest for replication security errors. The domain controller that represents the source of the inbound connection does not have to be an existing source to run this test; that is, a connection object from that domain controller does not have to exist on the destination domain controller. The test is useful in the following scenarios:

- A connection exists between a source and a destination, and you receive a security error.
- A connection should be created automatically by the Knowledge Consistency Checker (KCC) and you want to test why the connection does not exist.
- You are trying to create a connection between two domain controllers and you receive a security error.
- You want to determine whether a connection could be created if you wanted to add one on this destination from the specified source.

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group to test the connection between domain controllers in your domain or a member of the Enterprise Admins group to test the connection between domain controllers in different domains.
- Tool: Dcdiag.exe (Windows Support Tools) included in Windows Server 2003 SP1
- Operating system:
  - Although you can run the enhanced version of Dcdiag on computers that are running Windows XP Professional and Windows Server 2003 with no service pack installed, to run the new replication security test (**/test:CheckSecurityError**), you must run Dcdiag on a domain controller running Windows Server 2003 with SP1.
  - You can run the new Dcdiag replication security tests against domain controllers running the following operating systems:

    Windows 2000 Server with SP3

    Windows 2000 Server with SP4

    Windows Server 2003

    Windows Server 2003 with SP1

**To test the connection between two domain controllers for replication security errors**

1. At a command prompt, type the following command, and then press ENTER:

   **dcdiag /test:CheckSecurityError /ReplSource:** *SourceDomainControllerName*

   where *SourceDomainControllerName* is the DNS name, NetBIOS name, or distinguished name of the real or potential

"from" server that is represented by a real or potential connection object that you want to test. This command tests the connection between the domain controller on which you run the command and the source domain controller.

2. Copy the report into Notepad or an equivalent text editor.
3. Scroll to the Summary table near the bottom of the Dcdiag log file.
4. Note the names of all domain controllers that reported “Warn” or “Fail” status in the Summary table
5. Find the detailed breakout section for the problem domain controller by searching on the string “DC: *DomainControllerName*”.
6. Make the required configuration changes on the domain controllers.
7. Rerun **Dcdiag /test:CheckSecurityError /ReplSource:***SourceDomainControllerName* to validate configuration changes.

# Fixing Replication DNS Lookup Problems (Event IDs 1925, 2087, 2088)

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain controllers running Windows 2000 Server or Windows Server 2003 cannot replicate Active Directory updates if Domain Name System (DNS) lookup failures prevent a destination domain controller from contacting its source replication partner to request changes. Lookup failures occur when a destination domain controller cannot resolve its source replication partner's globally unique identifier (GUID)-based canonical name (CNAME) resource record to an Internet Protocol (IP) address by using DNS. GUID-based CNAME resource records are always registered in the DNS zone _msdcs.*ForestRootDomain*.

The most common DNS failures occur when DNS client settings are misconfigured on the destination or source domain controller, or the direct and intermediate DNS servers that are used to resolve the query are misconfigured. Network problems or domain controller disconnection problems might also be present. If the problem is due to DNS configuration errors or replication latency, the effect on Active Directory replication is minimized by new improvements to domain controller name resolution in Windows Server 2003 Service Pack 1 (SP1).

**Improvements to Domain Controller Name Resolution in SP1**
Domain controllers running Windows Server 2003 with SP1 have a more robust response to DNS name resolution failures. Rather than failing on the first attempt to resolve the IP address of a source domain controller by using its CNAME resource record, destination domain controllers running Windows Server 2003 with SP1 use alternate names to attempt resolution and also log events that report problems and prescribe solutions.

**DNS Failure Scenarios**
All domain controllers register multiple service location (SRV) resource records in DNS as well as a host address (A) resource record for each IP address of the domain controller, plus an additional host resource record for each IP address if the domain controller is a global catalog server. In addition, each domain controller registers a single CNAME resource record.

The following table shows the DNS resource records that are required for proper Active Directory functionality.

| Mnemonic | Type | DNS resource record |
|---|---|---|
| pdc | SRV | _ldap._tcp.pdc._msdcs.*DnsDomainName* |
| gc | SRV | _ldap_tcp.gc._msdcs.*DnsForestRootDomainName* |
| GclpAddress | A | _gc._msdcs.*DnsForestRootDomainName* |
| DsaCname | CNAME | *DsaGuid*._msdcs.*DnsForestRootDomainName* |
| kdc | SRV | _kerberos._tcp.dc._msdcs.*DnsDomainName* |
| dc | SRV | _ldap._tcp.dc._msdcs.*DnsDomainName* |
| None | A | *DomainControllerFQDN* |

In the CNAME resource record (*DSA_GUID*._msdcs.*ForestRootDNSDomainName*), *DSA_GUID* is the GUID of the NTDS Settings object (also called the Directory System Agent (DSA) object) for the domain controller. *ForestRootDNSDomainName* is the DNS name of the forest where the domain controller is located. Destination domain controllers use the CNAME resource record to identify and locate their replication partners.

The Net Logon service on the domain controller registers all SRV resource records when the operating system starts up and at regular intervals thereafter. The DNS client service on the domain controller registers the DNS host A resource record.

A domain controller uses the following steps to locate its replication partner:

1. The destination domain controller queries its DNS server to look for the CNAME resource record of its replication partner. On domain controllers running Windows 2000 Server or Windows Server 2003 with no service pack applied, if this lookup fails to resolve the CNAME resource record to an IP address, DNS lookup (and replication) fails.

2. On domain controllers running Windows Server 2003 with SP1, if the CNAME lookup is unsuccessful, the domain

controller looks for the DNS A resource record of its replication partner. For example, the domain controller looks for DC03.corp.contoso.com.

3. If the DNS A resource record lookup is unsuccessful, the domain controller performs a network basic input/output system (NetBIOS) broadcast by using the host name of its replication partner. For example, the domain controller uses DC03.

When lookups fail, events that describe the condition are logged in the Directory Service event log.

**DNS Events for Lookup Failure**
Two new events, event ID 2087 and event ID 2088, are logged on destination domain controllers running Windows Server 2003 with SP1:

- If all lookups fail, event ID 2087 is logged.
- If lookup succeeds but either the first or second attempt fails, event ID 2088 is logged.

On domain controllers running Windows 2000 Server or Windows Server 2003 with no service pack applied, the destination domain controller that cannot successfully locate its replication partner in DNS logs event ID 1925.

Regardless of whether replication succeeds or fails, if you receive event ID 1925, event ID 2087, or event ID 2088, you should investigate and correct the cause of the failure because incorrect DNS configuration can affect other essential operations — including logon authentication and access to network resources — on member computers, domain controllers, and application servers. In addition, although fallback name resolution might allow replication to occur, it introduces unnecessary latency and overhead into the replication process.

**DNS Requirements for CNAME Lookup Success**
Although name resolution in Windows Server 2003 with SP1 is more aggressive at ensuring that replication can occur when a CNAME lookup fails, failure of this method indicates that either the DNS clients or DNS servers are not configured properly. It is important to understand the requirements for successful CNAME lookup and to ensure that DNS is functioning accordingly.

Resolving the fully qualified, GUID-based, CNAME resource record of the source domain controller to the current IP address of the source domain controller requires the following DNS configurations:

1. In their respective TCP/IP client settings, the source domain controller and destination domain controller must be configured to resolve DNS names by using only valid DNS servers that directly host, forward, or delegate to the following DNS zones:

   a. _msdcs.*ForestRootDNSDomainName*, to resolve queries for computers in the forest.

   b. The DNS zone that corresponds to the primary DNS suffix of the respective target domain controller, to resolve queries for computers in the domain. (The source domain controller can resolve the domain name of the target domain controller, and the reverse is also true.) The primary DNS suffix is usually the same as the DNS name of the domain to which a computer is joined. You can view the primary DNS suffix in the properties of My Computer.

   If the DNS servers that the source domain controller is configured to use for name resolution do not host these zones directly, the DNS servers that are used must forward or delegate to DNS servers that do host these zones.

2. The source domain controller must have successfully registered the following resource records:

   - GUID-based CNAME resource record in the DNS zone _msdcs.*ForestRootDNSDomainName*
   - Host A resource record in the DNS zone that corresponds to its primary DNS suffix

**Potential Preliminary Failures Due to Replication Latency**
At the time that the destination domain controller queries its DNS servers for the location of its source replication partner, DNS configurations might be correct on both the source and destination domain controllers, but DNS resource record registrations might be in flux as a result of configuration changes on the source domain controller. In this case, DNS lookup can fail as a

result of replication latency, as follows:

- If the source domain controller changes the DNS server on which it registers its CNAME and host A resource records, it is possible that the initial DNS server that the destination domain controller queries to resolve the name of the source domain controller is different than any of the DNS servers on which the CNAME and host A resource records for the source domain controller are currently registered. In this case, DNS replication latency or failures might prevent DNS records that are successfully registered on the DNS servers that the source controller uses from being located by the DNS server that is queried by the destination domain controller.

- If the Active Directory domain of the DNS server that the destination domain controller uses initially has a parent-child relationship with the Active Directory domain of the servers on which the source domain controller registers its resource records, the forwarder and delegation configuration on both the DNS servers that the source domain controller uses and the DNS servers that the destination domain controller uses, as well as any intermediate DNS servers that are used to resolve the DNS query, must be valid. Any required records on those DNS servers might be subject to replication latency and failure.

Understanding these basic requirements for name resolution that locates the source replication partner provides a more meaningful context for working through solutions when you have replication DNS lookup problems. Choose a problem from the following list that best describes your situation, and then step through the suggested fix:

Event ID 1925: Attempt to establish a replication link failed due to DNS lookup problem

Event ID 2087: DNS lookup failure caused replication to fail

Event ID 2088: DNS lookup failure occurred with replication success

# Event ID 1925: Attempt to establish a replication link failed due to DNS lookup problem

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you receive event ID 1925 with the error message that Domain Name System (DNS) lookup failed, inbound replication of a directory partition has failed on the destination domain controller, and you must fix the DNS problem.

An example of the event text is as follows:

```
Event Type:Warning
Event Source:NTDS KCC
Event Category:Knowledge Consistency Checker
Event ID:1925
Date:3/24/2005
Time:9:15:46 AM
User:NT AUTHORITY\ANONYMOUS LOGON
Computer:DC3
Description:
The attempt to establish a replication link for the following
writable directory partition failed.

Directory partition:
CN=Configuration,DC=contoso,DC=com
Source domain controller:
CN=NTDS Settings,CN=DC1,CN=Servers,CN=Default-First-Site-
Name,CN=Sites,CN=Configuration,DC=contoso,DC=com
Source domain controller address:
f8786828-ecf5-4b7d-ad12-8ab60178f7cd._msdcs.contoso.com
Intersite transport (if any):

This domain controller will be unable to replicate with the
source domain controller until this problem is corrected.

User Action
Verify if the source domain controller is accessible or
network connectivity is available.

Additional Data
Error value:
8524 The DSA operation is unable to proceed because of a DNS
lookup failure.
```

**Solution**

Proceed with DNS testing as described in "Event ID 2087: DNS lookup failure caused replication to fail."

# Event ID 2087: DNS lookup failure caused replication to fail

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When a destination domain controller running Windows Server 2003 with Service Pack 1 (SP1) receives event ID 2087 in the Directory Service event log, attempts to resolve the globally unique identifier (GUID) in the canonical name (CNAME) resource record, the fully qualified domain name (FQDN), and the network basic input/output system (NetBIOS) name to the Internet Protocol (IP) address of the source domain controller have all failed. Failure to locate the source replication partner prevents replication with that source until the problem is fixed.

An example of the event text is as follows:

```
Event Type:Error
Event Source:NTDS Replication
Event Category:DS RPC Client
Event ID:2087
Date:3/9/2005
Time:11:00:21 AM
User:NT AUTHORITY\ANONYMOUS LOGON
Computer:DC3
Description:
Active Directory could not resolve the following DNS host name of
the source domain controller to an IP address. This error prevents
additions, deletions and changes in Active Directory from replicating
between one or more domain controllers in the forest. Security
groups, group policy, users and computers and their passwords will
be inconsistent between domain controllers until this error is
resolved, potentially affecting logon authentication and access
to network resources.

Source domain controller:
dc2
Failing DNS host name:
b0069e56-b19c-438a-8a1f-64866374dd6e._msdcs.contoso.com

NOTE: By default, only up to 10 DNS failures are shown for any
given 12 hour period, even if more than 10 failures occur.  To
log all individual failure events, set the following diagnostics
registry value to 1:

Registry Path:
HKLM\System\CurrentControlSet\Services\NTDS\Diagnostics\22 DS RPC Client

User Action:

1) If the source domain controller is no longer functioning or
its operating system has been reinstalled with a different
computer name or NTDSDSA object GUID, remove the source domain
controller's metadata with ntdsutil.exe, using the steps outlined
in MSKB article 216498.

2) Confirm that the source domain controller is running Active
Directory and is accessible on the network by typing
"net view \\<source DC name>" or "ping <source DC name>".

3) Verify that the source domain controller is using a valid
DNS server for DNS services, and that the source domain
controller's host record and CNAME record are correctly
registered, using the DNS Enhanced version of DCDIAG.EXE
available on http://www.microsoft.com/dns

dcdiag /test:dns

4) Verify that that this destination domain controller is using
a valid DNS server for DNS services, by running the DNS Enhanced
version of DCDIAG.EXE command on the console of the destination
domain controller, as follows:
```

```
dcdiag /test:dns

5) For further analysis of DNS error failures see KB 824449:
http://support.microsoft.com/?kbid=824449

Additional Data
Error value:
11004 The requested name is valid, but no data of the requested
type was found.
```

**Cause**

Failure to resolve the current CNAME resource record of the source domain controller to an IP address can have the following causes:

- The source domain controller is powered off, is offline, or resides on an isolated network, and Active Directory and Domain Name System (DNS) data for the offline domain controller has not been deleted to indicate that the domain controller is inaccessible.
- One of the following conditions exists:
  - The source domain controller has not registered its resource records in DNS.
  - The destination domain controller is configured to use an invalid DNS server.
  - The source domain controller is configured to use an invalid DNS server.
  - The DNS server that is used by the source domain controller does not host the correct zones or the zones are not configured to accept dynamic updates.
  - The direct DNS servers that are queried by the destination domain controller cannot resolve the IP address of the source domain controller as a result of nonexistent or invalid forwarders or delegations.
- Active Directory has been removed on the source domain controller and then reinstalled with the same IP address, but knowledge of the new NTDS Settings GUID has not reached the destination domain controller.
- Active Directory has been removed on the source domain controller and then reinstalled with a different IP address, but the current host address (A) resource record for the IP address of the source domain controller is either not registered or does not exist on the DNS servers that are queried by the destination domain controller as a result of replication latency or replication error.
- The operating system of the source domain controller has been reinstalled with a different computer name, but its metadata either has not been removed or has been removed and not yet inbound-replicated by the destination domain controller.

**Solution**

First, determine whether the source domain controller is functioning. If the source domain controller is not functioning, remove its remaining metadata from Active Directory.

If the source domain controller is functioning, continue with procedures to diagnose and solve the DNS problem, as needed:

- Use Dcdiag to diagnose DNS problems.
- Register DNS SRV resource records plus host records.
- Synchronize replication between the source and destination domain controllers.
- Verify consistency of the NTDS Settings GUID.

#### Determine Whether a Domain Controller Is Functioning

To determine whether the source domain controller is functioning, use the following test.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Users group in the domain of the domain controller.
- Tools: Net view

#### To determine whether a domain controller is functioning

- To confirm that the domain controller is running Active Directory and is accessible on the network, at a command prompt type the following command, and then press ENTER:

  **net view ** *SourceDomainControllerName*

  where *SourceDomainControllerName* is the NetBIOS name of the domain controller.

This command displays the Netlogon and SYSVOL shares, indicating that the server is functioning as a domain controller. If this test shows that the domain controller is not functioning on the network, determine the nature of the disconnection and whether the domain controller can be recovered or whether its metadata must be removed from Active Directory manually. If the domain controller is not functioning and cannot be restored, use the procedure in the following section, "Clean Up Domain Controller Metadata," to delete the data from Active Directory that is associated with that server.

#### Clean Up Domain Controller Metadata

If tests show that the domain controller is no longer functioning but you still see objects representing the domain controller in Active Directory Sites and Services, replication will continue to be attempted, and you must remove these objects from Active Directory manually. You must use Ntdsutil to clean up (delete) the metadata for the defunct domain controller.

If the defunct domain controller is the last domain controller in the domain, you should also remove the metadata for the domain. Allow sufficient time for all global catalog servers in the forest to inbound-replicate the domain deletion before promoting a new domain with the same name.

The process for cleaning up metadata is improved in the version of Ntdsutil that is included with Windows Server 2003 SP1. Instructions for cleaning up metadata with the Windows Server 2003 version of Ntdsutil and the Windows Server 2003 SP1 version of Ntdsutil are provided in the following procedure.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Enterprise Admins group.
- Tools: Ntdsutil (System32 command-line tool)

#### To clean up server metadata

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **ntdsutil**

3. At the **ntdsutil:** command prompt, type the following command, and then press ENTER:

   **metadata cleanup**

4. Perform metadata cleanup as follows:

| **Note** |
| --- |
| If you are removing domain metadata as well as server metadata, skip the following procedure and use the procedure that begins at step a. |

- If you are performing server metadata cleanup only and you are using the version of Ntdsutil.exe that is included with Windows Server 2003 SP1, at the **metadata cleanup:** command prompt, type the following, and then press ENTER:

  **remove selected server** *ServerName*

  Or

  **remove selected server** *ServerName1***on***ServerName2*

| Value | Description |
|---|---|
| *ServerName*, *ServerName1* | The distinguished name of the domain controller whose metadata you want to remove, in the form cn=*ServerName*,cn=Servers,cn=*SiteName*, cn=Sites,cn=Configuration,dc=*ForestRootDomain* |
| *ServerName2* | The DNS name of the domain controller to which you want to connect and from which you want to remove server metadata |

- If you are performing metadata cleanup by using the version of Ntdsutil.exe that is included with Windows Server 2003 with no service pack, or if you are performing both domain metadata cleanup and server metadata cleanup, perform metadata cleanup as follows:

a. At the **metadata cleanup:** command prompt, type the following command, and then press ENTER:

   **connection**

b. At the **server connections:** command prompt, type the following command, and then press ENTER:

   **connect to server** *Server*

c. At the **connection:** command prompt, type the following command, and then press ENTER:

   **quit**

d. At the **metadata cleanup:** command prompt, type the following command, and then press ENTER:

   **select operation target**

e. At the **select operation target:** command prompt, type the following command, and then press ENTER:

   **list sites**

f. A numbered list of sites appears. Type the following command, and then press ENTER:

   **select site** *SiteNumber*

g. At the **select operation target:** command prompt, type the following command, and then press ENTER:

   **list domains in site**

h. A numbered list of domains in the selected site appears. Type the following command, and then press ENTER:

   **select domain** *DomainNumber*

i. At the **select operation target:** command prompt, type the following command, and then press ENTER:

   **list servers in site**

j. A numbered list of servers in a domain and site is displayed. Type the following command, and then press ENTER:

   **select server** *ServerNumber*

k. At the **select operation target:** command, type the following command, and then press ENTER:

   **quit**

l. At the **metadata cleanup:** command, type the following command, and then press ENTER:

   **remove selected server**

m. If the server whose metadata you have removed is the last domain controller in the domain and you want to remove the domain metadata, at the **metadata cleanup:** command prompt, type the following command, and then press ENTER:

   **remove selected domain**

   Metadata for the domain that you selected in step h is removed.

n. At the **metadata cleanup:** and **ntdsutil:** command prompts, type **quit**, and then press ENTER.

| Value | Description |
|---|---|
| *Server* | The DNS name of a domain controller that you want to connect to |
| *SiteNumber* | The number that is associated with the site of the server that you want to clean up, which appears in the list |
| *DomainNumber* | The number that is associated with the domain of the server that you want to clean up, which appears in the list |
| *ServerNumber* | The number that is associated with the server that you want to clean up, which appears in the list |

**Use Dcdiag to Diagnose DNS Problems**

If the domain controller is functioning online, continue by using Dcdiag to diagnose and fix DNS problems that might be interfering with Active Directory replication.

Use the following procedures to complete this process:

- Verify connectivity and basic DNS functionality.
- Verify registration of the CNAME resource record in DNS.
- Verify and enable secure dynamic updates.

Before you begin these procedures, gather the following information, which is contained in the event ID 2087 message text:

- The FQDN of the source domain controller and destination domain controller
- The IP address of the source domain controller

The updated version of Dcdiag that is included in Windows Support Tools in Windows Server 2003 SP1 contains tests that provide consolidated and improved testing of basic and advanced DNS features. You can use this tool to diagnose basic DNS functionality and dynamic updates.

When you use the enhanced SP1 version of Dcdiag for DNS testing, there are specific requirements that do not apply to all Dcdiag tests.

**Requirements**

- Administrative credentials: To complete the new DNS tests that are available in the SP1 version of Dcdiag, you must be a member of the Enterprise Admins group.
- Tools: Dcdiag.exe
- Operating system:
  - You can run the enhanced version of Dcdiag on computers running the following operating systems:

    Windows XP Professional

    Windows Server 2003

    Windows Server 2003 with SP1
  - You can run the new Dcdiag DNS tests against Microsoft DNS servers that are installed on domain controllers running the following operating systems:

    Windows 2000 Server with Service Pack 3 (SP3)

    Windows 2000 Server with Service Pack 4 (SP4)

    Windows Server 2003

    Windows Server 2003 with SP1

| **Note** |
| --- |
| You can use the **/f:** switch in Dcdiag commands to save the output to a text file. Use **/f:***FileName* to generate the file in the location that is indicated in *FileName*, for example, **/f:c:\Test\DnsTest.txt**. |

**Verify Basic DNS Functionality**

To verify the settings that might interfere with Active Directory replication, you can begin by running the basic DNS test that ensures that DNS is operating properly on the domain controller.

The basic DNS test checks the following:

- Connectivity: The test determines whether domain controllers are registered in DNS, can be contacted by PING, and have Lightweight Directory Access Protocol / remote procedure call (LDAP/RPC) connectivity. If the connectivity test fails on a domain controller, no other tests are run against that domain controller. The connectivity test is performed automatically before any other DNS test is run.
- Essential services: The test confirms that the following services are running and available on the tested domain controller:
  - DNS Client service
  - Net Logon service
  - Key Distribution Center (KDC) service
  - DNS Server service (if DNS is installed on the domain controller)
- DNS client configuration: The test confirms that DNS servers on all adapters are reachable.

- Resource record registrations: The test confirms that the address (A) resource record of each domain controller is registered on at least one of the DNS servers that is configured on the client.

- Zone and server of authority (SOA): If the domain controller is running the DNS Server service, the test confirms that the Active Directory domain zone and SOA record for the Active Directory domain zone are present.

- Root zone: Checks if the root (.) zone is present.

**To verify basic DNS functionality**

1. At a command prompt, type the following command, and then press ENTER:

   **dcdiag /test:dns /s:** *SourceDomainControllerName* **/DnsBasic**

   where *SourceDomainControllerName* is the distinguished name, NetBIOS name, or DNS name of the domain controller.

   As an alternative, you can test all domain controllers in the forest by typing **/e:** instead of **/s:**.

2. Copy the report into Notepad or an equivalent text editor.

3. Scroll to the Summary table near the bottom of the Dcdiag log file.

4. Note the names of all domain controllers that report "Warn" or "Fail" status in the Summary table.

5. Find the detailed breakout section for the problem domain controller by searching on the string "DC: *DomainControllerName*".

6. Make the required configuration changes on DNS clients and DNS servers.

7. To validate the configuration changes, rerun **Dcdiag /test:DNS** with the **/e:** or **/s:** switch.

If the basic DNS test shows no errors, continue by verifying that resource records that are used to locate domain controllers are registered in DNS.

**Verify Resource Record Registration**
The destination domain controller uses the DNS CNAME resource record to locate its source domain controller replication partner. Although domain controllers running Windows Server 2003 with SP1 can locate source replication partners by using FQDNs or, if that fails, NetBIOS names, the presence of the CNAME record is expected and should be verified for proper DNS functioning.

You can use Dcdiag to verify registration of all resource records that are essential for domain controller location by using the **dcdiag /test:dns /DnsRecordRegistration** test. This test verifies registration of the following resource records in DNS:

- CNAME (the GUID-based resource record that locates a replication partner)

- A (the host resource record that contains the IP address of the domain controller)

- LDAP SRV (the service resource records that locate LDAP servers)

- GC SRV (the service resource records that locate global catalog servers)

- PDC SRV (the service resource records that locate primary domain controller (PDC) operations masters)

As an alternative, you can use the following procedure to check for only the CNAME resource record.

**To verify CNAME resource record registration**

1. In the DNS console, locate any domain controller that is running the DNS Server service, where the server hosts the DNS zone with the same name as the Active Directory domain of the domain controller.

2. In the console tree, click the zone that is named _msdcs.*Dns_Domain_Name*.

| Note |
| --- |
| In Windows 2000 Server DNS, _msdcs.*Dns_Domain_Name* is a subdomain of the DNS zone for the Active Directory domain name. In Windows Server 2003 DNS, _msdcs.*Dns_Domain_Name* is a separate zone. |

3. In the details pane, verify that the following resource records are present:
   - A CNAME resource record that is named *Dsa_Guid*._msdcs.*Dns_Domain_Name*
   - A corresponding A resource record for the name of the DNS server

If the CNAME resource record is not registered, verify that dynamic updates are functioning properly. Use the test in the following section.

**Verify Dynamic Updates**

If the basic DNS test shows that resource records do not exist in DNS, use the dynamic update test to diagnose why the Net Logon service did not register the resource records automatically. To verify that the Active Directory domain zone is configured to accept secure dynamic updates and to perform registration of a test record (_dcdiag_test_record), use the following procedure. The test record is deleted automatically after the test.

**To verify dynamic updates**

- At a command prompt, type the following command, and then press ENTER:

  **dcdiag /test:dns /s:** *SourceDomainControllerName* **/DnsDynamicUpdate**

  where *SourceDomainControllerName* is the distinguished name, NetBIOS name, or DNS name of the domain controller.

  As an alternative, you can test all domain controllers by using the **/e:** switch instead of the **/s:** switch.

If secure dynamic update is not configured, use the following procedure to configure it.

**To enable secure dynamic updates**

1. Open the DNS console.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, verify that the zone type is Active Directory–integrated.
4. In **Dynamic Updates**, click **Secure only**.

**Register DNS Resource Records**

If DNS resource records do not appear in DNS for the source domain controller, you have verified dynamic updates, and you want to register DNS resource records immediately, you can force the registration manually by using the following procedure. The Net Logon service on a domain controller registers the DNS resource records that are required for the domain controller to be located on the network. The DNS Client service registers the host A resource record that the CNAME record points to.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the forest root domain or a member of the Enterprise Admins group.
- Tools: **net stop/start**, **ipconfig**

**To register DNS resource records manually**

1. To initiate registration of domain controller Locator resource records manually on the source domain controller, at a command prompt type the following commands, and then press ENTER after each command:

   **net stop net logon & net start net logon**

2. To initiate registration of the host A resource record manually, at a command prompt type the following command, and then press ENTER:

**ipconfig /flushdns & ipconfig /registerdns**

3. Wait 15 minutes, and then review events in Event Viewer to ensure proper registration of the resource records.

Repeat the procedure in the "Verify Resource Record Registration" section earlier in this guide to verify that the resource records appear in DNS.

#### Synchronize Replication Between the Source and Destination Domain Controllers

After you complete DNS testing, use the following procedure to synchronize replication on the inbound connection from the source domain controller to the destination domain controller.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the domain of the destination domain controller.

- Tool: Active Directory Sites and Services

#### To synchronize replication from a source domain controller

1. Open Active Directory Sites and Services.

2. In the console tree, double-click the **Sites** container, double-click the site of the domain controller to which you want to synchronize replication, double-click the **Servers** container, double-click the server object of the domain controller, and then click **NTDS Settings**.

3. In the details pane, in the **From Server** column, locate the connection object that shows the name of the source domain controller.

4. Right-click the appropriate connection object, and then click **Replicate Now**.

5. Click **OK**.

If replication does not succeed, use the procedure in the following section to verify consistency of the NTDS Settings GUID.

#### Verify Consistency of the NTDS Settings GUID

If you have performed all DNS tests and other tests and replication does not succeed, use the following procedure to verify that the GUID of the NTDS Settings object that the destination domain controller is using to locate its replication partner matches the GUID that is currently in effect on the source domain controller itself. To perform this test, you view the object GUID as it appears in the local directories of each domain controller.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the domain of the destination domain controller.

- Tool: Ldp (Windows Support Tools)

#### To verify consistency of the NTDS Settings GUID

1. Click **Start**, click **Run**, type **Ldp**, and then click **OK**.

2. On the **Connection** menu, click **Connect**.

3. In the **Connect** dialog box, leave the **Server** box empty.

4. In **Port**, type **389**, and then click **OK**.

5. On the **Connection** menu, click **Bind**.

6. In the **Bind** dialog box, provide Enterprise Admins credentials. If it is not already selected, click **Domain**.

7. In **Domain**, type the name of the forest root domain, and then click **OK**.

8. On the **View** menu, click **Tree**.

9. In the **Tree View** dialog box, type:

   **CN=Configuration,DC=Forest_Root_Domain**

   and then click **OK**.

10. Navigate to the object CN=NTDS Settings,CN=*SourceServerName*,CN=Servers,CN=*SiteName*, CN=Sites,CN=configuration,DC=*ForestRootDomain*.

11. Double-click the **NTDS Settings** object and, in the details pane, view the value for the attribute **objectGUID**. Right-click that value, and then copy it to Notepad.

12. On the **Connection** menu, click **Disconnect**.

13. Repeat steps 2 through 11, but in step 3, type the name of the source domain controller, for example, DC03.

14. In Notepad, compare the values of the two GUIDs.

15. If the values do not match, the destination domain controller must receive replication of the valid GUID. Check the GUID value on other domain controllers and attempt replication on the destination domain controller with a different domain controller that has the correct GUID.

16. If the values match, verify that the GUID matches the GUID in the *Dsa_Guid*._msdcs.*Dns_Domain_Name* resource record for the source domain controller, as follows:

    a. Note the primary DNS servers that each domain controller identifies in the TCP/IP properties in their Network Settings. All the DNS servers that are listed in the respective TCP/IP properties should be able to indirectly or directly resolve this CNAME resource record.

    b. From the servers that are listed, identify the authoritative name server or servers for this domain zone by looking at the server names that are listed for the name server (NS) resource records at the root of the zone. (In the DNS console, select the forward lookup zone for the root domain, and view the NS records in the details pane).

    c. On the name server or servers obtained in step b, open the DNS console, and double-click the forward lookup zone for the forest root domain name. Double-click the _msdcs folder, and note the CNAME resource records that exist for your server name.

    d. If there are no records present or the records are incorrect, see article 241505, SRV Records Missing After Implementing Active Directory and Domain Name System, on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=69994).

# Event ID 2088: DNS lookup failure occurred with replication success

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When a destination domain controller running Windows Server 2003 with Service Pack 1 (SP1) receives event ID 2088 in the Directory Service event log, attempts to resolve the globally unique identifier (GUID) in the canonical name (CNAME) resource record to an Internet Protocol (IP) address for the source domain controller failed. However, the destination domain controller tried other means to resolve the name and succeeded by using either the fully qualified domain name (FQDN) or the network basic input/output system (NetBIOS) name of the source domain controller. Although replication was successful, the DNS problem should be diagnosed and resolved.

An example of the event text is as follows:

```
Event Type:Warning
Event Source:NTDS Replication
Event Category:DS RPC Client
Event ID:2088
Date:3/21/2005
Time:2:29:34 PM
User:NT AUTHORITY\ANONYMOUS LOGON
Computer:DC3
Description:
Active Directory could not use DNS to resolve the IP address of the
source domain controller listed below. To maintain the consistency
of Security groups, group policy, users and computers and their passwords,
Active Directory successfully replicated using the NetBIOS or fully
qualified computer name of the source domain controller.

Invalid DNS configuration may be affecting other essential operations on
member computers, domain controllers or application servers in this
Active Directory forest, including logon authentication or access to network
resources.

You should immediately resolve this DNS configuration error so that
this domain controller can resolve the IP address of the source
domain controller using DNS.

Alternate server name:
dc1
Failing DNS host name:
4a8717eb-8e58-456c-995a-c92e4add7e8e._msdcs.contoso.com

NOTE: By default, only up to 10 DNS failures are shown for any given
12 hour period, even if more than 10 failures occur.  To log all
individual failure events, set the following diagnostics registry
value to 1:

Registry Path:
HKLM\System\CurrentControlSet\Services\NTDS\Diagnostics\22 DS RPC Client

User Action:

1) If the source domain controller is no longer functioning or its
operating system has been reinstalled with a different computer
name or NTDSDSA object GUID, remove the source domain controller's
metadata with ntdsutil.exe, using the steps outlined in MSKB article 216498.

2) Confirm that the source domain controller is running Active Directory
and is accessible on the network by typing "net view \\<source DC name>"
or "ping <source DC name>".

3) Verify that the source domain controller is using a valid DNS server
for DNS services, and that the source domain controller's host record
and CNAME record are correctly registered, using the DNS Enhanced
version of DCDIAG.EXE available on http://www.microsoft.com/dns
```

```
dcdiag /test:dns

4) Verify that that this destination domain controller is using a
valid DNS server for DNS services, by running the DNS Enhanced
version of DCDIAG.EXE command on the console of the destination
domain controller, as follows:

dcdiag /test:dns

5) For further analysis of DNS error failures see KB 824449:
http://support.microsoft.com/?kbid=824449

Additional Data
Error value:
11004 The requested name is valid, but no data of the requested
type was found
```

**Cause**

Failure to resolve the source domain controller name by using the CNAME resource record in DNS can be due to DNS misconfigurations or delays in DNS data propagation.

**Solution**

Proceed with DNS testing as described in "Event ID 2087: DNS lookup failure caused replication to fail."

# Fixing Replication Connectivity Problems (Event ID 1925)

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Network connectivity problems can make it impossible for domain controllers to form replication partnerships. Various events and errors can indicate a problem with network connectivity that is preventing replication from occurring.

Use the procedures in Event ID 1925: Attempt to establish a replication link failed due to connectivity problem to diagnose and fix replication connectivity problems.

# Event ID 1925: Attempt to establish a replication link failed due to connectivity problem

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The description text in event ID 1925 reports that the attempt to establish a replication link for the following writable directory partition failed, and the description text provides the distinguished name of the directory partition that the destination is attempting to replicate from the source. The error code in the event gives more specific information about the cause of the problem.

An example of the event text is as follows:

```
Event Type:Warning
Event Source:NTDS KCC
Event Category:Knowledge Consistency Checker
Event ID:1925
Date:3/24/2005
Time:9:15:46 AM
User:NT AUTHORITY\ANONYMOUS LOGON
Computer:DC3
Description:
The attempt to establish a replication link for the following
writable directory partition failed.

Directory partition:
CN=Configuration,DC=contoso,DC=com
Source domain controller:
CN=NTDS Settings,CN=DC1,CN=Servers,CN=Default-First-Site-
Name,CN=Sites,CN=Configuration,DC=contoso,DC=com
Source domain controller address:
f8786828-ecf5-4b7d-ad12-8ab60178f7cd._msdcs.contoso.com
Intersite transport (if any):
CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=contoso,DC=com
This domain controller will be unable to replicate with the source
domain controller until this problem is corrected.

User Action
Verify if the source domain controller is accessible or network
connectivity is available.

Additional Data
Error value:
1908 Could not find the domain controller for this domain.
```

**Cause**

When event ID 1925 contains error 1908, "Could not find the domain controller for this domain," Active Directory replication has failed as a result of a connectivity problem between the domain controller that reported the error and the source domain controller that is named in the event text.

**Solution**

Use the following tests to solve this problem:

- Verify wide area network (WAN) connectivity.
- Determine the maximum packet size, and change it if necessary.
- Force replication, and capture replication traffic in Network Monitor.
- Analyze network traces to see if any traffic is not reaching the source domain controller.

**Verify WAN Connectivity**

Verify that there are no basic connectivity problems with the underlying network between the domain controllers, especially if they are separated by a WAN link or firewalls. For information about testing this type of problem, see article 310099,

Description of the Portquery.exe command-line utility, on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=69995), and see article 159211, Diagnoses and treatment of black hole routers, on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=69996).

**Determine Maximum Packet Size**

By default, the Kerberos authentication protocol in Windows 2000, Windows XP, and Windows Server 2003 uses the User Datagram Protocol (UDP) when the data can be fit in packets of less than 2,000 bytes. Any data above this value uses TCP to carry the packets. Packets of more than 1,500 bytes are often dropped by a device such as a firewall on the network.

To avoid this problem, you can determine the size of packet that your network can accommodate. Then, you can edit the registry so that the maximum number of bytes for using UDP is set to the lowest value that you receive, less 8 bytes to account for header size.

Use the **ping** command to test the size of packets that the network can accommodate.

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Users group and have the **Log on locally** right on the domain controller.
- Tool: PING

**To determine the lowest common packet size**

1. From the destination domain controller, ping the source domain controller by its Internet Protocol (IP) address. At a command prompt, type the following command, and then press ENTER:

   **ping** *IP_address* **-f -l 1472**

2. From the source domain controller, use the command in step 1 to ping the destination domain controller by its IP address.
3. If the **ping** command completes in both directions, no additional modification is required.
4. If the **ping** command fails in either direction, monotonically lower the number that you use in the **-l** parameter until you find the lowest common packet size that works between the source and destination domain controllers.

| **Note** |
| --- |
| The version of Dcdiag that is included with Windows Server 2003 SP1 Support Tools provides the following method to perform this test:<br><br>**dcdiag /test:CheckSecurityError /s:***SourceDomainControllerName* |

You can edit the registry to set the maximum size of packets to the value that you determined by the PING method, less 8 bytes to account for header size. As an alternative, you can edit the registry so that the maximum number of bytes for using UDP is always exceeded and Kerberos always uses TCP.

You can change the default value of 2,000 bytes by modifying the registry entry **MaxPacketSize** in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\ Kerberos\Parameters**. Use the following procedure to change this registry setting.

| **Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the domain of the domain controller.

- Tool: Regedit.exe change the maximum packet size

**To change the maximum packet size**

1. Click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\ Kerberos\Parameters**.
3. Edit or, if it does not exist in the details pane, create the entry **MaxPacketSize** as follows:
   - To edit the entry if it exists in the details pane:

     Right-click **MaxPacketSize**; click **Modify**; and then, in the **Value data** box, type **1** to force Kerberos to use TCP, or type the value that you established to lower the value to the appropriate maximum size.

   - To create the entry if it does not exist in the details pane:

     Right-click **Parameters**, click **New DWORD Value**, type the name **MaxPacketSize**, and then go to step 3a to edit the entry.

4. Click **OK**.
5. You must restart the domain controller for this change to take effect.

For information about importing an Administrative Template into Group Policy so that this value can be set for all the Windows 2000–based, Windows Server 2003-based, or Windows XP-based computers in the enterprise, see article 244474, "How to force Kerberos to use TCP instead of UDP in Windows Server 2003, in Windows XP, and in Windows 2000," on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=69997).

**Capture Network Traces During Replication**
Use Network Monitor to capture simultaneous traces on both source and destination domain controllers while attempting to replicate (all traffic to and from each domain controller; plus, set the capture buffer to a sufficiently large value). You must select the addresses of the domain controllers from the address database and add them to the capture filter. Start the capture, and then start replication between the two domain controllers. Look for Kerberos fragmentation, out-of-order packets, latency, or network traffic that originates on one side of the connection and does not arrive at the other side.

For information about installing Network Monitor, see Network Monitor on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42987).

**Create an Address Database**
To use address pairs in a capture filter, you must first build an address database. After the database is created, you can use the addresses that are listed in the database to specify address pairs in a capture filter.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the forest root domain or the Enterprise Admins group.

- Tool: Network Monitor

**To create an address database**

1. Open Network Monitor.
2. If you are prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Start**.
4. On the **Capture** menu, click **Stop and View**.
5. On the **Display** menu, click **Find All Names**.

6. In the **Find All Names** dialog box, click **OK**. All addresses are added to the address database.
7. On the **Windows** menu, click the local connection.

You can use the names in the addresses database to specify address pairs in the capture filter.

**Capture Network Frames**

To capture frames that are sent from a specific computer on your network to your computer or that are sent from your computer to a specific computer on your network, specify one or more address pairs in a capture filter. You can monitor up to four address pairs simultaneously.

An address pair consists of:

- The addresses of the two computers between which you want to monitor traffic.
- Arrows that specify the traffic direction that you want to monitor.
- The INCLUDE or EXCLUDE keywords, which indicate how Network Monitor should respond to a frame that meets a filter's specifications.

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the forest root domain or the Enterprise Admins Group in the forest.
- Tool: Network Monitor

**To capture network frames**

1. Open Network Monitor.
2. If you are prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Buffer Settings.**
4. **In the Capture Buffer Settings** dialog box, set the buffer and frame size as appropriate, and then click **OK**.
5. On the **Capture** menu, click **Filter**.
6. In the **Capture Filter** dialog box, double-click **Address Pairs**.
7. In the **Address Expressions** dialog box, select an address in Station 1 and an address in Station 2 for the computers whose traffic you want to capture.
8. In the **Direction** box, select one of the symbols:

   <--> to monitor the traffic that passes in either direction between the addresses that you have selected.

   --> or <-- to monitor only the traffic that passes in one direction between the computers..
9. Click **OK** twice.
10. On the **Capture** menu, click **Start**.

**Force Replication**

When you have Network Monitor started to capture traffic between the two domain controllers, use the following procedure to force synchronization between the computers so that you can capture the replication traffic in Network Monitor.

**Requirements**

- Credentials: To complete this procedure, you must be a member of the Domain Admins group in the forest root domain or the Enterprise Admins group in the forest.
- Tools: Active Directory Sites and Services (Administrative Tools)

**To synchronize replication from a source domain controller**

1. Open Active Directory Sites and Services.
2. Double-click the **Sites** container, double-click the site of the domain controller to which you want to synchronize replication, double-click the **Servers** container, double-click the server object of the domain controller, and then click **NTDS Settings**.
3. In the **From Server** column in the details pane, locate the connection object that shows the name of the source domain controller.
4. Right-click the appropriate connection object, and then click **Replicate Now**.
5. Click **OK**.

Analyze the traces from both domain controllers to see if there is any traffic that is not getting to the other domain controller. For information about using Network Monitor, see Network Monitor overview on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41936).

# Fixing Replication Topology Problems (Event ID 1311)

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Knowledge Consistency Checker (KCC) constructs and maintains the Active Directory replication topology automatically. Every 15 minutes, the KCC examines the sum of all directory partition replicas that reside on domain controllers in the forest, as well as administrator-defined settings for connections, sites, and site links.

Although generation of the replication topology occurs automatically, administrative configuration errors can result in an Active Directory replication topology that is inconsistent with the physical connections that are available. In Active Directory it is possible to create objects for which there is no physical network support. For example, Active Directory Sites and Services allows you to create a site object and assign subnet addresses that do not exist. The KCC will attempt to use these objects to create connections between domain controllers, but replication cannot occur because the network does not exist to support the replication topology as it is configured.

Event ID 1311 is logged in the Directory Service event log when the replication configuration information in Active Directory does not accurately reflect the physical topology of the network. Use the procedures in Event ID 1311: Replication configuration does not reflect the physical network to identify and fix topology problems.

# Event ID 1311: Replication configuration does not reflect the physical network

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Event ID 1311 is logged in the Directory Service log when configuration errors or unavailable domain controllers prevent replication of a directory partition between domain controllers in different sites.

An example of the event text is as follows:

```
Event Type:Error
Event Source:NTDS KCC
Event Category:Knowledge Consistency Checker
Event ID:1311
Date:3/9/2005
Time:6:39:58 PM
User:NT AUTHORITY\ANONYMOUS LOGON
Computer:DC3
Description:
The Knowledge Consistency Checker (KCC) has detected problems with
the following directory partition.

Directory partition:
CN=Configuration,DC=contoso,DC=com

There is insufficient site connectivity information in Active Directory
Sites and Services for the KCC to create a spanning tree replication
topology. Or, one or more domain controllers with this directory
partition are unable to replicate the directory partition information.
This is probably due to inaccessible domain controllers.

User Action
Use Active Directory Sites and Services to perform one of the
following actions:
- Publish sufficient site connectivity information so that the
KCC can determine a route by which this directory partition can
reach this site. This is the preferred option.
- Add a Connection object to a domain controller that contains
the directory partition in this site from a domain controller
that contains the same directory partition in another site.

If neither of the Active Directory Sites and Services tasks correct
this condition, see previous events logged by the KCC that identify
the inaccessible domain controllers.
```

**Cause**

This problem can have the following causes:

- Site link bridging is enabled on a network that does not support physical network connectivity between two domain controllers in different sites that are connected by a site link.
- **Bridge all site links** is enabled in Active Directory Sites and Services, but the network does not allow network connectivity between any two domain controllers in the forest.
- One or more sites are not contained in a site link.
- Site links contain all sites, but the site links are not interconnected. This condition is known as disjointed site links.
- One or more domain controllers are offline.
- Bridgehead domain controllers are online, but errors occur when they try to replicate a required directory partition between Active Directory sites.

- Administrator-defined preferred bridgehead servers are online, but they do not host the required directory partition. The most common misconfiguration is to define non–global catalog servers as bridgehead servers.

- Preferred bridgeheads are defined correctly by the administrator, but they are currently offline.

- The bridgehead server is overloaded because the server is undersized, too many branch sites are trying to replicate changes from the same hub domain controller, or the replication schedules on site links or connection objects are too frequent.

- The Knowledge Consistency Checker (KCC) has built an alternate path around an intersite connection failure, but it continues to retry the failing connection every 15 minutes.

**Solution**

Use the following procedures for troubleshooting event ID 1311:

- Identify the scope of the problem.

- Check site link bridging.

- Determine whether the network is fully routed.

- Verify that all sites are connected.

- Check preferred bridgehead servers.

**Identify the Scope of the Problem**

Identify the scope of the problem by determining whether event ID 1311 is being logged on all domain controllers in the forest that hold the intersite topology generator (ISTG) role or just on site-specific domain controllers.

First, use the following procedure to locate the ISTG role holders for all sites.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in a domain in the forest.

- Tool: Ldp (Windows Support Tools)

**To locate the ISTG role holders for all sites**

1. Click **Start**, click **Run**, type **Ldp**, and then click **OK**.
2. On the **Connection** menu, click **Connect**.
3. In the **Connect** dialog box, leave the **Server** box empty.
4. In **Port**, type **389**, and then click **OK**.
5. On the **Connection** menu, click **Bind**.
6. In the **Bind** dialog box, provide Enterprise Admins credentials. Click **Domain** if it is not already selected.
7. In **Domain**, type the name of the forest root domain, and then click **OK**.
8. On the **Browse** menu, click **Search**.
9. In **Base dn**, type:

   **CN=Sites,CN=Configuration,DC=** *Forest_Root_Domain*

10. In **Filter**, type:

    **(CN=NTDS Site Settings)**

11. For **Scope**, click **Subtree**.

12. Click **Options**, and in the **Attributes** box, scroll to the end of the list, type:

    **;interSiteTopologyGenerator**

    and then click **OK**.

13. In the **Search** dialog box, click **Run**.

14. Review the **interSiteTopologyGenerator** entries in the output, and make a note of the domain controller names.

Determine the scope of the event by checking the Directory Service event logs of all ISTG role holders in the forest, or check at least a significant number of ISTG role holders.

If event ID 1311 continues to be logged on ISTG role holders, continue with the next step.

#### Check Site Link Bridging

Use the following procedure to determine if site link bridging is enabled.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in a domain in the forest.

- Tool: Active Directory Sites and Services (Administrative Tools)

#### Determine if site link bridging is enabled

1. Open Active Directory Sites and Services.

2. In the console tree, double-click the **Sites** container, and then double-click the **Inter-Site Transports** container.

3. Right-click the **IP** container. If **Bridge all site links** is selected, site link bridging is enabled.

The **Bridge all site links** setting requires a fully routed network. If the network is not fully routed, you must create site link bridges manually.

#### Determine Whether the Network Is Fully Routed

Determine whether a fully routed network connection exists between two sites.

If the network is fully routed, continue by verifying that the sites are connected.

If the network is not fully routed and site link bridging is enabled, either make the network fully routed, or disable site link bridging and then create the necessary site links and site link bridges. For information about creating site links, see Linking Sites for Replication.

| **Note** |
| --- |
| Site link bridging is enabled by default. As a best practice, leave site link bridging enabled for fully routed networks. |

#### Disable Site Link Bridging

If the network is not fully routed and site link bridging is enabled, use the following procedure to disable site link bridging.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the forest root domain or a member of the Enterprise Admins group.

- Tool: Active Directory Sites and Services (Administrative Tools)

#### Determine if site link bridging is enabled

1. Open Active Directory Sites and Services.
2. In the console tree, double-click the **Sites** container, and then double-click the **Inter-Site Transports** container.
3. Right-click the **IP** container. If **Bridge all site links** is selected, click it to disable it.

#### Create a Site Link Bridge

If the network is not fully routed, be sure that you have created site links to connect all sites. When all site links are created, use the following procedure to create a site link bridge.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the forest root domain or a member of the Enterprise Admins group.
- Tool: Active Directory Sites and Services (Administrative Tools)

#### To create a site link bridge

1. Open Active Directory Sites and Services.
2. In the console tree, double-click the **Sites** container, and then expand the **Inter-Site Transports** container.
3. Right-click the **IP** container, and then click **New Site Link Bridge**.
4. In **Name**, type a name for the site link bridge.
5. Click two or more site links to be bridged, and then click **Add**.

Wait for a period of time that is twice as long as the longest replication interval in the forest. If event ID 1311 continues to be logged on ISTG role holders, continue with the next step.

#### Verify That All Sites Are Connected

If the network is fully routed, use the Repadmin command-line tool to view site links to ensure that intersite replication can occur between domain controllers in different sites.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Enterprise Admins group or the Domain Admins group in the forest root domain.
- Tool: Repadmin.exe (Windows Support Tools)

#### To view site links

1. At a command prompt, type the following command, and then press ENTER:

   **repadmin /showism "CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=** *Forest_Root_Domain* **"**

   where *Forest_Root_Domain* is the name of the forest root domain.

2. In the output, review the information for the sites that are listed. For each site, the output of the command shows a string of three numbers separated by colons. The numbers represent <cost>:<replication interval>:<options>. Strings with a value of "-1:0:0" indicate a possible missing site link.

#### Check Preferred Bridgehead Servers

If you have designated preferred bridgehead servers, the ISTG selects bridgehead servers only from that list of servers. If no servers in the list for the site can replicate a domain directory partition that has domain controllers in other sites, the ISTG selects a bridgehead server that can replicate the domain, if one is available in the site. However, if at least one server in the list can replicate a domain but the server is unavailable, the ISTG does not select an alternate bridgehead server and replication of updates to that domain does not occur in the site. In this case, you might have domain controllers that are capable of replicating the domain, but replication does not occur because preferred bridgehead servers have been selected and none is available for the domain.

Check the list of preferred bridgehead servers in the site, and ensure that preferred bridgehead servers for the domain in question are available. Use the following procedure to check the list of preferred bridgehead servers.

To see all servers that have been selected as preferred bridgehead servers in a forest, you can use ADSI Edit to view the **bridgeheadServerListBL** attribute on the IP container object.

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Users group in a domain in the forest.
- Tool: Adsiedit.msc (Windows Support Tools)

**To view the list of preferred bridgehead servers**

1. Click **Start**, click **Run**, type **adsiedit.msc**, and then click **OK**.
2. In the console tree, double-click **Configuration Container**, and then double-click **CN=Configuration,DC=ForestRootDomainName**, **CN=Sites**, and **CN=Inter-Site Transports**.
3. Right-click **CN=IP**, and then click **Properties**.
4. In **Attributes**, double-click **bridgeheadServerListBL**.
5. If any preferred bridgehead servers are selected in any site in the forest, the **Values** box displays the distinguished name for each server object that is currently selected as a preferred bridgehead server.

Verify that all domain controllers in the list are online and functioning as domain controllers.

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Users group in the domain of the domain controller.
- Tool: Net view

**To determine whether a domain controller is functioning**

- To confirm that a domain controller is running Active Directory and is accessible on the network, at a command prompt type the following command, and then press ENTER:

  **net view ** *DomainControllerName*

  where *DomainControllerName* is the network basic input/output system (NetBIOS) name of the domain controller.

This command displays the Netlogon and SYSVOL shares, indicating that the server is functioning as a domain controller. If this test shows that the domain controller is not functioning on the network, determine the nature of the disconnection and whether the domain controller can be recovered.

If a domain controller that is selected as a preferred bridgehead server is not available, use the following procedure to select another preferred bridgehead server in the site that can replicate the domain.

**Requirements**

- Administrative credentials: To complete this procedure, you must be a member of the Domain Admins group in the domain of the selected domain controller or a member of the Enterprise Admins group.
- Tool: Active Directory Sites and Services (Administrative Tools)

**To designate a preferred bridgehead server**

1. Open Active Directory Sites and Services.
2. In the console tree, double-click the **Sites** container, and then expand the **Servers** container.

3. Right-click the server object for the domain controller that you want to make a preferred bridgehead server, and then click **Properties**.

4. On the **General** tab, click the intersite transport or transports for which this server will be a preferred bridgehead server, and then click **Add**.

# Additional Resources for Troubleshooting Active Directory

Updated: May 1, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For specific information about troubleshooting Active Directory problems, see the following resources:

- Active Directory Management Pack Technical Reference for MOM 2005 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41369)

For information about Active Directory known issues and best practices, see the following resources:

- Known Issues for Creating Domain and Forest Trusts
- Best Practices for Domain and Forest Trusts

For general information about how Active Directory works and how to manage and configure Active Directory, see the following resources:

- Administering Active Directory Operations
- Active Directory Collection on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=34157)

# Monitoring and Troubleshooting Active Directory Replication Using Repadmin

Updated: March 12, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

This document describes how to use the Repadmin.exe tool to monitor, diagnose, and troubleshoot common replication problems in your Active Directory® environment. All the information in this document applies to computers running the Microsoft® Windows® 2000 Server and Windows Server® 2003 operation systems. This document includes the following topics:

- Repadmin Introduction and Technology Overview
- Repadmin Requirements, Syntax, and Parameter Descriptions
- Repadmin Usage Scenarios
- Repadmin for Experts

To obtain a copy of this guide in .doc file format, see Troubleshooting replication with repadmin on the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkID=129020).

**Publication and revision history**
The following table summarizes the revision history for this guide, including its original publication on Microsoft TechNet.

| Date | Revision |
| --- | --- |
| June 2008 | Original publication on TechNet. |
| March 2010 | Updated with new commands for managing read-only domain controllers in Windows Server 2008 and Windows Server 2008 R2. For more information, see Administer Passwords and Password Replication Policy for Read-Only Domain Controllers with Repadmin.exe. |

# Repadmin Introduction and Technology Overview

Updated: September 17, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Repadmin.exe is a command line tool that is designed to assist administrators in diagnosing, monitoring, and troubleshooting Active Directory replication problems.

**Active Directory replication dependencies**

Active Directory replication has the following dependencies:

- **Routable IP infrastructure.** The replication topology depends on a routable IP infrastructure from which you can map IP subnet address ranges to site objects. This mapping generates the information that client workstations use to communicate with domain controllers that are close by—when there is a choice—rather than with domain controllers that are located across wide area network (WAN) links.

- **DNS.** The Domain Name System (DNS) that resolves DNS names to IP addresses. Active Directory requires that DNS is properly designed and deployed so that domain controllers can correctly resolve the DNS names of replication partners.

- **Remote procedure call (RPC).** Active Directory replication requires IP connectivity and the remote procedure call (RPC) to transfer updates between replication partners.

- **Kerberos version 5 (V5) authentication.** The authentication protocol for both authentication and encryption that is required for all Active Directory RPC replication.

- **Lightweight Directory Services Protocol (LDAP).** The primary access protocol for Active Directory. Replication of an entire replica of an Active Directory domain, as occurs when Active Directory is installed on an additional domain controller in an existing domain, uses LDAP communication rather than RPC.

- **NetLogon.** NetLogon dynamically registers the globally unique identifier (GUID) CNAME in DNS that a domain controller uses to resolve its partner's host name and IP address for Active Directory replication.

- **Intersite Messaging.** Intersite Messaging is required for Simple Mail Transfer Protocol (SMTP) intersite replication and for site coverage calculations. If the forest functional level is Windows 2000, Intersite Messaging is also required for intersite topology generation.

**Glossary of replication terms**

The following table lists terms that are commonly used in discussions about Active Directory replication.

| Term | Definition |
|---|---|

| | |
|---|---|
| Active Directory replication | Active Directory is a distributed directory service, in which not all objects in the directory are stored on every domain controller. In addition, all domain controllers in a domain can be updated directly, not just one primary domain controller. Active Directory replication is the means by which changes that are made on one domain controller are synchronized with all other appropriate domain controllers in the domain or forest that store copies of the same information. Data integrity is maintained by tracking changes on each domain controller and updating other domain controllers in a systematic way. Replication uses a connection topology that is created automatically to make optimal use of beneficial network connections. |
| Active Directory replication topology | Replication topology is the current set of Active Directory connections by which domain controllers in a forest communicate over local area networks (LANs) and WANs to synchronize the directory partition replicas that the domain controllers have in common. Replication topology generation is usually dynamic. It adapts to the network conditions and availability of domain controllers. As a result of how much we rely and depend on directory services today, it is very important to ensure that a directory replication topology is fine-tuned to maintain and deliver the expected level of performance. |
| Active Directory sites | A site is a part of the network with high bandwidth connectivity. By definition, it is a collection of well-connected computers, based on IP subnets. You can use the Active Directory Sites and Services snap-in to administer sites. Because sites control how replication occurs, changes that you make with this snap-in affect how efficiently domain controllers within a domain (but separated by great distances) will coalesce. |
| Knowledge Consistency Checker (KCC) | A part of the ISTG role in Active directory. The KCC checks and, as an option, re-creates topology information for the Active Directory domain. |
| Intersite Topology Generator (ISTG) | This is a role that one domain controller in an Active Directory site must perform.The ISTG designates one or more bridgehead servers to perform replication between sites. |
| Multimaster replication | Every domain controller can receive originating updates to data for which it is authoritative, rather than having a single domain controller that receives all original updates (also known as single-master replication, such as Microsoft Windows NT® 4.0 replication). |
| Pull replication | Domain controllers request (pull) changes rather than send (push) changes that might not be necessary. |
| Store-and-forward replication | Each domain controller communicates with a subset of domain controllers to transfer replication changes, rather than one domain controller being responsible for communicating with every other domain controller that requires the change. |
| High water mark | High water mark is a value that the destination domain controller maintains to keep track of the most recent changes that it has received from a specific source domain controller for an object in a specific partition. High water mark prevents irrelevant objects from being considered by the source domain controller with respect to a single destination. |
| Up-to-dateness vector | The up-to-dateness vector is a value that the destination domain controller maintains for tracking the originating updates that are received from all source domain controllers. When a destination domain controller requests changes for a directory partition, it provides its up-to-dateness vector to the source domain controller. The source domain controller then uses this value to reduce the set of attributes that it sends to the destination domain controller. |

**Glossary of other replication-related terms**

The following table lists terms that are related to other technologies that depend on Active Directory replication topology.

| Term | Definition |
|---|---|
| File Replication Service (FRS) | The replication service in Windows 2000 Server and Windows Server 2003 that is used to replicate the SYSVOL shared folder. |

| | |
|---|---|
| Replica set | The collection of servers that are all replicating a given set of directories is called a replica set. With an appropriate topology design and sufficient network support, a Windows 2000 or Windows Server 2003 FRS replica set can span thousands of computers. It is also possible for a single computer to be a member of multiple replica sets. |
| Topology | Topology defines the set of connections that are used to send updates between members of a replica set. The topology definition includes both the connections and the properties of those connections, such as the schedule, enabled and disabled flags, and so on. |
| Disconnected operation | FRS can operate even if some or all member computers are disconnected from each other for periods of time. Changes can be accepted by any computer, and changes are replicated to other member computers when connectivity is reestablished. |
| Authenticated RPC with encryption | To provide secure communications, FRS uses the Kerberos authentication protocol for authenticated RPC to encrypt and tamper-proof the data that is sent between replication partners. |

# Repadmin Requirements, Syntax, and Parameter Descriptions

Updated: March 12, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

You can use the **repadmin** command to perform replication tasks and to manage and modify the replication topology, force replication events, and display replication metadata and up-to-dateness vectors. This topic covers:

- System requirements
- File requirements
- Repadmin command-line options
- Repadmin subcommands
- Repadmin /listhelp
- CSV format

**System requirements**

The following are the system requirements for **repadmin**:

- Windows XP Professional, Windows Vista®, Windows Server 2003, or Windows Server 2008
- Administrator rights on the domain controller:
    - Required replication rights can be delegated
    - Some commands do not require Administrator rights

**File requirements**

Repadmin.exe is included in the Windows Server 2003 Service Pack 1 (SP1) Support tools. You must install the Support tools before you can use them. For more information about how to install the Support tools, see Windows Server 2003 SP1 Support Tools in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkID=44321).

To obtain the Support tools if you do not have the Windows Server 2003 operating system disc, see Windows Server 2003 SP1 32-bit Support Tools on the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkID=70775).

Previous versions of **repadmin** have similar functionality, but they have some limitations regarding the workstations that they can be run on and which functions they can perform. The following table lists the versions of **repadmin**, which operating systems they can be run on, and which domain controllers they can target.

| Version | Client operating system | Target operating system | Important feature sets |
|---|---|---|---|
| Windows 2000 | Windows 2000 and later | All Active Directory versions | /sync<br>/propcheck<br>/showreps<br>/showvector<br>/showmeta |

| | | | |
|---|---|---|---|
| Windows Server 2003 | Windows XP Professional and Windows Server 2003 | All Active Directory versions | /notifyopt<br>/replsummary<br>/replicate<br>/replsingleobj<br>/removelingeringobjects<br>/rehost and /unhost<br>/showmsg<br>/showattr<br>/syncall<br>/viewlist<br>*DC_LIST* |
| Windows Server 2003 with SP 1 | Windows XP Professional and Windows Server 2003 | All Active Directory versions<br>Rehost requires Windows 2000 Server SP4 and later<br>Remove lingering objects requires Windows Server 2003 | /showbackup<br>/rehost bug fix<br>/regkey |
| Active Directory Application Mode (ADAM) | Windows XP Professional and Windows Server 2003 | All Active Directory versions | /setattr<br>/listhelp |

| Deprecated subcommands (from Windows 2000 Server) | Equivalent or improved subcommands in Windows Server 2003 |
|---|---|
| /sync | /repl or /replicate |
| /propcheck | /showchanges |
| /showreps | /showrepl |
| /showvector | /showutdvec |
| /showmeta | /showobjmeta |

**Repadmin command-line options**

Repadmin is executed at the command prompt, and it contains several subcommands, which are described in detail in the following section.

**Syntax**

```
repadmin <subcommand> [<dsa>] [/u: <UserName>] [/pw: {<Password> | *}] [/rpc] [/ldap] [/homeserver:
<dsaname>]
```

**Parameters**

| Parameter | Description |
|---|---|
| <subcommand> | One of the **repadmin** subcommands that is described in the subcommands section. |
| <Dsa> | Directory System Agent (DSA) represents the domain controller to be targeted by the repadmin subcommand.<br>Not all **repadmin** subcommands require the *dsa* parameter<br>Type **repadmin /listhelp** at the command line for additional information about the *dsa* parameter. |

| | |
|---|---|
| /u:<UserName> | Specifies the account name to use for binding to the directory. By default, **/u** uses the account name with which the user is currently logged on. You can use any of the following formats to specify an account name:<br>• account name (for example, Bob)<br>• domain\account name (for example, contoso\Bob)<br>• user principal name (UPN) (for example, Bob@contoso.com) |
| /pw {<Password> \| *} | Specifies the password to use for authentication. If you type *****, you are prompted for a password. |
| /rpc | Forces **repadmin** to communicate by using a remote procedure call (RPC) session. |
| /ldap | Forces **repadmin** to communicate by using a Lightweight Directory Access Protocol (LDAP) session. If LDAP communication fails, **repadmin** attempts to communicate by using RPC. LDAP is the default communication method for **repadmin**. |
| /homeserver: <dsaname> | Forces **repadmin** to run against a specific domain controller, which is determined by the forest membership of the directory server that is represented by <*dsaname*>.<br>You can specify <*dsaname*> in the following formats:<br><*Computername*>, <*Dnsname*>, <*Dsaguid*>, *, ., "site:<*site*>", "fsmo_dnm:", or "fsmo_schema:". |

**Repadmin subcommands**

| Subcommand | Syntax and description |
|---|---|
| bind | repadmin /bind [*dsa*]<br>Connects to and displays the replication features for a directory server. |
| bridgeheads | repadmin /bridgeheads [*dsa*]<br>Lists the directory servers that act as bridgehead servers for a specified site. |
| checkprop | repadmin /checkprop [*dsa*] *Naming ContextOriginatingDCInvocationIDOriginatingUSN*<br>Compares the properties of specified directory servers to determine if they are up to date with each other. The source directory server contains the original information that must be checked. The data on the destination directory server is compared to the data on the source directory server. |
| dsaguid | repadmin /dsaguid [*dsa*] [*GUID*]<br>Returns a server name when given a globally unique identifier (GUID). |
| failcache | repadmin /failcache [*dsa*]<br>Displays a list of failed replication links that are detected by the Knowledge Consistency Checker (KCC). |
| istg | repadmin /istg [*dsa*] [/verbose]<br>Returns the computer name of the Intersite Topology Generator (ISTG) server for a specified site. |
| kcc | repadmin /kcc [*dsa*] [/async]<br>Forces KCC to calculate replication topology for a specified directory server. By default, this calculation occurs every 15 minutes. |

| | |
|---|---|
| latency | repadmin /latency [*dsa*] [/verbose]<br><br>Displays the amount of time between replications, by using the ISTG Keep Alive time stamp. The ISTG Keep Alive time stamp is not used in forests that are set to the Windows Server 2003 forest functional level. Instead, in those environments, use **repadmin /showutdvec /latency**. |
| notifyopt | repadmin /notifyopt [*dsa*] *Naming Context* [/first:*Value*] [/subs:*Value*]<br><br>Displays or sets the notification timing settings for replication of a specified directory partition. |
| queue | repadmin /queue [*dsa*]<br><br>Displays tasks that are waiting in the replication queue. |
| prp | Repadmin /prp [*operation*] *RODC* [*additional arguments*]<br><br>Displays or modified the Password Replication Policy for a read-only domain controller (RODC).<br><br>This command is available only for versions of Repadmin that are included in Windows Server 2008, Windows Server 2008 R2, or Remote Server Administration Tools.<br><br>The *operation* can be **view**, **add**, **delete**, or **move**. For **view**, **add**, and **delete**, *RODC* can be either *RODC_Name* or *****. For **move**, *RODC* must be *RODC_name*. |
| querysites | repadmin /querysites *FromSiteRDNToSite1RDN* [*ToSite2RDN*...]<br><br>Uses routing information to determine the cost of a route from a specified site to another specified site or sites. The **querysites** parameter does not allow the use of alternate credentials. The relative distinguished names that are used in this command are case sensitive. |
| replicate | Syntax 1<br><br>repadmin /replicate *destination_dsasource_dsa* [/force] [/async] [/full] [/addref]<br><br>Syntax 2<br><br>repadmin /replicate *destination_dsa* [/force] [/async] [/full] [/addref] /allsources<br><br>Starts a replication event for the specified directory partition between the source and destination directory servers. You can determine the source GUID when you view the replication partners by using **showrepl**. |
| replsingleobj | repadmin /replsingleobject *dsaDsaSourceGUIDObjectDN*<br><br>Replicates a single object between any two directory servers that have partitions in common. The two directory servers do not have a replication agreement. You can show replication agreements by using the **repadmin /showrepl** command. |
| replsummary | repadmin /replsummary [*dsa*] [/bysrc] [/bydest] [/errorsonly][/sort:{delta\|partners\|failures\|error\|percent}]<br><br>Summarizes the replication state and relative health of an Active Directory forest. |
| rodcpwdrepl | repadmin /rodcpwdrepl [*DSA_list*] *Hub DCUser1 DN* [*User2 DNUser3 DN*]<br><br>Triggers replication of passwords for the specified users from the source *Hub DC* to one or more RODCs.<br><br>This command is available only for versions of Repadmin that are included in Windows Server 2008, Windows Server 2008 R2, or Remote Server Administration Tools. |
| showattr | repadmin /showattr *dsa* [*OBJ_LIST*] [*OBJ_LIST_OPTIONS*] [/attr\|/attrs: *attributeattribute* ...] [/allvalues] [/long] [/nolongblob] [/nolongblob] [/nolongfriendly] [/dumpallblob]<br><br>The **/showattr** operation displays the attributes and contents of an object. |
| showcert | repadmin /showcert *dsa*<br><br>Displays the certificates (used with Simple Mail Transfer Protocol (SMTP)–based replication) that are loaded on a specified directory server. |

| | |
|---|---|
| showchanges | Syntax 1<br><br>repadmin /showchanges *source_dsaNaming Context* [/cookie: *File*] [/atts: *attribute1*,*attribute2*,...]<br><br>Syntax 2<br><br>repadmin /showchanges *dest_dsaSourcedsaObjectGUIDNaming Context* [/verbose] [/statistics] [/noincremental] [/objectsecurity] [/ancestors] [/atts: *attribute1*,*attribute2*,...] [/filter: *ldap filter*]<br><br>Displays changes from a specified directory partition or changes to a specified object. "Syntax 1" saves changes to a directory partition. If this information is saved to a file, you can run the **getchanges** operation again for comparison. "Syntax 2" lists changes to a specified object. For this command to run properly, the account under which the command is run must possess the **replication get changes** right on the specified directory partition. |
| showconn | repadmin /showconn [*dsa*] [*ServerRDN* \| *ContainerDN* \| *dsa_GUID*] [/From:*ServerRDN*] [/intersite]<br><br>Displays the connection objects for a specified directory server. The default is local site. |
| showctx | repadmin /showctx [*dsa*] [/nocache]<br><br>Displays a list of computers that have opened sessions with a specified directory server. |
| showism | repadmin /showism [*TransportDN*] [/verbose]<br><br>Queries the Intersite Messaging Service (ISM) for site routes. This operation cannot be executed remotely. |
| showmsg | repadmin /showmsg {*Win32Error* \| *DSEventID* \| *NTDSMSG*}<br><br>Displays the error message for a given error number. |
| showncsig | repadmin /showncsig [*dsa*]<br><br>Each directory server maintains a directory partition signature list. This command displays a list of the removed application partition GUIDs. You can configure an application directory partition to be held or not held on a particular directory server by using **ntdsutil** (for Active Directory). |
| showobjmeta | repadmin /showobjmeta [*dsa*] *ObjectDN* [/nocache] [/linked]<br><br>Displays the replication metadata for a specified object that is stored in the directory, including attribute ID, version number, originating and local update sequence number (USN), and originating server's GUID and Date and Time stamp. When you compare the replication metadata for the same object on different directory servers, you can determine whether replication has occurred. |
| showoutcalls | repadmin /showoutcalls [*dsa*]<br><br>Displays calls that have been made by the specified directory server to other directory servers but not yet answered. |
| showproxy | Syntax 1<br><br>repadmin /showproxy [*dsa*] [*Naming Context*] [matchstring]<br><br>Syntax 2<br><br>repadmin /showproxy [*dsa*] [*ObjectDN*] [matchstring] /movedobject<br><br>Lists cross-domain move proxy objects. When an object is moved from one domain to another, a marker remains in the original domain. This marker is called a proxy. |
| showrepl | repadmin /showrepl [*dsa*] [*SourceDCObjectGUID*] [*Naming Context*] [/verbose] [/nocache] [/repsto] [/conn] [/csv] [/all] [/errorsonly] [/intersite]<br><br>Displays replication information. Inbound replica links are displayed by default. Outbound links can also be shown, as well as connections corresponding to those links. The command also displays errors that correspond to replica links that cannot be created by KCC. This helps an administrator build a visual representation of the replication topology and see the role of each directory server in the replication process. |

| | |
|---|---|
| showcig | repadmin /showsig [*dsa*]<br><br>Displays the retired invocation IDs on a directory server. A directory server changes its invocation ID when it is restored or when it rehosts an application partition. |
| showtime | repadmin /showtime [*DSTimeValue*]<br><br>Converts a directory service time value to string format for both the local and the UTC time zones. |
| showtrust | repadmin /showtrust [*dsa*]<br><br>Lists all Active Directory domains that are trusted by a specified Active Directory domain. |
| showutdvec | repadmin /showutdvec *dsaNaming Context* [/nocache] [/latency]<br><br>Displays the highest USN for the specified directory server. This information shows how up to date a replica is with its replication partners. |
| showvalue | repadmin /showvalue [*dsa*] *ObjectDN* [*AttributeName*] [*ValueDN*] [/nocache]<br><br>Displays the values of the type, last modified time, originating directory server, and distinguished name of a specified object. |
| syncall | repadmin /syncall *dsa* [*Naming Context*] [*Flags*]<br><br>Synchronizes a specified directory server with all replication partners. This command contains several subcommands, which are described in the usage scenarios.<br><br>By default, if no directory partition is provided in the *NamingContext* parameter, the command performs its operations on the configuration directory partition. |
| viewlist | repadmin /viewlist [*dsa*] [*OBJ_LIST*]<br><br>Displays a list of directory servers. |
| oldhelp | Displays a list of the operations that have been deprecated in this version of **repadmin**. |

**Repadmin /listhelp**

| Arguments | Values | Description |
|---|---|---|
| DC_LIST | "*" | All domain controllers in the enterprise |
| | DC_Name | See under DC_NAME argument |
| | Part-server_name* | Would pick "part_server_name_dc_01" and "part_server_name_dc_02" but not server "part_server_diff_name". |
| | Site:*site_name* | All domain controllers in the specified site. |
| | Gc: | All global catalog servers in the enterprise. |
| | Fsmo_*fsmo_type*:*fsmo_dn* | See under FSMO_TYPE |
| FSMO_TYPE | | Types of operations master (also known as flexible single master operations or FSMO) role holders require different base distinguished names or relative distinguished names. |
| | Fsmo_dnm: | Enterprise-wide FSMO; does not take any distinguished name (also known as DN). |
| | Fsmo_schema: | Enterprise-wide FSMO; does not take any distinguished name. |
| | Fsmo_pdc: | Domain-specific FSMO; takes the distinguished name of the domain that the user specifies. |

| | | |
|---|---|---|
| | Fsmo_rid: | Domain-specific FSMO; takes the distinguished name of the domain that the user specifies. |
| | Fsmo_im: | Domain-specific FSMO; takes the distinguished name of the domain that the user specifies. |
| | Fsmo_istg: | Site-specific quasi-FSMO; takes the relative distinguished name of the site. |
| DC_NAME | | |
| | "." | Tells **repadmin** to try to pick a domain controller for you. |
| | Server_dns | Specifies a server by DNS. |
| | Dc_dsa_guid | Specifies a specific server by its Directory System Agent (DSA) GUID. |
| | Server_obj_rdn | Specifies a server by its server object relative distinguished name (usually the same as its NetBios name). |
| | Dsa_dn | Specifies a server by the distinguished name of its DSA object. |
| OBJ_LIST | | |
| | Ncobj:NC_NAME | Specifies the use of the distinguished name of NC Head that is specified in NC_NAME. |
| | Dsaobj: | Specifies the use of the distinguished name of the DSA that **repadmin** is connected to. |
| NC_NAME | Config: | Configuration directory partition. |
| | Schema: | Schema directory partition. |
| | Domain: | Domain directory partition for the domain of the domain controller that **repadmin** is running against. |
| OBJ_LIST OPTIONS | {/onelevel \| /subtree} /filter:{*ldap_filter*} | With these options, you can use the **showattr** and **viewlist** commands to cover a list of objects, instead of just a single object. |

**CSV format**

The output that **repadmin /showrepl** returns can be difficult to navigate when you are troubleshooting replication errors or viewing replication topology in a large enterprise. There is a new feature (**/CSV**) that you can use to force **/showrepl** output to print in a tightly constrained comma-separated-value (CSV) format for programmatic manipulation or quick import and correlation in Excel.

The CSV format is also an effective way to exchange **repadmin** outputs because it is not prone to user errors.

To generate output as a .csv (comma-delimited) file, perform the following steps:

1. Open a command prompt, type the following command, and then press ENTER:

   ```
   repadmin /showrepl <DC_NAME> /csv > Repl.csv
   ```

2. Open Repl.csv, and then delete or hide column **A** and both **RPC** and **SMTP** columns.

3. Select row **2**. Click **View**, and then click **Freeze Panes**.

4. Highlight the column heading row. Click **Data**, point to **Filter**, and then click **AutoFilter**.

5. Click the drop-down arrow to display replication status based on your situation.

REPLICATION STATUS.csv

| | A | B | C | D | E | F | G | H | I |
|---|---|---|---|---|---|---|---|---|---|
| 1 | Destination Site | Destination DC | Naming Context | Source DC Site | Source DC | Total Failures | Last Failure | Last Success | Last Failure |
| 2 | HUB | BRANCH-HUB-BH | CN=Configuration,DC=Contoso,DC=c | BRANCH1 | BRANCH1 | 0 | 0 | 9/18/2005 1:58 | 0 |
| 3 | HUB | BRANCH-HUB-BH | CN=Schema,CN=Configuration,DC=C | BRANCH1 | BRANCH1 | 0 | 0 | 9/18/2005 1:58 | 0 |

REPLICATION STATUS

# Repadmin Usage Scenarios

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

This section includes explanations and examples for the following usage scenarios:

- Monitor Forest-Wide Replication
- Display Replication Partners and Status of a Domain Controller
- Replication Latency
- View Replication Metadata of an Object
- Display the Attributes of a Specific Object
- How Up to Date Are My Domain Controllers?
- Can I Look at My Connection Objects and Schedule Details?
- Fine-Tuning Change Notification Values
- Forcing Replication
- Keeping Track of Changes That Have Occurred Over a Period of Time
- Usage of Repadmin When Troubleshooting Event ID 1311
- Subcommands Not Covered Under the Previous Scenarios
- Oldhelp

# Monitor Forest-Wide Replication

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Maintaining the health of enterprise-wide directory replication is very important so that the users, services, machines, and applications that rely on it can operate successfully. The Windows Server 2003 version of repadmin has enhanced functionality that makes it easier to monitor forest-wide directory replication and it is compatible with Windows 2000 domains.

**Repadmin /replsummary** summarizes the replication state and relative health of an Active Directory forest by inventorying and contacting every domain controller in the forest, collecting information such as replication deltas and replication failures.

It will also identify any domain controllers that could not be contacted and would report the failure reason (for an example, see Figure 3.1.4).

**Syntax**

```
Repadmin /replsummary <DC_LIST> [/bysrc] [/bydest] [/errorsonly] [/sort:{delta | partners | failures | error
| percent}]
```

| Parameters | Definition |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller or a list of domain controllers separated by a space that the object will be replicated to. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| **/bysrc** | Shows the output of **repadmin /replsummary**, from the perspective of the replication source (outbound domain controller), in the form of a table. This means that a given source directory server is "pulled on" by multiple client domain controllers. The table is sorted in order of the source domain controllers that are having the most problems, across all the clients in the configuration set. This parameter does not display the destination domain controller. |
| **/bydest** | Shows the output of **repadmin /replsummary**, from the perspective of the replication destination, in the form of a table. This means that a given replication destination (inbound domain controller) is pulling the changes from one or more replication source(s). The table shows the inbound domain controllers and what problems they are having with their partners. The table is sorted in order of the inbound domain controllers that are having the most problem with inbound replication, across all the possible partners in the configuration set. This parameter does not display the source domain controller. |
| **/errorsonly** | Shows only the domain controllers where the partner error is not zero. |
| **/sort:{delta \| partners \| failures \| error \| percent}** | Sorts the replsummary table by the specified column heading. |

**Note**

The **/bysrc** and **/bydest** parameters may be specified at the same time. If they are specified at the same time, repadmin displays the **/bysrc** table first and the **/bydest** table next. If the parameters **/bysrc** and **/bydest** are both absent, repadmin picks the best one and displays the one with the least number of partner errors.

**Simple usage of repadmin /replsummary**

```
C:\>repadmin /replsummary
Replication Summary Start Time: 2005-01-04 22:36:30

Beginning data collection for replication summary, this may take awhile:
  .........

```

**How to interpret the output**

The output of **repadmin /replsummary** is organized by destination and source domain controllers. You should focus on the destination domain controllers first, because the replication model is pull-based. Replication between domain controllers does not use a "push" mechanism. If the replication is within a site, a domain controller (DC1) notifies another domain controller (DC2) that it has updates, and then the DC2 pulls the updates from DC1. If the replication is between sites, a domain controller requests updates at a scheduled time and if updates are available, the domain controller pulls the updates from a domain controller in the other site.

| Fields of interest | Definition |
|---|---|
| ….. | Each dot after the first three represents a domain controller, with not more than 50 dots per line. So, if you have two lines full of dots, it indicates 97 domain controllers (100-3).<br><br>In figure 3.1.1, there are nine dots, which relates to six domain controllers (9-3). |
| Destination DC | Replication destination. A single destination might be pulling data from one or more sources.<br><br>In figure 3.1.1, we are focusing on ROOTDC01. |
| Source DC | Replication source. Multiple destinations might be pulling from a single source.<br><br>In figure 3.1.1, we do not yet know the source domain controller. |
| Largest delta | Denotes the longest replication gap amongst all replication links for a particular domain controller.<br><br>In figure 3.1.1, the largest delta is 45m:47s. |
| Total | Replica links for a particular domain controller (one for each naming context on each domain controller). Please note that this is not the connection objects or replication partners per domain controller.<br><br>In figure 3.1.1, we have seven replication links. |
| Fails | Total number of replica links failing to replicate for one reason or the other. This will never be greater than the Total field.<br><br>No failures in our example. |
| Percentage | Percentage of failures in relation to the total replica links on the domain controller. |

**How to make more sense of some of the fields**

We ran **repadmin /showrepl** against ROOTDC01 to get detailed replication status. Always focus on inbound neighbors because replication is inbound.

If you notice Figure 3.1.1, the time replsummary taken was 22:36:30. Now, if you look at the schema naming context replication time, 21:49:44 from figure 3.1.2, the difference is 45m:47s, which relates to the largest delta.

- Interestingly, 45 minutes is relatively high in our example because our partners belong to the same site. This is because the default periodic replication frequency is once per hour within a site and because the schema naming context did not have any changes, periodic replication took place only at 21:49:44 as opposed to other partitions that replicated in response to change notifications from its partners.

- We also see seven replica links, one for each naming context on each domain controller.

C:\>_
```

**Common factors that influence the largest delta field**

- Periodic intrasite replication frequency.
- Intersite replication schedule and frequency.
- Redundant replication paths with staggered replication schedules.
- Intrasite and intersite change notifications; first and subsequent replication notification delay values.

**Where do REPADMIN /REPLSUMMARY read replication status information?**

- Similar to **/showrepl**, **Repadmin /replsummary** gathers this information from the **Reps-from** and **Repsto multivalued** attributes stored at the root of each directory partition replica (also known as naming contexts) stored on the domain controller. It is local to the domain controller and not replicated.
- The **Repsfrom** attribute contains configuration and persistent state information associated with inbound replication from each source replica of that directory partition.
- The **Repsto** attribute contains outbound change notification partners. Typically this list would be your intrasite partners.

**Wild card and other parameter usage**

The following example uses a wildcard character to show the replication summary for all of the domain controllers in the forest that have a name that begins with 'ROOT'.

```
C:\>repadmin /replsummary root* /bysrc /bydest /sort:delta
Replication Summary Start Time: 2005-01-04 22:50:10

Beginning data collection for replication summary, this may take awhile:
  .....

Source DC           largest delta  fails/total  %%  error
 BRANCH-HUB-BH             56m:26s    0 /   7    0
 ROOTDC01                  13m:41s    0 /   4    0
 ROOTDNS                   01m:36s    0 /   4    0

Destination DC    largest delta    fails/total  %%  error
 ROOTDNS                   56m:26s    0 /   8    0
 ROOTDC01                     :36s    0 /   7    0

C:\>_
```

**Important**

- If there are no inbound partners for a given domain controller, none would be listed under the Destination DC list. Similarly, if there are no outbound partners for a given domain controller, none would be listed under the Source DC list.

- So it is important to tally the total number of domain controllers in the forest and compare that against the Destination DC and Source DC lists to achieve an accurate view. **Repadmin /viewlist *** should list all the domain controllers in the forest.

- At this time of writing, the total number of replication links that would be reported in the replsummary output is limited to 999.

- If the replication destination has never replicated from the source, the largest delta would report as **unknown**.

**Replsummary reporting failures**

The following example reports replication failure and a domain controller that could not be reached, with the error codes and reasons.

```
C:\>repadmin /replsummary /bysrc /bydest /sort:delta /homeserver:rootdns
Replication Summary Start Time: 2005-01-05 00:04:54

Beginning data collection for replication summary, this may take awhile:
  .........

Source DC           largest delta  fails/total  %%  error
 BRANCH2               01h:25m:48s    3 /   3  100  (1722) The RPC server is unavailable.
 ROOTDNS                   56m:34s    0 /   7    0
 ROOTDC01                  56m:34s    0 /   6    0
 BRANCH1                   23m:05s    0 /   3    0
 BRANCH3                   22m:24s    0 /   5    0
 BRANCH-HUB-BH             18m:01s    0 /  15    0

Destination DC    largest delta    fails/total  %%  error
 BRANCH-HUB-BH         01h:24m:33s    3 /  16   18  (1722) The RPC server is unavailable.
 BRANCH1                   16m:55s    0 /   3    0
 ROOTDC01                  15m:20s    0 /   7    0
 ROOTDNS                   11m:20s    0 /   8    0
 BRANCH3                      :42s    0 /   5    0

Experienced the following operational errors trying to retrieve replication information:
          58 - BRANCH2.research.contoso.com

C:\>_
```

```
C:\>net helpmsg 58

The specified server cannot perform the returned operation.

C:\>net helpmsg 1722

The RPC server is unavailable.
```

In our example, the following occurred:

- We could not reach BRANCH2 and hence the error 58.

- "RPC server is unavailable" being reported by BRANCH-HUB-BH co-relates to the above finding. It could mean that BRANCH2 domain controller is either down or not reachable due to communication link problem.

- We also used **/homeserver:rootdns** to demonstrate that sometimes you have to specify a server (/homeserver: <domain controller name>) if you are not running the command from a domain controller.

# Display Replication Partners and Status of a Domain Controller

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

When troubleshooting replication errors, it is helpful to know who are the replication partners of a specific domain controller and the status of replication with each of those partners.

**Repadmin /showrepl** displays the replication partners (**RepsFrom** and **RepsTo**) for each naming context that is held on the specified domain controller. By enumerating each **RepsFrom** and each **RepsTo** for each domain controller, you can visualize the replication topology for each naming context.

It also indicates whether the domain controller is also a global catalog server. Inbound replica links are displayed by default. Outbound links can also be shown, as well as connections that correspond to those links. The command also displays errors that correspond to replica links that cannot be created by the Knowledge Consistency Checker (KCC). This helps the administrator build a visual representation of the replication topology and see the role of each directory server in the replication process.

**Syntax**

```
Repadmin /showrepl <DC_LIST> <SourceDCObjectGUID> [NamingContext] [/verbose] [/nocache] [/repsto] [/conn]
[/csv] [/all] [/errorsonly] [/intersite]
```

| Parameters | Definition |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller or a list of domain controllers separated by a space that the object will be replicated to. See above for detailed syntax. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| *SourceDCObjectGUID* | Specifies the unique hexadecimal number that identifies the object whose replication events will be listed. |
| **NamingContext** | Specifies the distinguished name of the directory partition. |
| **/verbose** | Lists detailed information. |
| **/nocache** | Specifies that globally unique identifiers (GUIDs) are left in hexadecimal form. By default, GUIDs are translated into strings. |
| **/repsto** | Lists the directory servers that pull replication information from the specified directory partition. To see the outbound neighbors, specify **/repsto** or **/all**. |
| **/conn** | Displays the connection objects that are associated with each link. |
| **/csv** | Displays the output of the **repadmin /showrepl** operation in a Comma Separated Variable (CSV) format for viewing and analysis in Microsoft Excel. Repadmin supports redirection of screen output to a file. |
| **/all** | Displays all replication partners. |
| **/errorsonly** | Only shows the partnership if it has an error associated with it. |
| **/intersite** | Only shows this partnership if the source server belongs to a different site than the site of the server on which the command is being run. |

**Show replication partners and replication status**

The following example uses the **showrepl** operation of repadmin to display the replication status of ROOTDNS in relation to its partners. In our example, there are no problems reported because replication is running properly. There is lot of information one could gather from this output and please read the comments next to each line explaining what it means.

Figure 3.2.1

```
C:\>repadmin /showrepl rootdns
```

```
HUB\ROOTDNS (Site name and domain controller name)

Last attempt @ 2005-01-05 00:53:34 was successful.

HUB\ROOTDC01 via RPC (Replication link)

DC object GUID: 2a92f776-6c0f-4cb4-a111-f5dcd447af6c

Last attempt @ 2005-01-05 00:53:34 was successful.
```

In the output under INBOUND NEIGHBORS, repadmin.exe shows the Lightweight Directory Access Protocol (LDAP) distinguished name of each directory partition for which inbound directory replication has been attempted, the site and name of the source domain controller, and whether it succeeded or not, as follows:

- Last attempt @ YYYY-MM-DD HH:MM.SS was successful.
- Last attempt @ [Never] was successful.

If repadmin.exe reports any of the following conditions, further investigation is required:

- The last successful inter-site replication was prior to the last scheduled replication.
- The last intra-site replication was longer than one hour ago.
- Replication was never successful.

DC Object GUID is a reference point used in the Active Directory and Domain Name System (DNS) to locate a domain controller primarily for the purposes of replication. This GUID is automatically generated for each domain controller, is unique when created, and will not be duplicated.

DC invocationID – Active Directory database has its own GUID, which the Directory System Agent (DSA) uses to identify the

database instance (version of the database). The database GUID is stored in the **invocationId** attribute on the nTDSDSA object. Although the DSA GUID never changes for the lifetime of the domain controller, the Active Directory database GUID (also known as the invocation ID or database signature) is changed during the Active Directory restore process to ensure the consistency of the replication process. In Windows Server 2003, it changes when application directory partitions are removed or added to the domain controller.

**Using repadmin /showrepl to display detailed and precise information**

The following **showrepl** output is returned by combining <*Naming Context*> and **/verbose**.

```
C:\>repadmin /showrepl rootdns DC=contoso,DC=com /verbose
HUB\ROOTDNS
DC Options: IS_GC
Site Options: (none)
DC object GUID: 076cd5dd-e25e-4897-acd2-7c8691621522
DC invocationID: 076cd5dd-e25e-4897-acd2-7c8691621522

==== INBOUND NEIGHBORS ======================================

DC=contoso,DC=com
    HUB\ROOTDC01 via RPC
        DC object GUID: 2a92f776-6c0f-4cb4-a111-f5dcd447af6c
        Address: 2a92f776-6c0f-4cb4-a111-f5dcd447af6c._msdcs.contoso.com
        DC invocationID: 195f73bb-5c65-4d14-a1fd-39d0adec3d0c
        SYNC_ON_STARTUP DO_SCHEDULED_SYNCS WRITEABLE
        USNs: 941080/OU, 941080/PU
        Last attempt @ 2005-01-05 01:04:34 was successful.

C:\>_
```

For two domain controllers to engage in replication, they have to first resolve each other's GUID CNAME to a host name and the host name to an IP address, such as the following:

```
C:\>ping 2a92f776-6c0f-4cb4-a111-f5dcd447af6c._msdcs.contoso.com

Pinging rootdc01.contoso.com [192.168.0.101] with 32 bytes of data:

Reply from 192.168.0.101: bytes=32 time<1ms TTL=128
```

**2a92f776-6c0f-4cb4-a111-f5dcd447af6c._msdcs.contoso.com** is the GUID **CNAME** registration in DNS.

**High-watermark value**

The high-watermark value is not required for any administrative task. However, it can help you deduce the state of progress on that replication link. You can see the high-watermark in the output of the **repadmin /showrepl /verbose** command in Figure 3.2.2. Look for lines that begin with USNs:. The high-watermark USN is the number that is followed by **/OU**.

The object update (OU) USN saves the position when in the middle of a replication cycle. It stays the same as the property update (PU) when replication is not occurring, and increases during a replication cycle. At the end of the cycle, the final USN replicated becomes the PU value and the OU is left to match. Thus, the OU indicates progress within a cycle, and the PU indicates the last update seen at the conclusion of a successful cycle. A PU of zero means that the link has never completed a successful cycle, as is the case when performing its first synchronization on a new domain controller connection. If the OU and PU are not equal, it means a replication cycle is in progress.

The following table lists **nbrflagoptions**, which are flags that define expected replication actions with its partner.

| Nbrflagoptions | Meaning |
|---|---|
| WRITEABLE | The local copy of the naming context is writable. |
| SYNC_ON_STARTUP | Replication of this naming context from this source is attempted when the destination server is booted. This normally only applies to intrasite neighbors. |

| | |
|---|---|
| DO_SCHEDULED_SYNCS | Perform replication on a schedule. This flag is normally set unless the schedule for this naming context/source is "never," that is, the empty schedule. |

**Showing outbound neighbors**

By default, **repadmin /showrepl** does not display outbound neighbors, as with previous versions. The **/repsto** parameter provides this feature, as shown in Figure 3.2.5.

```
C:\>repadmin /showrepl rootdns CN=Configuration,DC=contoso,DC=com  /repsto
HUB\ROOTDNS
DC Options: IS_GC
Site Options: (none)
DC object GUID: 076cd5dd-e25e-4897-acd2-7c8691621522
DC invocationID: 076cd5dd-e25e-4897-acd2-7c8691621522

**Some of the repadmin /showrepl Error Messages and their root cause**

The following table lists some **repadmin /showrepl** errors and their root cause. The next sections after the table explain some errors in more detail.

| Repadmin error | Root cause |
|---|---|
| No inbound neighbors | If no items appear in the "Inbound Neighbors" section of the output generated by the **repadmin /showrepl** command, the domain controller could not establish replication links with another domain controller. |
| Access denied | A replication link exists between two domain controllers, but replication cannot be properly performed. |
| Last attempt at <date - time> failed with the "Target account name is incorrect." | This problem can be related to connectivity, DNS, or authentication issues.<br><br>If it is a DNS error, the local domain controller could not resolve the GUID–based DNS name of its replication partner. |
| No more end point | This can be caused because no more end-points are available to establish the TCP session with the replication partner.<br><br>This error can also result when the replication partner can be contacted, but its RPC interface is not registered. This usually indicates that the domain controller's DNS name is registered but with the wrong IP address. |
| LDAP Error 49 | The domain controller computer account might not be synchronized with the Key Distribution Center (KDC). |
| Cannot open LDAP connection to local host. | The administration tool could not contact Active Directory. |
| Active Directory replication has been preempted | An inbound replication in progress was interrupted by a higher priority replication request, such as a request generated manually by using the **repadmin /syncall** command. |
| Replication posted, waiting. | The domain controller posted a replication request and is waiting for an answer. Replication is in progress from this source. |

| | |
|---|---|
| Last attempt @ never was successful | The KCC successfully created the replication link between the local domain controller and its replication partner, but because of the schedule or possible bridgehead overload, replication has not occurred.<br><br>A large backlog of inbound replication must be performed on this domain controller. |

**No inbound neighbors**

A "no inbound neighbor" error appears in the **repadmin /showrepl** command output when one or more of the following conditions exists:

- No connection object exists to indicate which domain controller(s) this domain controller should replicate from. These connection objects are typically created by the KCC. However, in some environments, administrators have turned off the part of KCC (Intersite) that creates connection objects for inbound replication from domain controllers in other sites, relying on manual connections instead.

- One or more connection objects exist, but the domain controller cannot contact the source domain controller to create the replication links. In this case, the KCC logs events each time it runs (by default, every 15 minutes) detailing the error that occurred when it attempted to add the replication links.

- Existing replication links has been inadvertently deleted in between KCC executions.

Repadmin in this scenario could be used only to diagnose. The following table explains subcommand usage that can help you diagnose the problems leading to this situation.

| Subcommand | Description |
|---|---|
| **Repadmin /showrepl** | Verify replication status. |
| **Repadmin /showconn** | Verify whether a valid connection object exists between the source and destination. |
| **Repadmin /failcache** | Resolve the underlying connection translation problems. For more information about using **Repadmin /failcache**, see Repadmin /failcache. |
| **Repadmin /KCC** | Ensure that a connection object (Automatic or Manual) has been created properly between the domain controller and its replication partner. And then force the KCC to run so that the connection object is translated to an appropriate replication link. |

**Active Directory replication has been preempted**

When Active Directory replication has been preempted, an inbound replication in progress was interrupted by a higher priority replication request. An example of a higher priority replication request is a request generated manually by using the **repadmin /sync** command.

Repadmin in this scenario could be used only to diagnose. The following table explains subcommand usage that can help you diagnose the problems leading to this situation.

| Subcommand | Description |
|---|---|
| **Repadmin /showrepl** | Verify replication status. |
| **Repadmin /queue** | Check how many inbound synchronizations are in the queue. |

**Last attempt @ never was successful**

Last attempt @ never was successful error typically indicates that KCC successfully created the replication link between the local domain controller and its replication partner, but because of the schedule or possible bridgehead overload, replication has not occurred.

Repadmin in this scenario may be used for both diagnosis and resolution. The following table explains subcommand usage that can help you diagnose or solve the problems.

| Subcommand | Description |
| --- | --- |
| **Repadmin /showrepl** | Verify replication status. |
| **Repadmin /queue** | Check how many inbound synchronizations are in the queue. |
| **Repadmin /sync** | Synchronize replication from a source domain controller. |

**Access denied**

This error indicates that the local domain controller failed to authenticate against its replication partner when creating the replication link or when trying to replicate over an existing link. This typically happens when the domain controller has been disconnected from the rest of the network for a long time and its computer account password is not synchronized with the computer account password that is stored in the Active Directory of its replication partner.

# Replication Latency

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

There are two mechanisms each specific to the underlying operating system functionality to measure replication latencies. Repadmin could be used against both environments based on the following table.

| Windows 2000 functionality | Windows Server 2003 functionality |
|---|---|
| **/latency** provides you replication latency report by measuring how recently the Intersite Topology Generator (ISTG) attribute has changed. | **/showutdvec** provides you replication latency report by leveraging a new field stored in the Up-To-Dateness (UTD) vector – "last successful replication timestamp." |
| Note that this report ceases to give meaningful results when the forest functional level is Windows Server 2003 because the **interSiteTopologyGenerator** on the **NTDS site settings object** is not updated at that functional level. | **/showutdvec** provides you replication latency report by leveraging a new field stored in the UTD vector – "last successful replication timestamp."<br>This timestamp records the last time the corresponding domain controller completed a successful replication cycle with its partner. The replication cycle may have occurred directly (direct replication partner) or indirectly (transitive replication partner). |
| Latency is shown for configuration naming context only. | Because this data is recorded on all domain controllers that host the partition, it is possible to identify non-replicating domain controllers from any domain controller in the forest that has a common partition between them. |

**Syntax**

The following command displays the amount of time between replications on a site by site basis from the perspective of the servers listed in <*DC_LIST*>, using the ISTG Keep Alive time stamp.

| **Note** |
|---|
| The ISTG Keep Alive time stamp is the mechanism used in Windows 2000 to determine whether a new ISTG is required for the site. Prior to Windows Server 2003, all ISTGs will record a time stamp every 30 minutes to indicate they are alive. After this gets replicated within the site, all of the domain controllers in the site know whether an ISTG is down or not by verifying this attribute, which is stored in Active Directory. |

**repadmin /latency** <*DC_LIST*>

```
C:\>repadmin /latency rootdns
Disclaimer:
1. Latency is shown for Configuration NC only.
2. Probes are sent once every half hour. Actual replication may occur more frequently.
3. What is normal Intersite replication frequency depends on many factors: site link schedules,
 intervals and bridgehead availability.

Gathering topology from site HUB (rootdns.contoso.com):

Replication Latency for site HUB (rootdns.contoso.com):
        Originating Site    Ver    Time Local Update    Time Orig. Update   Latency  Since Last

      =================  =====  ==================  ==================  ========  ==========

                    HUB   7263  2005-01-05 16:16:08  2005-01-05 16:16:08  00:00:00  00:36:40
                BRANCH3   1593  2005-01-05 16:28:31  2005-01-05 16:22:38  00:05:53  00:24:17
                BRANCH1   2720  2005-01-05 16:28:31  2005-01-05 15:56:14  00:32:17  00:24:17
                BRANCH2    919  2005-01-05 16:28:31  2005-01-05 16:15:50  00:12:41  00:24:17
```

**How to interpret the data**

In this example, the forest has only four sites.

| Field | Explanation |
|---|---|
| Origination site | This column has a row for each site in the forest |
| Ver | Version number for site specific **interSiteTopologyGenerator** |
| Time Local Update | Local time when the remote ISTG attribute change was replicated in. |
| Time Orig. Update | Time when the ISTG attribute was changed on the originating server. |
| Latency | Difference between the Time Orig. Update and Time Local Update |
| Since Last | Difference between the Tool execution time and Time Local Update |

Examining the UTD vector from time to time on one bridgehead server is another good way to ensure that replication is healthy. The (UTD) vector shows the last time that a domain controller has received updates from each replication partner for a particular naming context. The UTD vector is transitive in that one domain controller does not have to talk directly to another domain controller to receive an update from it.

```
repadmin /showutdvec <DC_LIST> <NamingContext> [/nocache][/latency]
```

| Parameters | Definition |
|---|---|
| *<DC_LIST>* | Specifies the host name of a domain controller or a list of domain controllers separated by a space that the object will be replicated to. For details about DC_LIST, see **repadmin /listhelp**. |
| *<NamingContext>* | Specifies the distinguished name of the directory partition. |
| **/nocache** | Specifies that globally unique identifier (GUIDs) are left in hexadecimal form. By default, GUIDs are translated into strings. |
| **/latency** | Sorts the information by the time required to complete the replication. By default, the information is sorted by Update Sequence Number (USN). |

```
C:\>repadmin /showutdvec rootdns cn=configuration,dc=contoso,dc=com /latency
Caching GUIDs.

C:\>_
```

**How to interpret the data**

- In Figure 3.3.2, there are four sites, two domains and six domain controllers in the forest.
- The output is a list of dates and times indicating the last time that inbound replication of the configuration container occurred from each domain controller. If an excessive amount of time has passed since replication last took place it could indicate a problem and there is reason to be concerned.
- The entries are listed by domain controller and the **/latency** parameter sorts the output by date/time.
- As given in the example, occasionally GUID's will be displayed instead of a domain controller's name. It is safe to ignore the GUID entries as these are a result of InvocationID changes or domain controllers being demoted or rebuilt and do not affect the health of the topology.
- HUB\ROOTDNS will always report the current date and time and the highest committed USN. The reason is that a domain controller does not keep itself in its own UTDVEC and always builds its entry on the fly based on the current

state.

- Latency from the perspective ROOTDNS is the difference between its current date/time with respect to other partners (direct or transitive) for the given Naming Context. For example, latency between ROOTDNS and BRANCH1 is 00:24:17.

**Display the latency only for the domain partition**

```
C:\>repadmin /showutdvec rootdns dc=contoso,dc=com /latency
Caching GUIDs.
..
HUB\ROOTDC01                          @ USN    944916 @ Time 2005-01-05 17:53:34
HUB\ROOTDNS                           @ USN    793295 @ Time 2005-01-05 17:54:22

C:\>_
```

In this example, we are only interested in the domain naming context latency. Both the domain controllers are running Windows Server 2003 and reside in the same site; hence the latency is less than a minute. Also please note that we are only displaying the domain members and not the whole forest due to the scope of the naming context.

While it is important to measure replication latencies, it is equally important to understand that intersite replication depends on many factors such as:

- Site link schedules and intervals
- Availability of bridgehead servers and their load
- Whether change notifications are enabled
- LAN/WAN infrastructure

# View Replication Metadata of an Object

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Displays the replication metadata for a specified object stored in Active Directory, such as attribute ID, version number, originating and local Update Sequence Number (USN), and originating server's globally unique identifier (GUID) and date and time stamp. By comparing the replication metadata for the same object on different domain controllers, an administrator can determine whether replication has occurred.

**Syntax**

```
repadmin /showobjmeta <DC_LIST> <ObjectDN> [/nocache] [/linked]
```

| Parameters | Definitions |
|---|---|
| <DC_LIST> | Specifies the host name of a domain controller or a list of domain controllers separated by a space that the object will be replicated to. For details about DC_LIST, see **repadmin /listhelp**. |
| <ObjectDN> | Specifies the distinguished name of the object. |
| **/nocache** | Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings. |
| **/linked** | Displays metadata associated with, but not stored with, the specified object. |

**Example 1: Metadata of a group object**

In this example, we are viewing the metadata of a group object (Domain Admins) and therefore the forward links (members) are listed as well.

```
C:\>repadmin /showobjmeta branch-h* "cn=domain admins,cn=users,dc=research,dc=contoso,dc=com"

repadmin running command /showobjmeta against server BRANCH-HUB-BH.research.contoso.com

```

Figure 3.4.2 is the metadata of Lee from HUB domain controller (where the change was made) and Figure 3.4.3 is the metadata from the BRANCH3 domain controller. The attribute **logonHours** has been highlighted for clarity.

BRANCH-HUB-BH has version 2, last Orig. time/date is 2005-01-06 01:19:59 and Orig.USN as 20654.

BRANCH3 is still on version 1, last Orig. time/date is 2005-01-06 00:52:03 and Orig.USN as 20578 and hence the logon succeeds in BRANCH3 because that domain controller has not yet replicated the update.

```
C:\>repadmin /showobjmeta branch3 "cn=lee Oommen,cn=users,dc=research,dc=contoso,dc=com"

# Display the Attributes of a Specific Object

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

The **/showattr** operation displays the attributes and contents of an object.

**Syntax**

```
repadmin /showattr <DC_LIST> <OBJ_LIST> <OBJ_LIST_OPTIONS> [/atts: <<att1>>,<<att2>>,...] [/allvalues]
[/long] [/dumpallblob]
```

| Parameters | Definition |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller or a list of domain controllers separated by a space that the object will be replicated to. For details about DC_LIST, see **repadmin /listhelp**. |
| <*OBJ_LIST*> | This parameter takes a distinguished name or a special keyword that expands into a distinguished name. The keywords are as follows:<br>• **Ncobj:config:** Distinguished name of the Configuration partition of the domain controller<br>• **Ncobj:schema:** Distinguished name of the Schema partition of the domain controller<br>• **Ncobj:domain:** Distinguished name of the Domain partition of the domain controller<br>• **Dsaobj:** NTDS settings object of the directory server |
| <*OBJ_LIST_OPTIONS*> | The OBJ_LIST_OPTION parameter is required to perform a generic Lightweight Directory Access Protocol (LDAP) search from the command line. The parameter requires a BaseDN, with the ability to use a search modifier option. The valid search modifier options are as follows:<br>• **/filter:**<*ldap_filter*><br>• **/base**<br>• **/subtree**<br>• **/onelevel** |
| **[/atts:** <*att1*>,**<att2>,...** | Returns only the attributes that are specified. Separate each listed attribute with a comma. |
| **/allvalues** | For an attribute, the tool only displays 20 values unless this flag is specified, in which case it shows all values. |
| **/long** | Displays one value per line. |
| **/dumpallblob** | Dumps the BLOB in a default byte-by-byte format if there is not a friendly formatted interpretation available for it. |

**Note**

A BLOB in this context means an attribute that is not a simple type, like a string or an integer. A BLOB is a complex structured type that is stored as binary bytes. To make sense of the BLOB, a program must interpret it and format it. A friendly BLOB is a BLOB that the program knows about and can format in an understandable way. The program has a list of BLOBs that it understands.

**Example: Display select attributes**

Please note how we specify the naming context as ncobj:domain:

```
C:\>repadmin /showattr ROOTDC01 ncobj:domain: /filter:"(&(objectCategory=us
er)(samaccountname=lee))" /subtree /atts:displayname,description,mail,membe
rof /long
DN: CN=lee,CN=Users,DC=contoso,DC=com

# How Up to Date Are My Domain Controllers?

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

**Checkprop** compares properties of specified domain controllers to determine if they are up-to-date with each other. The source domain controller contains the original information that needs to be checked. The destination domain controller data is compared to the source domain controller data.

**Syntax**

```
repadmin /checkprop <DC_LIST> <NamingContext> <OriginatingDCInvocationID> <OriginatingUSN>
```

| Parameter | Definition |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| <*NamingContext*> | Specifies the distinguished name of the directory partition on the source domain controller. |
| <*OriginatingDCInvocationID*> | Specifies the unique hexadecimal number that identifies an object on a source domain controller. The InvocationID can be retrieved by using the **/showrepl** operation. |
| <*OriginatingUSN*> | Specifies the Update Sequence Number (USN) for the object on the source domain controller. The USN is for the object whose InvocationID is already listed. |

**Example: Checking replication latency on the BRANCH3 domain controller**

Latency output reveals that the highest OriginatingUSN that BRANCH3 has knowledge of for its HUB site bridgehead server, BRANCH-HUB-BH, is **137844**. It is also apparent that the last successful replication attempt with this HUB site bridgehead server was just less than 5 minutes.

```
C:\>repadmin /showutdvec branch3 cn=configuration,dc=contoso,dc=com /latency

C:\>_
```

**Example: Comparing how up-to-date other domain controllers in the enterprise are with respect to the OriginatingUSN**

In Figure 3.6.2, note that **BRANCH2** domain controller is not up-to-date with the rest of the domain controllers.

```
C:\>repadmin /checkprop branch3 cn=configuration,dc=contoso,dc=com 0cc4891a-4cca-49e8-bbc8
-123de8d656ab 137844
HUB\ROOTDNS: yes (USN 137844)
HUB\ROOTDC01: yes (USN 137844)
HUB\BRANCH-HUB-BH: yes (USN 137844)
BRANCH1\BRANCH1: yes (USN 137844)
BRANCH2\BRANCH2: ** NO! ** (USN 137829)
BRANCH3\BRANCH3: yes (USN 137844)

C:\>_
```

**Example: Further investigation from the perspective of the BRANCH2 domain controller**

Latency was calculated for BRANCH2 which revealed that it is not aware of the latest OriginatingUSN from BRANCH-HUB-BH and in fact it is behind by approximately 20 minutes. Because the latency in this example is just less than 20 minutes (replication interval being 30 minutes) it is expected to catch up during the next replication cycle.

```
C:\>repadmin /showutdvec branch2 cn=configuration,dc=contoso,dc=com /latency

# Can I Look at My Connection Objects and Schedule Details?

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Every domain controller that is also a member of the SYSVOL replica set has to have at least one inbound connection. Otherwise, Active Directory and File Replication Service (FRS) would not replicate inbound. The **/showconn** subcommand is very useful to verify this especially:

- When you don't have access to the graphical user interface (GUI)

or

- When you find it task-oriented to directly connect to the various domain controllers from the user interface (UI) to look at Active Directory topology from the perspective of that domain controller.

  The **/showconn** subcommand displays the connection objects for a specified domain controller. The default is the local site.

**Syntax**

```
repadmin /showconn <DC_LIST> {<ServerRDN> | <ContainerDN> | <DC_GUID>} [/From: <ServerRDN>] [/intersite]
```

| Parameter | Definition |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller from where to read the configuration, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| <*ServerRDN*> | Specifies the relative distinguished name of a server. |
| <*ContainerDN*> | Specifies the distinguished name of a container. |
| <*DC_GUID*> | Specifies the unique hexadecimal number that identifies the domain controller. The globally unique identifier (GUID) can be retrieved by using the **/showreps** operation. |
| **/intersite** | Displays only those connection objects that are between sites. |

**Example: Simple usage of /showconn**

Figure 3.7.1 shows a simple example of output returned by **/showconn**.

```
          C:\>repadmin /showconn branch1
Base DN: CN=BRANCH1,CN=Sites,CN=Configuration,DC=contoso,DC=com
=====  KCC CONNECTION OBJECTS  ================================
Connection --
     Connection name : ed5e0d25-bec3-4556-9f18-f24cf4ea3a57
     Server DNS name : BRANCH1.research.contoso.com
     Server DN  name : CN=NTDS Settings,CN=BRANCH1,CN=Servers,CN=BRANCH1,CN=Sites,CN=C
onfiguration,DC=contoso,DC=com
          Source: HUB\BRANCH-HUB-BH
               No Failures.
          TransportType: IP
          options:  isGenerated overrideNotifyDefault
          ReplicatesNC: DC=DomainDnsZones,DC=research,DC=contoso,DC=com
          Reason:  IntersiteTopology
               Replica link has been added.
          ReplicatesNC: DC=ForestDnsZones,DC=contoso,DC=com
          Reason:  IntersiteTopology
               Replica link has been added.
          ReplicatesNC: CN=Configuration,DC=contoso,DC=com
          Reason:  IntersiteTopology
               Replica link has been added.
```

```
          ReplicatesNC: DC=research,DC=contoso,DC=com
          Reason:  IntersiteTopology
               Replica link has been added.
1 connections found.
```

In the example in figure 3.7.1, there is only one connection object for the BRANCH1 site. It is also automatically created (options: isgenerated). Depending on the number of connection objects, we may have to further qualify our query to just list what we are interested in such as in the following cases:

Figure 3.7.2

```
repadmin /showconn BRANCH1 CN=HUB,CN=Sites,CN=Configuration,DC=contoso,DC=com
/intersite /v
Here repadmin contacts BRANCH1 DC and list all the incoming intersite connections for
HUB site with verbose details.
```

Figure 3.7.3

```
repadmin /showconn BRANCH-HUB-BH BRANCH-HUB-BH /from:BRANCH3
Here repadmin contacts the BRANCH-HUB-BH DC which is also located in the HUB site and
displays just the connection object from BRANCH3 DC to BRANCH-HUB-BH.
```

With the verbose switch, showconn provides you much more information such as the following:

- Connection replication schedule
- Partition Replication Schedule Loading

Figure 3.7.4 Connection replication schedule

```
day: 0123456789ab0123456789ab
Sun: ffffffffffffffffffffffff
Mon: ffffffffffffffffffffffff
Tue: ffffffffffffffffffffffff
Wed: ffffffffffffffffffffffff
Thu: ffffffffffffffffffffffff
Fri: ffffffffffffffffffffffff
Sat: ffffffffffffffffffffffff
```

Every single number of the above represents one hour of the day as a decimal 4-bit value. Each single bit represents 15 minutes of this hour.

So if we have "1" in decimal, then one bit is set in binary (0001) and we replicate once per hour in which case the output will be:

111111111111111111111111

If the decimal value is five (0101 in binary) we replicate twice per hour, for example:

555555555555555555555555

Finally if it is F (1111) we replicate four times per hour:

FFFFFFFFFFFFFFFFFFFFFFFF

So in our example we replicate four times per hour for the entire week.

# Fine-Tuning Change Notification Values

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Replication within a site occurs as a response to changes elsewhere in the site. Replication across sites occurs based on the replication schedule and interval. It is also possible to enable change notifications across sites.

When a change occurs on a domain controller, two configurable intervals determine the delay between the following events:

- Notification to the first partner.
- Notification to each subsequent partner.

The above two intervals serve to:

- Stagger network traffic caused by replication.
- Spreads out the load of responding to replication requests from its partners.

The following table lists the default notification delays:

| Operating system | Notify first partner (sec) | Subsequent partner (sec) | Forest functional level |
|---|---|---|---|
| Windows 2000 | 300 | 30 | Windows 2000 |
| Windows Server 2003 (upgraded from Windows 2000)<br>**Note**<br>If you changed the default values, then those values that you set are retained after you upgrade from Windows 2000 to Windows Server 2003. | 300 | 30 | Windows 2000 |
| Windows Server 2003 | 15 | 3 | Windows 2000 |
| Windows Server 2003 (either upgraded from Windows 2000 or a clean install) | 15 | 3 | Windows Server 2003 |

The following table lists the storage location of notification delay values for each operating system.

| Operating system | Location | Attribute |
|---|---|---|
| Windows 2000 Server | HKLM\SYSTEM\CSS\Services\NTDS\Parameters | • Replicator notify pause after modify (secs)<br>• Replicator notify pause between Directory System Agent (DSAs) (secs) |

| | | |
|---|---|---|
| Windows Server 2003 | Cross-reference object for each directory partition in the configuration partition. | • msDS-Replication-Notify-First-DSA-Delay<br>• msDS-Replication-Notify-Subsequent-DSA-Delay |

**Repadmin /notifyopt** could be used to view or change the notification timing settings of a specified directory partition in Windows Server 2003.

**Syntax**

```
repadmin /notifyopt <DC_LIST> <NamingContext> [/first: Value] [/subs: Value]
```

| Parameter | Definition |
|---|---|
| *<DC_List>* | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about *<DC_LIST>*, see **repadmin /listhelp.** |
| *<NamingContext>* | Specifies the distinguished name of the directory partition on the source domain controller. |
| **/first** | The number of seconds after a change is made before the domain controller notifies its first replication partner that there is a change. |
| **/subs** | Once the first replication partner is notified of a change, the subs parameter specifies the number of seconds to wait before notifying the next replication partner. |

**Example 1: Displaying the default notification delay on the ForestDnsZones partition**

```
C:\>repadmin /notifyopt rootdns DC=ForestDnsZones,DC=contoso,DC=com

Current Notification Options:
Replication-Notify-First-DSA-Delay is not set.
Replication-Notify-Subsequent-DSA-Delay is not set.

C:\>_
```

**Example 2: Changing the defaults to 300/30 on the ForestDnsZones**

```
C:\>repadmin /notifyopt rootdns DC=ForestDnsZones,DC=contoso,DC=com /first:300 /
subs:30

Current Notification Options:
Replication-Notify-First-DSA-Delay is not set.
Replication-Notify-Subsequent-DSA-Delay is not set.
The set operation is allowed on the Domain Naming Master Only.
Your Domain Naming Master is: CN=ROOTDC01,CN=Servers,CN=HUB,CN=Sites,CN=Configur
ation,DC=contoso,DC=com

C:\>repadmin /notifyopt rootdc01 DC=ForestDnsZones,DC=contoso,DC=com /first:300
/subs:30

Current Notification Options:
Replication-Notify-First-DSA-Delay is not set.
Replication-Notify-Subsequent-DSA-Delay is not set.

New Notification Options:
Replication-Notify-First-DSA-Delay: 300
Replication-Notify-Subsequent-DSA-Delay: 30

C:\>_
```

**Note**

In order to make this change, you have to run **/notifyopt** against the Domain Naming Master. See the highlighted text in figure 3.8.2.

# Forcing Replication

Updated: July 14, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Sometimes it becomes necessary to forcefully replicate objects and entire partitions between domain controllers that may or may not have replication agreements

| **Important** |
| --- |
| These are very powerful subcommands and should be used sparingly as they do not follow replication agreements that are in place and have the potential to cause replication storm and break Active Directory if not used properly. |

**Replicate a single object between two domain controllers**

The **repadmin /replsingleobj** command replicates a single object between any two domain controllers that have partitions in common. The two domain controllers do not require a replication agreement between them. Replication agreements can be shown by using the **repadmin /showreps** command.

**Syntax**

```
repadmin /replsingleobj <DC_LIST> <Source DSA_Name> <ObjectDN>
```

| Parameter | Definition |
| --- | --- |
| <*DC_LIST*> | Specifies the host name of a domain controller or a list of domain controllers separated by a space that the object will be replicated to. For details about <*DC_LIST*>, see **repadmin /listhelp** |
| <*Source DSA_Name*> | Specifies the name of the source domain controller. You can specify a host name or the unique hexadecimal number that identifies the source domain controller. You can retrieve the objectGUID by using the **/showreps** operation. |
| <*ObjectDN*> | Specifies the distinguished name of the object. |

**Example: Replicate a single object between all the branch domain controllers by using wild card character**

```
C:\>repadmin /replsingleobj branch* 8168c4c2-bf27-4f92-88ce-3d502b596596 "cn=lee Oo
en,cn=users,dc=research,dc=contoso,dc=com"

repadmin running command /replsingleobj against server BRANCH-HUB-BH.research.conto
.com

Successfully replicated object cn=lee Oommen,cn=users,dc=research,dc=contoso,dc=com
o BRANCH-HUB-BH.research.contoso.com from <GUID=8168c4c2-bf27-4f92-88ce-3d502b59659
.

repadmin running command /replsingleobj against server BRANCH1.research.contoso.com

Successfully replicated object cn=lee Oommen,cn=users,dc=research,dc=contoso,dc=com
o BRANCH1.research.contoso.com from <GUID=8168c4c2-bf27-4f92-88ce-3d502b596596>.

repadmin running command /replsingleobj against server BRANCH2.research.contoso.com

Successfully replicated object cn=lee Oommen,cn=users,dc=research,dc=contoso,dc=com
o BRANCH2.research.contoso.com from <GUID=8168c4c2-bf27-4f92-88ce-3d502b596596>.

repadmin running command /replsingleobj against server BRANCH3.research.contoso.com

Successfully replicated object cn=lee Oommen,cn=users,dc=research,dc=contoso,dc=com
o BRANCH3.research.contoso.com from <GUID=8168c4c2-bf27-4f92-88ce-3d502b596596>.

C:\>_
```

**Force a replication event between two partners**

The **repadmin /replicate** command starts a replication event for the specified directory partition between the source and destination domain controllers. The source universally unique identifier (UUID) can be determined when viewing the replication partners by using the **/showreps** operation.

| **Important** |
| --- |
| The **repadmin /replicate** command will not work if the partners do not have the specified partition in common or replication agreement between them. |

**Syntax1**

```
repadmin /replicate <Destination_DC_LIST> <Source_DC_NAME> <Naming Context> [/force] [/async] [/full]
[/addref] [/readonly]
```

**Syntax2**

```
repadmin /replicate <Destination_DC_LIST> <Naming Context> [/allsources] [/force] [/async] [/full] [/addref]
[/readonly]
```

| Parameter | Definition |
|---|---|
| <*Destination_DC_LIST*> | Specifies the host name of the destination domain controller (Directory Server Agent) with which you want to replicate. For details about <*DC_LIST*>, see **repadmin /listhelp.** |
| <*Source_DC_NAME*> | Specifies the host name of the source domain controller with which you want to replicate. This parameter accepts a globally unique identifier (GUID), GUID-based Domain Name System (DNS) name, or the name of a server object. |
| <*Naming Context*> | Specifies the distinguished name of the directory partition. |
| **/force** | This parameter is used to override the Disable Replication option on a server. |
| **/async** | Specifies that the replication will be asynchronous. This means that repadmin starts the replication event, but it does not expect an immediate response from the destination domain controller. Use this parameter when there are slow links between domain controllers. |
| **/full** | Forces a full replication of all objects from the destination domain controller. |
| **/addref** | Directs the source to check for a notification entry on the source. If the source does not have a notification entry for this destination, one is added. |
| **/allsources** | A given destination can have multiple sources for the same naming context. Directs the destination to sync with all sources instead of just one. This parameter cannot be used with <*Destination_DC_LIST*>. |
| **/readonly** | This parameter is ignored by the **/replicate** operation. |

**Example: replicate in domain partition between two specific partners**

In the example in figure 3.9.2.1, we are attempting to replicate in domain partition between two specific partners. But the source domain controller is rejecting replication requests as configured by the administrator for valid reasons.

```
C:\>repadmin /replicate branch1 branch-hub-bh dc=research,dc=contoso,dc=com

DsReplicaSync() failed with status 8456 (0x2108):
    The source server is currently rejecting replication requests.

C:\>_
```

In the next example, we run **repadmin /showrepl** against the source domain controller (BRANCH-HUB-BH) to read the domain controller options. Figure 3.9.2.2 highlights that outbound replication is currently disabled (DISABLE_OUTBOUND_REPL).

```
C:\>repadmin /showrepl branch-hub-bh
HUB\BRANCH-HUB-BH
DC Options: DISABLE_OUTBOUND_REPL
Site Options: (none)
DC object GUID: 9090b7ce-53a6-4a44-91bf-b50ed232be53
DC invocationID: 0cc4891a-4cca-49e8-bbc8-123de8d656ab

==== INBOUND NEIGHBORS ======================================

CN=Configuration,DC=contoso,DC=com
    BRANCH2\BRANCH2 via RPC
```

We could work around this by using the **/force** switch as seen in figure 3.9.2.3. However, use caution you when using the force replication feature. The **/force** switch is dangerous because it overrides any precautions that have been implemented by an enterprise administrator to address specific business needs. For example, in a large forest with hundreds of sites connected across unreliable WAN links, use of the **/force** switch to replicate changes across forest might cause a replication storm (depending on the changes) that the WAN could not handle.

```
C:\>repadmin /replicate branch1 branch-hub-bh dc=research,dc=contoso,dc=com
 /force
Sync from branch-hub-bh to branch1 completed successfully.

C:\>_
```

**Force a replication event with all partners**

the **repadmin /syncall** command synchronizes a specified domain controller with all replication partners.

**Syntax**

```
repadmin /syncall <DC> [<NamingContext>] [<Flags>]
```

| Parameter | Definition |
|---|---|
| *<DC>* | Specifies the host name of the domain controller to synchronize with all replication partners. |
| *<NamingContext>* | Specifies the distinguished name of the directory partition. |
| *<Flags>* | Performs specific actions during the replication. |

The following table lists the flags that you can use with **repadmin /syncall**.

| Flag | Description |
|---|---|
| /a | Abort if any server is unavailable. |
| /A | Sync all naming contexts which are held on the home server. |
| /d | Identify servers by distinguished name in messages. |
| /e | Enterprise, cross sites |
| /h | Print this help screen. |
| /i | Iterate indefinitely. |
| /l | Perform showreps on each server pair in path instead of synchronizing. |
| /j | Synchronize adjacent servers only. |
| /p | Pause for possible user abort after every message. |
| /P | Push changes outward from home server. |
| /q | Run in quiet mode, suppress call back messages. |
| /Q | Run in very quiet mode, report fatal errors only. |
| /s | Do not synchronize. |
| /S | Skip initial server response check. |

**Important**

Use this command and the above flags cautiously or you can damage the replication system because this command does not follow replication agreements nor honor any replication restrictions such as DISABLE_INBOUND_REPL or DISABLE_OUTBOUND_REPL

**Example 1: Synchronizing Configuration Partition within the site**

```
C:\>repadmin /syncall branch-hub-bh cn=configuration,dc=contoso,dc=com
Syncing partition: cn=configuration,dc=contoso,dc=com
CALLBACK MESSAGE: The following replication is in progress:
    From: 076cd5dd-e25e-4897-acd2-7c8691621522._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: The following replication completed successfully:
    From: 076cd5dd-e25e-4897-acd2-7c8691621522._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: The following replication is in progress:
    From: 2a92f776-6c0f-4cb4-a111-f5dcd447af6c._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: The following replication completed successfully:
    From: 2a92f776-6c0f-4cb4-a111-f5dcd447af6c._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: SyncAll Finished.
SyncAll terminated with no errors.
```

There will be two callback messages for each partner in figure 3.9.3.1. One reports the progress and the other reports either

success or failure (with explanation). Also notice that domain controllers are denoted by their GUID CNAMES as used in replication.

**Example 2: Crossing site boundaries and other features**

By default, **repadmin /syncall** does not cross site boundaries as depicted in figure 3.9.3.2. BRANCH-HUB-BH does not have any domain members in its own site for domain dc=research,dc=contoso,dc=com. In this case, use **/e**.

```
C:\>repadmin /syncall branch-hub-bh dc=research,dc=contoso,dc=com
Syncing partition: dc=research,dc=contoso,dc=com
CALLBACK MESSAGE: SyncAll Finished.
SyncAll terminated with no errors.

C:\>_
```

In figure 3.9.3.3, we are using three additional flags. The **/d** flag would translate the GUID CNAME to the distinguished name of the domain controller. The **/e** flag is used to cross site boundaries. The **/a** flag is used to abort if any domain controller is unavailable. In this example, the BRANCH2 domain controller was not reachable and therefore, the process was aborted.

```
C:\>repadmin /syncall branch-hub-bh dc=research,dc=contoso,dc=com /d /e /a
Syncing partition: dc=research,dc=contoso,dc=com
CALLBACK MESSAGE: Error contacting server CN=NTDS Settings,CN=BRANCH2,CN=Se
rvers,CN=BRANCH2,CN=Sites,CN=Configuration,DC=contoso,DC=com (network error
): 1722 (0x6ba):
    The RPC server is unavailable.

SyncAll cancelled by user request.

C:\>_
```

In figure 3.9.3.4, **repadmin /syncall** did succeed because the problem with the BRANCH2 domain controller was fixed. Also notice that we omitted the **/d** switch so that the GUID names are not translated.

```
C:\>repadmin /syncall branch-hub-bh dc=research,dc=contoso,dc=com /e /a
Syncing partition: dc=research,dc=contoso,dc=com
CALLBACK MESSAGE: The following replication is in progress:
    From: 1b510929-29d7-4a60-a877-aa64e027bb29._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: The following replication completed successfully:
    From: 1b510929-29d7-4a60-a877-aa64e027bb29._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: The following replication is in progress:
    From: 8168c4c2-bf27-4f92-88ce-3d502b596596._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: The following replication completed successfully:
    From: 8168c4c2-bf27-4f92-88ce-3d502b596596._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com
CALLBACK MESSAGE: The following replication is in progress:
    From: 7e50725f-29c4-4d8a-80a2-c165e1c94e79._msdcs.contoso.com
    To  : 9090b7ce-53a6-4a44-91bf-b50ed232be53._msdcs.contoso.com

```

# Keeping Track of Changes That Have Occurred Over a Period of Time

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

There could be multiple occasions where we would be interested in finding out the number of changes that are either pending replication or that have occurred to a specified directory partition over a period of time.

For example:

- You may want to get statistics of all the changes that have occurred to a domain partition over a period of one day or one week so that you can use this data to either support or calculate intersite replication bandwidth requirements.
- This will help with troubleshooting replication issues and reviewing changes that have not replicated between two partners.

The **repadmin /showchanges** command has two syntaxes that can helpful in these situations.

**Syntax1**

```
repadmin /showchanges <SourceDC> <NamingContext> [/cookie: <File>] [/atts: <attribute>,<attribute>,...]
```

**Syntax2**

```
repadmin /showchanges <DestDC> <SourceDCObjectGUID> <NamingContext> [/verbose] [/statistics] [/noincremental]
[/objectsecurity] [/ancestors] [/atts: <attribute1>,<attribute2>,...] [/filter: <ldap filter>]
```

| Parameter | Description |
|---|---|
| <*DestDC*> | Specifies the host name of the destination domain controller from which to enumerate the host domain controllers. |
| <*SourceDC*> | Specifies the host name of the domain controller that hosts the directory partition whose changes you want to view. |
| <*NamingContext*> | Specifies the distinguished name of the directory partition. |
| **/cookie:** <*File*> | Specifies a name for the file to which list changes are saved. |
| **/atts:** <*attribute*>,<*attribute*>,... | Returns only the attributes specified. Separate each listed attribute with a comma. |
| <*SourceDCObjectGUID*> | Specifies the unique hexadecimal number that identifies the object whose changes will be listed. The objectGUID can be retrieved by using the **/showreps** operation. |
| **/verbose** | Lists detailed information. |
| **/statistics** | Displays a summary of information about changes instead of a list of individual changes. |
| **/noincremental** | Returns changes in value change format, which lists current values for attributes as well with attributes that have been added or deleted. If not specified, changes are returned in attribute change format, which shows only the current value of the attribute. |
| **/objectsecurity** | Overrides the need for the GetChanges right to the directory partition. By default, this right is necessary to run the **GetChanges** parameter. However, only changes that the currently logged on user has the rights to view are displayed. |
| **/ancestors** | Returns changes in Update Sequence Number (USN) order. |
| **/filter:** <*ldap filter*> | Returns only those changes that meet the filter requirements. |

Syntax 1 can be used to compare changes that occurred to a specified directory partition over a period of time.

The idea here is to:

1. Create a cookie file that saves changes to a directory partition that could be used for later comparisons. The first time you use the cookie option, it may take a long time (depending on the size of your partition) to create the file. It is important to note that we store only metadata about all the changes that have occurred to this cookie file on the entire set of domain controllers.

2. Later on when you present this cookie file to any domain controller, it will update the cookie file and provide you with just the change deltas since the last time it was updated.

**Example: Compare changes occurred to configuration partition over a period of time**

```
C:\>repadmin /showchanges rootdns cn=configuration,dc=contoso,dc=com /cookie:config
Using cookie from file config (444 bytes)

==== SOURCE DC: rootdns ====

Objects returned: 3
(0) modify CN=NTDS Site Settings,CN=HUB,CN=Sites,CN=Configuration,DC=contoso,DC=com

s,CN=BRANCH1,CN=Servers,CN=BRANCH1,CN=Sites,CN=Configuration,DC=contoso,DC=com
New cookie written to file config (444 bytes)

C:\>_
```

**How to interpret the data**

- Prior to running the showchanges, a cookie file was created using the following syntax:

  **repadmin /showchanges . cn=configuration,dc=contoso,dc=com /cookie:config**

- Re ran **repadmin /showchanges** after some time against another domain controller, which not only displayed the changes but also updated the cookie file called **config**.

- Three objects have been changed. In our example, all the changes are pertaining to Intersite Topology Generators (ISTGs). Because the forest functional level is Windows 2000, we still update the ISTG Keep Alive stamp every 30 minutes.

- You could further apply filters to just target the partitions and objects of your interest.

**Display changes not replicated between two partners**
Syntax 2, shown earlier, is used here to display pending replication changes between partners.

**Example: Display pending replication changes (config partition) between two replication partners**
In this example (figure 3.10.1.1), we ran **repadmin /showchanges** to compare the destinations up-to-date vector with the source and determined that there are two outstanding changes for the configuration partition.

```
C:\>repadmin /showchanges branch3 9090b7ce-53a6-4a44-91bf-b50ed232be53 cn=configuration,dc
=contoso,dc=com
Building starting position from destination server branch3

C:\>
```

**Example: Usage of a filter**

In the following example (figure 3.10.1.2), we applied a filter (/filter:"(objectclass=sitelink)") to just provide only changes occurred to the sitelink objectclass since the last successful replication.

```
Objects returned: 1
(0) modify CN=HUB-BRANCH3,CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=cont
oso,DC=com
    1> objectGUID: 87c79531-4f3c-4850-9fff-2fdf13594f54
    1> instanceType: 0x4 = ( IT_WRITE )
    1> options: 0x2 = ( 0x2 )

C:\>_
```

**Example: listing only the summary as opposed to individual changes**

In the following example (figure 3.10.1.3), the previous changes are listed as summary obtained by the **/statistics** switch.

```

# Usage of Repadmin When Troubleshooting Event ID 1311

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

By all means, this topic is not about how to troubleshoot events that have Event ID 1311. In this topic, we are attempting to expose the various usage of repadmin while troubleshooting 1311 in Windows 2000 domains based on Microsoft Knowledge Base (KB) article 307593, How to Troubleshoot Event ID 1311 Messages on a Windows 2000 Professional Domain (http://go.microsoft.com/fwlink/?LinkId=121799). Some or all of the repadmin subcommands used here may be used in Windows Server 2003 environments as well.

The KB article RESOLUTION section has the following action plan. This topic examines how to apply the various repadmin subcommands against each action plan. All of the repadmin subcommands listed in this topic have associated examples either in this section or elsewhere in this document.

| Resolution steps from the KB article | Action plan by using repadmin |
|---|---|
| Determine if the event ID 1311 messages are site-specific or forest-wide. | To determine the scope of event ID 1311 messages:<br>1. First, find all the Inter Site Topology Generators (ISTG) in the forest.<br>2. Then, examine the Directory Service logs of all the ISTG domain controllers in the forest.<br>To determine the ISTG's, use Repadmin /ISTG. |
| Determine if site link bridging is turned on and if the network is fully routed. | To determine this, use **repadmin /showattr** (Determine if site link bridging is turned on). |
| Verify that all of the sites are defined in site links. | Every site defined in Active Directory must be hosted or reside in a site link.<br>The **repadmin /showism** command (Verify inter-site cost matrix and orphaned sites) is useful for locating improperly configured sites. |
| Detect and remove preferred bridgeheads. | To search for preferred bridgehead servers use **repadmin /showattr** (Determine if site link bridging is turned on). |
| Resolve Active Directory replication failures in the forest | When you want to discover and troubleshoot replication failures, the following repadmin subcommands can be useful:<br>• **repadmin /replsummary** (Monitor Forest-Wide Replication)<br>• **repadmin /showrepl** (Display Replication Partners and Status of a Domain Controller)<br>• Repadmin /failcache<br>• **repadmin /removelingeringobjects** (Windows Server 2003 only)<br>• Repadmin /KCC |
| Determine if source servers are overloaded. | A domain controller that is overloaded with a large number of direct replication partners or a replication schedule that is overly aggressive can create a backlog in which some partners never receive changes from a hub domain controller. The following subcommands can be useful in this situation:<br>• **repadmin /showrepl** (Display Replication Partners and Status of a Domain Controller)<br>• Repadmin /queue<br>• **repadmin /showctx** (Open sessions with the domain controller) |

| | |
|---|---|
| Determine if site links are disjointed. | "Disjoint site links" is an Active Directory configuration in which the topology is broken into two or more parts in which some sites do not replicate because site definitions and site link definitions are incorrect. Disjoint site links are the most difficult improper configuration to troubleshoot. The following subcommands may be useful in this situation:<br>• Repadmin /querysites<br>• **repadmin /showconn** (Can I Look at My Connection Objects and Schedule Details?)<br>• Repadmin /KCC<br>• **repadmin /showrepl** (Display Replication Partners and Status of a Domain Controller) |
| Delete connections if the KCC is in "Keep Connection Mode." | If the Knowledge Consistency Checker (KCC) builds a different path around a site-to-site connection failure, but it retries the failing connection every 15 minutes because it is in "connection keeping mode," delete all broken connections and let the KCC rebuild them. Wait two times the longest replication schedule in the forest. |

**Determine if site link bridging is turned on**

Site link bridging is enabled in Active Directory if the following conditions are true:

- The Bridge all site links check box is selected for the IP protocol and the SMTP protocol in the Active Directory Sites and Services snap-in.
- The Options attribute for the IP protocol and the SMTP protocol is NULL or set to zero (0) for the following distinguished name (DN) paths:

  CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=root domain of forest

  CN=SMTP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=root domain of forest

```
C:\>repadmin /showattr branch3 ncobj:config: /filter:(objectcategory=intersitetran
DN: CN=SMTP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=contoso,DC=com
    1> name: SMTP
    1> options: 0x1 = ( NTDSTRANSPORT_OPT_IGNORE_SCHEDULES )
DN: CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=contoso,DC=com
    1> name: IP
    1> options: 0x0 = (  )

C:\>_
```

There are two values that we could set from the graphical user interface (GUI): **Ignore Schedules** and **Bridge all site links**. In our example (figure 3.11.1), the IP transport has **Bridge all site links** enabled and SMTP transport has both values selected.

The following table lists the various values that the options attribute take.

| Option value | Description |
|---|---|
| 0X0 | Only **Bridge all site links** is selected from the above |
| 0X1 | Both the values are selected |
| 0X2 | None selected |
| 0X3 | Only **Ignore schedules** is selected |

**Detect preferred bridgeheads**

Preferred bridgeheads are selected when the following condition is true:

**bridgeheadTransportList** attribute is set to either one of the following values or both values:

- CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=<*root domain of forest*>
- CN=SMTP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,DC=<*root domain of forest*>

By using **repadmin /showattr**, we are setting the base at configuration partition and applying a filter for server **ObjectClass** and looking for all of the domain controllers that have this value set to use either IP or SMTP transports.

If the search returns any results, note the name of server in the distinguished name path in which the **bridgeheadTransportList** attribute is populated.

```
C:\>repadmin /showattr branch3 ncobj:config: /filter:(objectclass=server) /subtree
/atts:bridgeheadTransportList
DN: CN=ROOTDNS,CN=Servers,CN=HUB,CN=Sites,CN=Configuration,DC=contoso,DC=com
DN: CN=ROOTDC01,CN=Servers,CN=HUB,CN=Sites,CN=Configuration,DC=contoso,DC=com
    1> bridgeheadTransportList: CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configur
ation,DC=contoso,DC=com
DN: CN=BRANCH-HUB-BH,CN=Servers,CN=HUB,CN=Sites,CN=Configuration,DC=contoso,DC=com
DN: CN=BRANCH1,CN=Servers,CN=BRANCH1,CN=Sites,CN=Configuration,DC=contoso,DC=com
DN: CN=BRANCH2,CN=Servers,CN=BRANCH2,CN=Sites,CN=Configuration,DC=contoso,DC=com
DN: CN=BRANCH3,CN=Servers,CN=BRANCH3,CN=Sites,CN=Configuration,DC=contoso,DC=com

C:\>_
```

In the example in figure 3.11.2, ROOTDC01 is selected as a preferred Bridgehead for IP transport in site HUB.

**Verify inter-site cost matrix and orphaned sites**

**Repadmin /showism** displays intersite messaging routes calculated by the Intersite Messaging Service and is very useful for locating improperly configured sites. This operation cannot be executed remotely.

As the KCC runs through the progressions of analyzing intersite site links and connections, it must query the Intersite Messaging Service (ISM) service to retrieve data about the network configuration to make intelligent decisions about routing changes.

To display cost and frequency configurations of replication between sites, use the following command:

**Syntax**

```
repadmin /showism [<TransportDN>] [/verbose]
```

| Parameter | Description |
|---|---|
| <*TransportDN*> | Specifies whether the mail server is using SMTP or remote procedure call (RPC) to send messages. |
| **/verbose** | Lists detailed information. |

| **Note** |
|---|
| The **repadmin.exe /showism** cannot be executed against a remote domain controller. |

**Example: Display inter-site cost matrix**

```
C:\>repadmin /showism "CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,dc=contoso,dc=com"

==== TRANSPORT CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,dc=contoso,dc=com CONNECTIVITY INFORMATION FOR 5 SITES:
 ====

Site CN=BRANCH4,CN=Sites,CN=Configuration,DC=contoso,DC=com is not connected by this transport.
        0,    1,    2,    3,    4
Site(0) CN=BRANCH1,CN=Sites,CN=Configuration,DC=contoso,DC=com
    0:0:0, 200:30:1, 200:30:1, -1:0:0, 100:15:1
    All DCs in site CN=BRANCH1,CN=Sites,CN=Configuration,DC=contoso,DC=com (with trans & hosting NC) are bridgehead candidates.

Site(1) CN=BRANCH2,CN=Sites,CN=Configuration,DC=contoso,DC=com
    200:30:1, 0:0:0, 200:30:1, -1:0:0, 100:30:1
    All DCs in site CN=BRANCH2,CN=Sites,CN=Configuration,DC=contoso,DC=com (with trans & hosting NC) are bridgehead candidates.

Site(2) CN=BRANCH3,CN=Sites,CN=Configuration,DC=contoso,DC=com
    200:30:1, 200:30:1, 0:0:0, -1:0:0, 100:30:1
    All DCs in site CN=BRANCH3,CN=Sites,CN=Configuration,DC=contoso,DC=com (with trans & hosting NC) are bridgehead candidates.

Site(3) CN=BRANCH4,CN=Sites,CN=Configuration,DC=contoso,DC=com
    -1:0:0, -1:0:0, -1:0:0, 0:0:0, -1:0:0
    All DCs in site CN=BRANCH4,CN=Sites,CN=Configuration,DC=contoso,DC=com (with trans & hosting NC) are bridgehead candidates.

Site(4) CN=HUB,CN=Sites,CN=Configuration,DC=contoso,DC=com
    100:15:1, 100:30:1, 100:30:1, -1:0:0, 0:0:0
    All DCs in site CN=HUB,CN=Sites,CN=Configuration,DC=contoso,DC=com (with trans & hosting NC) are bridgehead candidates.

C:\>_
```

**How to interpret the data**

- Showism was used against the IP transport and hence the output is specific to IP.
- If a specific transport is not specified, the output will contain both IP and SMTP details.
- The numbers in an entry appear in the following order:
    - Cost: Replication interval: Options
- There are four key pieces of information:
    - Text regarding the status of bridgehead servers.
    - Total cost between two sites. The cost value indicates the preference for a network link for replicating directory information between sites.

- Frequency of replication in minutes between the two sites.
- Options for each replication link.

- In the example in figure 3.11.3, we have five sites and Bridge all site links is enabled, which means that site link transitivity is enabled. Therefore, if we see any "-1:0:0" entries for one or more covered Active Directory sites, we must ensure that the affected sites are listed in a site link. In this example, site Branch4 is not included in any site links and therefore disconnected from rest of the sites. Event 1311 will certainly occur here due to this configuration problem.

| Fields of interest | Definition |
|---|---|
| "0:0:0" | Each site matrix contains one "0:0:0" entry that refers to itself. |
| "200:30:1" | An entry that contains positive numbers for the cost value and replication interval value (for example, "200:30:1" or "100:15:1") indicates that the site connection is good. Specifically in our example for Site BRANCH1<br><br>Site(0) CN=BRANCH1,CN=Sites,CN=Configuration,DC=contoso,DC=com<br><br>0:0:0, 200:30:1, 200:30:1, -1:0:0, 100:15:1<br><br>• 200 stands for the cost to replicate from site(1) which is BRANCH2 that is an aggregate cost between two hops (100 + 100) because a direct replication link between the two sites does not exist.<br>• 30 is the replication interval that is common between the two branches<br>• 1 is the option on the site link which denotes “Change Notifications are enabled across the site link”<br><br>And so on the rest of the sites... |
| "-1:0:0" | A "-1:0:0" entry indicates that the site connection is not working. This occurs if one or more of the following conditions are true:<br>• Site is not included in a site link.<br>• Site does not host any domain controllers (this is known as an "uncovered" site).<br>• Replication protocol is not used. For example, if SMTP replication is not configured, the entries in the SMTP portion of the /SHOWISM matrix all appear as "-1:0:0". |

**Note**

- If site link bridging is enabled and the **repadmin /showism** command returns a site with a full complement of "-1:0:0" entries and one "0:0:0" entry is orphaned unless the site is uncovered (no domain controllers reside in that site).
- If site link bridging is disabled, "-1:0:0" entries are less meaningful. If this is the case, you must manually determine if each site is included in a site link. To do so, write down the list of sites and site links, and manually map each site to a site link.

**Repadmin /failcache**

**Repadmin /failcache** displays a list of replication failures that KCC is aware of. Run this command from the console of each ISTG domain controller in the forest to discover replication failures for bridgeheads in the site for that ISTG.

**Syntax**

```
repadmin /failcache <DC_LIST>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |

**Example: Display replication failures that KCC is aware of**

The example in figure 3.11.4 shows sample output from the **repadmin /failcache** command.

```
C:\>repadmin /failcache rootdc01
==== KCC CONNECTION FAILURES ============================
    BRANCH2\STUDENT4\0ADEL:81ca9fb4-c63f-4849-a614-66b0ccd665ab (deleted DSA)
        DC object GUID: eae07634-e94b-47b6-a1c2-39c2cb44d221
        4006 consecutive failures since 2005-01-04 01:54:39.
        Last error: 8524 (0x214c):
            The DSA operation is unable to proceed because of a DNS lookup failure.
    BRANCH3\BRANCH3\0ADEL:70163a17-2f67-45ee-a7dd-ebdafb1c7f11 (deleted DSA)
        DC object GUID: 267e815a-2809-43fb-97a4-fc65616f0776
        4006 consecutive failures since 2005-01-04 01:54:39.
        Last error: 8524 (0x214c):
            The DSA operation is unable to proceed because of a DNS lookup failure.

==== KCC LINK FAILURES ==================================
    HUB\BRANCH-HUB-BH
        DC object GUID: 9090b7ce-53a6-4a44-91bf-b50ed232be53
        No Failures.
    BRANCH3\STUDENT3\0ADEL:2ed00423-01e1-4545-9d72-c2d3396e7f28 (deleted DSA)
        DC object GUID: 8332869b-4e65-477b-b8a4-c28ffbaa8810
        No Failures.
    BRANCH1\STUDENT1\0ADEL:04c59341-9d78-45c1-aca6-abf7ccb00d39 (deleted DSA)
        DC object GUID: 0aa9b456-301d-4183-9e38-c4369f2bb03f
        No Failures.

C:\>_
```

The output from the **repadmin /failcache** command is divided into two sections explained in the following table.

| | |
|---|---|
| KCC Link Failures | Lists errors for existing connection links. The ISTG domain controller imports showreps ("repsfroms") data for every bridgehead server in its site. However, the ISTG domain controller does not list errors. The link failure cache is emptied at the beginning of every KCC run and refilled during the course of the current run. |
| KCC Connection Failures | Lists unsuccessful attempts to build connection objects between domain controllers ("reps from" or "reps to"). When you run the **repadmin /failcache** command from the ISTG domain controller, it lists entries that are imported from bridgeheads in the site. At the beginning of each KCC run, the KCC examines each entry in the connection failure cache and tries to DsBind to the failing server. If the bind succeeds, the entry is removed. |

In the example in figure 3.11.4.1, the failures are a result of some topology changes from the past and would continue to exist due to the value of the **replTopologyStayOfExecution** attribute, which determines how long domain controller metadata is retained in Active Directory after a domain controller has been removed.

**Example: Output when there are no failures**

When there are no failures, the output should appears as it does in figure 3.11.4.2.

```
C:\>repadmin /failcache

repadmin running command /failcache against server localhost

==== KCC CONNECTION FAILURES ============================
(none)

==== KCC LINK FAILURES ==================================
(none)

C:\>_
```

**Note**

The **repadmin /failcache** command differs from the **repadmin /showrepl** command in two ways:

- The **repadmin /showrepl** command shows the naming context that is failing.
- The **repadmin /failcache** command does not.

**Repadmin /KCC**

**Repadmin /KCC** forces the KCC to recalculate replication topology for a specified domain controller. By default, this recalculation occurs every 15 minutes.

**Syntax**

```
repadmin /kcc <DC_LIST> [/async]
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp.** |
| **/async** | Specifies that replication will be asynchronous. This means that repadmin starts the replication event, but it does not expect an immediate response from the destination domain controller. Use this parameter to start the KCC and not wait for it to finish. |

**Example 1: Running the KCC on the local domain controller**

```
C:\>repadmin /kcc

repadmin running command /kcc against server localhost

Consistency check on localhost successful.

C:\>_
```

**Example 2: Running the KCC against the ISTG of the HUB site**

```
C:\>repadmin /kcc fsmo_istg:hub

repadmin running command /kcc against server rootdns.contoso.com

Consistency check on rootdns.contoso.com successful.

C:\>_
```

**Example 3: Running the KCC against all the global catalog servers in the forest**

```
C:\>repadmin /kcc GC:

repadmin running command /kcc against server 076cd5dd-e25e-4897-acd2-7c8691621522._msdcs.c
ontoso.com

Consistency check on 076cd5dd-e25e-4897-acd2-7c8691621522._msdcs.contoso.com successful.

repadmin running command /kcc against server 2a92f776-6c0f-4cb4-a111-f5dcd447af6c._msdcs.c
ontoso.com

Consistency check on 2a92f776-6c0f-4cb4-a111-f5dcd447af6c._msdcs.contoso.com successful.

C:\>_
```

**Example 4: Running the KCC against all the domain controllers in the BRANCH2 site**

```
C:\>repadmin /kcc site:branch2

repadmin running command /kcc against server 8168c4c2-bf27-4f92-88ce-3d502b596596._msdcs.c
ontoso.com

Consistency check on 8168c4c2-bf27-4f92-88ce-3d502b596596._msdcs.contoso.com successful.

C:\>_
```

**Repadmin /ISTG**

**Repadmin /ISTG** returns the server name of the ISTG server for a specified site.

**Syntax**

```
repadmin /istg <DC_LIST> [/verbose]
```

| Parameters | Descriptions |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| **/verbose** | Lists detailed information. |

**Example: Display ISTGs in my environment**

```
C:\>repadmin /istg /verbose

repadmin running command /istg against server localhost

Gathering topology from site BRANCH3 (BRANCH3.research.contoso.com):
                Site                 ISTG
      ==================   =================
               BRANCH3              BRANCH3
               BRANCH1              BRANCH1
                   HUB              ROOTDNS
               BRANCH2              BRANCH2

C:\>_
```

In the example in figure 3.11.6, the ISTGs are listed from the perspective of the local domain controller from which the command was run. It is important to note that this information may be different from the perspective of each domain controller, depending on the forest-wide Active Directory convergence time and replication status.

**Repadmin /querysites**

**Repadmin /querysites** use routing information to determine cost of a route from a specified site to another specified site or sites.

**Syntax**

```
repadmin /querysites <FromSiteRDN> <ToSite1RDN> <ToSite2RDN>...]
```

| Parameter | Description |
|---|---|
| <*FromSiteRDN*> | Specifies the relative distinguished name of the site from which the cost is calculated. |
| <*ToSite1RDN*> | Specifies the relative distinguished name of the site to which the cost is calculated. |

**Example 1: Display cost between BRANCH1 and HUB**

```
C:\>repadmin /querysites BRANCH1 HUB
From site: BRANCH1

To Site Name                                                    Cost
------------                                                    ----
HUB                                                             100

C:\>_
```

**Example 2: Display cost between BRANCH1 and BRANCH2**

Due to site link transitivity, the cost from BRANCH1 to BRANCH2 is aggregated by adding the cost from BRANCH1 to HUB (100) with the cost from HUB to BRANCH2 (100).

```
C:\>repadmin /querysites BRANCH1 BRANCH2
From site: BRANCH1

To Site Name                                                    Cost
------------                                                    ----
BRANCH2                                                         200

C:\>_
```

**Example 3: Display cost between BRANCH1 and Branch2**

Note that the relative distinguished name of the site is case sensitive and hence the error.

```
C:\>repadmin /querysites BRANCH1 Branch2
From site: BRANCH1

To Site Name                                                    Cost
------------                                                    ----

C:\>_
```

**Note**

- The relative distinguished name of the site is case sensitive.
- The **repadmin /querysites** parameter does not allow the use of alternate credentials.

**Repadmin /queue**

**Repadmin /queue** displays tasks that are waiting in the replication queue.

**Syntax**

```
repadmin /queue <DC_LIST>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |

**Example: Display the queue length against the local domain controller**

Under normal circumstances this list should always be empty and the command should be run outside of the replication window when troubleshooting domain controller overload was caused due to replication requests.

```
C:\>repadmin /queue

repadmin running command /queue against server localhost

Queue contains 0 items.

C:\>_
```

**Example: Queue contains one item**

```
repadmin running command /queue against server BRANCH-HUB-BH.research.contoso.com

Queue contains 1 items.
Current task began executing at 2005-02-14 12:24:21.
Task has been executing for -1 minutes, -12 seconds.

[36368] Enqueued 2005-02-14 12:24:21 at priority 590

```

**Repadmin /bridgeheads**

**Repadmin /bridgeheads** lists the bridgehead servers for a specified site.

**Syntax**

```
repadmin /bridgeheads [<DC_LIST>] [/verbose]
```

| Parameter | Description |
|---|---|

| | |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| **/verbose** | Lists detailed information. |

For clarity:

- The following example shows only bridgeheads only for the HUB site.
- The following example shows the normal and verbose modes to help compare them.
- "The RPC service is unavailable" status is abbreviated as **RPC.**
- "The operation completed successfully" status is abbreviated as **status.**

**Example 1: Repadmin /bridgeheads rootdns**

```
Bridgeheads for site HUB (rootdns.contoso.com):
Source Site    Local Bridge  Trns         Fail. Time    #    Status
===========    ============  ====     ==============   ===   ======
BRANCH2       BRANCH-HUB-BH   IP 2005-02-14 14:18:52    3    RPC.
Configuration research
BRANCH1       BRANCH-HUB-BH   IP             (never)    0    Success.
Configuration ForestDnsZones DomainDnsZones research
BRANCH3       BRANCH-HUB-BH   IP             (never)    0    Success.
Configuration DomainDnsZones ForestDnsZones research
```

**Example 2: Repadmin /bridgeheads rootdns /verbose**

```
Bridgeheads for site HUB (rootdns.contoso.com):
Source Site    Local Bridge  Trns         Fail. Time    #    Status
===========    ============  ====     ==============   ===   ======
BRANCH2        BRANCH-HUB-BH  IP  2005-02-14 14:18:52   3    RPC.

research       2005-02-14 14:53:15  2005-02-14 14:53:15  0   Success.
```

**How to interpret the data**

**Repadmin /bridgeheads** is run remotely against a domain controller in the HUB site and the output is the perspective of the topology for ROOTDNS. In these examples, we are seeing local bridgehead server **BRANCH-HUB-BH** is having replication problems with the remote bridgehead server in the **BRANCH2** site.

| Fields of interest | Explanation |
|---|---|
| Source Site | Source site from where the local bridge head (inbound) is pulling data. Remember replication is always inbound. |
| Local Bridge | Local Bridge head server for the site for which the tool is displaying results. In the example in figure 3.11.9.2, BRANCH-HUB-BH is the bridgehead server of the HUB site. |
| Trns | In the example in figure 3.11.9.2, the transport is IP. |
| Fail time | This is the last successful replication time. |
| # | Number of failures since the last successful replication time. |

| | |
|---|---|
| Status | Replication status. |
| Naming Context | Directory partition. Remember Bridgeheads are partition specific. |
| Attempt time | Last replication attempt time with the remote bridgehead. |
| Success time | Last successful replication time with the remote bridgehead. |
| #Fail | Number of attempts since the failure per partition. |
| Last result | Latest replication status. |

**Note**

Replication is performed for each partition. But sometimes we do not see the Schema partition listed in the previous example as a naming context (partition) and hence there are no bridgeheads listed. This is not a limitation of the tool; it has to do with the how information is stored in the connection object that is queried to determine the bridgehead. If you see the configuration partition in the output, it is implied that schema is also included because the KCC calculates the configuration and schema partitions to have the same replication topology.

**Repadmin /showmsg**

**Repadmin /showmsg** displays the error message for a given error number.

**Syntax**

```
repadmin /showmsg <Win32Error> | <DSEventID> /NTDSMSG}
```

| Parameter | Description |
|---|---|
| <*Win32Error*> | Returns a short description of the given Win32 error code. |
| <*DSEventID*> **/NTDSMSG** | Returns the actual event log text for the specified event ID. |

**Example: Display the error message for the win32error 1722 and DS event ID 1404**

```
C:\>repadmin /showmsg 1722
1722 = 0x6ba = "The RPC server is unavailable."

C:\>repadmin /showmsg 1404 /ntdsmsg
1404 = 0x57c = "The local domain controller is now the intersite topology genera
enerating and maintaining intersite replication topologies for this site."

C:\>_
```

**Repadmin /viewlist**

By default, this subcommand is used to displays a list of domain controllers. It could also be used to form an Lightweight Directory Access Protocol (LDAP) query to list only objects in the directory.

**Syntax**

```
repadmin /viewlist <DC_LIST> <OBJ_LIST>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| <*OBJ_LIST*> | This parameter takes a distinguished name (DN) or a special keyword that expands into a DN. The keywords are:<br>• **Ncobj:config:** This keyword is the Configuration directory partition for the forest.<br>• **Ncobj:schema:** This keyword is the Schema directory partition for the forest.<br>• **Ncobj:domain:** This keyword is the domain partition DN of the home server.<br>• **Dsaobj**: This keyword is the NTDS settings object of the home server. |

**Example 1: Display all the DC's in the forest**

```
C:\>repadmin /viewlist *
DC_LIST[1] = rootdns.contoso.com
DC_LIST[2] = rootdc01.contoso.com
DC_LIST[3] = BRANCH-HUB-BH.research.contoso.com
DC_LIST[4] = BRANCH1.research.contoso.com
DC_LIST[5] = BRANCH2.research.contoso.com
DC_LIST[6] = BRANCH3.research.contoso.com

C:\>_
```

**Example 2: Display all the Group Policy objects in the domain directory partition for the domain of the domain controller that repadmin is running against**

```
C:\>repadmin /viewlist branch3 ncobj:domain: /subtree /filter:"(objectclass=groupPolicyContainer)"
DC_LIST[1] = branch3
    OBJ_LIST[1] = CN={6AC1786C-016F-11D2-945F-00C04fB984F9},CN=Policies,CN=System,DC=research,DC=contoso,DC=com
    OBJ_LIST[2] = CN={31B2F340-016D-11D2-945F-00C04FB984F9},CN=Policies,CN=System,DC=research,DC=contoso,DC=com

C:\>_
```

Note the usage of **OBJ_LIST** and **OBJ_LIST OPTIONS**. For details please refer to **repadmin /listhelp**.

**Open sessions with the domain controller**

The **repadmin /showctx** command displays a list of computers that have opened sessions with a specified domain controller.

**Syntax**

```
repadmin /showctx <DC_LIST> [/nocache]
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| **/nocache** | Specifies that globally unique identifiers (GUIDs) are left in hexadecimal form. By default, GUIDs are translated into strings. |

**Example: Show open sessions with a DSA**

```
C:\>repadmin /showctx branch1
Caching GUIDs.
..
3 open context handles.

# Subcommands Not Covered Under the Previous Scenarios

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

This topic covers additional subcommands that you can use with repadmin.

**Display replication features**

The **repadmin /bind** command connects to, and displays the replication features for a directory partition on a domain controller.

**Syntax**

```
repadmin /bind <DC_LIST>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |

**Example: Display replication features on the local domain controller, which is running Windows Server 2003**

Note that the LINKED_VALUE_REPLICATION is set to NO because the forest functional level is set to Windows 2000 instead of Windows Server 2003.

```
C:\>repadmin /bind

repadmin running command /bind against server localhost

Bind to localhost succeeded.
Extensions supported:
    BASE                            : Yes
    ASYNCREPL                       : Yes
    REMOVEAPI                       : Yes

```

**Server object GUID (DSA GUID) & Database GUID**

The **repadmin /dsaguid** command returns a server name when given a globally unique identifier (GUID).

**Syntax**

```
repadmin /dsaguid <DC_LIST> <GUID>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |

| | |
|---|---|
| *<GUID>* | Specifies the unique hexadecimal number that identifies the domain controller. The globally unique identifier (GUID) can be retrieved by using the **showreps** operation. |

**Example: Display the domain controller name when given a GUID**
Look at the usage of "." here for *<DC_LIST>*.

```
C:\>repadmin /dsaguid . 1b510929-29d7-4a60-a877-aa64e027bb29

repadmin running command /dsaguid against server localhost

Caching GUIDs.
..
"1b510929-29d7-4a60-a877-aa64e027bb29" = BRANCH1\BRANCH1.

C:\>_
```

Please refer to **repadmin /showrepl** for a detailed explanation and difference between DSA GUID and Database GUID.

**Certificates loaded on a domain controller**
The **repadmin /showcert** command displays the server certificates loaded on a specified domain controller.

**Syntax**
```
repadmin /showcert <DC_LIST>
```

| Parameter | Description |
|---|---|
| *<DC_LIST>* | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about *<DC_LIST>*, see **repadmin /listhelp.** |

**Retired Application partition GUIDs (signature)**
Each domain controller has a naming context signature list. The **repadmin /showncsig** command displays a list of the removed application directory partition GUIDs. An application directory partition can be configured to be held or not held on a particular domain controller by using **ntdsutil.**

**Syntax**
```
repadmin /showncsig <DC_LIST>
```

| Parameter | Description |
|---|---|
| *<DC_LIST>* | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about *<DC_LIST>*, see **repadmin /listhelp.** |

**Example: Display the recently retired ForestDnsZone application directory partition on the local domain controller**

```
C:\>repadmin /showncsig

repadmin running command /showncsig against server localhost

BRANCH3\BRANCH3

Current DC invocationID: ae8ccd6c-c8ad-4c74-b8a5-4aa6c7dfc017
Retired NC invocationID: ae8ccd6c-c8ad-4c74-b8a5-4aa6c7dfc017
NC 439b3266-cb29-42cd-a3b3-d524ec63a618 retired on 2005-02-14 17:03:35 at USN 61676

C:\>_
```

The following information is displayed in figure 3.12.4:

- Partition name
- InvocationID at the time of removal
- Highest update sequence number (USN) at the time of removal
- Date of removal

**Unanswered replication calls**
The **repadmin /showoutcalls** command displays calls that have not yet been answered, made by the specified domain controller to other domain controllers.

**Syntax**
```
repadmin /showoutcalls <DC_LIST>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp.** |

**Example: Hub domain controller waiting for the request to be answered from a spoke domain controller**

```
repadmin running command /showoutcalls against server BRANCH-HUB-BH.research.contoso.
com

BRANCH-HUB-BH.research.contoso.com has 1 outgoing DRS RPC calls in progress:

Call type: DRS_CALL_GET_NC_CHANGES
Target server: 1b510929-29d7-4a60-a877-aa64e027bb29._msdcs.contoso.com
Handle info: bound 1 FromCache 1 InCache 1
Client thread id: 2112
Time call started: 2005-02-16 17:07:34
Call timeout: 5 minutes
Call duration: 0 minutes and 7 seconds
```

**showproxy**
Lists cross domain move proxy objects. When an object is moved to another domain, a marker is left in the old domain indicating that the object used to be there. This is called the proxy.

**Syntax1**
```
repadmin /showproxy <DC_LIST> <NamingContext> [matchstring]
```

**Syntax2**
```
repadmin /showproxy <DC_LIST> <ObjectDN> [matchstring] /movedobject
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp.** |
| <*NamingContext*> | Specifies the distinguished name of the directory partition on the source domain controller. |
| **matchstring** | Specifies the distinguished name of the object. |
| <*ObjectDN*> | Specifies a filter for the output. Type a string of characters that must be present in the distinguished name in order to display the object. |
| **/movedobject** | Displays a history of information from the original domain on a moved object after it has reached the new domain. |

**Retired Database GUIDs (signature)**
The **repadmin /showsig** command displays the retired InvocationIDs on a domain controller. A domain controller changes its InvocationID on being restored or when re-hosting an application partition.

**Syntax**
```
repadmin /showsig <DC_LIST>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp.** |

**Example 1: Simple usage of no retired signatures**

```
C:\>repadmin /showsig rootdns
HUB\ROOTDNS

Current DC invocationID: 076cd5dd-e25e-4897-acd2-7c8691621522

No retired signatures.

C:\>_
```

**Example 2: Simple usage of retired signature**

```
C:\>repadmin /showsig

repadmin running command /showsig against server localhost

BRANCH3\BRANCH3

Current DC invocationID: 23a13880-47de-4602-ac24-212fa6c68fdd
ae8ccd6c-c8ad-4c74-b8a5-4aa6c7dfc017 retired on 2005-02-15 18:49:09 at USN 63018

C:\>_
```

**Convert directory service time to readable time**

The **repadmin /showtime** command converts a directory service time value to string format for both the local and the Coordinated Universal Time (UTC) time zones.

**Syntax**

```
repadmin /showtime <DSTimeValue>
```

| Parameter | Description |
|---|---|
| <*DSTimeValue*> | Specifies the time value that needs to be converted. |

| **Note** |
|---|
| With parameters omitted, **repadmin /showtime** displays the current system time in both the directory service format and string format. |

**Example 1: Usage with directory service time format**

```
C:\>repadmin /showtime 12753060350
12753060350 = 0x2f82441fe = 05-02-16 20:45.50 UTC = 2005-02-16 15:45:50 local

C:\>_
```

**Example 2: Current system time**

```
C:\>repadmin /showtime
12753060520 = 0x2f82442a8 = 05-02-16 20:48.40 UTC = 2005-02-16 15:48:40 local

C:\>
```

**Active Directory domains trusted by domain controller**

The **repadmin /showtrust** command lists all Active Directory domains (in the same forest) that are trusted by the specified domain controller's domain.

**Syntax**

```
repadmin /showtrust <DC_LIST>
```

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller, or a list of domain controllers, separated by a space. For details about <*DC_LIST*>, see **repadmin /listhelp**. |

**Example: Display Active Directory domains that are trusted by the domain of the local domain controller**

```
C:\>repadmin /showtrust

repadmin running command /showtrust against server localhost

Domain Trust Info:
    TRUSTED   : DC=contoso,DC=com
    TRUSTED   : DC=research,DC=contoso,DC=com

C:\>_
```

**Linked Distinguished Name values**

The **repadmin /showvalue** command is used to list only linked distinguished name values. Linked distinguished name values can also be obtained by the **repadmin /showobjmeta** subcommand with the **/linked** switch.

**Syntax**

```
repadmin /showvalue <DC_LIST> ObjectDN <AttributeName> <ValueDN> [/nocache]
```

| Parameter | Description |
|---|---|

| | |
|---|---|
| *<DC_LIST>* | Specifies the host name of a domain controller, or a list of domain controllers, separated by a space. For details about **DC_LIST**, see **repadmin /listhelp**. |
| *<ObjectDN>* | Specifies the distinguished name of the object. |
| *<AttributeName>* | Specifies a single attribute whose value you want to display. |
| *<ValueDN>* | Specifies the distinguished name of the attribute that is displayed. |
| **/nocache** | Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings. |

**Example: Display members of the Domain Admins group**

Note that showvalue lists value for only forward links. Backward links (such as **memberOf**) are not obtained.

```
C:\>repadmin /showvalue rootdns "CN=Domain Admins,CN=Users,DC=contoso,DC=com" /verbose
3 entries.

# Oldhelp

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Oldhelp displays a list of the operations that have been deprecated in the Windows Server 2003 version of repadmin.

**sync**
Starts a replication event for the specified directory partition between the source and destination domain controllers. The source universally unique identifier (UUID) can be determined when viewing the replication partners by using the showreps operation.

**Syntax**
```
repadmin /sync <NamingContext> <DestDC> <SourceDCUUID> [/force] [/async] [/full] [/addref] [/allsources]
```

| Parameter | Description |
|---|---|
| <*NamingContext*> | Specifies the distinguished name of the directory partition. |
| <*DestDC*> | Specifies the host name of the domain controller (Directory Server Agent) with which you want to replicate. |
| <*SourceDCUUID*> | Specifies the unique hexadecimal number that identifies the object whose changes will be listed. The objectGUID can be retrieved by using the showreps operation. |
| **/force** | Overrides the normal replication schedule |
| **/async** | Specifies that the replication will be asynchronous. This means that repadmin starts the replication event, but it does not expect an immediate response from the destination domain controller. Use this parameter when there are slow links between domain controllers. |
| **/full** | Forces a full replication of all objects from the destination domain controller. |
| **/addref** | Directs the source to check for a notification entry on the source. If the source does not have a notification entry for this destination, one is added. |
| /**allsources** | A given destination can have multiple sources for the same naming context. Directs the destination to sync with all sources instead of just one. |

**propcheck**
Compares properties of specified domain controllers to determine if they are up-to-date with each other. The source domain controller contains the original information that needs to be checked. The destination domain controller data will be compared to the source domain controller data.

**Syntax**
```
repadmin /propcheck <NamingContext> <OriginatingDCInvocationID> <OriginatingUSN> <DestDC>
```

| Parameter | Description |
|---|---|
| <*NamingContext*> | Specifies the distinguished name of the directory partition on the source domain controller. |
| <*OriginatingDCInvocationID*> | Specifies the unique hexadecimal number that identifies an object on a source domain controller. The InvocationID can be retrieved by using the showreps operation. |
| <*OriginatingUSN*> | Specifies the update sequence number (USN) for the object on the source domain controller. The USN is for the object whose InvocationID is already listed. |
| *DestDC* | Specifies the host name of the destination domain controller from which to enumerate the host domain controllers. |

**getchanges**
Displays changes from a specified directory partition or changes to a specified object. Syntax 1 saves changes to a directory partition. If this information is saved to a file the getchanges operation can be run again for comparison. Syntax 2 lists changes to a specified object.

**Syntax1**
```
repadmin /getchanges <NamingContext> <SourceDC> [/cookie: <File>] [/atts: <attribute1>,<attribute2>,...]
```

**Syntax2**
```
repadmin /getchanges <NamingContext> <DestDC> <SourceDCObjectGUID> [/verbose] [/statistics] [/noincremental]
[/objectsecurity] [/ancestors] [/atts: <attribute1>,<attribute2>,...] [/filter: <ldap filter>]
```

| Parameter | Description |
|---|---|
| <*NamingContext*> | Specifies the distinguished name of the directory partition. |
| <*SourceDC*> | Specifies the host name of the domain controller that hosts the directory partition whose changes you want to view. |
| **cookie:** <*File*> | Specifies a name for the file to which list changes are saved. |
| **atts:** <*attribute1*>,<*attribute2*> | Returns only the attributes specified. Separate each listed attribute with a comma. |
| <*DestDC*> | Specifies the host name of the destination domain controller from which to enumerate the host domain controllers. |
| <*SourceDCObjectGUID*> | Specifies the unique hexadecimal number that identifies the object whose changes will be listed. The objectGUID can be retrieved by using the showreps operation. |
| **/verbose** | Lists detailed information. |
| **/statistics** | Displays a summary of information about changes instead of a list of individual changes. |
| **/noincremental** | Returns changes in value change format, which lists current values for attributes as well as what attributes have been added or deleted. If not specified, changes are returned in attribute change format, which shows only the current value of the attribute. |
| **/objectsecurity** | Overrides the need for the Get Changes right to the directory partition. By default this right is needed to run the **/getchanges** parameter. However, only changes that the currently logged on user has the rights to view are displayed. |
| **/filter:** <*ldap filter*> | Returns only those changes that meet the filter requirements. |
| **/ancestors** | Returns changes in USN order |

| **Note** |
|---|
| The information from Syntax1 can be saved to a file for later comparison. |

**showreps**
Displays the replication partners for each directory partition on the specified domain controller. Helps the administrator build a visual representation of the replication topology and see the role of each domain controller in the replication process.

**Syntax**
```
repadmin /showreps <NamingContext> <DC> <SourceDCObjectGUID> [/verbose] [/nocache] [/repsto] [/conn] [/all]
```

| Parameter | Description |
|---|---|
| <*NamingContext*> | Specifies the distinguished name of the directory partition. |
| *DC* | Specifies the host name of the domain controller. |

| | |
|---|---|
| *<SourceDCObjectGUID>* | Specifies the unique hexadecimal number that identifies the object whose replication events will be listed. |
| **/verbose** | Lists detailed information. |
| **/nocache** | Specifies that globally unique identifier (GUIDs) are left in hexadecimal form. By default, GUIDs are translated into strings. |
| **[/repsto]** | Lists the domain controllers that pull replication information from the specified directory partition. |
| **/conn** | Displays the connection objects associated with each link. |
| **/all** | Displays all replication partners. |

**showvector**
Displays the highest USN for the specified domain controller. This information shows how up-to-date a replica is with its replication partners.

**Syntax**
```
repadmin /showvector <NamingContext> <DC> [/nocache] [/latency]
```

| Parameter | Description |
|---|---|
| *<NamingContext>* | Specifies the distinguished name of the directory partition. |
| *<DC>* | Specifies the host name of the domain controller. |
| **/nocache** | Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings. |
| **/latency** | Sorts the information by the time required to complete the replication. By default the information is sorted by USN. |

**showmeta**
Displays the replication metadata for a specified object stored in Active Directory such as attribute ID, version number, originating and local Update Sequence Number (USN), and originating server's GUID and Date and Time stamp. By comparing the replication metadata for the same object on different domain controllers, an administrator can determine whether replication has taken place.

**Syntax**
```
repadmin /showmeta <ObjectDN> <DC> [/nocache] [/linked]
```

| Parameter | Description |
|---|---|
| *<ObjectDN>* | Specifies the distinguished name of the object. |
| *<DC>* | Specifies the host name of the domain controller that hosts the object. |
| **/nocache** | Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings. |
| **/linked** | Displays metadata associated with, but not stored with the specified object. |

# Administer Passwords and Password Replication Policy for Read-Only Domain Controllers with Repadmin.exe

Published: March 15, 2010

Updated: March 15, 2010

Applies To: Windows Server 2008, Windows Server 2008 R2

This topic describes the following commands that were added to Repadmin.exe in Windows Server 2008 to manage passwords and Password Replication Policy (PRP) for read-only domain controllers (RODCs). RODCs are available in Windows Server 2008 and Windows Server 2008 R2.

Repadmin.exe is built into Windows Server 2008 and Windows Server 2008 R2. It is available if you have the Active Directory Domain Services (AD DS) server role or the Active Directory Lightweight Directory Services (AD LDS) server role installed. It is also available if you install the Active Directory Domain Services Tools that are part of the Remote Server Administration Tools (RSAT). For more information, see How to Administer Microsoft Windows Client and Server Computers Locally and Remotely (http://go.microsoft.com/fwlink/?LinkID=177813).

In Windows Server 2008 and Windows Server 2008 R2, you must run command-line-based tools from an elevated command prompt. To open an elevated Command Prompt using the credentials of a Domain Admin, click **Start**. In **Start Search**, type **runas /user:<domainName>\<domainAdminAccountUser> cmd**, and then press ENTER. Replace **<domainName>** with the domain name, and replace **<domainAdminUser>** with the name of a user account that is a member of the Domain Admins group in that domain.

- repadmin /prp
- repadmin /rodcpwdrepl

For more information about managing passwords and the PRP for RODCs, see Administering the Password Replication Policy (http://go.microsoft.com/fwlink/?LinkId=185778).

**repadmin /prp**
You can use this command to view or modify the PRP for an RODC. The PRP determines which account passwords are allowed to be cached on an RODC and which account are denied from being cached.

**Syntax**

```
Repadmin /prp [operation] RODC [additional arguments]
```

**Operations**
The **repadmin /prp** command can perform the following operations:

- Add
- Delete
- Move
- View

Additional arguments are available for each operation.

**Add**
Adds the specified security principal to the **msDS-RevealOnDemandGroup** attribute that is associated with the RODC. (This attribute is also known as the Allowed List.)

**Note**

You cannot use **repadmin /prp** commands to add an account to the Deny List or remove an account from the Deny List. To configure the Deny List, you can use the Active Directory Users and Computers snap-in or you can create a script. For example, if you want to deny members of the group RODC2Admins from caching passwords on RODC2, which is located in the Branch2 organizational unit (OU) of hq.cpandl.com, you can use the following script:

```
'The following items specify to Clear, Update, Append, or Delete a property of an
Active Directory object
Const ADS_PROPERTY_CLEAR = 1
Const ADS_PROPERTY_UPDATE = 2
Const ADS_PROPERTY_APPEND = 3
Const ADS_PROPERTY_DELETE = 4

Const ATT = "msDS-NeverRevealGroup"
'The setting for ATT determines which list will be modified
'msDS-AuthenticatedToAccountlist is for the authenticated to or Auth2 list
'msDS-RevealedList is for the password revealed or cached list
'msDS-RevealOnDemandGroup is for the allowed to authenticate list
'msDS-NeverRevealGroup is for the denied from authenticating list

'PRPObj defines the object that needs to be modified in the PRP list
PRPObj = "CN=RODC2Admins,OU=Branch2,DC=hq,DC=cpandl,DC=com"

'RODCObj defines the RODC for which the PRP should be modified
RODCObj = "LDAP://CN=RODC2,OU=Domain Controllers,DC=hq,DC=cpandl,DC=com"

'Sets the object to modify based on the LDAP path set in RODCObj
Set objComputer = GetObject(RODCObj)

'Implements the change, which, depending on the word after ADS_PROPERTY_, is a CLEAR,
UPDATE, APPEND, or DELETE operation
objComputer.PutEx ADS_PROPERTY_APPEND, ATT, Array(PRPObj)
objComputer.SetInfo

'Confirms that the modification has taken place (this is optional)
wscript.echo "Modified list attributes for object " & PRPObj

'Closes the script
wscript.quit(0)
```

**Syntax**

```
repadmin /prp add <RODC> allow <PRINCIPAL>
```

**Additional parameters**

| Parameter | Definition |
|---|---|
| <RODC> | Specifies the host name of the RODC. You can specify the single-label host name or the fully qualified domain name (FQDN). In addition, you can use an asterisk (*) as a wildcard character to specify multiple RODCs in one domain. |
| <PRINCIPAL> | Specifies the name of the security principal that you want to add to the Allowed List. |

**Delete**

Deletes one or more specified security principals from the **msDS-AuthenticatedToAccountList** attribute or from the **msDS-RevealOnDemandGroup** attribute that is associated with the RODC. (The **AuthenticatedToAccountList** attribute is also known as the Authenticated to List, and the **msDS-RevealOnDemandGroup** attribute is also known as the Allowed List.)

**Syntax**

```
repadmin /prp delete <RODC> allow {<PRINCIPAL>|/all}
repadmin /prp delete <RODC> auth2 /all
```

**Additional parameters**

| Parameter | Definition |
|---|---|

| | |
|---|---|
| <RODC> | Specifies the host name of the RODC. You can specify the single-label host name or the FQDN. In addition, you can use an asterisk (*) as a wildcard character to specify multiple RODCs in one domain. |
| <PRINCIPAL> | Specifies the name of the security principal that you want to delete from the Allowed List. Specify **/all** to have the operation delete all security principals. |
| /all | Specifies all security principals. You cannot delete only one security principal from the **msDS-AuthenticatedToAccountList** attribute. |

**Move**

Moves all the security principals from the **msDS-AuthenticatedToAccountList** attribute to the specified group. If the group does not exist, this command creates the group. If necessary, this command also adds the group to the **msDS-RevealOnDemandGroup** attribute of the RODC. (The **msDS-AuthenticatedToAccountList** attribute is also known as the Authenticated To List, and the **msDS-RevealOnDemandGroup** attribute is also known as the Allowed List.)

**Syntax**

```
repadmin /prp move <RODC> <Group> [/noauth2cleanup] [/users_only | /comps_only]
```

**Additional parameters**

| Parameter | Definition |
|---|---|
| <RODC> | Specifies the host name of the RODC. For this operation, you can specify the single-label host name or the FQDN. |
| <Group> | Specifies the name of the security group to which you want to move the security principals. If the security group does not exist, this command creates the security group in the built-in **Users** container. You can specify the name of the security group but not the distinguished name. |
| /noauth2cleanup | Retains the list of security principals in the **msDS-AuthenticatedToAccountList** attribute after the Move operation is complete. By default, the **msDS-AuthenticatedToAccountList** attribute is cleared. |
| /users_only | Moves only user accounts from the **msDS-AuthenticatedToAccountList** attribute to the specified group. The group is then added to the **msDS-RevealOnDemandGroup** attribute. |
| /comps_only | Moves only computer accounts from the **msDS-AuthenticatedToAccountList** attribute to the specified group. The group is then added to the **msDS-RevealOnDemandGroup** attribute. |

**View**

Displays the security principals in the specified list or displays the current PRP setting (allowed or denied) for a specified user.

**Syntax**

```
repadmin /prp view <RODC> {<List_Name>|<User>}
```

**Additional parameters**

| Parameter | Definition |
|---|---|
| <RODC> | Specifies the host name of the RODC. You can specify the single-label host name or the FQDN. In addition, you can use an asterisk (*) as a wildcard character to specify multiple RODCs in one domain. |
| <List_Name> | Specifies all the security principals that are in the list that you want to view. The valid list names are as follows:<br>• auth2: The list of security principals that the RODC has authenticated.<br>• reveal: The list of security principals for which the RODC has cached passwords.<br>• allow: The list of security principals in the **msDS-RevealOnDemandGroup** attribute. The RODC can cache passwords for this list of security principals only.<br>• deny: The list of security principals in the **msDS-NeverRevealGroup** attribute. The RODC cannot cache passwords for any security principals in this list. |

| | |
|---|---|
| <User> | Specifies the effective PRP setting (allowed or denied) for the specified user. You can specify the user name only or the distinguished name. |

**Example 1: View the PRP of an RODC**
The following examples show how to view the accounts that are configured in the PRP that applies to an RODC with the host name RODC2 in the domain hq.cpandl.com.

To view the accounts that are allowed to have their passwords cached on the RODC, use the following command:

```
repadmin /prp view rodc2.hq.cpandl.com allow
```

To view the accounts that are denied from having their passwords cached on the RODC (also known as the Deny list), use the following command:

```
repadmin /prp view rodc2.hq.cpandl.com deny
```

**Example 2: View accounts that an RODC has authenticated**
To review the list of authenticated accounts for RODC2 in the hq.cpandl.com domain, use the following command:

```
repadmin /prp view rodc2.hq.cpandl.com auth2
```

**Example 3: Clear the list of authenticated accounts**
Note that this command does not actually remove account passwords from an RODC. It only deletes the list of those accounts.

There is no mechanism to erase passwords after they are cached on an RODC. If you want to clear a password that is stored on an RODC, reset the password in the hub site. This way, the password that is cached in the branch will no longer be valid for accessing any resources in the hub site or other branches. In the branch that contains the RODC on which the password may have been compromised, the password will still be valid for authentication purposes until the next replication cycle, at which time its value that is stored on the RODC will be changed to Null. The new password will be cached only after the user authenticates with it—or the new password is prepopulated on the RODC—and if the PRP has not been changed.

To clear the list of authenticated accounts for RODC2, use the following command:

```
repadmin /prp delete rodc2 auth2 /all
```

**Example 4: Configure the PRP**
To add an account named RODC2users from a top-level OU named West in the domain hq.cpandl.com to the Allowed List (or to remove it from the Allowed List) for an RODC computer with a hostname of RODC2, use one of the following commands:

**Note**

To find the Lightweight Directory Access Protocol (LDAP) distinguished name of a directory object from the command line, you can use the **dsquery** command. For example, if you want to find the distinguished name of a group that has "RODC" as part of its name from a computer in the local domain, you can run the command **dsquery group –name *RODC*.** The asterisks around "RODC" indicate that any number of characters can come before or after the letters RODC. If instead you want to find the distinguished name of a computer or user, substitute either the word **computer** or the word **user** (respectively) for the word **group** in the command. For more information about **dsquery** command syntax, see Dsquery (http://go.microsoft.com/fwlink/?LinkId=120196).

To allow the account RODC2users to be cached on RODC2, use the following command:

```
repadmin /prp add rodc2.hq.cpandl.com allow
cn=RODC2users,ou=west,dc=hq,dc=cpandl,dc=com
```

To remove the account from the Allowed List, use the following command:

```
repadmin /prp delete rodc2.hq.cpandl.com allow
cn=RODC2users,ou=west,dc=hq,dc=cpandl,dc=com
```

**Example 5: Move accounts that an RODC has authenticated to the Allowed RODC Password Replication Policy Group**
To move the current list of only the users from RODC2 to the Allowed List, use the following command:

```
Repadmin /prp move rodc2 /users_only
```

**Note**

| |
|---|
| You cannot selectively move entries from the Auth2 list to the Allowed List by using the **repadmin /prp move** command. However, when you have created an appropriate group, you can use Active Directory Users and Computers, Dsadd, and similar tools to add users or computers to that group. |

**Example 6: View accounts with cached passwords on an RODC**

To see the accounts with cached passwords on an RODC with the host name RODC2 in the domain contoso.com, use the following command:

```
repadmin /prp view rodc2.contoso.com reveal
```

| **Important** |
|---|
| If you have a large number of accounts cached, the **repadmin /prp view <hostname> reveal** command might return only a subset of the accounts. For more information, see Repadmin /PRP might return only a subset of accounts (http://go.microsoft.com/fwlink/?LinkId=185775). |

**repadmin /rodcpwdrepl**

Triggers replication of passwords for the specified users from the source (Hub site domain controllers) to one or more RODCs.

For each destination RODC, the ability to cache the user's password is evaluated before the operation succeeds. In other words, the specified user must be in the Allowed RODC Password Replication Group and not be a member of the Denied RODC Password Replication Group for the destination RODC. You can specify passwords for multiple users, but if a user's password is not allowed to be cached for a destination RODC, the request for that specific user and destination RODC will fail.

**Syntax**

```
Repadmin /rodcpwdrepl <hostnameRODC> <hostnameWDC> <User1LdapPath> <Computer1LdapPath> <UserNLdapPath>
<ComputerNLdapPath>
```

| Parameters | Definitions |
|---|---|
| <hostnameRODC> | The host name or FQDN of the target RODC's password cache that you want to prepopulate. If you are running the command from outside the target domain, use the FQDN. |
| <hostnameWDC> | The host name or FQDN of the writable domain controller that is the replication partner of the RODC. If you are running the command from outside the target domain, use the FQDN. |
| <User1LdapPath> | The LDAP distinguished name of a user account password that you want to prepopulate. |
| <Computer1LdapPath> | The LDAP distinguished name of a computer account whose password that you want to populate. You must add the computer accounts of the users or they will not be able to log on. |
| <UserNLdapPath> | The LDAP distinguished name of another user account password that you want to populate. |
| <ComputerNLdapPath> | The LDAP distinguished name of another computer whose account password you want to prepopulate. You must add the computer accounts of the users or they will not be able to log on. |

**Example**

The following command prepopulates the password cache for an RODC named RODC2 in the domain hq.cpandl.com, using the writeable domain controller named WS2008A to transfer the passwords for a user account for Mike Danseglio (MikeDan) and his computer named MDVista1. The MikeDan account is in a top-level OU named B1 Users, and the MDVista1 account is in the default Computers container.

```
repadmin /rodcpwdrepl rodc2.hq.cpandl.com ws2008a.hq.cpandl.com "cn=mikedan,ou=b1
users,dc=hq,dc=cpandl,DC=com" cn=mdvista1,cn=Computers,dc=hq,dc=cpandl,dc=com
```

# Repadmin for Experts

Updated: July 10, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

The previous topics in this guide have looked at how an administrator can use **repadmin** to view the replication topology (sometimes referred to as **Reps-From** and **Reps-To**) as seen from the perspective of each domain controller, monitor forest-wide replication, diagnose replication problems, and perform miscellaneous tasks.

The following sections are used for advanced operations only. These commands have the potential to break your Active Directory installation, and they should be used only under the expert guidance of Microsoft Customer Support Service representative or engineer.

**Add, Modify, or Delete replication links**

During normal operation, the Knowledge Consistency Checker (KCC) automatically manages the replication topology for each naming context held on domain controllers.

Although in normal practice this should not be necessary, repadmin can be used to manually create the replication topology. This topology would be temporary in nature by default and would last until the next time the KCC is run. So we need to engage these steps only during troubleshooting issues related to Active Directory replication.

| **Note** |
| --- |
| During the normal course of operations, there is no requirement for manual creation of the replication topology. Incorrect use of this tool may adversely impact the replication topology. |

**Syntax**

```
Repadmin /add <Naming Context> <Dest DC> <Source DC> [/asyncrep] [/syncdisable] [/dsadn:< Source DC DN>]
[/transportdn:< Transport DN>] [/mail] [/async] [/readonly]

Repadmin /mod <Naming Context> <Dest DC> <Source GUID> [/readonly] [/srcdsaaddr:< dns address>]
[/transportdn:< Transport DN>] [+nbrflagoption] [-nbrflagoption]

Repadmin /delete <Naming Context> <Dest DC> [<Source DC Address>] [/localonly] [/nosource] [/async]
```

The following table lists the purpose for each of the subcommands.

| Subcommand | Purpose |
| --- | --- |
| **add** | The **add** command will create a **RepsFrom** attribute on the destination domain controller for the specified naming context and initiate a replication request. During a normal replication cycle, the destination domain controller will request updates from the source domain controller. |
| **mod** | The **mod** command will modify the **RepsFrom** attribute on the destination domain controller for the specified naming context and initiate a replication request. During a normal replication cycle, the destination domain controller will request updates from the source domain controller. |
| **delete** | The **delete** command will remove a **RepsFrom** attribute on the destination domain controller for the specified naming context. |

The following table lists the parameters that can be used with the subcommands.

| Parameter | Description |
| --- | --- |
| *<Naming Context>* | Specifies the distinguished name of the directory partition. |
| *<Dest DC>* | Domain controller to which the link is created. |
| *<Source DC>* | Domain controller from which to source the partition. |

| | |
|---|---|
| **asyncrep** | Queue the replication event, but do not wait for the replication to complete before you return control to the user. |
| **syncdisable** | Add the **RepsFrom** attribute but do not participate in the replication cycle. To perform replication between the destination and source domain controllers, **repadmin /sync /force** must be used. |
| **/dsadn:**<<*Source DC DN*> | |
| **transportdn** | The distinguished name of the Inter Site Message transport, only used for mail-based replication. |
| **mail** | specify that the replication is mail-based, therefore requires the **/transportdn** option. |
| **async** | Queue the **add/delete** operation without interrupting the current replication cycle and return control to the user. |
| **readonly** | Specify that the partition is read-only. |
| **/srcdsaaddr:**<*dns address*> | |
| **nbrflagoption** | |
| **localonly** | Do not delete the corresponding **RepsTo** attribute on the source Directory System Agent (DSA). |
| **nosource** | When you remove a read-only naming context such as the global catalog, the associated data stored in the directory is removed in blocks of 500 objects. This allows the **/delete** command to be re-executed without having to specify the Source DSA to remove the remaining objects. |

When you create temporary replication links between replication partners, the process could fail if the KCC starts while you are performing the procedure. The KCC will delete any replication links for which no corresponding connection object exists.

Because these commands can take a very long time to complete as they trigger the replication of the corresponding naming context, it is important to ensure that KCC do not disturb the process. This is where you would use +DISABLE_NTDSCONN_XLATE which effectively disables capability for the KCC to translate connection objects to replication links.

**Add, Modify, or Delete outbound replication partners**

Similar to inbound replication (**Reps-From**) partners, outbound replication (**Reps-To**) partners are instantiated from connection objects by a process called "Connection Translation."

Both **Reps-From** and **Reps-To** attributes are for each partition and they are not replicated. **Reps-To** is only needed when the destination requires the source to notify him that there is a change in the partition at the source, and the destination should synchronize. Because **Reps-To** attributes are used for notification, if the destination has a **Reps-From** marked NO_NOTIFY, then the source will not have a **Reps-To**.

Depending on the underlying operating system, sometimes you might see outbound partners lingering. While Windows Server 2003 takes care of this, Windows 2000 would need some help cleaning out lingering outbound partners.

**Syntax**

```
Repadmin /addrepsto <Naming Context> <DC> <Reps-To DC> <Reps-To DC GUID> Repadmin /updrepsto <Naming Context>
<DC> <Reps-To DC> <Reps-To DC GUID> Repadmin /delrepsto <Naming Context> <DC> <Reps-To DC> <Reps-To DC GUID>
```

The following table lists the purpose for each of the subcommands.

| Subcommand | Purpose |
|---|---|
| **addrepsto** | This will create a **Reps-To** attribute on the domain controller for the specified naming context. Ordinarily there is no requirement to perform this command as the KCC will automatically create the **Reps-To** attributes on destination DSAs based on other DSAs **Reps-From** entries. |
| **updrepsto** | This will update the **Reps-To** attribute on the domain controller for the specified naming context. More specifically it updates the network address used by the source DSA to contact the destination DSA. |

| | |
|---|---|
| **delrepsto** | Delrepsto deletes the **Reps-To** attribute on the domain controller for the specified naming context. |

The following table lists the parameters that can be used with the subcommands.

| Parameter | Description |
|---|---|
| <*Naming Context*> | Specifies the distinguished name of the directory partition. |
| <*DC*> | The domain controller on which the **Reps-To** attribute is modified. |
| <*Reps-To DC*> | Outbound replication partner. |
| <*Reps-To DC GUID*> | DSA globally unique identifier (GUID) of outbound replication partner. |

**Hosting and unhosting read-only partitions**

Hosting and unhosting global catalog partitions is convenient, especially when you want to ensure a faster global catalog removal process. As noted in the following table, these subcommands will also facilitate removal of lingering objects from Active Directory.

| | |
|---|---|
| Global catalog removal process | In Windows 2000 versions earlier than Service Pack 4 (SP4), when the IS_GC bit is turned off, the KCC deletes the read-only objects at a rate of only 500 for each time the KCC runs, which allows a maximum of 2000 object removals for each hour. This presents some challenges in large environments. In order to make the global catalog removal faster, you could potentially remove one partition at a time by using the unhost subcommand. |
| Lingering Objects | A lingering object is an object that is present on one replica, but on another replica it has been deleted and removed from the directory by the garbage collection process.<br><br>When lingering object exists only in one or more read-only naming contexts (global catalog), it makes it all the more difficult to delete the object. Clearing the IS_GC bit may not always be appropriate, because it removes all read-only naming contexts from the global catalog server.<br><br>Unhosting and rehosting a read-only naming context is therefore sometimes considered to be a good solution, especially because you could specify the source to be a good replica that does not contain lingering objects. |

**Syntax**

```
Repadmin /rehost <DC_LIST> <Naming Context> <Good Source DC Address> [/application] Repadmin /unhost
<DC_LIST> <Naming Context> Repadmin /removesources <DC_LIST> <Naming Context>
```

The following table lists the purpose for each of the subcommands.

| Subcommand | Purpose |
|---|---|
| **rehost** | Add a specific read-only partition to a global catalog server. |
| **unhost** | Remove a specific read-only partition from a global catalog server. |
| **removesources** | Removes all replication links for a given naming context. This does not delete the connection objects, so the KCC will build new links on it regular cycle as required. |

The following table lists the parameters that can be used with the subcommands.

| Parameter | Description |
|---|---|
| <*DC_LIST*> | Specifies the host name of a domain controller or a list of domain controllers separated by a space that the object will be replicated to. For details about <*DC_LIST*>, see **repadmin /listhelp**. |
| <*Naming Context*> | Specifies the distinguished name of the directory partition. |

| | |
|---|---|
| *<Good Source DC Address>* | Specify the source domain controller. |
| **/application** | Application directory partition |

**Detecting and removing lingering objects**

There are multiple methods that are available to detect or remove lingering objects from Active Directory. This depends on the operating system version that the domain controller is running. Repadmin could be used to detect or remove lingering objects from a directory partition when the source and destination domain controllers are running Windows Server 2003 and therefore the scope here is limited to the following:

- Introduction to lingering objects
- Repadmin usage in Windows Server 2003

A lingering object is an object that is present on one replica, but on another replica it has been deleted and removed from the directory by the garbage collection process.

This condition can occur for a variety of reasons including:

- Prolonged misconfigurations (such as those that cause event ID 1311 messages)
- Prolonged errors in name resolution, authentication or the replication engine that block inbound replication.
- Bringing a domain controller online after it has been offline for a period greater than the **TombStone Lifetime** (TSL).
- Advancing system time or reducing TSL values in an attempt to accelerate garbage collection before end-to-end replication has taken place for all naming contexts in the forest.

Symptoms that you may have lingering objects:

- Active Directory replication is prevented from occurring.
- A user account that no longer exists still appears in the Global Address list for E-mail clients.
- A universal group that no longer exists still appears in a user's access token.
- E-mail messages cannot be delivered due to duplicate e-mail address on two different user objects.

Regardless of the reason, a deleted object can remain on a domain controller in either of the following circumstances:

- A domain controller goes offline immediately prior to the deletion of an object on another domain controller, and remains offline for a period that exceeds the tombstone lifetime.
- A domain controller goes offline immediately following the deletion of an object on another domain controller but prior to receiving replication of the tombstone, and remains offline for a period that exceeds the tombstone lifetime.

What to do with a lingering object?

Determining what to do with a lingering object depends on whether or not it was intended.

| Action | Explanation |
|---|---|
| Unintended | Use repadmin to delete the lingering object on a domain controller that is running Windows Server 2003. |

| | |
|---|---|
| Intended | Change the replication consistency on the inbound domain controller (DC). The object will be re-animated on this DC. See strict and loose replication consistency below |

**Strict and loose replication consistency**

If the attributes of a lingering object never change, the object is never considered for replication. However, if an attribute changes, the attribute is considered for outbound replication. The problem with an attribute update for a lingering object is that the receiving domain controller does not hold the object for the attribute being replicated. An update cannot be performed because the entire object does not exist on the receiving domain controller. What happens next depends on the replication consistency set on the domain controller.

| Replication consistency | Explanation |
|---|---|
| Loose | When replication consistency is set to loose, the receiving domain controller detects that it does not have the object for the attribute that is being replicated. The inbound partner requests the entire object from the outbound partner, and reanimates the object on its copy of the directory. The same process repeats on all domain controllers that do not have a copy of the object. This mechanism can be used to cause lingering objects to "reanimate" across the entire forest. If a lingering object is discovered and its presence is intended, then perform any update to the object. As long as replication consistency is set to loose on all domain controllers, the object will be reanimated as it replicates around the forest. "Loose replication consistency" is the default for Windows 2000 domain controllers, with the exception of domain controllers that have the MS01-044 security rollup package installed. For more information about the MS01-044 security rollup package, see article 297860 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkID=122508). |
| Strict | The default behavior for domain controllers that run Windows Server 2003 (and domain controllers that are upgraded from Windows NT 4.0) is to block inbound replication for each naming context when a domain controller receives an update to an object that it does not have. Replication is halted in the naming context for the object until the lingering object is removed or the replication mode is set to "loose." |

**Storage for Consistency Setting**

The setting for replication consistency is in the registry on each domain controller.

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters

Entry name: Strict Replication Consistency

Data type: REG_DWORD

Values: 1 for enabled; 0 for disabled

Default: 1 (enabled)

**Note**

There was a post-SP2 hotfix (also included in the security rollup package from November 2001) that used a different registry value. A setting of 0 will not recreate the missing object (strict), and a setting of 1 will create the missing object. This value is only needed with the November version of the hotfix.

- Value Name: Correct Missing Objects
- Data type: REG_DWORD
- Value data: 1

The repadmin /removelingeringobjects command does the following:

- Designates an up-to-date domain controller as the authority.
- Compares the Active Directory database objects on the authoritative server with the objects that are on the suspected domain controller that contains the lingering objects.

- With **/advisory_mode**, the subcommand logs the potential deletions to the Directory Service log.
- Without **/advisory_mode**, the subcommand removes the lingering objects.

**Syntax**

```
Repadmin /removelingeringobjects <Dest_DC_LIST> <Source DC GUID> <NC> [/ADVISORY_MODE]
```

| Parameter | Description |
|---|---|
| *<Dest_DC_LIST>* | The domain controller that is suspected to have lingering objects. |
| *<Source DC GUID>* | Source domain controller GUID used to compare with the suspected domain controller. |
| *<NC>* | Specifies the distinguished name of the directory partition. |
| **/ADVISORY_MODE** | Read-only mode. |

| **Note** |
|---|
| During lingering object removal, Event ID 1937 is logged to the Directory Service log. This information includes the source domain controller, the objects that are removed, and a total count of all the objects that are removed. |

**Advanced domain controller options**

By using the option subcommand, we could change the **options** attribute stored on the NTDS Settings Object. The **options** attribute determines the following behaviors on a domain controller:

- Global catalog installation and removal
- Enable or disable inbound or outbound replication
- Disable connection translation

Note that disabling inbound or outbound replication is specific to the domain controller where you target the operation. So this does not disable intrasite or intersite replication. It just disables Active Directory replication for that domain controller. If the domain controller happens to be the bridgehead server and the Intersite Topology Generator (ISTG) is disabled, then effectively intersite replication to and from that site is disabled.

**Syntax**

```
Repadmin /options <DC> [{+|-} IS_GC] [{+|-} DISABLE_INBOUND_REPL] [{+|- DISABLE_OUTBOUND_REPL] [{+|-} DISAB
LE_NTDSCONN_XLATE]
```

+|- turns on or off the associated parameter.

| Parameter | Description |
|---|---|
| *<DC>* | Domain controller |
| **IS_GC** | DSA is a global catalog server. |
| **DISABLE_INBOUND_REPL** | Disables inbound replication. |
| **DISABLE_OUTBOUND_REPL** | Disables outbound replication. |
| **DISAB LE_NTDSCONN_XLATE** | Turns off the capability of the KCC to translate connection objects to replication links. |

The following table lists the possible values for the options attribute.

| Value | Description |
|---|---|

| | |
|---|---|
| 1 | Global catalog server |
| 2 | Disable inbound replication |
| 3 | 2 + 1 |
| 4 | Disable outbound replication |
| 5 | 4 + 1 |
| 6 | 4 + 2 |
| 7 | 4 + 2 + 1 |
| 8 | Disable connection translation |

The following table lists the purpose for the possible procedures using the **options** attribute.

| Procedure | Purpose |
|---|---|
| Disable Outbound Replication | Use this procedure to disable Active Directory replication from a domain controller. The domain controller continues to receive inbound replication.<br><br>**Repadmin /options** <*ServerName*> **+disable_outbound_repl** where <*ServerName*> is the name of the domain controller on which you want to disable outbound replication. The tool reports the current options (the options that were in effect prior to pressing ENTER) and the new options (all options that are in effect after pressing ENTER). |
| Disable inbound Replication | Similar to the above step you could disable inbound replication to a server as well.<br><br>**repadmin /options** <*ServerName*> **+disable_inbound_repl** |
| Disable the ability of the KCC to translate connection objects. | When creating temporary replication links between replication partners, the process could fail if the KCC starts while you perform the procedure. The KCC will delete any replication links for which no corresponding connection object exists. |

**Advanced site options**

By using the **siteoptions** subcommand, we could change the options attribute stored on the NTDS Site Settings Object.

**Syntax**

```
Repadmin /siteoptions <DC> /site:< Site> [{+|-}IS_AUTO_TOPOLOGY_DISABLED] [{+|-} IS_TOPL_CLEANUP_DISABLED]
[{+|-} IS_TOPL_MIN_HOPS_DISABLED] [{+|-} IS_TOPL_DETECT_STALE_DISABLED] [{+|-}
IS_INTER_SITE_AUTO_TOPOLOGY_DISABLED] [{+|-} IS_GROUP_CACHING_ENABLED] [{+|-} FORCE_KCC_WHISTLER_BEHAVIOR]
[{+|-} FORCE_KCC_W2K_ELECTION] [{+|-} IS_RAND_BH_SELECTION_DISABLED] [{+|-} IS_SCHEDULE_HASHING_ENABLED]
[{+|-} IS_REDUNDANT_SERVER_TOPOLOGY_ENABLED]
```

| Parameter | Description |
|---|---|
| <*DC*> | Domain controller |
| site: <*Site*> | Site name where the domain controller resides |
| IS_AUTO_TOPOLOGY_DISABLED | Disables the automatic generation of intra-site topology. |
| IS_TOPL_CLEANUP_DISABLED | Disables the cleanup or unneeded connection objects and replication links. |
| IS_TOPL_MIN_HOPS_DISABLED | Disables the KCC rule that all intrasite replication partners should be no more than three hops from any other partner. |
| IS_TOPL_DETECT_STALE_DISABLED | Disables the detection by the KCC of failing replication links and the behavior of the KCC to route around failing links. Use this with the KCC Branch Office mode. |

| | |
|---|---|
| IS_INTER_SITE_AUTO_TOPOLOGY_DISABLED | Disables the automatic generation of the intersite topology. Commonly used for creating manual connections, either by hand or with MKDSX. |
| IS_GROUP_CACHING_ENABLED | Enables group caching for use with “no-GC logon.” This setting is also exposed in the UI of Active Directory Sites and Services. |
| FORCE_KCC_WHISTLER_BEHAVIOR | Forces the KCC to operate using the new spanning tree algorithm. It’s not recommended to manually change this setting. The recommended alternative is to raise the forest functional level to Windows Server 2003. |
| FORCE_KCC_W2K_ELECTION | Forces the Windows 2000 domain controller ISTG election logic. The default is for any Windows Server 2003 domain controller to assume the ISTG role. |
| IS_RAND_BH_SELECTION_DISABLED | Disables the new random bridgehead selection behavior. Reverts to Windows 2000 KCC behavior of using a single bridgehead server. |
| IS_SCHEDULE_HASHING_ENABLED | Creates a random schedule on each new connection object based in hashed value. Helps to balance the load on bridgehead servers. |
| IS_REDUNDANT_SERVER_TOPOLOGY_ENABLED | Creates two inbound connection objects from different domain controllers in a hub site. Reduces impact on FRS (vvjoin) during failover. |

**Miscellaneous**

The following table lists nbrflagoptions.

| Parameter | Definition |
|---|---|
| SYNC_ON_STARTUP | Replication of this naming context from this source is attempted when the destination server is booted. This normally only applies to intra-site neighbors. |
| DO_SCHEDULED_SYNCS | Perform replication on a schedule. This flag is normally set unless the schedule for this naming context and source is "never", that is, the empty schedule. |
| WRITEABLE | The local copy of the naming context is writable. |
| TWO_WAY_SYNC | If set, indicates that when inbound replication is complete, the destination server must tell the source server to synchronize in the reverse direction. This feature is used in dial-up scenarios where only one of the two servers can initiate a dial-up connection. For example, this option would be used in a corporate headquarters and branch office, where the branch office connects to the corporate headquarters over the Internet by means of a dial-up ISP connection. |
| NEVER_SYNCED | Synchronization has never been successfully completed from this source. |
| IGNORE_CHANGE_NOTIFICATIONS | This neighbor is set to disable notification-based synchronizations. Within a site, domain controllers synchronize with each other based on notifications when changes occur. This setting prevents this neighbor from performing synchronizations that are triggered by notifications. The neighbor will still do synchronizations based on its schedule, or in response to manually requested synchronizations. |
| DISABLE_SCHEDULED_SYNC | This neighbor is set to not perform synchronizations based on its schedule. The only way this neighbor will perform synchronizations is in response to change notifications or to manually requested synchronizations. |
| COMPRESS_CHANGES | Changes received from this source are to be compressed. This is normally set if, and only if, the source server is in a different site. |
| NO_CHANGE_NOTIFICATIONS | No change notifications should be received from this source. Normally set if, and only if, the source server is in a different site. |

# Administering Active Directory Operations

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides administering information for Active Directory in the Microsoft Windows Server 2003 and Windows Server 2003 with Service Pack 1 (SP1) operating systems. Information includes detailed procedures for managing domain controllers, sites, trusts, and other components of Active Directory.

**In this guide**

- Introduction to Administering Active Directory
- New in This Guide for Administering Active Directory
- Administering Domain and Forest Trusts
- Administering the Windows Time Service
- Administering SYSVOL
- Administering the Global Catalog
- Administering Operations Master Roles
- Administering Active Directory Backup and Restore
- Administering Intersite Replication
- Administering the Active Directory Database
- Administering Domain Controllers
- Additional Resources for Administering Active Directory

| **Note** |
| --- |
| You cannot install Active Directory on a server running Windows Server 2003, Web Edition, but you can join the server to an Active Directory domain as a member server. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition, on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=9253). |

# Introduction to Administering Active Directory

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide explains how to administer Microsoft Active Directory. These activities are part of the operating phase of the information technology (IT) life cycle. If you are not familiar with this guide, review the following sections of this introduction.

**When to Use This Guide**

You should use this guide when:

- You want to manage common Active Directory problems that are associated with misconfiguration.
- You want to configure Active Directory to increase network availability.

This guide assumes a basic understanding of what Active Directory is, how it works, and why your organization uses it to access, manage, and secure shared resources across your network. You should also have a thorough understanding of how Active Directory is deployed and managed in your organization. This includes an understanding of the mechanism your organization uses to configure and manage Active Directory settings.

This guide can be used by organizations that have deployed Windows Server 2003 and Windows Server 2003 with Service Pack 1 (SP1). It includes information that is relevant to different roles within an IT organization, including IT operations management and administrators. It contains high-level information that is required to plan an Active Directory operations environment. This information provides management-level knowledge of Active Directory and the IT processes required to operate it.

In addition, this guide contains more detailed procedures that are designed for operators who have varied levels of expertise and experience. Although the procedures provide operator guidance from start to finish, operators must have a basic proficiency with the Microsoft Management Console (MMC) and snap-ins and know how to start administrative programs and access the command line. If operators are not familiar with Active Directory, it might be necessary for IT planners or IT managers to review the relevant operations in this guide and provide the operators with parameters or data that must be entered when the operation is performed.

**How to Use this Guide**

The operations areas are divided into the following types of content:

- **Objectives** are high-level goals for managing, monitoring, optimizing, and securing Active Directory. Each objective consists of one or more high-level tasks that describe how the objective is accomplished.
- **Tasks** are used to group related procedures and provide general guidance for achieving the goals of an objective.
- **Procedures** provide step-by-step instructions for completing the task.

If you are an IT manager who will be delegating tasks to operators within your organization, you will want to:

- Read through the objectives and tasks to determine how to delegate permissions and whether you need to install tools before operators perform the procedures for each task.
- Before assigning tasks to individual operators, ensure that you have all the tools installed where operators can use them.
- When necessary, create “tear sheets” for each task that operators perform within your organization. Cut and paste the task and its related procedures into a separate document and then either print these documents or store them online, depending on the preference of your organization.

# New in This Guide for Administering Active Directory

Updated: May 8, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This operations guide is updated periodically to incorporate new content, customer feedback, and corrections. The following sections provide details about content that is new or updated in this version of the guide.

**New Content**

- August 2005: Performing an Authoritative Restore of Active Directory Objects contains new procedures for regenerating the group memberships of restored user objects and group objects. This functionality is available in the version of Ntdsutil.exe that is included with Windows Server 2003 with Service Pack 1 (SP1).

- February 2006: Enable Remote Desktop contains a new procedure to enable Remote Desktop remotely by using the registry.

- February 2006: Known Issues for Adding Domain Controllers in Remote Sites contains the additional information that moving the Ntds.dit file takes less time than copying the file when you restore a system state backup.

**Updated Content**

- April 2006: Performing an Authoritative Restore of Active Directory Objects contains corrected information about the details of updating back-link attributes.

# Administering Domain and Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides administrators with step-by-step instructions for managing and securing Windows Server 2003 domain and forest trusts. The way that you create or configure trusts plays an important role in operating and securing your network infrastructure. How you create or configure domain and forest trusts in Windows Server 2003 also determines how far network communications extend within a forest or across forests.

| **Note** |
| --- |
| You cannot install Active Directory on a server running Windows Server 2003, Web Edition, but you can join the server to an Active Directory domain as a member server. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition, on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=9253). |

# Introduction to Domain and Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By using Windows Server 2003 domain and forest trusts, service administrators can create or extend collaborative relationships between two or more domains or forests. Windows Server 2003 domains and forests can also trust Kerberos realms and other Windows Server 2003 forests, as well as Microsoft Windows® 2000 domains and Windows NT® 4.0 domains.

When a trust exists between two domains, the authentication mechanisms for each domain trust the authentications coming from the other domain. Trusts help to provide controlled access to shared resources in a resource domain (the trusting domain) by verifying that incoming authentication requests come from a trusted authority (the trusted domain). In this way, trusts act as bridges that allow only validated authentication requests to travel between domains.

How a specific trust passes authentication requests depends on how it is configured. Trust relationships can be one-way, providing access from the trusted domain to resources in the trusting domain, or two-way, providing access from each domain to resources in the other domain. Trusts are also either nontransitive, in which case a trust exists only between the two trust partner domains, or transitive, in which case a trust automatically extends to any other domains that either of the partners trusts.

In some cases, trust relationships are established automatically when domains are created; in other cases, administrators must choose a type of trust and explicitly establish the appropriate relationships. The specific types of trusts that are used and the structure of the resulting trust relationships in a given trust implementation depend on such factors as how Active Directory is organized and whether different versions of Windows coexist on the network.

# Best Practices for Domain and Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following best practices are proven to increase availability, ensure trouble-free operations, or ease administration when you use them to administer domain and forest trusts:

**When your forest contains domain trees with many child domains and you observe noticeable user authentication delays between the child domains, you can optimize the user authentication process between the child domains by creating shortcut trusts to mid-level domains in the domain tree hierarchy.**

For more information, see When to create a shortcut trust on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42644).

**Keep a current list of trust relationships for future reference.**

You can use the Nltest.exe tool to display and record a list of these trusts. For more information, see "Nltest.exe: NLTest Overview" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42642).

**Perform regular backups of domain controllers to preserve all trust relationships within a particular domain.**

For more information, see Back up system state.

# Managing Domain and Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

It is necessary to manage domain and forest trusts when your organization needs to collaborate with users or resources that are located in other domains, realms, or forests in your organization and in other organizations. To set up an environment that takes advantage of trusts, you must first create and configure the appropriate trusts that will enable your organization to communicate effectively with users or resources in other places.

The following objectives are part of managing domain and forest trusts:

- Creating Domain and Forest Trusts
- Configuring Domain and Forest Trusts

# Creating Domain and Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In Windows Server 2003, there are four trust types that must be created manually. External trusts, realm trusts, and forest trusts help provide interoperability with domains outside your forest or with realms. Shortcut trusts optimize access to resources and logons that are made between domain trees in the same forest.

The following tasks for creating domain and forest trusts are described in this objective:

- Creating External Trusts
- Creating Shortcut Trusts
- Creating Forest Trusts
- Creating Realm Trusts

| **Note** |
| --- |
| A trust does not inherently allow users in a trusted domain to have access to resources in a trusting domain. Users have access when they are assigned the appropriate permissions. In some cases, users in trusted domains may have implicit access if the resources are assigned to Authenticated Users. |

**New Trust Wizard Terminology**

You create trusts in Windows Server 2003 with the New Trust Wizard. Before you use the New Trust Wizard, review the following terminology. Each highlighted term represents the exact term as it is used in the wizard:

- **This domain:** The domain from which you launch the New Trust Wizard. When you start the wizard, it immediately verifies your administrative credentials in the domain for which you are the administrator. Therefore, the wizard uses the term “this domain” to represent the domain that you are currently logged on to.
- **Local domain / Local forest:** The domain or forest where you start the New Trust Wizard.
- **Specified domain / Specified forest:** The other domain or forest that this local domain or local forest will trust. Although the New Trust Wizard is aware of the domain context in which it is running, it does not have knowledge of the other domain that you want to create the relationship with. After you type the name of the other domain or forest in the **Trust Name** page, that name is used whenever the wizard refers to the specified domain or specified forest.
- **Two-way trust:** A trust relationship between two domains in which both domains trust each other. For example, domain A trusts domain B, and domain B trusts domain A. All parent-child trusts are two-way trusts.
- **One-way: incoming trust:** A one-way trust relationship between two domains in which the direction of the trust points toward the domain from which you start the New Trust Wizard (and which is identified in the wizard as **This domain**). When the direction of the trust points toward your domain, users in your domain can access resources in the specified domain. For example, if you are the domain administrator in domain A and you create a one-way, incoming trust to domain B, this provides a relationship through which users who are located in domain A can access resources in domain B. Because this relationship is one-way, users in domain B cannot access resources in domain A.
- **One-way: outgoing trust:** A one-way trust relationship between two domains in which the direction of the trust points toward the domain that is identified as **Specified domain** in the New Trust Wizard. When the direction of trust points toward the specified domain, users in the specified domain can access resources in your domain. For example, if you are the domain administrator in domain A and you create a one-way, outgoing trust to domain B, this provides a relationship through which users who are located in domain B can access resources in domain A. Because this relationship is one way, users in domain A cannot access resources in domain B.

- **Both sides of the trust:** When you create external trusts, shortcut trusts, or forest trusts, you have the option to create each side of the trust separately or both sides of the trust simultaneously. If you choose to create each side of the trust separately, you must run the New Trust Wizard twice — once for each domain. When you create trusts separately, you must supply the same trust password for each domain. As a security best practice, all trust passwords should be strong passwords.

- **Domain-wide authentication:** An authentication setting that permits unrestricted access by any users in the specified domain to all available shared resources that are located in the local domain. This is the default authentication setting for external trusts.

- **Forest-wide authentication:** An authentication setting that permits unrestricted access by any users in the specified forest to all available shared resources that are located in any of the domains in the local forest. This is the default authentication setting for forest trusts.

- **Selective authentication:** An authentication setting that restricts access over an external trust or forest trust to only those users in a specified domain or specified forest who have been explicitly given authentication permissions to computer objects (resource computers) that reside in the local domain or the local forest. This authentication setting must be enabled manually.

- **Trust password:** An option in which both domains in a trust relationship share a password, which is stored in the trusted domain object (TDO) object in Active Directory. When you choose this option, a strong trust password is generated automatically for you. You must use the same password when you create a trust relationship in the specified domain. If you choose to create both sides of the trust simultaneously, you run the New Trust Wizard once.

# DNS and NetBIOS Name Resolution to Create External, Realm and Forest Trusts

Published: July 23, 2009

Updated: July 24, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Before you create a domain or forest trust, there are name resolution requirements that must be met so that you can establish the trust successfully. These requirements ensure that the forest or domain can resolve the address of the domain controllers in the target forest or domain to support the creation and ongoing operation of the trust.

For all trusts except trusts across forests, the New Trust Wizard and its command-line equivalents allow you to refer to domains that participate in a trust by their Domain Name System (DNS) or NetBIOS domain names. For trusts across forests, you must use a DNS name.

Although Windows Internet Name Service (WINS) has been used to support trusts in the past, the focus of this topic is configuring DNS to create and operate a trust.

**DNS Name Resolution**

You can use DNS to resolve names for a forest or domain for which you are attempting to establish a trust. Most DNS names are fully qualified, which means that there is a dot (.) in the name between the forest root domain and a top-level domain, such as .com, .gov, and .local. There are rare instances in which Active Directory domains are created with a single-label DNS domain name, such as “contoso”. When you type in the name of a remote domain in the New Trust wizard that you are expecting to be resolved by DNS, then you should enter the DNS name of the remote domain (not its NetBIOS or WINS name).

The DNS servers that the domain controllers in one forest use may not be able to resolve the DNS names for domain controllers in another forest, and the other way around. If the DNS names for trusting domains are not registered with an Internet Register, then the DNS Servers used by DCs in the trusted domain cannot use forwarders to resolve the DNS queries needed to support the trust. There are two common DNS configurations that you can choose from when you establish DNS name resolution between domains and forests:

- Conditional forwarders
- Secondary zones with zone transfers enabled

| **Note** |
| --- |
| Stub zones can be used to resolve DNS names, but are less commonly used than secondary zones and conditional forwarders; therefore, they are not covered in this document. |

**Using Conditional Forwarders vs. Using Secondary Zones**

There are several conditions you should take into account when choosing between conditional forwarders or secondary zones with zone transfers (to resolve DNS names that your DNS Servers are not authoritative for). When you decide whether to use conditional forwarders or secondary zones with zone transfers enabled, there are several considerations you should take into account before choosing either configuration.

The benefit of using a conditional forwarder is that it is much easier to configure and troubleshoot than a zone transfer. The process of configuring a conditional forwarder is straightforward: all you need to know is the DNS domain name of the domain that houses the DNS server that you are configuring to forward requests and the IP address of the target DNS server.

However, a conditional forwarder is not an efficient way to keep a DNS server that hosts a parent zone aware of the authoritative DNS servers for a child zone. If you use a conditional forwarder, whenever the authoritative DNS servers for the child zone change, the conditional forwarder setting on the DNS server that hosts the parent zone must be configured manually with the IP address for each new authoritative DNS server for the child zone.

Using a secondary zone with zone transfers enabled is beneficial because this configuration maintains a list of all the authoritative DNS servers for the secondary copy of the zone, and the list is updated as DNS servers are added and removed from the target forest or domain. Secondary zones also host a full copy of the DNS zone.

The drawbacks to using secondary zones with zone transfers enabled are that this configuration is much more complicated to configure and maintain and you do not have the direct, point-to-point contact with a DNS server in the target forest or domain as you do with a conditional forwarder. In addition, with secondary zones you expose hosts to IP address mappings for all hosts in the zone. This can expose the domain or forest to security risks due to unauthorized access.

**Conditional Forwarders**

You can use conditional forwarders to route queries between the domains or forests for which you are establishing a forest or domain trust. Conditional forwarders route names to a specified DNS server in the target domain or forest for queries that the conditional forwarders cannot resolve.

For example, if you establish a two-way, forest trust between the fabrikam.com and contoso.com forests, you configure a conditional forwarder in the fabrikam.com forest to route queries that it cannot resolve to a name server in the contoso.com forest. You then configure a conditional forwarder in the contoso.com forest to route names that it cannot resolve to the fabrikam.com forest.

For more information about conditional forwarders, see the following:

- Using forwarders (http://go.microsoft.com/fwlink/?LinkId=157391)
- How to Configure Conditional Forwarders in Windows Server 2008 (http://go.microsoft.com/fwlink/?LinkId=157393). This post not only explains how to configure a conditional forwarder in Windows Server 2008, it also explains how to configure a conditional forwarder in Windows Server 2003.

The following flowchart explains how to troubleshoot instances in which conditional forwarders are not correctly performing name resolution to the target forest or domain. The flowchart shows a one-way, transitive, outgoing, forest trust between forest A (trusting) and forest B (trusted). Simply put, users in forest B have access to specified resources in forest A. To complete the steps in the following flowchart, use the credentials of a member of the Domain Admins group. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

**Secondary Zones with Zone Transfers Enabled**

Zone transfers replicate DNS databases across a set of DNS servers. If you want to establish a trust between two forests, you can configure the DNS server in the trusting domain or forest to host a secondary zone of the trusted forest, with zone transfers enabled.

For example, if you want to establish a two-way trust between the fabrikam.com and contoso.com forests, you configure the DNS server in the fabrikam.com forest to host a secondary zone of the contoso.com forest's namespace, and the reverse. After

you configure the secondary zones in each forest, you then allow zone transfers between the two forests. For more information about secondary zones or zone transfers, see the following:

- Adding a Secondary DNS Server to a Zone (http://go.microsoft.com/fwlink/?LinkId=157397)
- Understanding zones and zone transfers (http://go.microsoft.com/fwlink/?LinkId=157398)
- Understanding Zone Types (http://go.microsoft.com/fwlink/?LinkId=157399)

**DNS Resource Records That Are Required for Secondary Zones**

There are two DNS resource records that must be registered properly on the DNS server that hosts the secondary copy of the trusted domain or forest:

- Service (SRV) resource record (_ldap._tcp.dc._msdcs.<*computer account domain*>)
- Host (A) resource record

These records must be in place and registered properly before you establish a domain or forest trust.

The following flowchart explains how to troubleshoot instances in which secondary zones with zone transfers enabled are not correctly performing name resolution to the target domain or forest. The flowchart shows a one-way, transitive, outgoing, forest trust between forest A (trusting) and forest B (trusted). Simply put, users in forest B have access to specified resources in forest A. To complete the steps in the following flowchart, use the credentials of a member of the Domain Admins group. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

# Known Issues for Creating Domain and Forest Trusts

Updated: October 1, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Review the following known issues before creating domain and forest trusts in Windows Server 2003:

- You cannot delegate the creation of trusts to any user who is not a member of the Domain Admins or Enterprise Admins groups. Even though you can grant a user the Create TDO (Trusted Domain Object) right or the Delete TDO right in the System container of a domain, the user will not be granted the right to create a trust. This issue occurs because Netlogon and the trust-creation tools (Active Directory Domains and Trusts and Netdom) are designed so that only members of the Domain Admins group and the Enterprise Admins group can create trusts. However, any user who is a member of the Incoming Forest Trust Builders group can create one-way, incoming forest trusts to your forest. For more information about the Incoming Forest Trust Builders group, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

- When you are logged on locally to a domain controller and you try to create a new trust by using Active Directory Domains and Trusts, the operation may be unsuccessful and you may receive the message “Access denied.” This issue occurs only if you are logged on locally to the domain controller as an ordinary user (meaning that the user is not logged on as Administrator or as a member of any administrative groups for the domain). By default, ordinary users are blocked from logging on locally to a domain controller unless Group Policy is modified to permit this.

- When you use Active Directory Domains and Trusts to create a trust, you may receive the message “Operation failed. Parameter incorrect.” This issue may occur if you try to establish a trust relationship when the source domain and the target domain have one or more of the following identifiers that are the same:

  - Security identifier (SID)

  - Domain Name System (DNS) name

  - Network basic input/output system (NetBIOS) name

  To resolve this issue, rename all conflicting identifiers before you try to create the trust.

- The option to create a forest trust does not appear in the New Trust Wizard. This issue typically occurs when one or both of the Windows Server 2003 forests are not set to the Windows Server 2003 forest functional level. For more information about forest functional levels, see Active Directory Functional Levels Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41698).

- There are restrictions in the number and types of trusts that can be created when you target a Microsoft Windows Small Business Server 2003 domain.

# Creating External Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can create an external trust to form a one-way or two-way, nontransitive trust with domains that are outside your forest. External trusts are sometimes necessary when users need access to resources that are located in a Windows NT 4.0 domain or in a domain that is in a separate Active Directory forest that is not joined by a forest trust.

For example, if you have a Windows Server 2003–based domain whose users want to gain access to resources that are stored in a Windows NT–based domain, you must create a trust relationship in which the Windows NT–based domain trusts the users from the Windows Server 2003–based domain. In this case, the Windows NT–based domain is the trusting domain, and the Windows Server 2003–based domain is the trusted domain.

For more information about external trusts, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

| **Note** |
| --- |
| Trusts that are created between Windows NT 4.0 domains and Active Directory domains are one-way and nontransitive, and they require network basic input/output system (NetBIOS) name resolution. |

**Task requirements**

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to create an external trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

| **Note** |
| --- |
| If you have the appropriate administrative credentials for each domain, you can create both sides of an external trust at the same time. To create both sides of the trust, simultaneously, follow the appropriate procedure below that contains the words “both sides of the trust” in the procedure title. For example, the procedure “Create a one-way, incoming, external trust for both sides of the trust” provides the steps to follow when you have the administrative credentials for both domains and you want to use the New Trust Wizard to create an incoming, external trust in one operation. For more information about how the “both sides of the trust” option works, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages. |

You can create an external trust by using any of the following procedures, depending on the requirements of your organization and the administrative credentials that you have when you create the trust:

- Create a one-way, incoming, external trust for one side of the trust
- Create a one-way, incoming, external trust for both sides of the trust
- Create a one-way, outgoing, external trust for one side of the trust
- Create a one-way, outgoing, external trust for both sides of the trust
- Create a two-way, external trust for one side of the trust
- Create a two-way, external trust for both sides of the trust

# Create a one-way, incoming, external trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a one-way, incoming, external trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal domain uses his or her credentials to create the second side of the trust. If you have administrative credentials for both domains that are involved in the trust, you can use the procedure Create a one-way, incoming, external trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A one-way, incoming, external trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to access resources in another Active Directory domain (outside your forest) or in a Windows NT 4.0 domain. For example, if you are the administrator of sales.wingtiptoys.com and users in that domain need to access resources in the marketing.tailspintoys.com domain (which is located in another forest), you can use this procedure (in conjunction with another procedure, which is executed by the administrator in the other forest) to establish one side of the relationship so that users in your domain can access resources in the marketing.tailspintoys.com domain.

You can create this external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create an external trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, incoming, external trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: incoming**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.

   With the administrator of the other domain, agree on a secure channel password to be used in establishing the trust.
9. On the **Trust Selections Complete**page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.
    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

12. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain or specified forest must follow the procedure Create a one-way, outgoing, external trust for one side of the trust, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Create a one-way, incoming, external trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a one-way, incoming, external trust, and it requires you to have administrative credentials for your domain as well for the reciprocal domain. If you have administrative credentials only for your domain, you can use the procedure Create a one-way, incoming, external trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal domain create a one-way, outgoing, external trust from his or her domain.

A one-way, incoming, external trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to access resources in another Active Directory domain (outside your forest) or in a Windows NT 4.0 domain. For example, if you are the administrator of sales.wingtiptoys.com and users in that domain need to access resources in the marketing.tailspintoys.com domain (which is located in another forest) you can use this procedure to establish a relationship so that users in your domain can access resources in the marketing.tailspintoys.com domain.

You can create this external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create an external trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, incoming, external trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: incoming**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Outgoing Trust Authentication Level--Specified Domain** page, do one of the following, and then click **Next**:
   - Click **Domain-wide authentication**.
   - Click **Selective authentication**.
10. On the **Trust Selections Complete** page, review the results, and then click **Next**.
11. On the **Trust Creation Complete** page, review the results, and then click **Next**.
12. On the **Confirm Incoming Trust** page, do one of the following:

- If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.
- If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

13. On the **Completing the New Trust Wizard** page, click **Finish**.

# Create a one-way, outgoing, external trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a one-way, outgoing, external trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal domain uses his or her credentials to create the second side of the trust. If you have administrative credentials for both domains that are involved in the trust, you can use the procedure Create a one-way, outgoing, external trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A one-way, outgoing, external trust will allow resources in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to be accessed by users in a different Active Directory domain (outside your forest) or in a Windows NT 4.0 domain. For example, if you are the administrator of sales.wingtiptoys.com and you have resources in that domain that need to be accessed by users in the marketing.tailspintoys.com domain (which is located in another forest), you can use this procedure to establish one side of the relationship so that users in the marketing.tailspintoys.com domain can access the resources in sales.wingtiptoys.com.

You can create this external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create an external trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, outgoing, external trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: outgoing**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Outgoing Trust Authentication Level** page, do one of the following, and then click **Next**:
   - Click **Domain-wide authentication**.
   - Click **Selective authentication**.
9. On the **Trust Password** page, type the trust password twice, and then click **Next**.
10. On the **Trust Selections Complete**page, review the results, and then click **Next**.
11. On the **Trust Creation Complete** page, review the results, and then click **Next**.
12. On the **Confirm Outgoing Trust** page, do one of the following:

- If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

- If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the **specified domain.**

13. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain or specified forest must follow the procedure Create a one-way, incoming, external trust for one side of the trust, using his or her administrative credentials and the exact same trust passwordthat was used during this procedure. |

# Create a one-way, outgoing, external trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a one-way, outgoing, external trust, and it requires you to have administrative credentials for your domain as well as for the reciprocal domain. If you have administrative credentials only for your domain, you can use the procedure Create a one-way, outgoing, external trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal domain create a one-way, incoming, external trust from his or her domain.

A one-way, outgoing, external trust allows resources in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to be accessed by users in a different Active Directory domain (outside your forest) or in a Windows NT 4.0 domain. For example, if you are the administrator of sales.wingtiptoys.com and you have resources in that domain that need to be accessed by users in the marketing.tailspintoys.com domain (which is located in another forest), you can use this procedure to establish one side of the relationship so that users in the marketing.tailspintoys.com domain can access the resources in sales.wingtiptoys.com.

You can create this external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create an external trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, outgoing, external trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: outgoing**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Outgoing Trust Authentication Level--Local Domain** page, do one of the following, and then click **Next**:
   - Click **Domain-wide authentication**.
   - Click **Selective authentication**.
10. On the **Trust Selections Complete** page, review the results, and then click **Next**.
11. On the **Trust Creation Complete** page, review the results, and then click **Next**.
12. On the **Confirm Outgoing Trust** page, do one of the following:

- If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

- If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.

13. On the **Completing the New Trust Wizard** page, click **Finish**.

# Create a two-way, external trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a two-way, external trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal domain uses his or her credentials to create the second side of the trust. If you have administrative credentials for both domains that are involved in the trust, you can use the procedure Create a two-way, external trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A two-way, external trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) and users in the reciprocal domain to access resources in either of the two domains.

You can create this external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create an external trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a two-way, external trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **Two-way**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Outgoing Trust Authentication Level** page, do one of the following, and then click **Next**:
   - Click **Domain-wide authentication**.
   - Click **Selective authentication**.
9. On the **Trust Password** page, type the trust password twice, and then click **Next**.
10. On the **Trust Selections Complete**page, review the results, and then click **Next**.
11. On the **Trust Creation Complete** page, review the results, and then click **Next**.
12. On the **Confirm Outgoing Trust** page, do one of the following:
    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.
    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate

administrative credentials from the specified domain.

13. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.

    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

14. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain or specified forest must follow this same procedure, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Create a two-way, external trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a two-way, external trust, and it requires you to have administrative credentials for your domain as well as for the reciprocal domain. If you have administrative credentials only for your domain, you can use the procedure Create a two-way, external trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal domain create a one-way, outgoing, external trust from his or her domain.

A two-way, external trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) and users in the reciprocal domain to access resources in either of the two domains.

You can create this external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create an external trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a two-way, external trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **Two-way**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Outgoing Trust Authentication Level--Local Domain** page, do one of the following, and then click **Next**:
   - Click **Domain-wide authentication**.
   - Click **Selective authentication**.
10. On the **Outgoing Trust Authentication Level--Specified Domain** page, do one of the following, and then click **Next**:
    - Click **Domain-wide authentication**.
    - Click **Selective authentication**.
11. On the **Trust Selections Complete** page, review the results, and then click **Next**.
12. On the **Trust Creation Complete** page, review the results, and then click **Next**.

13. On the **Confirm Outgoing Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.

14. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.

    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

15. On the **Completing the New Trust Wizard** page, click **Finish**.

# Creating Shortcut Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A shortcut trust is a manually created trust that shortens the trust path to improve the speed at which authentications, which are made between domain trees, are processed. This can result in faster logon times and faster access to resources. A trust path is a chain of multiple trusts that enables trust between domains that are not adjacent in the domain namespace. For example, if users in domain A need to gain access to resources in domain C, you can create a direct link from domain A to domain C through a shortcut trust relationship, bypassing domain B in the trust path.

For more information about shortcut trusts, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**Task requirements**

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to create a shortcut trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

| **Note** |
| --- |
| If you have the appropriate administrative credentials for each domain, you can create both sides of a shortcut trust at the same time. To create both sides of the trust, follow the appropriate procedure below that contains the words “for both sides of the trust” in the title. For example, the procedure “Create a one-way, incoming, shortcut trust for both sides of the trust” explains how to configure both sides of a shortcut trust. For more information about how the “both sides of the trust” option works, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages. |

You can create a shortcut trust by using any of the following procedures, depending on the requirements of your organization and the administrative credentials that you have when you create the trust:

- Create a one-way, incoming, shortcut trust for one side of the trust
- Create a one-way, incoming, shortcut trust for both sides of the trust
- Create a one-way, outgoing, shortcut trust for one side of the trust
- Create a one-way, outgoing, shortcut trust for both sides of the trust
- Create a two-way, shortcut trust for one side of the trust
- Create a two-way, shortcut trust for both sides of the trust

# Create a one-way, incoming, shortcut trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a one-way, incoming, shortcut trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal domain uses his or her credentials to create the second side of the trust. If you have administrative credentials for both domains that are involved in the trust, you can use the procedure Create a one-way, incoming, shortcut trust for both sides of the trust to create both sides in one simultaneous operation.

A one-way, incoming, shortcut trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to more quickly access resources in another domain (which is nested within another domain tree) in your forest. For example, if you are the administrator of sales.wingtiptoys.com and users in that domain need to access resources in the marketing.tailspintoys.com domain (which is a child domain of the tailspintoys.com tree root domain), you can use this procedure to establish one side of the relationship so that users in your domain can more quickly access resources in the marketing.tailspintoys.com domain.

You can create this shortcut trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a shortcut trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, incoming, shortcut trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: incoming**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.
    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

12. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain or specified forest must follow the procedure Create a one-way, outgoing, shortcut trust for one side of the trust, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Create a one-way, incoming, shortcut trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a one-way, incoming, shortcut trust, and it requires you to have administrative credentials for your domain as well for the reciprocal domain. If you have administrative credentials only for your domain, you can use the procedure Create a one-way, incoming, shortcut trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal domain create a one-way, outgoing, shortcut trust from his or her domain.

A one-way, incoming, shortcut trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to more quickly access resources in another domain (which is nested within another domain tree) in your forest. For example, if you are the administrator of sales.wingtiptoys.com and users in that domain need to access resources in the marketing.tailspintoys.com domain (which is a child domain of the tailspintoys.com tree root domain), you can use this procedure to establish one side of the relationship so that users in your domain can more quickly access resources in the marketing.tailspintoys.com domain.

You can create this shortcut trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a shortcut trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, incoming, shortcut trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: incoming**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.
    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

12. On the **Completing the New Trust Wizard** page, click **Finish**.

# Create a one-way, outgoing, shortcut trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a one-way, outgoing, shortcut trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal domain uses his or her credentials to create the second side of the trust. If you have administrative credentials for both domains that are involved in the trust, you can use the procedure Create a one-way, outgoing, shortcut trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A one-way, outgoing, shortcut trust allows resources in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to be accessed more quickly by users in another domain (which is nested within another domain tree) in your forest. For example, if you are the administrator of marketing.tailspintoys.com and resources in that domain need to be accessed by users in the sales.wingtiptoys.com domain (which is a child domain of the wingtiptoys.com tree root domain), you can use this procedure to establish one side of the relationship so that users in the sales.wingtiptoys.com domain can more quickly access resources in the marketing.tailspintoys.com domain.

You can create this shortcut trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a shortcut trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, outgoing, shortcut trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: outgoing**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Outgoing Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.

12. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain or specified forest must follow the procedure Create a one-way, incoming, shortcut trust for one side of the trust, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Create a one-way, outgoing, shortcut trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a one-way, outgoing, shortcut trust, and it requires that you have administrative credentials for your domain as well as for the reciprocal domain. If you have administrative credentials only for your domain, you can use the procedure Create a one-way, outgoing, shortcut trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal domain create a one-way, incoming, shortcut trust from his or her domain.

A one-way, outgoing, shortcut trust allows resources in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to be accessed more quickly by users in another domain (which is nested within another domain tree) in your forest. For example, if you are the administrator of marketing.tailspintoys.com and resources in that domain need to be accessed by users in the sales.wingtiptoys.com domain (which is a child domain of the wingtiptoys.com tree root domain), you can use this procedure to establish one side of the relationship so that users in the sales.wingtiptoys.com domain can more quickly access resources in the marketing.tailspintoys.com domain.

You can create this shortcut trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a shortcut trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, outgoing, shortcut trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: outgoing**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Outgoing Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate

administrative credentials from the specified domain.

12. On the **Completing the New Trust Wizard** page, click **Finish**.

# Create a two-way, shortcut trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a two-way, shortcut trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal domain uses his or her credentials to create the second side of the trust. If you have administrative credentials for both domains that are involved in the trust, you can use the procedure Create a two-way, shortcut trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A two-way, shortcut trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) and users in the reciprocal domain to more quickly access resources in either domain (when both domains are separated by a domain tree) in your forest.

You can create this shortcut trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a shortcut trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a two-way, shortcut trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **Two-way**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.
9. On the **Trust Selections Complete**page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Outgoing Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.

12. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.

- If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

13. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain must follow this same procedure using his or her administrative credentials and the exact same trust passwordthat was used during this procedure. |

# Create a two-way, shortcut trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a two-way, shortcut trust, and it requires you to have administrative credentials for your domain as well as for the reciprocal domain. If you have administrative credentials only for your domain, you can use the procedure Create a two-way, shortcut trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal domain create a two-way, shortcut trust from his or her domain.

A two-way, shortcut trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) and users in the reciprocal domain to more quickly access resources in either domain (when both domains are separated by a domain tree) in your forest.

You can create this shortcut trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a shortcut trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a two-way, shortcut trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **External trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **Two-way**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Trust Selections Complete**page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Outgoing Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.

12. On the **Confirm Incoming Trust** page, do one of the following:

- If you do not want to confirm this trust, click **No, do not confirm the incoming trust.**

- If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

13. On the **Completing the New Trust Wizard** page, click **Finish**.

# Creating Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In a Windows Server 2003 forest, you can link two disjoined Windows Server 2003 forests together to form a one-way or two-way, transitive trust relationship. You can use a two-way, forest trust to form a transitive trust relationship between every domain in both forests.

For more information about forest trusts, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**Task requirements**

The following requirements, features, or settings are necessary to create forest trusts successfully:

- You can create a forest trust only between two Windows Server 2003 forests; forest trusts cannot be extended implicitly to a third Windows Server 2003 forest.
- To create a forest trust, you must set the forest functional level for both of the Windows Server 2003 forests that are involved in the trust relationship to Windows Server 2003. For more information about functional levels, see Active Directory Functional Levels Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41698).
- To create a forest trust successfully, you must set up your Domain Name System (DNS) environment properly. If there is a root DNS server that you can make the root DNS server for the DNS namespaces of both forests, make it the root server by ensuring that the root zone contains delegations for each of the DNS namespaces. Also, update the root hints of all DNS servers with the new root DNS server.
- If there is no shared root DNS server and the root DNS servers for each forest DNS namespace are running a member of the Windows Server 2003 family, configure DNS conditional forwarders in each DNS namespace to route queries for names in the other namespace.
- If there is no shared root DNS server and the root DNS servers for each forest DNS namespace are not running a member of the Windows Server 2003 family, configure DNS secondary zones in each DNS namespace to route queries for names in the other namespace. For more information about configuring DNS to work with Active Directory, see DNS Support for Active Directory Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41699).

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to create a forest trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

| **Note** |
| --- |
| If you have the appropriate administrative credentials for each forest, you can create both sides of a forest trust at the same time. To create both sides of the forest trust, follow the appropriate procedure below that contains the words “for both sides of the trust” in the title. For example, the procedure “Create a one-way, incoming, forest trust for both sides of the trust” explains how to configure both sides of the trust. For more information about how the “both sides of the trust” option works, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages. |

You can create a forest trust by using any one of the following procedures, depending on the requirements of your

organization and the administrative credentials that you have when you create the trust:

- Create a one-way, incoming, forest trust for one side of the trust
- Create a one-way, incoming, forest trust for both sides of the trust
- Create a one-way, outgoing, forest trust for one side of the trust
- Create a one-way, outgoing, forest trust for both sides of the trust
- Create a two-way, forest trust for one side of the trust
- Create a two-way, forest trust for both sides of the trust

# Create a one-way, incoming, forest trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a one-way, incoming, forest trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal forest uses his or her credentials to create the second side of the trust. If you have administrative credentials for both forests that are involved in the trust, you can use the procedure Create a one-way, incoming, forest trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A one-way, incoming, forest trust allows users in your Windows Server 2003 forest (the forest that you are logged on to at the time that you run the New Trust Wizard) to access resources in another Windows Server 2003 forest. For example, if you are the administrator of the wingtiptoys.com forest and users in that forest need to access resources in the tailspintoys.com forest, you can use this procedure to establish one side of the relationship so that users in your forest can access resources in any of the domains that make up the tailspintoys.com forest.

You can create this forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a forest trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory. If you are a member of the Incoming Forest Trust Builders group, you can create one-way, incoming, forest trusts to your forest. For more information about the Incoming Forest Trust Builders group, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**To create a one-way, incoming, forest trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Forest trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: incoming**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Trust Creation Complete** page, review the results, and then click **Next**.
11. On the **Confirm Incoming Trust** page, do one of the following:
    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.
    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate

administrative credentials from the specified domain.

12. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain (the forest root domain in the specified forest) must complete the procedure Create a one-way, outgoing, forest trust for one side of the trust, using their administrative credentials and the exact same trust passwordthat was used during this procedure. |

# Create a one-way, incoming, forest trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a one-way, incoming, forest trust, and it requires you to have administrative credentials for your forest as well as for the reciprocal forest. If you have administrative credentials only for your forest, you can use the procedure Create a one-way, incoming, forest trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal forest create a one-way, outgoing forest trust from his or her domain.

A one-way, incoming, forest trust allows users in your Windows Server 2003 forest (the forest that you are logged on to at the time that you run the New Trust Wizard) to access resources in another Windows Server 2003 forest. For example, if you are the administrator of the wingtiptoys.com forest and users in that forest need to access resources in the tailspintoys.com forest, you can use this procedure to establish one side of the relationship so that users in your forest can access resources in any of the domains that make up the tailspintoys.com forest.

You can create this forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a forest trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory. If you are a member of the Incoming Forest Trust Builders group, you can create one-way, incoming, forest trusts to your forest. For more information about the Incoming Forest Trust Builders group, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**To create a one-way, incoming, forest trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Forest trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: incoming**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Outgoing Trust Authentication Level--Specified Forest** page, do one of the following, and then click **Next**:
   - Click **Forest-wide authentication**.
   - Click **Selective authentication**.
10. On the **Trust Selections Complete** page, review the results, and then click **Next**.
11. On the **Trust Creation Complete** page, review the results, and then click **Next**.

12. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.

    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

13. On the **Completing the New Trust Wizard** page, click **Finish**.

# Create a one-way, outgoing, forest trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a one-way, outgoing, forest trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal forest uses his or her credentials to create the second side of the trust. If you have administrative credentials for both forests that are involved in the trust, you can use the procedure Create a one-way, outgoing, forest trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A one-way, outgoing, forest trust allows resources in your Windows Server 2003 forest (the forest that you are logged on to at the time that you run the New Trust Wizard) to be accessed by users in another Windows Server 2003 forest. For example, if you are the administrator of the wingtiptoys.com forest and resources in that forest need to be accessed by users in the tailspintoys.com forest, you can use this procedure to establish one side of the relationship so that users in the tailspintoys.com forest can access resources in any of the domains that make up the wingtiptoys.com forest.

You can create this forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a forest trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory. If you are a member of the Incoming Forest Trust Builders group, you can create one-way, incoming, forest trusts to your forest. For more information about the Incoming Forest Trust Builders group, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**To create a one-way, outgoing, forest trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Forest trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: outgoing**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Outgoing Trust Authentication Level** page, do one of the following, and then click **Next**:
   - Click **Forest-wide authentication**.
   - Click **Selective authentication**.
9. On the **Trust Password** page, type the trust password twice, and then click **Next**.
10. On the **Trust Selections Complete** page, review the results, and then click **Next**.

11. On the **Trust Creation Complete** page, review the results, and then click **Next**.
12. On the **Confirm Outgoing Trust** page, do one of the following:
    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.
    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.
13. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator for the specified domain (the forest root domain in the specified forest) must follow the procedure Create a one-way, incoming, forest trust for one side of the trust, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Create a one-way, outgoing, forest trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a one-way, outgoing, forest trust, and it requires you to have administrative credentials for your forest as well as for the reciprocal forest. If you have administrative credentials only for your domain, you can use the procedure Create a one-way, outgoing, forest trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal forest create a one-way, incoming, external trust from his or her forest.

A one-way, outgoing, forest trust allows resources in your Windows Server 2003 forest (the forest that you are logged on to at the time that you run the New Trust Wizard) to be accessed by users in another Windows Server 2003 forest. For example, if you are the administrator of the wingtiptoys.com forest and resources in that forest need to be accessed by users in the tailspintoys.com forest, you can use this procedure to establish one side of the relationship so that users in the tailspintoys.com forest can access resources in any of the domains that make up the wingtiptoys.com forest.

You can create this forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a forest trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory. If you are a member of the Incoming Forest Trust Builders group, you can create one-way, incoming, forest trusts to your forest. For more information about the Incoming Forest Trust Builders group, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**To create a one-way, outgoing, forest trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Forest trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **One-way: outgoing**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Outgoing Trust Authentication Level--Local Forest** page, do one of the following, and then click **Next**:
   - Click **Forest-wide authentication**.
   - Click **Selective authentication**.
10. On the **Trust Selections Complete**page, review the results, and then click **Next**.
11. On the **Trust Creation Complete** page, review the results, and then click **Next**.

12. On the **Confirm Outgoing Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust.** Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.

13. On the **Completing the New Trust Wizard** page, click **Finish**.

# Create a two-way, forest trust for one side of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates one side of a two-way, forest trust. Although one side of a trust will be created successfully, the new trust will not function until the administrator for the reciprocal forest uses his or her credentials to create the second side of the trust. If you have administrative credentials for both forests that are involved in the trust, you can use the procedure Create a two-way, forest trust for both sides of the trust to create both sides of the trust in one simultaneous operation.

A two-way, forest trust allows users in your forest (the forest that you are logged on to at the time that you run the New Trust Wizard) and users in the reciprocal forest to access resources in any of the domains in either of the two forests.

You can create this forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a forest trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory. If you are a member of the Incoming Forest Trust Builders group, you can create one-way, incoming, forest trusts to your forest. For more information about the Incoming Forest Trust Builders group, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**To create a two-way, forest trust for one side of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Forest trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **Two-way**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **This domain only**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Outgoing Trust Authentication Level** page, do one of the following, and then click **Next**:
   - Click **Forest-wide authentication**.
   - Click **Selective authentication**.
9. On the **Trust Password** page, type the trust password twice, and then click **Next**.
10. On the **Trust Selections Complete**page, review the results, and then click **Next**.
11. On the **Trust Creation Complete** page, review the results, and then click **Next**.
12. On the **Confirm Outgoing Trust** page, do one of the following:
    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.

- If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.

13. On the **Confirm Incoming Trust** page, do one of the following:

    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust.**

    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.

14. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the domain administrator in the specified forest must follow this same procedure, using his or her administrative credentials and the exact same trust passwordthat was used during this procedure. |

# Create a two-way, forest trust for both sides of the trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure creates both sides of a two-way, forest trust, and it requires you to have administrative credentials for your forest as well as for the reciprocal forest. If you have administrative credentials only for your forest, you can use the procedure Create a two-way, forest trust for one side of the trust to create your side of the trust. Then, have the administrator for the reciprocal forest create a one-way, outgoing forest trust from his or her forest.

A two-way, forest trust allows users in your forest (the forest that you are logged on to at the time that you run the New Trust Wizard) and users in the reciprocal forest to access resources in any of the domains in either of the two forests.

You can create this forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a forest trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory. If you are a member of the Incoming Forest Trust Builders group, you can create one-way, incoming, forest trusts to your forest. For more information about the Incoming Forest Trust Builders group, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**To create a two-way, forest trust for both sides of the trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Forest trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **Two-way**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.

   For more information about the selections that are available on the **Sides of Trust** page, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages.
8. On the **User Name and Password** page, type the user name and password for the appropriate administrator in the specified domain.
9. On the **Outgoing Trust Authentication Level--Local Forest** page, do one of the following, and then click **Next**:
   - Click **Forest-wide authentication**.
   - Click **Selective authentication**.
10. On the **Outgoing Trust Authentication Level--Specified Forest** page, do one of the following, and then click **Next**:
    - Click **Forest-wide authentication**.
    - Click **Selective authentication**.

11. On the **Trust Selections Complete** page, review the results, and then click **Next**.
12. On the **Trust Creation Complete** page, review the results, and then click **Next**.
13. On the **Confirm Outgoing Trust** page, do one of the following:
    - If you do not want to confirm this trust, click **No, do not confirm the outgoing trust**. Note that if you do not confirm the trust at this stage, the secure channel will not be established until the first time the trust is used by users.
    - If you want to confirm this trust, click **Yes, confirm the outgoing trust**, and then supply the appropriate administrative credentials from the specified domain.
14. On the **Confirm Incoming Trust** page, do one of the following:
    - If you do not want to confirm this trust, click **No, do not confirm the incoming trust**.
    - If you want to confirm this trust, click **Yes, confirm the incoming trust**, and then supply the appropriate administrative credentials from the specified domain.
15. On the **Completing the New Trust Wizard** page, click **Finish**.

# Creating Realm Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can create a realm trust to form a one-way or two-way, nontransitive or transitive trust with non-Windows Kerberos realms in your organization. You can create the trust when you log on to the domain, or you can use the **Run as** command to create the trust for a different domain.

For more information about realm trusts, see "How Domain and Forest Trusts Work" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

**Task requirements**

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to create a realm trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

| **Note** |
| --- |
| The New Trust Wizard in Active Directory Domains and Trusts does not support the creation of both sides of a realm trust at the same time. For more information about how the “both sides of the trust” option works, see the section "Sides of Trust" in Appendix: New Trust Wizard Pages. |

You can create a realm trust by using any of the following procedures, depending on the requirements of your organization and the administrative credentials that you have when you create the trust:

- Create a one-way, incoming, realm trust
- Create a one-way, outgoing, realm trust
- Create a two-way, realm trust

# Create a one-way, incoming, realm trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A one-way, incoming realm trust allows users in your Windows Server 2003 domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to access resources in the Kerberos realm. For example, if you are the administrator of the sales.wingtiptoys.com domain and users in that domain need to access resources in the Kerberos realm, you can use this procedure to establish a relationship so that users in the sales.wingtiptoys.com domain can access resources in the Kerberos realm.

You can create this realm trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a realm trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, incoming, realm trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Realm trust**, and then click **Next**.
6. On the **Transitivity of Trust** page, do one of the following:
   - To form a trust relationship with the domain and the specified realm only, click **Nontransitive**, and then click **Next**.
   - To form a trust relationship with the domain and the specified realm and all trusted realms, click **Transitive**, and then click **Next**.
7. On the **Direction of Trust** page, click **One-way: incoming**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the administrator of the realm must complete the trust, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Create a one-way, outgoing, realm trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A one-way, outgoing realm trust allows resources in your Windows Server 2003 domain (the domain that you are logged on to at the time that you run the New Trust Wizard) to be accessed by users in the Kerberos realm. For example, if you are the administrator of the sales.wingtiptoys.com domain and resources in that domain need to be accessed by users in the Kerberos realm, you can use this procedure to establish a relationship so that users in the Kerberos realm can access resources in the sales.wingtiptoys.com domain.

You can create this realm trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a realm trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a one-way, outgoing, realm trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Realm trust**, and then click **Next**.
6. On the **Transitivity of Trust** page, do one of the following:
   - To form a trust relationship with the domain and the specified realm only, click **Nontransitive**, and then click **Next**.
   - To form a trust relationship with the domain and the specified realm and all trusted realms, click **Transitive**, and then click **Next**.
7. On the **Direction of Trust** page, click **One-way: outgoing**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the administrator of the realm must complete the trust, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Create a two-way, realm trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A two-way, realm trust allows users in your domain (the domain that you are logged on to at the time that you run the New Trust Wizard) and users in the specified Kerberos realm to access resources in either the domain or the Kerberos realm.

You can create this realm trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a realm trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To create a two-way, realm trust**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to establish a trust with, and then click **Properties**.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the domain, and then click **Next**.
5. On the **Trust Type** page, click **Realm trust**, and then click **Next**.
6. On the **Transitivity of Trust** page, do one of the following:
   - To form a trust relationship with the domain and the specified realm only, click **Nontransitive**, and then click **Next**.
   - To form a trust relationship with the domain and the specified realm and all trusted realms, click **Transitive**, and then click **Next**.
7. On the **Direction of Trust** page, click **Two-way**, and then click **Next**.

   For more information about the selections that are available on the **Direction of Trust** page, see the section "Direction of Trust" in Appendix: New Trust Wizard Pages.
8. On the **Trust Password** page, type the trust password twice, and then click **Next**.
9. On the **Trust Selections Complete** page, review the results, and then click **Next**.
10. On the **Completing the New Trust Wizard** page, click **Finish**.

| **Note** |
| --- |
| For this trust to function, the administrator of the realm must complete the trust, using his or her administrative credentials and the exact same trust password that was used during this procedure. |

# Configuring Domain and Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can remove manually created trusts, but you cannot remove the default, two-way, transitive trusts between domains in a forest. If you remove manually created trusts, it is particularly important to verify that you successfully removed the trusts if you are planning to re-create them.

The following tasks for removing a manually created trust are described in this objective:

- Validating and removing trusts
- Modifying Name Suffix Routing Settings

# Validating and removing trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After a trust has been established, you may need to verify that it is working as designed, or that communications over the trust are working, by using Active Directory tools to validate the trust's connectivity. It may also be necessary to remove an existing, manually created trust when connectivity between two domains is no longer necessary.

**Task requirements**

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to create a realm trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

To complete this task, perform the following procedures:

- Validate a trust
- Remove a manually created trust

# Validate a trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can validate all trusts that are made between domains, but you cannot validate realm trusts.

You can validate a trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to create a realm trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To validate a trust**

- Using the Windows interface
- Using the command line

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that contains the trust that you want to validate, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the trust to be validated, and then click **Properties**.
4. Click **Validate**.
5. Do one of the following, and then click **OK**:
   - Click **No, do not validate the incoming trust**.

     If you click this option, it is recommended that you repeat this procedure for the reciprocal domain.
   - Click **Yes, validate the incoming trust**.

     If you click this option, you must type a user account and password with administrative credentials for the reciprocal domain.

**Using the command line**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **netdom trust** *TrustingDomainName* **/d:** *TrustedDomainName* **/verify**

| Term | Definition |
|---|---|
| *TrustingDomainName* | Specifies the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the trusting domain in the trust that is being created. |
| *TrustedDomainName* | Specifies the DNS name (or NetBIOS name) of the domain that will be trusted in the trust that is being created. |

# Remove a manually created trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

It is possible to remove manually created shortcut trusts, external trusts, realm trusts, or forest trusts. It is not possible to remove default, two-way, transitive trusts between domains in a forest. It is particularly important to verify that you successfully remove trusts if you are planning to re-create them.

You can remove a manually created trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about the Netdom command-line tool, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To remove a manually created trust**

- Using the Windows interface
- Using a command prompt

**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that contains the trust that you want to remove, and then click **Properties**.
3. Click the **Trusts** tab.
4. In either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the trust to be removed, and then click **Remove**.
5. Do one of the following, and then click **OK**:
   - Click **No, remove the trust from the local domain only**.

     If you click this option, it is recommended that you repeat this procedure for the reciprocal domain.
   - Click **Yes, remove the trust from both the local domain and the other domain**.

     If you click this option, you must type a user account and password with administrative credentials for the reciprocal domain.

**Using the command line**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **netdom trust** *TrustingDomainName* **/d:** *TrustedDomainName* **/remove/UserD:***User* **/PasswordD:***

| Term | Definition |
|---|---|
| *TrustingDomainName* | Specifies the Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the trusting domain in the trust that is being created. |

| | |
|---|---|
| *TrustedDomainName* | Specifies the DNS name (or NetBIOS name) of the domain that will be trusted in the trust that is being created. |

**Note**

If you are using Netdom to remove a realm trust, you must add the **/force** option to the end of the command (after **/remove**) to remove the trust successfully.

# Modifying Name Suffix Routing Settings

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Name suffix routing is a mechanism that is used to manage how authentication requests are routed across Windows Server 2003 forests that are joined by forest trusts. To simplify the administration of authentication requests, when a forest trust is created, all unique name suffixes are routed by default. A unique name suffix is a name suffix within a forest, such as a user principal name (UPN) suffix, service principal name (SPN) suffix, or Domain Name System (DNS) forest or domain tree name that is not subordinate to any other name suffix. For example, the DNS forest name fabrikam.com is a unique name suffix within the fabrikam.com forest. For more information about name suffix routing, see Routing name suffixes across forests on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35414).

| **Note** |
| --- |
| You cannot enable a name suffix that is in conflict. If the conflict is with a local UPN name suffix, you must remove the local UPN name suffix before you can enable the routing name. If the conflict is with a name that is claimed by another trust partner, you must disable the name in the other trust before it can be enabled for this trust. |

**Task requirements**

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to create a realm trust, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

To complete this task, perform any of the following procedures:

- Modify the routing status of a name suffix
- Enable or disable an existing name suffix for routing
- Exclude name suffixes from routing to local forests

# Modify the routing status of a name suffix

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can change the routing status (enabled or disabled) of a name suffix by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to modify name suffix routing settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To modify the routing status of a name suffix**
**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the domain that you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)**or **Domains that trust this domain (incoming trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. On the **Name Suffix Routing** tab, under **Name suffixes in the x.x forest**, click the suffix for which you want to modify routing status, and then click **Edit**.
5. In **Existing name suffixes in x.x**, click the suffix that you want to modify, and then click **Enable** or **Disable**.

# Enable or disable an existing name suffix for routing

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to prevent authentication requests for specific name suffixes from being routed to a forest, or you can use this procedure to allow authentication requests for specific name suffixes to be routed to a forest. You can enable or disable an existing name suffix for routing by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to modify name suffix routing settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

| **Note** |
| --- |
| When you disable a name suffix, all children of that Domain Name System (DNS) name will also be disabled. |

### Administrative credentials

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To enable or disable an existing name suffix for routing**
**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. Click the **Name Suffix Routing** tab, and then, under **Name suffixes in the x.x forest,** do one of the following:
   - To enable a name suffix, click the suffix that you want to enable, and then click **Enable**. If the **Enable** button is unavailable, the name suffix is already enabled.
   - To disable a name suffix, click the suffix that you want to disable, and then click **Disable**. If the **Disable** button is unavailable, the name suffix is already disabled.

# Exclude name suffixes from routing to local forests

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can exclude existing name suffixes from routing to local forests by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to modify name suffix routing settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

| **Note** |
| --- |
| When you exclude a name suffix, all children of that Domain Name System (DNS) name will also be excluded. |

### Administrative credentials

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To exclude name suffixes from routing to local forests**
**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain (outgoing trusts)** or **Domains that trust this domain (incoming trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. On the **Name Suffix Routing** tab, under **Name suffixes in the x.x forest**, click the unique name suffix to exclude from routing, and then click **Edit**.
5. In **Name suffixes to exclude from routing to x.x**, click **Add**, type a DNS name suffix that is subordinate to the unique name suffix, and then click **OK**.

# Securing Domain and Forest Trusts

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you create a new trust in an existing Active Directory forest, all communications over that trust are tightly secured. However, when you create a trust between your domain and another domain outside your forest, there are certain security issues involved. For example, you might need to configure security identifier (SID) filtering to deny one domain the right to provide credentials for another domain. You can enable or disable SID filtering for external trusts or forest trusts.

The following tasks for securing domain and forest trusts are described in this objective:

- Configuring SID Filtering Settings
- Configuring Selective Authentication Settings

For more information about how the security settings for domain and forest trusts work, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

# Configuring SID Filtering Settings

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Security principals in Active Directory have an attribute, called SID history, to which domain administrators can add users' old security identifiers (SIDs). This is useful during Active Directory migrations because administrators do not need to modify access control lists (ACLs) on large numbers of resources and users can use their old SIDs to access resources. However, under some circumstances it is possible for attackers or rogue administrators that have compromised a domain controller in a trusted domain to use the SID history attribute (sIDHistory) to associate SIDs with new user accounts, granting themselves unauthorized rights. To help prevent this type of attack, Windows Server 2003 automatically enables SID filter quarantining on all external trusts that are created by a Windows Server 2003 domain controller. External trusts that are created using domain controllers running Windows 2000 Server with Service Pack 3 (SP3) or earlier must be manually configured to enable SID filter quarantining.

| **Note** |
| --- |
| You cannot turn off the default behavior in Windows Server 2003 that enables SID filter quarantining for newly created external trusts. External trusts that are created from domain controllers running Windows 2000 Server with SP3 or earlier do not enforce SID filter quarantining by default. |

You can use SID filter quarantining to filter out migrated SIDs that are stored in SID history from specific domains. For example, where an external trust relationship exists such that the one domain, Contoso (running Windows 2000 Server domain controllers), trusts another domain, Cpandl (also running Windows 2000 Server domain controllers), an administrator of the Contoso domain can manually apply SID filter quarantining to the Cpandl domain, which allows all SIDs with a domain SID from the Cpandl domain to pass but all other SIDs (such as those from migrated SIDs that are stored in SID history) to be discarded.

| **Note** |
| --- |
| Do not apply SID filter quarantining to trusts within a forest that is not using the Windows Server 2003 forest functional level, because doing so removes SIDs that are required for Active Directory replication. If the forest functional level is Windows Server 2003 and quarantining is applied between two domains within a forest, a user in the quarantined domain with universal group memberships in other domains in the forest may not be able to access resources in nonquarantined domains, because the group memberships from those domains are filtered when resources are accessed across the trust relationship. Likewise, SID filter quarantining should not be applied to forest trusts. |

To further secure your forest, consider enabling SID filter quarantining on all existing external trusts that are created by domain controllers running Windows 2000 Server SP3 or earlier. You can do this by using Netdom.exe to enable SID filter quarantining on existing external trusts or by recreating these external trusts from a domain controller running Windows Server 2003 or Windows 2000 Server with Service Pack 4 (SP4) or later. For more information about how to enable SID filtering on trusts that are created by Windows 2000 Server domain controllers, see the Windows 2000 Active Directory Operations Guide on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=18545).

For more information about how SID filtering works, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

**Task requirements**

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to configure SID filtering settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

To complete this task, perform the following procedures:

- Disable SID filter quarantining
- Reapply SID filter quarantining

# Verify SID filter quarantining

Updated: November 4, 2009

Applies To: Windows Server 2003, Windows Server 2008, Windows Server 2008 R2

You can use this procedure to verify the status of security identifier (SID) filter quarantining for an external trust or a forest trust using Netdom.exe.

For more information about the **netdom** command-line tool, see Netdom Overview (http://go.microsoft.com/fwlink/?LinkId=111537).

For more information about how SID filtering works, see Security Considerations for Trusts (http://go.microsoft.com/fwlink/?LinkID=111846)

Membership in **Domain Admins** or **Enterprise Admins** in Active Directory Domain Services (AD DS), or equivalent, is the minimum required to complete this procedure. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

**To verify SID filter quarantining from the trusting domain**

1. Open a command prompt.
2. At the command prompt, type the following syntax, and then press ENTER:

```
netdom trust <TrustingDomainName> /domain: <TrustedDomainName> /quarantine /userD:
<domainadministratorAcct> /passwordD: <domainadminpwd>
```

| Note |
| --- |
| For a description of the placeholder values, see Placeholder reference table. |

**To verify SID filter quarantining from the trusting forest**

1. Open a command prompt.
2. At the command prompt, type the following syntax, and then press ENTER:

```
netdom trust <TrustingDomainName> /domain: <TrustedDomainName> /enablesidhistory /userD:
<domainadministratorAcct> /passwordD: <domainadminpwd>
```

| Note |
| --- |
| For a description of the placeholder values, see Placeholder reference table. |

**To verify SID filter quarantining from the trusted domain**

1. Open a command prompt.
2. At the command prompt, type the following syntax, and then press ENTER:

```
netdom trust <TrustingDomainName> /userO:<domainadministratorAcct> /passwordO:<domainadminpwd> /domain:
<TrustedDomainName> /quarantine
```

| Note |
| --- |
| For a description of the placeholder values, see Placeholder reference table. |

**To verify SID filter quarantining from the trusted forest**

1. Open a command prompt.
2. At the command prompt, type the following syntax, and then press ENTER:

```
netdom trust <TrustingDomainName> /userO:<domainadministratorAcct> /passwordO:<domainadminpwd> /domain:
<TrustedDomainName> /enablesidhistory
```

| Note |
| --- |
| For a description of the placeholder values, see Placeholder reference table. |

**Placeholder reference table**

The following table describes the placeholder values in the syntax for the `netdom` command.

| Value | Description |
| --- | --- |
| <TrustingDomainName> | The Domain Name System (DNS) name (or NetBIOS name) of the trusting domain in the trust that is being created. |
| <TrustedDomainName> | The DNS name (or NetBIOS name) of the domain that will be trusted in the trust that is being created. |
| <domainadministratorAcct> | The user account name with the appropriate administrator credentials to modify the trust. |
| <domainadminpwd> | The password of the user account in *domainadministratorAcct*. |

# Disable SID filter quarantining

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Although it is not recommended, you can disable security identifier (SID) filter quarantining for an external trust by using the Netdom.exe tool. You should consider disabling SID filter quarantining only in the following situations:

- You have an equally high level of confidence in the administrators who have physical access to domain controllers in the trusted domain and the administrators with such access in the trusting domain.
- You have a strict requirement to assign universal groups to resources in the trusting domain, even when those groups were not created in the trusted domain.
- Users have been migrated to the trusted domain with their SID histories preserved, and you want to grant those users access to resources in the trusting domain based on the **SIDHistory** attribute.

For more information about how SID filtering works, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

You can disable SID filter quarantining by using the Netdom command-line tool. For more information about the Netdom command-line tool, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To disable SID filter quarantining**

1. To disable SID filter quarantining for the trusting domain, open a Command Prompt.
2. Type the following command, and then press ENTER:

   **Netdom trust** *TrustingDomainName* **/domain:** *TrustedDomainName* **/quarantine:No /userD:** *domainadministratorAcct* **/passwordD:** *domainadminpwd*

| Value | Description |
|---|---|
| *TrustingDomainName* | The Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the trusting domain in the trust that is being created. |
| *TrustedDomainName* | The DNS name (or NetBIOS name) of the domain that will be trusted in the trust that is being created. |
| *domainadministratorAcct* | The user account name with the appropriate administrator credentials to modify the trust. |
| *domainadminpwd* | The password of the user account in *domainadministratorAcct*. |

**Note**

You can enable or disable SID filter quarantining only from the trusting side of the trust. If the trust is a two-way trust, you can also disable SID filter quarantining in the trusted domain by using the domain administrator's credentials for the trusted domain and reversing the *TrustingDomainName* and *TrustedDomainName* values in the command-line syntax.

# Reapply SID filter quarantining

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can reapply security identifier (SID) filter quarantining to an external or forest trust that has had SID filter quarantining disabled. By default, Windows Server 2003 automatically enables SID filter quarantining on all external trusts that are created by a Windows Server 2003 domain controller. For more information about how SID filter quarantining works, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

You can reapply SID filter quarantining by using the Netdom command-line tool. For more information about the Netdom command-line tool, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

### Administrative credentials

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

#### To reapply SID filter quarantining

1. To reapply SID filter quarantining for the trusting domain, open a Command Prompt.
2. Type the following syntax, and then press ENTER:

   **Netdom trust** *TrustingDomainName* **/domain:** *TrustedDomainName* **/quarantine:Yes /userD:** *domainadministratorAcct* **/passwordD:** *domainadminpwd*

| Term | Definition |
|---|---|
| *TrustingDomainName* | The Domain Name System (DNS) name (or network basic input/output system (NetBIOS) name) of the trusting domain in the trust that is being created. |
| *TrustedDomainName* | The DNS name (or NetBIOS name) of the domain that will be trusted in the trust that is being created. |
| *domainadministratorAcct* | The user account name with the appropriate administrator credentials to modify the trust. |
| *domainadminpwd* | The password of the user account in *domainadministratorAcct*. |

# Configuring Selective Authentication Settings

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Trusts that are created between Windows Server 2003 forests can use legacy authentication settings (settings that were used in Windows 2000 Server) or selective authentication. Selective authentication is a security setting that can be enabled on external trusts and forest trusts between Windows Server 2003 forests. Selective authentication provides Active Directory administrators who manage a trusting forest more control over which groups of users in a trusted forest can access shared resources in the trusting forest. Because creating an external trust or forest trust provides a pathway for all authentication requests between the forests, this increased control is especially important when administrators need to grant access to shared resources in their organization's forest to a limited set of users in another organization's forest.

For more information about how selective authentication settings work, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

**Task requirements**

You can use either of the following tools to perform the procedures for this task:

- Active Directory Domains and Trusts
- Netdom.exe

For more information about how to use the Netdom command-line tool to configure selective authentication settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

To complete this task, perform the following procedures:

- Enable selective authentication over an external trust
- Enable selective authentication over a forest trust
- Enable domain-wide authentication over an external trust
- Enable forest-wide authentication over a forest trust
- Grant the Allowed to Authenticate permission on computers in the trusting domain or forest

# Enable selective authentication over an external trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Selective authentication over an external trust restricts access to only those users in a trusted domain who have been explicitly given authentication permissions to computer objects (resource computers) that reside in the trusting domain. To explicitly give authentication permissions to computer objects in the trusting domain to certain users, administrators must grant those users the **Allowed to Authenticate** permission in Active Directory. For more information, see Grant the Allowed to Authenticate permission on computers in the trusting domain or forest. For more information about how selective authentication works, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

You can enable selective authentication over an external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to configure selective authentication settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To enable selective authentication over an external trust**
**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under **Domains trusted by this domain (outgoing trusts)**, click the external trust that you want to administer, and then click **Properties**.
4. On the **Authentication** tab, click **Selective authentication**, and then click **OK**.

| **Note** |
| --- |
| Only the authentication settings for the outgoing trust are displayed when you click **Properties** and then click the **Authentication** tab in Active Directory Domains and Trusts. To view the correct authentication settings for the incoming side of a two-way, external trust, connect to a domain controller in the trusted domain, and then use Active Directory Domains and Trusts to view the authentication settings for the outgoing side of the same trust. |

# Enable selective authentication over a forest trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Selective authentication over a forest trust restricts access to only those users in a trusted forest who have been explicitly given authentication permissions to computer objects (resource computers) that reside in the trusting forest. To explicitly give authentication permissions to computer objects in the trusting forest to certain users, Administrators must grant those users the **Allowed to Authenticate** permission in Active Directory. For more information, see Grant the Allowed to Authenticate permission on computers in the trusting domain or forest. For more information about how selective authentication works, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

You can enable selective authentication over a forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to configure selective authentication settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory.

**To enable selective authentication over a forest trust**
**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain node for the forest root domain, and then click **Properties**.
3. On the **Trusts** tab, under **Domains trusted by this domain (outgoing trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. On the **Authentication** tab, click **Selective authentication**, and then click **OK**.

| **Note** |
| --- |
| Only the authentication settings for the outgoing trust are displayed when you click **Properties** and then click the **Authentication** tab in Active Directory Domains and Trusts. To view the correct authentication settings for the incoming side of a two-way, forest trust, connect to a domain controller in the forest root domain of the trusted forest, and then use Active Directory Domains and Trusts to view the authentication settings for the outgoing side of the same trust. |

# Enable domain-wide authentication over an external trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The domain-wide authentication setting permits unrestricted access by any users in the trusted domain to all available shared resources in the trusting domain. This is the default authentication setting for external trusts, and it is representative of the way authentications were routed — without restriction — over Windows 2000 Server trusts. For more information about the domain-wide authentication setting, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

You can enable domain-wide authentication over an external trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to configure selective authentication settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To enable domain-wide authentication over an external trust**
**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the domain that you want to administer, and then click **Properties**.
3. On the **Trusts** tab, under **Domains trusted by this domain (outgoing trusts)**, click the external trust that you want to administer, and then click **Properties**.
4. On the **Authentication** tab, click **Domain-wide authentication**, and then click **OK**.

| **Note** |
| --- |
| Only the authentication settings for the outgoing trust are displayed when you click **Properties** and then click the **Authentication** tab in Active Directory Domains and Trusts. To view the correct authentication settings for the incoming side of a two-way, external trust, connect to a domain controller in the trusted domain, and then use Active Directory Domains and Trusts to view the authentication settings for the outgoing side of the same trust. |

# Enable forest-wide authentication over a forest trust

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The forest-wide authentication setting permits unrestricted access by any users in the trusted forest to all available shared resources in any of the domains in the trusting forest. This is the default authentication setting for forest trusts, and it is representative of the way authentications were routed — without restriction — over Windows 2000 Server trusts. For more information about the forest-wide authentication setting, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

You can enable forest-wide authentication over a forest trust by using the New Trust Wizard in Active Directory Domains and Trusts or by using the Netdom command-line tool. For more information about how to use the Netdom command-line tool to configure selective authentication settings, see "Netdom.exe: Windows Domain Manager" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=41700).

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To enable forest-wide authentication over a forest trust**
**Using the Windows interface**

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click the forest root domain, and then click **Properties**.
3. On the **Trusts** tab, under **Domains trusted by this domain (outgoing trusts)**, click the forest trust that you want to administer, and then click **Properties**.
4. On the **Authentication** tab, click **Forest-wide authentication**, and then click **OK**.

| **Note** |
| --- |
| Only the authentication settings for the outgoing trust are displayed when you click **Properties** and then click the **Authentication** tab in Active Directory Domains and Trusts. To view the correct authentication settings for the incoming side of a two-way, forest trust, connect to a domain controller in the trusted domain (the forest root domain in the other forest), and then use Active Directory Domains and Trusts to view the authentication settings for the outgoing side of the same trust. |

# Grant the Allowed to Authenticate permission on computers in the trusting domain or forest

Updated: June 21, 2013

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For users in a trusted Windows Server 2003 domain or forest to be able to access resources in a trusting Windows Server 2003 domain or forest, where the trust authentication setting has been set to selective authentication, each user must be explicitly granted the **Allowed to Authenticate** permission on the security descriptor of the computer objects (resource computers) that reside in the trusting domain or forest. For more information about how the **Allowed to Authenticate** permission works, see "Security Considerations for Trusts" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35413).

| **Note** |
| --- |
| The **Allowed to Authenticate** permission can be set on computer objects that represent member servers running Windows NT Server 4.0, Windows 2000 Server, and Windows Server 2003. |

| **Note** |
| --- |
| By default, only members of the Account Operators, Administrators, Domain Admins, Enterprise Admins, and SYSTEM security groups that are located in the trusting domain can modify the **Allowed to Authenticate** permission. |

To enable access to resources over an external trust or forest trust that is set to selective authentication, complete the following procedure by using Active Directory Users and Computers from the trusting domain.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To grant the Allowed to Authenticate permission on computers in the trusting domain or forest**
**Using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click the **Computers** container or the container where your computer objects reside.
3. Right-click the computer object that you want users in the trusted domain or forest to access, and then click **Properties**.
4. On the **Security** tab, do one of the following:
   - In **Group or user names**, click the user names or group names for which you want to grant access to this computer, select the **Allow** check box next to the **Allowed to Authenticate** permission, and then click **OK**.
   - Click **Add**. In **Enter the object names to select**, type the name of the user object or group object for which you want to grant access to this resource computer, and then click **OK**. Select the **Allow** check box next to the **Allowed to Authenticate** permission, and then click **OK**.

# Appendix: New Trust Wizard Pages

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Understanding how user input is handled during the trust creation process will help you provide information when it is most necessary and help you better prepare for your specific procedure. This section explains the two most complex pages in the New Trust Wizard:

- **Direction of Trust**
- **Sides of Trust**

**Direction of Trust**

The **Direction of Trust** page in the New Trust Wizard is configured by an administrator in one domain to determine whether authentication requests should be routed from this domain to a specified domain, from the specified domain to this domain, or freely between both domains. The following options are available on the **Direction of Trust** page:

- **Two-way**: A two-way trust allows authentication requests that are sent by users in either domain or forest to be routed successfully to resources in either of the two domains or forests.
- **One-way: incoming**: A one-way, incoming trust allows authentication requests that are sent by users in your domain or forest (the domain or forest where you started the New Trust Wizard) to be routed successfully to resources in the other domain or forest.
- **One-way: outgoing**: A one-way, outgoing trust allows authentication requests that are sent by users in the other domain (the domain or forest that you are indicating in the New Trust Wizard as the specified domain or forest) to be routed successfully to resources in your domain or forest.

These options are explained in the following sections.

**Wizard Option: Two-way**

Use this option when you want to share resources equally between two domains or forests for all of the users that reside in both domains or forests. A two-way trust allows authentication requests that are sent by users in a trusted domain or forest to be routed successfully to the trusting domain or forest.

| **Note** |
| --- |
| Traditionally, documentation about domain and forest trusts have used the terms “trusting” and “trusted” to help administrators pinpoint the direction of the trust. Although this terminology is still used today to define and conceptualize how trusts work, it varies from the terminology that is used in the New Trust Wizard to help administrators determine the direction of trust. |

**Wizard Option: One-way: incoming**

Use this option when you want to allow authentication requests to be routed from your domain or forest (referred to as “this domain” or “this forest” in the wizard) to resources residing in a second domain or forest (referred to as “specified domain” or “specified forest” in the wizard). “One-way” in **One-way: incoming** means that this selection will create a one-way trust that can route authentications to resources in only one direction, while user access to those resources flows in the other direction. “Incoming” in **One-way: incoming** refers to the direction of the trust itself, not the direction in which authentication requests will flow. In other words, as shown in the following illustration, a "one-way incoming trust" means that your domain or forest will be the domain or forest that receives access to the resources in the other domain.

**Wizard Option: One-way: outgoing**

Use this option when you want to allow authentication requests to be routed to your domain or forest (referred to as “this domain” or “this forest” in the wizard) from users residing in a second domain or forest (referred to as “specified domain” or “specified forest” in the wizard). “One-way” in **One-way: outgoing** means that this selection will create a one-way trust that can route authentications to resources in only one direction, while user access to those resources flows in the other direction. “Outgoing” in **One-way: outgoing** refers to the direction of the trust itself, not the direction in which authentication requests will flow. In other words, as shown in the following illustration, a "one-way, outgoing trust" means that your domain or forest will provide access to resources that are located in your domain to users who are located in the other domain or forest.

**Sides of Trust**
In Windows NT 4.0 and Windows 2000, the only way to create trusts using the graphical user interface (GUI) was incrementally — one side of the trust at a time. When you create external trusts, shortcut trusts, realm trusts, or forest trusts in Windows Server 2003, you now have the option to create each side of the trust separately or both sides of the trust simultaneously.

**Wizard Option: This domain only**
Use this option when you want to create each side of the trust separately, which means that you must run the New Trust Wizard twice — once for each domain in the trust. Although the New Trust Wizard presents a different experience than previous version of Windows Server operating systems, this option provides behavior that is similar to the way that trusts were created in Windows NT 4.0 and Windows 2000. When you create trusts using this method, you must supply the same trust password for each domain. As a security best practice, all trust passwords should be strong passwords.

**Wizard Option: Both this domain and the specified domain**
This option provides administrators who possess the appropriate domain credentials for both domains in the trust relationship with the option to quickly create both sides of a trust by completing a single instance of the New Trust Wizard. When you select this option, a strong trust password is automatically generated for you. For this selection to be successful, the administrator running the wizard must acquire the appropriate administrative credentials for each domain in the trust relationship

# Administering the Windows Time Service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Time synchronization is critical for the proper operation of many Windows services and line-of-business applications. The Windows® Time service uses the Network Time Protocol (NTP) to synchronize computer clocks on the network so that an accurate clock value, or time stamp, can be assigned to network validation and resource access requests.

This guide provides information for administering the Windows Time service in the Microsoft Windows Server 2003 operating system.

**In this guide**

- Introduction to Administering the Windows Time Service
- Managing the Windows Time Service

# Introduction to Administering the Windows Time Service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Microsoft® Windows Server™ 2003 Windows Time service, also known as W32Time, synchronizes the date and time for all computers running on a Windows Server 2003 network. The service integrates NTP and time providers, making it a reliable and scalable time service for enterprise administrators.

The purpose of the Windows Time service is to make sure that all computers that are running versions of Windows 2000 Server, Windows Server 2003, or Windows XP in an organization use a common time. To guarantee appropriate common time usage, the Windows Time service uses a hierarchical relationship that controls authority and does not permit loops. A domain controller at the top of the hierarchy provides authoritative time to all other domain controllers, and domain clients use domain controllers as their time source. By default, the domain controller at the top of the hierarchy is the primary domain controller (PDC) operations master (also known as flexible single master operations or FSMO) in the forest root domain.

**Windows time source selection**

By default, Windows-based computers use the following sources for time synchronization:

- For computers that are joined to a domain, the first query is to a time source in the parent domain.

| **Note** |
| --- |
| Computers that are not joined to a domain and are running Windows XP or Windows XP Home Edition are configured to synchronize with time.windows.com by default. |

- If the time client is in a single-domain forest, the first query is to the PDC emulator in the domain.

- All PDC emulator operations masters follow the hierarchy of domains in the selection of their inbound time partner. A PDC emulator can synchronize its time from the PDC emulator in the parent domain or any domain controller in the parent domain.

For more information about time source selection, see How Windows Time Service Works on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=117753).

The authoritative time source at the root of the forest can acquire its time either by connecting to an installed hardware clock on the internal network, or by connecting to an external Network Time Protocol (NTP) server, which is connected to a hardware device. If no domain controller is configured as the authoritative time source in the forest root domain, the domain controller that holds the PDC emulator operations master role uses its internal clock to provide time to forest computers.

**External NTP time servers**

Many external NTP servers are available over the Internet. Use the following information to select an NTP server:

- The National Institute of Standards and Technology (NIST) in Boulder, Colorado, which is used as the external time provider by the Microsoft time server (time.windows.com). NIST provides the Automated Computer Time Service (ACTS), which can set a computer clock with an uncertainty of less than 10 milliseconds. For more information about NTP and for a list of external time servers, see Set Your Computer Clock Via the Internet: NIST Internet Time Service (ITS) (http://go.microsoft.com/fwlink/?LinkId=112035).

- The U.S. Naval Observatory (USNO) Time Service Department in Washington, DC, is another reliable source for accurate time synchronization in the United States. To see a list of USNO servers and their descriptions, see USNO Network Time Servers (http://go.microsoft.com/fwlink/?LinkId=112036).

- Many other sites throughout the world can be used for time synchronization. For more NTP server lists and search criteria, see the NTP Servers Web site (http://go.microsoft.com/fwlink/?LinkId=116972).

For the most highly accurate time synchronization, configure a hardware clock, such as a radio or Global Positioning System

(GPS) device, as the time source for the PDC. There are many consumer and enterprise devices that use NTP, which makes it possible for you to install the device on an internal network for use with the PDC.

You use the **w32tm** command-line tool to configure Windows Time Service. For a detailed technical reference of the Windows Time service, that includes complete documentation of the **w32tm** command-line tool and time service registry settings, see the Windows Time Service Technical Reference (http://go.microsoft.com/fwlink/?LinkID=100940).

**W32tm and net time**

The **net time** commands are predecessors of **w32tm** commands and should not be used to configure the Windows Time Service or to set the time on a computer while the Windows Time Service is actively running. We recommend that you configure and display the Windows Time Service information for Windows XP and Windows Server 2003 operating systems by using the**w32tm** commands.

Although the command **net time /querysntp** may appear to display the Simple Network Time Protocol (SNTP) server for Windows XP and Windows Server 2003 operating systems, it does not display complete time configuration information. You can use the command **w32tm /dumpreg /subkey:parameters** to determine whether the computer is configured to synchronize time from the domain hierarchy or from a manual list of time servers. The command output includes a line labeled **Type** that identifies the time synchronization method that is in use by the client. The following **Type** line outputs are possible for the time client:

- **NoSync**: The client does not synchronize time.
- **NTP**: The client synchronizes time from an external time source. Review the values in the **NtpServer** line in the output to see the name of the server or servers that the client uses for time synchronization.
- **NT5DS**: The client is configured to use the domain hierarchy for its time synchronization.
- **AllSync**: The client synchronizes time from any available time source, including domain hierarchy and external time sources.

# Managing the Windows Time Service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You initially configure the Windows 2003 Time service (W32Time) when you deploy your Active Directory forest root domain. Thereafter, it requires little day-to-day management. After you make changes on your network however, including when you add certain client computers, move the PDC emulator operations master role, or simply change the time source for you network, you might need to perform some of the following tasks:

- Configuring a time source for the forest
- Configuring Windows-based clients to synchronize time
- Restoring Windows Time service to default settings

# Configuring a time source for the forest

Updated: September 23, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The first domain controller that you deploy in a domain holds the primary domain controller (PDC) emulator operations master (also known as flexible single master operations or FSMO) role for the domain. By default, the domain controller that holds the PDC emulator master role in the forest root domain is the reliable time source at the top of the time-source domain hierarchy for the forest. As soon as you install the first domain controller in the forest, set the PDC emulator in the forest root domain to synchronize from a valid Network Time Protocol (NTP) source or from a hardware clock installed on the network. If no time source is configured on the PDC emulator or any other domain controller in the forest root domain, the PDC emulator advertises as a reliable time source and uses its internal clock as the source for forest synchronization. In this case, no manual configuration is required.

After initial deployment of your network, you typically reconfigure the time service on the PDC emulator in the forest root domain in only two situations:

- You move the PDC emulator role to a different computer. In this case, you must configure the Windows Time service for the new PDC emulator master role holder and reconfigure the original PDC emulator master role holder to synchronize from the domain and not from an external or internal time source.

- You change the time source for the PDC emulator. For example, you change from synchronizing with an external source to synchronizing with an internal hardware device.

In some environments, one or more domain controllers are configured to act as standby PDC emulator role holders. If the current PDC emulator fails or is otherwise unavailable, the role can quickly be transferred to the standby. If you anticipate moving the PDC emulator role and want to avoid reconfiguring the new and old PDC emulator every time the role is moved, you can configure a domain controller in the forest root domain that is not the PDC emulator as the reliable time source for the forest. In this way, the root of the time service stays the same and remains properly configured.

| **Note** |
| --- |
| Make sure that the domain controller that you configure to be the forest time source is highly available and, if it is not the PDC emulator, that it does not hold other operations master roles that might need to be transferred. |

Use the following recommendations for configuring the time source for the forest root domain, in this order of preference:

1. Install a hardware clock, such as a radio or Global Positioning System (GPS) device, as the time source for the forest root domain and configure Windows Time service (W32time) on the PDC emulator or other domain controller to synchronize with this device. Many consumer and enterprise devices are available that use NTP. You can install the device on an internal network and configure the PDC emulator to use it as its time source.

   Hardware clocks have the following advantages:

   - More secure. You do not have to connect to the Internet.

   - Highest accuracy, although the accuracy level of NTP servers is as high as that of Windows Time Service (that is, the effect of the higher accuracy is not appreciated).

   Hardware clocks have the following disadvantage:

   - Expense and maintenance. You must purchase and install a hardware clock, whereas you can connect to a public time server at no cost and without hardware installation.

2. Configure the Windows Time service on the PDC emulator or other domain controller to synchronize with an external time server. Computer clocks synchronize with external time servers by using the NTP protocol over an IPnetwork. You

can manually configure the PDC emulator in the forest root domain to synchronize with the external time source.

External time servers have the following advantages:

- Low cost or no cost. Cost is usually limited to bandwidth.
- Good accuracy. Although hardware clocks have the highest accuracy, the accuracy of a hardware clock can actually exceed the accuracy of Windows Time Service, so the comparison of accuracy is not relevant.

External time servers have the following disadvantage:

- Security risk. NTP synchronization with an external time source is not authenticated and is therefore less secure than if time is sourced from inside the network.

Many GPS receivers and other time devices can function as NTP servers on a network. You can configure your Active Directory forest to synchronize time from these external hardware devices only if they are also acting as NTP servers on your network. To do so, configure the domain controller functioning as the PDC emulator in your forest root to synchronize with the NTP server provided by the GPS device. To do so, see Configure the Windows Time service on the PDC emulator in the Forest Root Domain (http://go.microsoft.com/fwlink/?LinkId=91969).

If you are using an external time source, you can use the following sites to select an NTP server:

- USNO NTP Network Time Servers (http://go.microsoft.com/fwlink/?LinkId=112036)
- Set Your Computer Clock Via the Internet: NIST Internet Time Service (ITS) (http://go.microsoft.com/fwlink/?LinkId=112035)
- The NTP Public Services Project (http://go.microsoft.com/fwlink/?LinkId=180528/bin/view/Servers/WebHome)

If you choose to implement an NTP time synchronization product other than the Windows Time service, you must disable the Windows Time service on the forest root domain reliable time source. All NTP servers need access to UDP port 123. If the Windows Time service is running on a Windows Server 2003–based computer, port 123 will remain occupied for the Windows Time service.

**Task requirements**

The following tools are required to perform the procedures for this task:

- W32tm.exe
- Services snap-in if you need to disable the Windows Time service

Perform the following procedures as needed to configure a time source for your forest:

1. Configure the Windows Time service on the PDC emulator in the Forest Root Domain
2. If you move the role of the PDC emulator to a new domain controller, Change the Windows Time service configuration on the previous PDC emulator.
3. If you are implementing a time synchronization product other than the Windows Time service in your environment that uses the NTP protocol, Disable the Windows Time service to free UDP port 123 on the network.

# Configure the Windows Time service on the PDC emulator in the Forest Root Domain

Updated: March 17, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Configure the Windows Time service (W32time) on the primary domain controller (PDC) emulator operations master (also known as flexible single master operations or FSMO) in the forest root domain when you deploy a new forest root domain or when you move the role of the PDC emulator in the forest root domain to a new domain controller. If you move the role of the PDC emulator to a new domain controller, you must also change the configuration of the Windows Time service on the previous PDC emulator. For more information, see Change the Windows Time service configuration on the previous PDC emulator.

| **Important** |
| --- |
| If the PDC emulator for your forest root domain is not configured or if it is unable to synchronize time from an external source, the PDC emulator for the forest logs W32time Event ID 12 in the System log of Event Viewer. For additional troubleshooting information, see Microsoft Knowledge Base article 816042 (http://go.microsoft.com/fwlink/?LinkID=60402) |

Before you configure the Windows Time service on the PDC emulator, you can determine the time difference between it and the source as a means to test basic Network Time Protocol (NTP) communication. After completing the configuration on the PDC emulator, be sure to monitor the System log in Event Viewer for W32time errors.

| **Note** |
| --- |
| For more information about the **w32tm** command, type **w32tm /?** at a command prompt or see Windows Time Service Tools and Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42984). |

### Administrative Credentials

To perform this procedure locally on the PDC emulator, you must be a member of the Administrators group. To perform this procedure from a remote computer, you must be a member of the Domain Admins group.

**To configure the Windows Time service on the PDC emulator**

1. Open a Command Prompt.
2. Type the following command to display the time difference between the local computer and a target computer, and then press ENTER:

   **w32tm /stripchart /computer:** *target* **/samples:** *n* **/dataonly**

   | Value | Definition |
   | --- | --- |
   | *target* | Specifies the Domain Name System (DNS) name or IP address of the NTP server that you are comparing the local computer's time against, for example, time.windows.com. |
   | *n* | Specifies the number of time samples that will be returned from the target computer to test basic NTP communication. |

3. Open User Datagram Protocol (UDP) port 123 for outgoing traffic if needed.
4. Open UDP port 123 (or a different port that you have selected) for incoming NTP traffic.
5. Type the following command to configure the PDC emulator, and then press ENTER:

   **w32tm /config /manualpeerlist:** *peers* **/syncfromflags:manual /reliable:yes /update**

   where *peers* specifies the list of DNS names or IP addresses of the NTP time source that the PDC emulator synchronizes from. For example, you can specify time.windows.com. When specifying multiple peers, use a space as the delimiter and enclose them in quotation marks. For more information about the NTP servers that you can use, see Microsoft

Knowledge Base article 262680 (http://go.microsoft.com/fwlink/?LinkID=60401).

For example, to configure your PDC emulator to use the following list of fictional time servers:

a. ntp1.fabrikam.com

b. ntp.contoso.com

c. time.fineartschool.net

Run the following command:

```
w32tm /config /manualpeerlist:"ntp1.fabrikam.com ntp.contoso.com time.fineartschool.net" /reliable:yes
/update
```

# Change the Windows Time service configuration on the previous PDC emulator

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the following procedure to change the Windows Time service configuration on the previous PDC emulator after you transfer the role to a new domain controller. The previous PDC emulator will now automatically synchronize time with the domain hierarchy, getting it's time from the new reliable time source.

| **Note** |
| --- |
| For more information about the **w32tm** command, type **w32tm /?** at a command prompt or see Windows Time Service Tools and Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42984). |

### Administrative Credentials

To perform this procedure locally on the PDC emulator, you must be a member of the Administrators group. To perform this procedure from a remote computer, you must be a member of the Domain Admins group.

**To change the Windows Time service configuration on the previous PDC emulator**

1. Open a Command Prompt.
2. Type the following command and then press ENTER:

   **w32tm /config /syncfromflags:domhier /reliable:no /update**
3. Type the following command and then press ENTER:

   **net stop w32time**
4. Type the following command and then press ENTER:

   **net start w32time**

# Configure a domain controller in the parent domain as a reliable time source

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to configure a domain controller as a reliable time source if you anticipate moving the PDC emulator role and do not want to reconfigure the Windows Time service afterward. If you are configuring a domain controller as a reliable time source for the forest root domain, perform the procedure Change the Windows Time service configuration on the previous PDC emulator in addition to this procedure. Although you have not moved the PDC emulator role, you must still configure the existing PDC emulator to no longer be the reliable time source for the domain.

| **Note** |
| --- |
| For more information about the **w32tm** command, type **w32tm /?** at a command prompt or see Windows Time Service Tools and Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42984). |

### Administrative Credentials

To perform this procedure locally on the domain controller, you must be a member of the Administrators group. To perform this procedure from a remote computer, you must be a member of the Domain Admins group.

**To configure a domain controller in the parent domain as a reliable time source**

1. Open a Command Prompt.
2. Type the following command and press ENTER:

   **W32tm /config /reliable:yes /update**

# Configure the PDC emulator to synchronize from its internal hardware clock

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the following procedure to configure the PDC emulator in the forest root domain to synchronize from its internal hardware clock and remain the reliable time source in the forest root domain.

| **Note** |
| --- |
| For more information about the **w32tm** command, type **w32tm /?** at a command prompt or see Windows Time Service Tools and Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42984). |

### Administrative Credentials

To perform this procedure locally on the PDC emulator, you must be a member of the Administrators group. To perform this procedure from a remote computer, you must be a member of the Domain Admins group.

**To configure the PDC emulator to synchronize from its internal hardware clock**

1. Open a Command Prompt.
2. Type the following command and then press ENTER:

   **w32tm /config /syncfromflags:domhier /reliable:yes /update**
3. Type the following command and then press ENTER:

   **net stop w32time**
4. Type the following command and then press ENTER:

   **net start w32time**

# Disable the Windows Time service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to disable the Windows Time service if you choose to implement another time synchronization product that uses the NTP protocol.

**Administrative Credentials**

To perform this procedure on the local computer, you must be a local Administrator on the PDC emulator. To perform this procedure on a remote computer, you must be a member of the Domain Admins group.

**To disable the Windows Time service**

1. Open the Services snap-in.
2. Right-click **Windows Time**, and select **Properties**. The **Windows Time Properties** dialog box appears.
3. In the **Startup type** box, select **Disabled** from the drop-down menu.
4. Click **OK**. Verify that the Startup Type for the time service appears as **Disabled**.

# Configuring Windows-based clients to synchronize time

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Certain Windows-based client computers do not automatically synchronize their time with the Active Directory domain. The following client computers do not automatically synchronize to the domain time by using the Windows Time service:

- Client computers that run in a pre-Windows 2000 domain environment.
- Client computers that run in a UNIX environment.
- Computers that are not joined to a domain.

Configure these computers to request time from a particular source, such as a domain controller in the domain. If you do not specify a source that is synchronized with the domain, each computer's internal hardware clock governs its time.

**Task requirements**

The following tool is required to perform the procedures for this task:

- W32tm

Use either of the following procedures to configure your Windows-based clients to synchronize time:

- Configure a manual time source for a selected client computer

  -or-

- Configure a client computer for automatic domain time synchronization

# Configure a manual time source for a selected client computer

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you configure a manual time source for a client computer, you can determine the time difference between it and the source as a means to test basic NTP communication. After completing the configuration on the selected client computer, be sure to monitor the System log in Event Viewer for W32Time errors.

| **Note** |
| --- |
| For more information about the **w32tm** command, type **w32tm /?** at a command prompt or see Windows Time Service Tools and Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42984). |

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer. To perform this procedure from a remote computer, you must be a member of the Domain Admins group.

**To configure a manual time source for a selected client computer**

1. Open a Command Prompt.
2. Type the following command to display the time difference between the local computer and a target computer, and then press ENTER:

   **w32tm /stripchart /computer:** *target* **/samples:** *n* **/dataonly**

   | Value | Definition |
   | --- | --- |
   | *target* | Specifies the DNS name or IP address of the NTP server that you comparing the local computer's time against. |
   | *n* | Specifies the number of time samples that will be returned from the target computer to test basic NTP communication. |

3. Open UDP port 123 for outgoing traffic on firewall if needed.
4. Open UDP port 123 (or a different port you have selected) for incoming NTP traffic.
5. Type the following command to configure a manual time source for the selected computer and then press ENTER:

   **w32tm /config /manualpeerlist:** *peers* **/syncfromflags:manual /update**

   where *peers* specifies the list of DNS names or IP addresses of the NTP time source(s) that the selected computer will synchronize from. When specifying multiple peers, use a space as the delimiter and enclose them in quotation marks.

| **Tip** |
| --- |
| For links to SNTP server lists, see article 262680 in the Microsoft Knowledge Base (http://support.microsoft.com/kb/262680). |

# Configure a client computer for automatic domain time synchronization

Updated: September 28, 2009

Applies To: Windows 7, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Vista

Some computers that are joined to a domain are configured to synchronize from a manual time source. Use the following procedure to configure a client computer that is currently synchronizing with a manually specified computer, to automatically synchronize time with the domain hierarchy.

| **Note** |
| --- |
| For more information about the **w32tm** command, type **w32tm /?** at a command prompt or see Windows Time Service Tools and Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42984). |

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer. To perform this procedure from a remote computer, you must be a member of the Domain Admins group.

**To configure a client computer for automatic domain time synchronization**

1. Open a Command Prompt.
2. Type the following command and then press ENTER:

   **w32tm /config /syncfromflags:domhier /update**
3. Type the following command and then press ENTER:

   **net stop w32time**
4. Type the following command and then press ENTER:

   **net start w32time**

To resolve this problem automatically, click the Fix this problem link. Then, click Run in the File Download dialog box.

Fix this problem

| **Important** |
| --- |
| This automated fix only applies to computers that are joined to a domain. |

| **Note** |
| --- |
| This wizard may be in English only; however, the automatic fix also works for other language versions of Windows. |

| **Note** |
| --- |
| If you are not on the computer that has the problem, save the automatic fix to a flash drive or to a CD so that you can run it on the computer that has the problem. If you do not want to use the automatic fix, you can do it yourself by performing the steps in the procedure above. |

# Restoring Windows Time service to default settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If the local Windows Time service settings are incorrectly configured, restoring the Windows Time service to its default settings might be more efficient than troubleshooting the problem.

**Task requirements**

The following tools are required to perform the procedures for this task:

- W32tm.exe

Perform the following procedure to restore local Windows Time service to the default settings:

- Restore Windows Time service on local computer to default settings

# Restore Windows Time service on local computer to default settings

Updated: September 28, 2009

Applies To: Windows 7, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Vista

Use this procedure to restore the Windows Time service on the local computer to the default settings.

| Note |
| --- |
| For more information about the **w32tm** command, type **w32tm /?** at a command prompt or see Windows Time Service Tools and Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42984). |

### Administrative Credentials

To perform this procedure on the local computer, you must be a member of the Administrators group. To perform this procedure on a remote computer, you must be a member of the Domain Admins group.

**To restore Windows Time service on local computer to default settings**

1. Open a Command Prompt.
2. Type the following command and then press ENTER:

   **net stop w32time**
3. Type the following command and then press ENTER:

   **w32tm /unregister**
4. Type the following command and then press ENTER:

   **w32tm /register**
5. Type the following command and then press ENTER:

   **net start w32time**

To resolve this problem automatically, click the Fix this problem link. Then, click Run in the File Download dialog box.

Fix this problem

| Note |
| --- |
| This wizard may be in English only; however, the automatic fix also works for other language versions of Windows. |

| Note |
| --- |
| If you are not on the computer that has the problem, save the automatic fix to a flash drive or to a CD so that you can run it on the computer that has the problem. If you do not want to use the automatic fix, you can do it yourself by performing the steps in the procedure above. |

# Administering SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This SYSVOL Administering guide provides administering information for the Active Directory SYSVOL shared folder in the Microsoft Windows Server 2003 operating system.

**In this guide**

- Introduction to Administering SYSVOL
- Managing SYSVOL

**Acknowledgements**

Published: March 2005

# Introduction to Administering SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Windows Server 2003 System Volume (SYSVOL) is a collection of folders and reparse points in the file systems that exist on each domain controller in a domain. SYSVOL provides a standard location to store important elements of Group Policy objects (GPOs) and scripts so that the File Replication service (FRS) can distribute them to other domain controllers within that domain.

| **Note** |
| --- |
| Only the Group Policy template (GPT) is replicated by SYSVOL. The Group Policy container (GPC) is replicated through Active Directory replication. To be effective, both parts must be available on a domain controller. |

FRS monitors SYSVOL and, if a change occurs to any file stored on SYSVOL, then FRS automatically replicates the changed file to the SYSVOL folders on the other domain controllers in the domain.

The day-to-day operation of SYSVOL is an automated process that does not require any human intervention other than watching for alerts from the monitoring system. Occasionally, you might perform some system maintenance as you change your network.

This objective describes the basic tasks required for managing SYSVOL in order to maintain capacity and performance of SYSVOL, for hardware maintenance, or for data organization.

**Key considerations for administering SYSVOL**

To manage SYSVOL, ensure that FRS properly replicates the SYSVOL data and that enough space is provided to store SYSVOL. Implement a monitoring system to detect low disk space and potential FRS disruptions so that you can address those issues before the system stops replicating. You can use the Ultrasound utility to monitor FRS. To download Ultrasound, see Ultrasound - Monitoring and Troubleshooting Tool for File Replication Service (FRS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=23439).

Other key considerations for managing SYSVOL are:

- Capacity.

Depending upon the configuration of your domain, SYSVOL can require a significant amount of disk space to function properly. During the initial deployment, SYSVOL might be allocated adequate disk space to function. However, as your Active Directory grows in size and complexity, the required capacity can exceed the available disk space.

If you receive indications that disk space is low, determine if the cause is due to inadequate physical space on the disk or a registry setting that limits the size of the staging area. By modifying a setting in the registry, you can allocate more staging area space, rather than relocating SYSVOL or the staging area. Increasing the space allocation in the registry is much faster and easier than relocation

- Performance.

Any changes made to SYSVOL are automatically replicated to the other domain controllers in the domain. If the files stored in SYSVOL change frequently, the replication increases the input and output for the volume where SYSVOL is located. For example, editing a GPO can potentially force a GPO-level replication. If the volume is also host to other system files, such as the directory database or the pagefile, then the increased input and output for the volume can impact the performance of the server.

- Hardware maintenance.

System maintenance, such as removal of a disk drive, can require you to relocate SYSVOL. Even if the maintenance occurs on a different disk drive, verify that that maintenance does not affect the system volume. Logical drive letters could change after you add and remove disks. FRS locates SYSVOL by using pointers stored in the directory and the registry. If drive letters change after you add or remove disk drives, be aware that these pointers are not automatically updated.

- Backing up Group Policy objects (GPOs).

The successful operation of Group Policy is heavily dependant on the reliable operation of SYSVOL. Key components of the GPO exist in the SYSVOL (in the policies subdirectory) and it is essential that these remain in sync with related components in Active Directory. Therefore, backing up only the SYSVOL component does not represent a full and complete backup of your GPOs. The Group Policy Management Console (GPMC) provides both UI-based and scriptable methods for backing up GPOs. It is important that you back up GPOs as part of your regular backup/disaster recovery processes. Soon after installation of a new domain, the default domain and default domain controllers' GPOs should be backed up. They should also be backed up after any subsequent changes are made.

**Understanding the SYSVOL folder structure**

Before you attempt to relocate all or portions of the system volume, you must clearly understand the folder structure and the relationships between the folders and the path information that is stored in the registry and the directory itself. When folders are relocated, any associated parameters that are stored in the registry and the directory must be updated to match the new location. The folder structure contains junctions that might also require updating when folders get moved to a new location.

Maintaining the relationship between the folders, junctions, and stored parameters is important when you must relocate all or portions of SYSVOL. Failure to do so can result in files being replicated to or from the wrong location. It can also result in files failing to replicate, yet FRS will not report any errors. Due to the configuration error, FRS looks in the wrong location for the files that you want to replicate.

The folder structure used by the system volume uses a feature called a junction point. Junction points look like folders and behave like folders (in Windows Explorer you cannot distinguish them from regular folders), but they are not folders. A junction point contains a link to another folder. When a program opens it, the junction point automatically redirects the program to the folder to which the junction point is linked. The redirection is completely transparent to the user and the application.

For example if you create two folders, C:\Folder1 and C:\Folder2, and create a junction called C:\Folder3, and then link the junction back to Folder1, Windows Explorer displays three folders:

\Folder1

\Folder2

\Folder3

If you open Folder3, Windows Explorer is redirected to Folder1 and displays the contents of Folder1. You receive no indication of the redirection because it is transparent to the user and to Windows Explorer. If you look at the contents of Folder1, you see that it is exactly the same as the contents displayed when you open Folder3. If you open a command prompt and list a directory, all three folders appear in the output. The first two are type <DIR> and Folder3 is type <JUNCTION>. If you list a directory of Folder3, you see the contents of Folder1.

| **Note** |
| --- |
| To create or update junctions, you need the Linkd.exe tool supplied with the Windows 2000 Server Resource Kit. Linkd allows you to create, delete, update, and view the links that are stored in junction points. |

By default, the system volume is contained in the %systemroot%\SYSVOL folder. The tree of folders contained within this folder can be extensive, depending on how your network uses FRS. When relocating folders in the system volume, ensure that you move all folders (including any hidden folders) and ensure that the relationships of the folders do not change unintentionally. When you relocate folders, you need to be concerned with the first three levels of subdirectories in order to properly update the parameters used by FRS. These levels are affected by junction points and parameter settings. These folders include:

- %systemroot%\SYSVOL
- %systemroot%\SYSVOL\Domain
- %systemroot%\SYSVOL\Domain\DO_NOT_REMOVE_Ntfrs_ Preinstalled_Directory
- %systemroot%\SYSVOL\Domain\Policies
- %systemroot%\SYSVOL\Domain\Scripts

- %systemroot%\SYSVOL\Staging
- %systemroot%\SYSVOL\Staging\Domain
- %systemroot%\SYSVOL\Staging Areas
- %systemroot%\SYSVOL\Staging Areas FQDN
- %systemroot%\SYSVOL\Sysvol
- %systemroot%\SYSVOL\Sysvol FQDN

(where FQDN is the fully qualified domain name of the domain that this domain controller hosts.)

| **Note** |
| --- |
| If any of the folders do not appear in Windows Explorer, click **Tools** and then click **Folder Options**. On the **View** tab, select **Show hidden files and folders**. |

If you use Windows Explorer to view these folders, they appear to be typical folders. If you open a command prompt and type dir to list these folders, you will notice two special folders are listed as <JUNCTION>. Both folders labeled FQDN are junction points. The junction in %systemroot%\SYSVOL\Sysvol links to %systemroot%\SYSVOL\Domain. The junction in %systemroot%\SYSVOL\Staging Areas is linked to %systemroot%\SYSVOL\Staging\Domain. If you change the path to the folders to which the junctions are linked, you must also update the junctions, including drive letter changes and folder changes.

Besides junction points linking to folders within the system volume tree, the registry and the directory also store references to folders. These references contain paths that you must update if you change the location of the folder. FRS uses two values that are stored in the directory. The first value, fRSRootPath, points to the location of the policies and scripts that are stored in SYSVOL. By default, this location is the %systemroot%\SYSVOL\Domain folder. The second value, fRSStagingPath, points to the location of the folders used as the staging area. By default, this location is the %systemroot%\SYSVOL\Staging\Domain folder. The Net Logon service uses a parameter stored in the registry to identify the location of the folder that it uses to create the SYSVOL and NETLOGON share points. By default, this path is %systemroot%\SYSVOL\Sysvol. If you change the paths to these folders, you must update these values.

When relocating SYSVOL, you first move the entire folder structure to a new location; then you update all the junction points and the parameters that are stored in the registry and the directory in order to maintain the relationships between the parameters, the folders, and the junctions. Optionally, you can relocate the staging area and leave the rest of the system volume at its original location. In this case, you must update the fRSStagingPath parameter in the directory and the junction point stored at %systemroot%\SYSVOL\staging areas.

# Managing SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks for managing SYSVOL are described in this objective:

- Changing the Space Allocated to the Staging Area
- Relocating the Staging Area
- Relocating SYSVOL Manually
- Updating the System Volume Path
- Restoring and Rebuilding SYSVOL

# Changing the Space Allocated to the Staging Area

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The staging area stores files prior to being replicated and stores files that it has just received through replication. Although FRS compresses the data and attributes of the replicated files to save space in the Staging Area folder and reduce the time that is needed to replicate the files, this method requires making and storing a copy of every file prior to replication and can require a substantial amount of disk space.

The default size of the staging area is 660 megabytes (MB). The minimum size is 10 MB and the maximum size is 2 terabytes. You can adjust the size limit of the Staging Folder by setting the value in kilobytes (KB) of the Staging Space Limit registry entry in HKEY_Local_Machine\System\CurrentControlSet\Services\NtFrs\Parameters. For more information about setting the Staging Space Limit in the registry, see KB article 329491 in the Microsoft Knowledge Base.

**Task requirements**

The following tools are required to perform the procedures for this task:

- Net.exe
- Regedit.exe
- Event Viewer

To complete this task, perform the following procedures in order:

1. Stop the File Replication service
2. Change the space allocated to the Staging Area folder
3. Start the File Replication service

# Stop the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to stop the File Replication service.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To stop the File Replication service**

1. Open a Command Prompt.
2. Type the following command and then press Enter:

   **net stop ntfrs**

# Change the space allocated to the Staging Area folder

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure outlines the steps needed to modify the registry entry that restricts the amount of disk space allocated to the staging area in SYSVOL.

| ⚠Caution |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Administering Active Directory Backup and Restore. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To change the space allocated to the Staging Area folder**

1. Click **Start**, and then click **Run**.
2. In the Run dialog box, type **regedit** and then press Enter.
3. In the Registry Editor, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NtFrs\Parameters**.
4. Double-click **Staging Space Limit in KB** to open the **Edit DWord Value** dialog box.
5. In the **Base frame**, select **Decimal**.
6. For **Value Data** enter a value from 10000 through 2000000000. Do not use commas. Click **OK**.
7. Close the Registry Editor.

# Start the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to restart the File Replication service and review the FRS event log to ensure that the restart succeeded.

**Administrative Credentials**

To perform this procedure you must be a member of the Domain Admins group in Active Directory.

**To start the File Replication service**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **net start ntfrs**

3. You can use Event Viewer to verify that NTFRS restarted correctly. Event ID 13501 indicates that the service restarted. Look for event ID 13516 to verify that the domain controller is running and ready for service. If you moved SYSVOL to a new location or relocated the Staging Area folder, look for event IDs 13553 and 13556, which indicate success.

# Relocating the Staging Area

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By default, the Active Directory Installation Wizard installs the Staging Area folder within the SYSVOL. The Active Directory Installation Wizard creates two folders—Staging and Staging Area—which FRS uses for the staging process. When you relocate the staging area, you can change the name. Ensure that you identify the proper area in case it is renamed in your environment.

Two parameters determine the location of the staging area. One parameter, *fRSStagingPath*, is stored in the directory and contains the path to the actual location that FRS uses to stage files. The other parameter is a junction point stored in the Staging Area folder in SYSVOL that links to the actual location that FRS uses to stage files. When relocating the staging area, you must update these two parameters to point to the new location.

Except where noted, perform these procedures on the domain controller that contains the Staging Area folder that you want to relocate.

**Task requirements**

To perform this task it is necessary that you understand the folder structure used by the system volume. For more information, see Introduction to Administering SYSVOL.

The following tools are required to perform the procedures for this task:

- Active Directory Sites and Services (Administrative Tool)
- Event Viewer
- Net.exe
- Dcdiag.exe (Windows Support Tools)
- Regedit.exe
- ADSI Edit.msc (Windows Support Tools)
- Linkd.exe (Windows Server 2003 Resource Kit Tools)

| **Note** |
| --- |
| To create or update junctions, you need the Linkd.exe tool supplied with Windows Server 2003 Resource Kit Tools on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=16544. Linkd allows you to create, delete, update, and view the links that are stored in junction points. |

To complete this task, perform the following procedures in order:

1. Identify replication partners
2. Check the status of the shared SYSVOL

   You do not need to perform the test on every partner, but you need to perform enough tests to be confident that the shared system volumes on the partners are healthy.
3. Verify replication with other domain controllers
4. Gather the SYSVOL path information
5. Reset the File Replication service staging folder to a different logical drive

# Identify replication partners

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to examine the Connection objects for a domain controller and determine its replication partners.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To identify replication partners**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container to display the list of sites.
3. Double-click the site that contains the domain controller for which you want to determine Connection objects.

| **Note** |
| --- |
| If you do not know the site in which the domain controller is located, open a command prompt and type **ipconfig** to get the IP address of the domain controller. Use the IP address to Verify that an IP address maps to a subnet and determine the site association. |

4. Expand the **Servers** folder to display the list of servers in that site.
5. Expand the name of your domain controller to display its NTDS settings.
6. Double-click **NTDSSettings** to display the list of Connection objects in the details pane (these represent inbound connections used for replication). The **From Server** column displays the names of the domain controllers that are the replication partners.

# Check the status of the shared SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure involves checking Event Viewer to make sure that the File Replication service is started properly and then ensuring that the SYSVOL and Net Logon shared folders are created.

| **Note** |
| --- |
| You do not need to perform this procedure on every replication partner, but you need to perform it enough times to be confident that the shared system volumes on the replication partners are healthy. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To check the status of the shared SYSVOL**

1. Open Event Viewer.
2. In the Event Viewer tree, click **File Replication Service** to display the FRS events.
3. Look for an event 13516 with a date and time stamp that corresponds with the recent restart. It can take 15 minutes or more to appear. An event 13508 indicates that FRS is in the process of starting the service. An event 13509 indicates that the service has started successfully. Event 13516 indicates that the service is started, the folders are shared, and the domain controller is functional.
4. To verify the shared folder is created, open a command prompt and type **net share** to display a list of the shared folders on this domain controller, including Net Logon and SYSVOL.
5. At a command prompt, type **dcdiag /test:netlogons** and press ENTER.
6. Look for a message that states *computername* **passed test NetLogons** where *computername* is the name of the domain controller. If you do not see the test passed message, some problem will prevent replication from functioning. This test verifies that the proper logon privileges are set to allow replication to occur. If this test fails, verify the permissions set on the Net Logon and SYSVOL shared folders.

# Verify replication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The tests performed in this procedure verify that different aspects of the replication topology are working properly. They check to see that objects are replicating and they verify that the proper logon permissions are set to allow replication to occur.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify replication is functioning**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **dcdiag /test:replications**

   | **Note** |
   | --- |
   | For this set of tests, the **/v** option is available. However, it does not display any significant additional information. Messages indicate that the connectivity and replications tests passed. |

3. To verify that the proper permissions are set for replication, type the following command and then press Enter:

   **dcdiag /test:netlogons**

   Messages indicate that the connectivity and netlogons tests passed.

# Gather the SYSVOL path information

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When relocating SYSVOL, you first move the entire folder structure to a new location; then you update all the junction points and the parameters that are stored in the registry and the directory in order to maintain the relationships between the parameters, the folders, and the junctions. Optionally, you can relocate the staging area and leave the rest of the system volume at its original location. In this case, you must update the fRSStagingPath parameter in the directory and the junction point stored at *%systemroot%*\SYSVOL\staging areas. For more information about the folder structure and the relationships between the folders and the path information stored in the registry and the SYSVOL directory itself see Introduction to Administering SYSVOL.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

Use the procedures below to locate the system volume path information and record the current values in the following table.

To relocate the staging area, record the information for rows 2 and 5.

| **Note** |
|---|
| To restore and rebuild SYSVOL, you will need the information from the domain controller that you are repairing recorded in rows 1, 2, and 3. Use the junctions located on the domain controller that you are copying from the SYSVOL folder structure to record the current value for rows 4 and 5. The new values for rows 4 and 5 are based on the domain controller that you are repairing. |

| | Parameter | Current Value | New Value |
|---|---|---|---|
| 1 | fRSRootPath | | |
| 2 | fRSStagingPath | | |
| 3 | Sysvol parameter in registry | | |
| 4 | Sysvol junction | | |
| 5 | Staging junction | | |

**To gather the system volume path information fRSRootPath and fRSStagingPath**

1. Click **Start**, click **Run**, type **adsiedit.msc**, and then press Enter.
2. Double-click **Domain [***computername***]** (where *computername* is the name of this domain controller). Verify that the Domain expands to display the domain component (DC=) folder.
3. Click the domain component to display the containers and OUs in the details pane.
4. Double-click **OU=Domain Controllers** to display the containers that represent the domain controllers.
5. Double-click the container that represents this domain controller (CN=*computername*) to display more containers.
6. Click the **CN=NTFRS Subscriptions** container.
7. In the details pane, right-click **CN=Domain System Volume**, and then click **Properties**.
8. Ensure that **Show mandatory attributes** is selected. Select it if it is not.
9. In **Attributes**, locate **fRSRootPath** and **fRSStagingPath** and record the current values in the table above.

10. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

11. Click **Cancel** to close the dialog box.

**SYSVOL parameter in the registry**

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.

2. In Registry Editor, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**.

3. **Sysvol** appears in the details pane. The current value is listed in the **Data** column.

4. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

5. Exit Registry Editor.

**SYSVOL junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Sysvol**.

| **Note** |
| --- |
| This assumes that the system volume is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

**Staging junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Staging Areas**.

| **Note** |
| --- |
| This assumes that the staging area is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

# Reset the File Replication service staging folder to a different logical drive

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to reset the FRS Staging folder to a different logical drive.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To reset the File Replication service staging folder to a different logical drive**

1. Click **Start**, click **Run**, type **adsiedit.msc**, and then press ENTER.
2. Under **Domain [***computername***]**, locate the NtFrs Subscriber object under the host computer account in Active Directory. The generic path for this attribute is: CN=Replica Set Name,CN=NTFRS Subscriptions,CN=*Computername*,DC=*Domain Name*,DC=COM.

   For example, to reset the staging path for the SYSVOL replica set of domain controller \\DC1 in the contoso.com domain, the distinguished name (also known as DN) path for the FrsStagingPath parameter is:

   CN=Domain System Volume (SYSVOL share), CN=NTFRS Subscriptions,CN=DC1,DC=CONTOSO,DC=COM

   Where (when you read the distinguished name path from right to left):

   DC=CONTOSO,DC=COM is the domain hosting the computer account.

   CN=DC1 is the host computer account in the domain naming context (NC).

   CN=NTFRS Subscriptions is the NtfrsSubscriber object that holds the FrsStagingPath parameter.

   CN=Domain System Volume (SYSVOL share) is the FRS subscriber object.
3. Right-click the **CN=Domain System Volume** container, and click **Properties**.
4. Ensure that the **Show mandatory attributes** check box is selected. Select it if it is not.
5. In **Attributes**, click **fRSStagingPath**, and then click **Edit**. The current value appears in the **Value** box in the **String Attribute Editor** dialog box.
6. Enter the path to the new location for the FRS Staging folder in the **Value** box and click **OK**.
7. Click **OK** to close Properties.
8. To make sure that the staging path has been updated in the registry:
   a. Click **Start**, click **Run**, and type **regedit** on the server where you are changing the staging path and then press ENTER.

   b. Locate the following subkey:

      **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Replica Sets**

   c. Double-click **Replica Sets**. All replica sets are displayed as a GUID.

   d. To locate the replica set you are updating the staging area for, click a GUID and, in the details pane, find the **Replica Set Name**. Repeat until you find the correct replica set.

   e. After you locate the correct GUID and replica set name, right-click **Replica Set Stage** and then click **Modify**.

   f. In the **Value data** box, type the new staging area path, and then click **OK**.

      When the service detects a change in the staging path, event ID 13563 is logged with a series of self-explanatory

steps on how to proceed:

Event Type: Warning

Event Source: NtFrs

Event Category: None

Event ID: 13563

Date: 3/6/2005

Time: 7:13:01 PM

User: N/A

Computer: <*Computer name*>

Description: The File Replication service has detected that the staging path for the replica set DOMAIN SYSTEM VOLUME (SYSVOL SHARE) has changed.

Current staging path = E:\Windows\Sysvol\Staging\Domain

New staging path = E:\Frsstage

The service will start using the new staging path after it restarts. The service is set to restart after every restart.

It is recommended that you manually restart the service to prevent loss of data in the Staging folder.

To manually restart the service do the following:

[1] Run "net stop ntfrs" or use the Services snap-in to stop File Replication service.

[2] Move all the staging files corresponding to replica set DOMAIN SYSTEM VOLUME (SYSVOL SHARE) to the new staging location. If more than one replica set are sharing the current staging folder then it is safer to copy the staging files to the new staging folder.

[3] Run "net start ntfrs" or use the Services snap-in to start File Replication service, followed by "net start ntfrs".

9. To perform steps 1 through 3 in the event message, open a Command Prompt.
10. Type the following command and then press ENTER:

    **net stop ntfrs**

11. Move all the staging files corresponding to replica set **DOMAIN SYSTEM VOLUME (SYSVOL SHARE)** to the new staging location. If more than one replica set is sharing the current Staging folder, then it is safer to copy the staging files to the new Staging folder.
12. At a command prompt type the following command and then press ENTER:

    **net start ntfrs**

    Microsoft recommends that you follow step 11 (step 2 in the preceding event message) because the FRS Staging folder may contain thousands or tens of thousands of files in the original Staging folder, all of which may be destined for one or more downstream partners. In Windows Explorer, you can view the files in the staging folder. On the **Folder Options** menu, click the **View** tab, and then click to select the **Show hidden files and folders** check box. Copy the files to the new Staging folder, and then follow the remaining steps in the event log message.

# Relocating SYSVOL Manually

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you must move the entire system volume, not just the Staging Area folder, then you can relocate the system volume manually. Because no utilities can automate this process, you must carefully move all folders and properly maintain the same level of security at the new location.

You can also move SYSVOL with the Active Directory wizard, but this requires that you remove Active Directory from the domain controller and then reinstall Active Directory after SYSVOL has been moved. This should only be considered in extreme cases, and only when the domain controller is not running any other services or applications.

Except where noted, perform these steps on the domain controller that contains the system volume that you want to move.

| **Caution** |
| --- |
| This procedure can alter security settings. After you complete the procedure, the security settings on the new system volume are reset to the default settings that were established when you installed Active Directory. You must reapply any changes to the security settings on the system volume that you made since you installed Active Directory. This will cause additional replication traffic. Note that failure to reset permissions can result in unauthorized access to Group Policy objects and logon and logoff scripts. |

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Active Directory Sites and Services (Administrative Tools)
- Event Viewer
- Windows Explorer
- Dcdiag.exe (Windows Support Tools)
- Regedit.exe
- ADSI Edit.msc (Windows Support Tools)
- Linkd.exe (Windows Server 2003 Resource Kit Tools)
- Net.exe
- Secedit.exe
- Notepad.exe

| **Note** |
| --- |
| To create or update junctions, you need the Linkd.exe tool supplied with Windows Server 2003 Resource Kit Tools on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=16544. Linkd allows you to create, delete, update, and view the links that are stored in junction points. |

To complete this task, perform the following procedures:

1. Identify replication partners
2. Check the status of the shared SYSVOL

3. Verify replication with other domain controllers
4. Gather the SYSVOL path information
5. Stop the File Replication service
6. Create the SYSVOL folder structure
7. Set the SYSVOL path
8. Set the staging area path

   If you have moved the Staging Area folder to a different location already, you do not need to do this step.

9. Prepare a domain controller for nonauthoritative SYSVOL restart
10. Update security on the new SYSVOL
11. Start the File Replication service
12. Check the status of the shared SYSVOL

# Identify replication partners

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to examine the Connection objects for a domain controller and determine its replication partners.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To identify replication partners**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container to display the list of sites.
3. Double-click the site that contains the domain controller for which you want to determine Connection objects.

| **Note** |
| --- |
| If you do not know the site in which the domain controller is located, open a command prompt and type **ipconfig** to get the IP address of the domain controller. Use the IP address to Verify that an IP address maps to a subnet and determine the site association. |

4. Expand the **Servers** folder to display the list of servers in that site.
5. Expand the name of your domain controller to display its NTDS settings.
6. Double-click **NTDSSettings** to display the list of Connection objects in the details pane (these represent inbound connections used for replication). The **From Server** column displays the names of the domain controllers that are the replication partners.

# Check the status of the shared SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure involves checking Event Viewer to make sure that the File Replication service is started properly and then ensuring that the SYSVOL and Net Logon shared folders are created.

| **Note** |
| --- |
| You do not need to perform this procedure on every replication partner, but you need to perform it enough times to be confident that the shared system volumes on the replication partners are healthy. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To check the status of the shared SYSVOL**

1. Open Event Viewer.
2. In the Event Viewer tree, click **File Replication Service** to display the FRS events.
3. Look for an event 13516 with a date and time stamp that corresponds with the recent restart. It can take 15 minutes or more to appear. An event 13508 indicates that FRS is in the process of starting the service. An event 13509 indicates that the service has started successfully. Event 13516 indicates that the service is started, the folders are shared, and the domain controller is functional.
4. To verify the shared folder is created, open a command prompt and type **net share** to display a list of the shared folders on this domain controller, including Net Logon and SYSVOL.
5. At a command prompt, type **dcdiag /test:netlogons** and press ENTER.
6. Look for a message that states *computername* **passed test NetLogons** where *computername* is the name of the domain controller. If you do not see the test passed message, some problem will prevent replication from functioning. This test verifies that the proper logon privileges are set to allow replication to occur. If this test fails, verify the permissions set on the Net Logon and SYSVOL shared folders.

# Verify replication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The tests performed in this procedure verify that different aspects of the replication topology are working properly. They check to see that objects are replicating and they verify that the proper logon permissions are set to allow replication to occur.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify replication is functioning**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **dcdiag /test:replications**

   | **Note** |
   | --- |
   | For this set of tests, the **/v** option is available. However, it does not display any significant additional information. Messages indicate that the connectivity and replications tests passed. |

3. To verify that the proper permissions are set for replication, type the following command and then press Enter:

   **dcdiag /test:netlogons**

   Messages indicate that the connectivity and netlogons tests passed.

# Gather the SYSVOL path information

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When relocating SYSVOL, you first move the entire folder structure to a new location; then you update all the junction points and the parameters that are stored in the registry and the directory in order to maintain the relationships between the parameters, the folders, and the junctions. Optionally, you can relocate the staging area and leave the rest of the system volume at its original location. In this case, you must update the fRSStagingPath parameter in the directory and the junction point stored at *%systemroot%*\SYSVOL\staging areas. For more information about the folder structure and the relationships between the folders and the path information stored in the registry and the SYSVOL directory itself see Introduction to Administering SYSVOL.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

Use the procedures below to locate the system volume path information and record the current values in the following table.

To relocate the staging area, record the information for rows 2 and 5.

| **Note** |
|---|
| To restore and rebuild SYSVOL, you will need the information from the domain controller that you are repairing recorded in rows 1, 2, and 3. Use the junctions located on the domain controller that you are copying from the SYSVOL folder structure to record the current value for rows 4 and 5. The new values for rows 4 and 5 are based on the domain controller that you are repairing. |

| | Parameter | Current Value | New Value |
|---|---|---|---|
| 1 | fRSRootPath | | |
| 2 | fRSStagingPath | | |
| 3 | Sysvol parameter in registry | | |
| 4 | Sysvol junction | | |
| 5 | Staging junction | | |

**To gather the system volume path information fRSRootPath and fRSStagingPath**

1. Click **Start**, click **Run**, type **adsiedit.msc**, and then press Enter.
2. Double-click **Domain [***computername***]** (where *computername* is the name of this domain controller). Verify that the Domain expands to display the domain component (DC=) folder.
3. Click the domain component to display the containers and OUs in the details pane.
4. Double-click **OU=Domain Controllers** to display the containers that represent the domain controllers.
5. Double-click the container that represents this domain controller (CN=*computername*) to display more containers.
6. Click the **CN=NTFRS Subscriptions** container.
7. In the details pane, right-click **CN=Domain System Volume**, and then click **Properties**.
8. Ensure that **Show mandatory attributes** is selected. Select it if it is not.
9. In **Attributes**, locate **fRSRootPath** and **fRSStagingPath** and record the current values in the table above.

10. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

11. Click **Cancel** to close the dialog box.

**SYSVOL parameter in the registry**

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.

2. In Registry Editor, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**.

3. **Sysvol** appears in the details pane. The current value is listed in the **Data** column.

4. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

5. Exit Registry Editor.

**SYSVOL junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Sysvol**.

| **Note** |
| --- |
| This assumes that the system volume is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

**Staging junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Staging Areas**.

| **Note** |
| --- |
| This assumes that the staging area is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

# Stop the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to stop the File Replication service.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To stop the File Replication service**

1. Open a Command Prompt.
2. Type the following command and then press Enter:

   **net stop ntfrs**

# Create the SYSVOL folder structure

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to create the SYSVOL folder structure. The %systemroot%\SYSVOL folder is at the top of the folder tree for the Windows system volume. To properly move SYSVOL, you must move the %systemroot%\SYSVOL folder and its contents. A subfolder of %systemroot%\SYSVOL is also named sysvol. Ensure that you move the proper folder (the %systemroot%\SYSVOL folder) and not the subfolder (%systemroot%\SYSVOL\sysvol). Do not confuse the two folders.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To create the SYSVOL folder structure**

1. In Windows Explorer, navigate to the folder that represents your current Windows system volume. By default, this is the %systemroot%\SYSVOL folder.
2. Right-click the **SYSVOL** folder, and then click **Copy**.
3. In Windows Explorer, navigate to the new location you created in the console tree, right-click the new location, and click **Paste**. You might see a dialog box stating that some files already exist and a prompt asking whether you want to continue copying the folder. At each such prompt, click **No**.
4. Verify that the folder structure was copied correctly. Compare the new folder structure to the original by opening a command prompt, typing the following command and pressing Enter to list the contents of the folders:

   **dir /s**

   Ensure that all folders exist. If any folders are missing at the new location (such as **\scripts**), then recreate them.

# Set the SYSVOL path

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to set the new path to the system volume in the registry.

| **Caution** |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Administering Active Directory Backup and Restore. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

#### To set the SYSVOL path

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.
2. Navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**.
3. Right-click **SysVol** and click **Modify**.
4. In the **Value data** box, in the **Edit String** dialog box, enter the new path, including the drive letter and click **OK**.
5. Close Registry Editor.

| **Note** |
| --- |
| The path in the registry points to the SYSVOL folder located inside the SYSVOL folder that is under the root. When updating the path in the registry, ensure that it still points to the SYSVOL folder inside the SYSVOL folder that is under the root. |

# Set the staging area path

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to modify the **fRSStagingPath** parameter for a domain controller in Active Directory in order to change the location of the Staging Area folder on that domain controller. Perform this procedure at the console of the domain controller that is hosting the SYSVOL that you must reconfigure.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To set the staging area path**

1. Double-click **Domain [***computername***]** (where *computername* is the name of this domain controller). Verify that the Domain expands to display the domain component (DC=) folder.
2. Click the domain component to display the containers and OUs in the details pane.
3. Double-click **OU=Domain Controllers** to display the containers that represent the domain controllers.
4. Double-click the container that represents this domain controller (CN=*computername*) to display more containers.
5. Click the **CN=NTFRS Subscriptions** container.
6. In the details pane, right-click **CN=Domain System Volume**, and then click **Properties**.
7. Ensure that **Show mandatory attributes** is selected. Select it if it is not.
8. In **Attributes**, click **fRSStagingPath**, and then click **Edit**. The current value appears in the **Value** box in the **String Attribute Editor** dialog box.
9. In the **Value** box, enter the complete path to the new location where you want to locate the Staging Area folder (the path to the new folder that you created earlier), including the drive letter and click OK.
10. Close ADSI Edit.
11. Open a Command Prompt.
12. Change the directory to %systemroot%\SYSVOL\staging areas.
13. Type the following command to list the contents of the directory and then press ENTER:

    **dir**

    Verify that <JUNCTION> appears in the DIR output.
14. Update the junction so that it points to the new location by typing the following command and then pressing ENTER:

    **linkd junctionname** *newpath*

    where *newpath* specifies the same value that you entered for **fRSStagingPath** earlier.

# Prepare a domain controller for nonauthoritative SYSVOL restart

Updated: April 15, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Initiate a nonauthoritative restore of SYSVOL by modifying the value of the BurFlags (backup/restore flags) registry entry. Changing the value to D2 (hexadecimal) or 210 (decimal) prior to disconnecting a domain controller initiates an automatic nonauthoritative restore of SYSVOL when the domain controller is restarted. This process results in a smaller database size and improved synchronization time because the domain controller does not reconcile and process every deletion and modification that took place from the time of the last SYSVOL update to the time the domain controller is restarted in the new site, thereby improving synchronization time. Instead, it processes only the latest changes.

Separate entries exist for global and replica-set-specific BurFlags, as follows:

- To initiate a nonauthoritative restart of SYSVOL when it is the only replica set that is represented on the domain controller, set the value of the global BurFlags (REG_DWORD) entry under

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Backup/Restore\Process at Startup**

- If other replica sets are represented on the domain controller and you want to update only SYSVOL, set the value of the replica-set-specific BurFlags (REG_DWORD) entry under

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Cumulative Replica Sets\SYSVOL GUID**

Modifying the replica-set-specific BurFlags entry requires identifying the SYSVOL GUID in the registry.

| ⚠**Caution** |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Administering Active Directory Backup and Restore. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To prepare a domain controller for nonauthoritative SYSVOL restart**

1. Click **Start**, click **Run**, type **regedit** and then click **OK**.
2. Navigate to

   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters**
3. Expand **Parameters**.
4. Modify one of the BurFlags entries as follows:

   To modify the global BurFlags entry:

   a. Expand **Backup/Restore** and then click **Process at Startup**.

   b. In the details pane, right-click **BurFlags** and click **Modify**.

   c. In the **Value data** box, type **D2** hexadecimal or **210** decimal.

   d. Click **OK** and close Registry Editor.

To modify the replica-set-specific BurFlags entry:

a. Expand both **Cumulative Replica Sets** and **Replica Sets**.

b. Match the GUID under **Replica Sets** to the identical GUID under **Cumulative Replica Sets**, and click the matching GUID under **Cumulative Replica Sets**.

c. In the details pane, right click **BurFlags** and click **Modify**.

d. In the **Value data** box, type **D2** hexadecimal or **210** decimal.

e. Click **OK** and close Registry Editor.

# Update security on the new SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure applies the default security settings to the new SYSVOL folders. The settings will be the equivalent of those set by default during Active Directory installation. If additional security settings have been applied to the system volume since Active Directory was installed, you must reapply those settings after completing this procedure.

| **Caution** |
| --- |
| Failure to reapply security changes made after Active Directory was installed might result in unauthorized access to logon and logoff scripts and Group Policy objects. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

#### To update security on the new SYSVOL

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.
2. Navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\ Services\Netlogon\Parameters**.

   Note the path stored under SysVol.
3. In **Control Panel**, double-click **System**.
4. On the **Advanced** tab, click **Environment Variables**.
5. Under **System Variables**, click **New**.
6. For **Variable name**, type **sysvol**.
7. For **Variable value**, type the path that you noted in step 2.
8. Click **OK** twice. Click **OK** again to close **Properties**.
9. Open Notepad and enter the following information:

   [Unicode]

   Unicode=yes

   [Version]

   signature="$CHICAGO$"

   Revision=1

   [Profile Description]

   Description=default perms for sysvol

   [File Security]

   ;"%SystemRoot%\SYSVOL",0,"D:AR(A;OICI;FA;;;BA)"

   "%Sysvol%",2,"D:P(A;CIOI;GRGX;;;AU)(A;CIOI;GRGX;;;SO) (A;CIOI;GA;;;BA)(A;CIOI;GA;;;SY)(A;CIOI;GA;;;CO)"

   "%Sysvol%\domain\policies",2,"D:P(A;CIOI;GRGX;;;AU) (A;CIOI;GRGX;;;SO)(A;CIOI;GA;;;BA)(A;CIOI;GA;;;SY) (A;CIOI;GA;;;CO) (A;CIOI;GRGWGXSD;;;PA)"

   Use this file to apply the security settings to the new SYSVOL folders. Save this file as Sysvol.inf.

   | **Note** |
   | --- |
   | Do not include a space after (A;CIOI;GRGX;;;SO), (A;CIOI;GRGX;;;AU), or (A;CIOI;GA;;;SY). |

10. Open a new Command Prompt. Do not use an existing command prompt that has been open on your desktop because it will not have the proper environment settings. Change the directory to the folder where you saved the Sysvol.inf file.
11. Type the following command all on one line and then press ENTER:

    **SECEDIT /Configure /cfg** *sectemplatepath* **\sysvol.inf /db** *sectemplatepath* **\sysvol.db /overwrite**

    where s*ectemplatepath* specifies the path to where you saved Sysvol.inf.

# Start the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to restart the File Replication service and review the FRS event log to ensure that the restart succeeded.

**Administrative Credentials**

To perform this procedure you must be a member of the Domain Admins group in Active Directory.

**To start the File Replication service**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **net start ntfrs**

3. You can use Event Viewer to verify that NTFRS restarted correctly. Event ID 13501 indicates that the service restarted. Look for event ID 13516 to verify that the domain controller is running and ready for service. If you moved SYSVOL to a new location or relocated the Staging Area folder, look for event IDs 13553 and 13556, which indicate success.

# Updating the System Volume Path

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you add or remove disk drives, the logical drive letters of the other drives on the system can change. If either your SYSVOL or Staging Area folder is located on one of the drives whose letter changes, FRS cannot locate them. You must update the paths that FRS uses to locate these folders in order to solve this problem. To change the path for the system volume, you need to make changes to the registry and in the directory. Changing the staging area path requires a change in the directory. Both changes require that you update the junction points. After updating the path information, you must restart File Replication service so it can reinitialize with the new values.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- ADSI Edit.msc
- Net.exe
- Regedit.exe
- Linkd.exe

To complete this task, perform the following procedures in order:

1. Gather the SYSVOL path information
2. Stop the File Replication service
3. Set the SYSVOL path
4. Set the staging area path
5. Start the File Replication service

# Gather the SYSVOL path information

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When relocating SYSVOL, you first move the entire folder structure to a new location; then you update all the junction points and the parameters that are stored in the registry and the directory in order to maintain the relationships between the parameters, the folders, and the junctions. Optionally, you can relocate the staging area and leave the rest of the system volume at its original location. In this case, you must update the fRSStagingPath parameter in the directory and the junction point stored at *%systemroot%*\SYSVOL\staging areas. For more information about the folder structure and the relationships between the folders and the path information stored in the registry and the SYSVOL directory itself see Introduction to Administering SYSVOL.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

Use the procedures below to locate the system volume path information and record the current values in the following table.

To relocate the staging area, record the information for rows 2 and 5.

| **Note** |
|---|
| To restore and rebuild SYSVOL, you will need the information from the domain controller that you are repairing recorded in rows 1, 2, and 3. Use the junctions located on the domain controller that you are copying from the SYSVOL folder structure to record the current value for rows 4 and 5. The new values for rows 4 and 5 are based on the domain controller that you are repairing. |

| | Parameter | Current Value | New Value |
|---|---|---|---|
| 1 | fRSRootPath | | |
| 2 | fRSStagingPath | | |
| 3 | Sysvol parameter in registry | | |
| 4 | Sysvol junction | | |
| 5 | Staging junction | | |

**To gather the system volume path information fRSRootPath and fRSStagingPath**

1. Click **Start**, click **Run**, type **adsiedit.msc**, and then press Enter.
2. Double-click **Domain [***computername***]** (where *computername* is the name of this domain controller). Verify that the Domain expands to display the domain component (DC=) folder.
3. Click the domain component to display the containers and OUs in the details pane.
4. Double-click **OU=Domain Controllers** to display the containers that represent the domain controllers.
5. Double-click the container that represents this domain controller (CN=*computername*) to display more containers.
6. Click the **CN=NTFRS Subscriptions** container.
7. In the details pane, right-click **CN=Domain System Volume**, and then click **Properties**.
8. Ensure that **Show mandatory attributes** is selected. Select it if it is not.
9. In **Attributes**, locate **fRSRootPath** and **fRSStagingPath** and record the current values in the table above.

10. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

11. Click **Cancel** to close the dialog box.

**SYSVOL parameter in the registry**

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.

2. In Registry Editor, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**.

3. **Sysvol** appears in the details pane. The current value is listed in the **Data** column.

4. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

5. Exit Registry Editor.

**SYSVOL junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Sysvol**.

| **Note** |
| --- |
| This assumes that the system volume is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

**Staging junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Staging Areas**.

| **Note** |
| --- |
| This assumes that the staging area is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

# Stop the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to stop the File Replication service.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To stop the File Replication service**

1. Open a Command Prompt.
2. Type the following command and then press Enter:

   **net stop ntfrs**

# Set the SYSVOL path

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to set the new path to the system volume in the registry.

| **Caution** |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Administering Active Directory Backup and Restore. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

#### To set the SYSVOL path

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.
2. Navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**.
3. Right-click **SysVol** and click **Modify**.
4. In the **Value data** box, in the **Edit String** dialog box, enter the new path, including the drive letter and click **OK**.
5. Close Registry Editor.

| **Note** |
| --- |
| The path in the registry points to the SYSVOL folder located inside the SYSVOL folder that is under the root. When updating the path in the registry, ensure that it still points to the SYSVOL folder inside the SYSVOL folder that is under the root. |

# Set the staging area path

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to modify the **fRSStagingPath** parameter for a domain controller in Active Directory in order to change the location of the Staging Area folder on that domain controller. Perform this procedure at the console of the domain controller that is hosting the SYSVOL that you must reconfigure.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To set the staging area path**

1. Double-click **Domain [***computername***]** (where *computername* is the name of this domain controller). Verify that the Domain expands to display the domain component (DC=) folder.
2. Click the domain component to display the containers and OUs in the details pane.
3. Double-click **OU=Domain Controllers** to display the containers that represent the domain controllers.
4. Double-click the container that represents this domain controller (CN=*computername*) to display more containers.
5. Click the **CN=NTFRS Subscriptions** container.
6. In the details pane, right-click **CN=Domain System Volume**, and then click **Properties**.
7. Ensure that **Show mandatory attributes** is selected. Select it if it is not.
8. In **Attributes**, click **fRSStagingPath**, and then click **Edit**. The current value appears in the **Value** box in the **String Attribute Editor** dialog box.
9. In the **Value** box, enter the complete path to the new location where you want to locate the Staging Area folder (the path to the new folder that you created earlier), including the drive letter and click OK.
10. Close ADSI Edit.
11. Open a Command Prompt.
12. Change the directory to %systemroot%\SYSVOL\staging areas.
13. Type the following command to list the contents of the directory and then press ENTER:

    **dir**

    Verify that <JUNCTION> appears in the DIR output.
14. Update the junction so that it points to the new location by typing the following command and then pressing ENTER:

    **linkd junctionname** *newpath*

    where *newpath* specifies the same value that you entered for **fRSStagingPath** earlier.

# Start the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to restart the File Replication service and review the FRS event log to ensure that the restart succeeded.

**Administrative Credentials**

To perform this procedure you must be a member of the Domain Admins group in Active Directory.

**To start the File Replication service**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **net start ntfrs**

3. You can use Event Viewer to verify that NTFRS restarted correctly. Event ID 13501 indicates that the service restarted. Look for event ID 13516 to verify that the domain controller is running and ready for service. If you moved SYSVOL to a new location or relocated the Staging Area folder, look for event IDs 13553 and 13556, which indicate success.

# Restoring and Rebuilding SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If your efforts to move SYSVOL or perform certain maintenance tasks fail, you must recreate or rebuild the SYSVOL on a single domain controller. Attempt to rebuild SYSVOL on a single domain controller only when all other domain controllers in the domain have a healthy and functioning SYSVOL. Do not attempt to rebuild SYSVOL until you correct any problems that are occurring with FRS in a domain.

Use these procedures only if you are working on a domain controller that does not have a functional SYSVOL.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Active Directory Sites and Services
- Event Viewer
- Dcdiag.exe
- ADSIEdit.msc
- Net.exe
- Regedit.exe
- Windows Explorer
- Linkd.exe
- Ultrasound for monitoring

To complete this task, perform the following procedures in order:

1. Identify replication partners
2. Check the status of the shared SYSVOL

   Because you will be copying the system volume from one of the partners, you need to make sure that the system volume you copy from the partner is up to date.
3. Verify replication with other domain controllers
4. Restart the domain controller in Directory Services Restore Mode locally

   If you are sitting at the console of the domain controller, locally restart a domain controller in Directory Services Restore Mode. If you are accessing the domain controller remotely using Terminal Services, remotely restart a domain controller in Directory Services Restore Mode.
5. Gather the SYSVOL path information
6. Stop the File Replication service
7. Prepare a domain controller for nonauthoritative SYSVOL restart

8. Import the SYSVOL folder structure
9. Start the File Replication service
10. Check the status of the shared SYSVOL

# Identify replication partners

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to examine the Connection objects for a domain controller and determine its replication partners.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To identify replication partners**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container to display the list of sites.
3. Double-click the site that contains the domain controller for which you want to determine Connection objects.

| **Note** |
| --- |
| If you do not know the site in which the domain controller is located, open a command prompt and type **ipconfig** to get the IP address of the domain controller. Use the IP address to Verify that an IP address maps to a subnet and determine the site association. |

4. Expand the **Servers** folder to display the list of servers in that site.
5. Expand the name of your domain controller to display its NTDS settings.
6. Double-click **NTDSSettings** to display the list of Connection objects in the details pane (these represent inbound connections used for replication). The **From Server** column displays the names of the domain controllers that are the replication partners.

# Check the status of the shared SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure involves checking Event Viewer to make sure that the File Replication service is started properly and then ensuring that the SYSVOL and Net Logon shared folders are created.

| **Note** |
| --- |
| You do not need to perform this procedure on every replication partner, but you need to perform it enough times to be confident that the shared system volumes on the replication partners are healthy. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To check the status of the shared SYSVOL**

1. Open Event Viewer.
2. In the Event Viewer tree, click **File Replication Service** to display the FRS events.
3. Look for an event 13516 with a date and time stamp that corresponds with the recent restart. It can take 15 minutes or more to appear. An event 13508 indicates that FRS is in the process of starting the service. An event 13509 indicates that the service has started successfully. Event 13516 indicates that the service is started, the folders are shared, and the domain controller is functional.
4. To verify the shared folder is created, open a command prompt and type **net share** to display a list of the shared folders on this domain controller, including Net Logon and SYSVOL.
5. At a command prompt, type **dcdiag /test:netlogons** and press ENTER.
6. Look for a message that states *computername* **passed test NetLogons** where *computername* is the name of the domain controller. If you do not see the test passed message, some problem will prevent replication from functioning. This test verifies that the proper logon privileges are set to allow replication to occur. If this test fails, verify the permissions set on the Net Logon and SYSVOL shared folders.

# Verify replication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The tests performed in this procedure verify that different aspects of the replication topology are working properly. They check to see that objects are replicating and they verify that the proper logon permissions are set to allow replication to occur.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify replication is functioning**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **dcdiag /test:replications**

   | **Note** |
   | --- |
   | For this set of tests, the **/v** option is available. However, it does not display any significant additional information. Messages indicate that the connectivity and replications tests passed. |

3. To verify that the proper permissions are set for replication, type the following command and then press Enter:

   **dcdiag /test:netlogons**

   Messages indicate that the connectivity and netlogons tests passed.

# Restart the domain controller in Directory Services Restore Mode locally

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have physical access to a domain controller, you can restart the domain controller in Directory Services Restore Mode locally. Restarting in Directory Services Restore Mode takes the domain controller offline. In this mode, the server is not functioning as a domain controller.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode locally**

1. Restart the domain controller.
2. When the screen for selecting an operating system appears, press F8.
3. On the **Windows Advanced Options** menu, select **Directory Services Restore Mode**.
4. When you are prompted, log on as the local administrator.

Restart the domain controller in Directory Services Restore Mode Remotely

# Gather the SYSVOL path information

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When relocating SYSVOL, you first move the entire folder structure to a new location; then you update all the junction points and the parameters that are stored in the registry and the directory in order to maintain the relationships between the parameters, the folders, and the junctions. Optionally, you can relocate the staging area and leave the rest of the system volume at its original location. In this case, you must update the fRSStagingPath parameter in the directory and the junction point stored at *%systemroot%*\SYSVOL\staging areas. For more information about the folder structure and the relationships between the folders and the path information stored in the registry and the SYSVOL directory itself see Introduction to Administering SYSVOL.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

Use the procedures below to locate the system volume path information and record the current values in the following table.

To relocate the staging area, record the information for rows 2 and 5.

| **Note** |
|---|
| To restore and rebuild SYSVOL, you will need the information from the domain controller that you are repairing recorded in rows 1, 2, and 3. Use the junctions located on the domain controller that you are copying from the SYSVOL folder structure to record the current value for rows 4 and 5. The new values for rows 4 and 5 are based on the domain controller that you are repairing. |

| | Parameter | Current Value | New Value |
|---|---|---|---|
| 1 | fRSRootPath | | |
| 2 | fRSStagingPath | | |
| 3 | Sysvol parameter in registry | | |
| 4 | Sysvol junction | | |
| 5 | Staging junction | | |

**To gather the system volume path information fRSRootPath and fRSStagingPath**

1. Click **Start**, click **Run**, type **adsiedit.msc**, and then press Enter.
2. Double-click **Domain [***computername***]** (where *computername* is the name of this domain controller). Verify that the Domain expands to display the domain component (DC=) folder.
3. Click the domain component to display the containers and OUs in the details pane.
4. Double-click **OU=Domain Controllers** to display the containers that represent the domain controllers.
5. Double-click the container that represents this domain controller (CN=*computername*) to display more containers.
6. Click the **CN=NTFRS Subscriptions** container.
7. In the details pane, right-click **CN=Domain System Volume**, and then click **Properties**.
8. Ensure that **Show mandatory attributes** is selected. Select it if it is not.
9. In **Attributes**, locate **fRSRootPath** and **fRSStagingPath** and record the current values in the table above.

10. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

11. Click **Cancel** to close the dialog box.

**SYSVOL parameter in the registry**

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.

2. In Registry Editor, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**.

3. **Sysvol** appears in the details pane. The current value is listed in the **Data** column.

4. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

5. Exit Registry Editor.

**SYSVOL junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Sysvol**.

| **Note** |
| --- |
| This assumes that the system volume is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

**Staging junction**

1. Open a Command Prompt.

2. Change the directory to *%systemroot%***\SYSVOL\Staging Areas**.

| **Note** |
| --- |
| This assumes that the staging area is still in the default location. If it has been relocated, substitute the appropriate paths into these instructions. |

3. At the command prompt, type **dir**. Verify that the fully qualified domain name (FQDN) is listed as type <JUNCTION>.

4. At the command prompt, type **linkd** *fqdn* (where *fqdn* is the domain name listed in the Dir output). This displays the value stored in the junction point. Press ENTER.

5. Record the current value in table above. Based on the folder structure discussed in detail in Introduction to Administering SYSVOL and the new location, record the new path value for this parameter in the table.

# Stop the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to stop the File Replication service.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To stop the File Replication service**

1. Open a Command Prompt.
2. Type the following command and then press Enter:

   **net stop ntfrs**

# Prepare a domain controller for nonauthoritative SYSVOL restart

Updated: April 15, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Initiate a nonauthoritative restore of SYSVOL by modifying the value of the BurFlags (backup/restore flags) registry entry. Changing the value to D2 (hexadecimal) or 210 (decimal) prior to disconnecting a domain controller initiates an automatic nonauthoritative restore of SYSVOL when the domain controller is restarted. This process results in a smaller database size and improved synchronization time because the domain controller does not reconcile and process every deletion and modification that took place from the time of the last SYSVOL update to the time the domain controller is restarted in the new site, thereby improving synchronization time. Instead, it processes only the latest changes.

Separate entries exist for global and replica-set-specific BurFlags, as follows:

- To initiate a nonauthoritative restart of SYSVOL when it is the only replica set that is represented on the domain controller, set the value of the global BurFlags (REG_DWORD) entry under

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Backup/Restore\Process at Startup**

- If other replica sets are represented on the domain controller and you want to update only SYSVOL, set the value of the replica-set-specific BurFlags (REG_DWORD) entry under

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Cumulative Replica Sets\SYSVOL GUID**

Modifying the replica-set-specific BurFlags entry requires identifying the SYSVOL GUID in the registry.

| ⚠**Caution** |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Administering Active Directory Backup and Restore. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To prepare a domain controller for nonauthoritative SYSVOL restart**

1. Click **Start**, click **Run**, type **regedit** and then click **OK**.
2. Navigate to

   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters**
3. Expand **Parameters**.
4. Modify one of the BurFlags entries as follows:

   To modify the global BurFlags entry:

   a. Expand **Backup/Restore** and then click **Process at Startup**.

   b. In the details pane, right-click **BurFlags** and click **Modify**.

   c. In the **Value data** box, type **D2** hexadecimal or **210** decimal.

   d. Click **OK** and close Registry Editor.

To modify the replica-set-specific BurFlags entry:

a. Expand both **Cumulative Replica Sets** and **Replica Sets**.

b. Match the GUID under **Replica Sets** to the identical GUID under **Cumulative Replica Sets**, and click the matching GUID under **Cumulative Replica Sets**.

c. In the details pane, right click **BurFlags** and click **Modify**.

d. In the **Value data** box, type **D2** hexadecimal or **210** decimal.

e. Click **OK** and close Registry Editor.

# Import the SYSVOL folder structure

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to copy the SYSVOL folder structure from another domain controller. The *%systemroot%*\SYSVOL folder is at the top of the folder tree for the Windows system volume. To properly import SYSVOL, you must copy the *%systemroot%*\SYSVOL folder and its contents.

To use this procedure, the default shared folder Admin$ must exist on the domain controller from which you plan to copy the SYSVOL folder structure. Some organizations remove this shared folder or rename it for security reasons. If this shared folder is not available, you must share the *%systemroot%* folder and name the share point Admin$. If you share the *%systemroot%* folder in order to complete this procedure, ensure that you remove the share point after the procedure is complete in order to maintain any security policies established on your network. If the Admin$ share has been renamed, then use the name assigned by your organization instead of Admin$ while completing this procedure.

| **Caution** |
| --- |
| Never copy information from the system volume on one domain controller to the system volume on another domain controller unless you have stopped the File Replication service and configured SYSVOL for a non-authoritative restore during startup. Failure to do so can cause invalid data to be replicated and cause the system volumes on various domain controllers to become inconsistent. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To import the SYSVOL folder structure**

1. Open Windows Explorer.
2. Navigate to the existing *%systemroot%***\SYSVOL** folder that you are rebuilding and delete it.
3. Connect to the **Admin$** share on the domain controller that you identified earlier as the replication partner from which you plan to copy the SYSVOL folder structure.
4. Once you are connected to the **Admin$** share point, verify that a folder labeled **SYSVOL** appears. Right-click the **SYSVOL** folder, and click **Copy**.
5. In the same directory, find some blank space and right-click. Click **Paste**. You might see a dialog box stating that some files already exist and a prompt asking whether you want to continue copying the folder. At each such prompt, click **No**.
6. Verify that the original **SYSVOL** folder and a new folder labeled **Copy of SYSVOL** both appear. Right-click **Copy of SYSVOL** and click **Rename**. Type **SYSVOL2** and press ENTER.
7. Open a command prompt. Change to the drive letter that represents the connection to the remote domain controller where you created the **SYSVOL2** folder.
8. Change the directory to **SYSVOL2\sysvol**.
9. Type **dir** and press ENTER. Verify that **<JUNCTION>** appears in the Dir output and is followed by the name of the domain.
10. You must update the path in this junction so that it points to the new location. Type the following command:

    **linkd** *junctionname newpath*

    where *newpath* is the new value you recorded in row 4 of the table in Gather the SYSVOL path information. Press ENTER.
11. If the staging area has been relocated and is no longer inside the SYSVOL folder, skip steps 10 and 11 and proceed to step 12. At a command prompt, change the directory to \SYSVOL2\staging areas under the copy of SYSVOL that you created. Type **dir** to list the contents and verify that **<JUNCTION>** appears in the Dir output.
12. Update the junction so that it points to the new location. Type the following command:

    **linkd** *junctionname newpath*

where *newpath* is the new value that you recorded in row 5 of Table 1 while gathering system volume path information. Press ENTER.

13. At the command prompt, change back to the *%systemroot%* for the domain controller that you are repairing.
14. From the command prompt, use the Xcopy command to copy the contents of the \SYSVOL2 folder you created to a new SYSVOL folder on your local drive. Type the following command:

    **xcopy** *drive* **:\sysvol2*.* sysvol*.* /s /e /h /c /y**

    where *drive* is the letter representing the connection to the remote domain controller. Press ENTER.
15. Verify that the folder structure copied correctly. Compare the new folder structure to the **SYSVOL** (not the SYSVOL2) on the remote domain controller. Open a command prompt and type **dir** to list the contents of the folders. Ensure that all folders exist.
16. Remove the **SYSVOL2** folder that you created on the remote domain controller.
17. Disconnect from the remote domain controller. If you had to create a shared folder on that domain controller in order to connect to it, remove the shared folder. Some organizations consider it a security risk to retain shared folders that are not in use.
18. Restart the domain controller in normal mode.

# Start the File Replication service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to restart the File Replication service and review the FRS event log to ensure that the restart succeeded.

**Administrative Credentials**

To perform this procedure you must be a member of the Domain Admins group in Active Directory.

**To start the File Replication service**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **net start ntfrs**

3. You can use Event Viewer to verify that NTFRS restarted correctly. Event ID 13501 indicates that the service restarted. Look for event ID 13516 to verify that the domain controller is running and ready for service. If you moved SYSVOL to a new location or relocated the Staging Area folder, look for event IDs 13553 and 13556, which indicate success.

# Administering the Global Catalog

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides information for administering the Active Directory Global Catalog in the Microsoft Windows Server 2003 operating system.

**In this guide**

- Introduction to Administering the Global Catalog
- Managing the Global Catalog

**Acknowledgements**

Published: March 2005

Applies to: Windows Server 2003 SP1

Writer: Mary Hillman

Editor: Jim Becker

# Introduction to Administering the Global Catalog

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Designate global catalog servers in sites to accommodate forest-wide directory searching and to facilitate domain client logons when universal groups are available (that is, when a domain has a domain functional level of Windows Server 2003 or Windows 2000 native). When universal groups are available in the domain, a domain controller must be able to locate a global catalog server to process a logon request.

**Global Catalog Placement**

Placement of global catalog servers in sites is a deployment task when you initially deploy your forest. As your forest grows, you might need to add more global catalog servers. To improve the speed of logging on and searching, place at least one global catalog server in each site and at least two global catalog servers if the site has multiple domain controllers. As a best practice, configure half of all domain controllers in a site to be global catalog servers if the site contains more than three domain controllers. If your deployment uses only a single domain, configure all domain controllers as global catalog servers. In a single-domain forest, configuring all domain controllers as global catalog servers requires no additional resources.

When placing global catalog servers, primary concerns are:

- Does any site have no global catalog servers?
- What domain controllers are designated as global catalog servers in a particular site?

**Initial Global Catalog Replication**

When you add a global catalog server to a site, the Knowledge Consistency Checker (KCC) updates the replication topology, after which replication of partial domain directory partitions that are available within the site begins. Replication of partial domain directory partitions that are available only from other sites begins at the next scheduled interval.

Adding subsequent global catalog servers within the same site requires only intrasite replication and does not affect network performance. Replication of the global catalog potentially affects network performance only when adding the first global catalog server in the site and the impact varies depending on the following conditions:

- The speed and reliability of the wide area network (WAN) link or links to the site.
- The size of the forest.

For example, in a forest that has a large hub site, five domains, and thirty small branch sites (some of which are connected by only dial-up connections), global catalog replication to the small sites takes considerably longer than replication of one or two domains to a few well-connected sites.

**Global Catalog Readiness**

A global catalog server is available to directory clients when it is locatable as a global catalog server in Domain Name System (DNS). Several conditions must be met before the global catalog server is ready to serve clients. These conditions are divided into seven levels (numbered 0 to 6) of readiness called occupancy levels. At each level, a specific degree of synchronization must be achieved before moving to the next level. By default, domain controllers running Windows Server 2003 require all levels to be reached before the global catalog is ready for use. At level 6, all partial, read-only directory partitions have been successfully replicated to the global catalog server. When the requirements of all occupancy levels have been satisfied, the Net Logon service on the global catalog server registers DNS service (SRV) resource records that identify the domain controller as a global catalog server in the site and in the forest.

In summary, a global catalog server is ready to serve clients when the following events occur, in this order:

- Occupancy level requirements are met by replicating read-only replicas.
- The **isGlobalCatalogReady** rootDSE attribute is set to TRUE.
- The Net Logon service on the domain controller has updated DNS with global catalog–specific SRV resource records.

At this point, the global catalog server begins accepting queries on ports 3268 and 3269.

**Global Catalog Removal**

When you remove the global catalog, the domain controller immediately stops advertising in DNS as a global catalog server. The KCC gradually removes the read-only replicas from the domain controller. On domain controllers running Windows Server 2003, the global catalog partial, read-only directory partitions are removed in the background, receiving a low priority so that high-priority services are not interrupted.

One reason that you might want to remove the global catalog from a domain controller is the availability of universal group membership caching in Windows Server 2003, which might eliminate the requirement for a global catalog server in a particular site.

Minimum hardware requirements for global catalog servers depend upon the numbers of users in the site. For disk space requirements and directory database storage guidelines, see "Assessing Disk Space and Memory Requirements" in Designing and Deploying Directory and Security Services on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45434).

For more information, see "How the Global Catalog Works" in the Windows Server 2003 Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=44139).

# Managing the Global Catalog

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Designate global catalog servers in sites to accommodate forest-wide directory searching and so that Active Directory can determine universal group membership of native-mode domain clients.

The following tasks for managing the global catalog are described in this objective:

- Configuring a Global Catalog Server
- Determining Global Catalog Readiness
- Removing the Global Catalog

# Configuring a Global Catalog Server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When conditions in a site warrant adding a global catalog server, you can configure a domain controller to be a global catalog server. Selecting the global catalog setting on the NTDS Settings object prompts the KCC to update the topology. After the topology is updated, then read-only partial domain directory partitions are replicated to the designated domain controller. When replication must occur between sites to create the global catalog, the site link schedule determines when replication can occur.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Active Directory Sites and Services
- Repadmin.exe
- Dcdiag.exe

To complete this task, perform the following procedures:

| **Note** |
| --- |
| Some procedures are performed only when you are configuring the first global catalog server in a site. |

1. Determine whether a domain controller is a global catalog server
2. Designate a domain controller to be a global catalog server
3. Monitor global catalog replication progress
4. Verify successful replication to a domain controller

# Determine whether a domain controller is a global catalog server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the setting on the NTDS Settings object to indicate whether a domain controller is designated as a global catalog server.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group in Active Directory.

**To determine whether a domain controller is a global catalog server**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container, expand the site of the domain controller you want to check, expand the **Servers** container, and then expand the **Server** object.
3. Right-click the **NTDS Settings** object, and then click **Properties**.
4. On the **General** tab, if the **Global Catalog** box is selected, the domain controller is designated as a global catalog server.

# Designate a domain controller to be a global catalog server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Setting the **Global Catalog** check box designates a domain controller as a global catalog server and initiates the process of replicating all domains to the server.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain where you are configuring the domain controller to be a global catalog server.

**To designate a domain controller to be a global catalog server**

1. Open Active Directory Sites and Services.
2. In the console tree expand the **Sites** container, and then expand the site in which you are designating a global catalog server.
3. Expand the **Servers** container and then expand the **Server** object for the domain controller that you want to designate as a global catalog server.
4. Right-click the **NTDS Settings** object for the target server, and then click **Properties**.
5. Select the **Global Catalog** check box, and then click **OK**.

# Monitor global catalog replication progress

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Monitor inbound replication progress to see how many (percentage) of the partial read-only directory partitions in the forest have replicated to a new global catalog server.

| **Note** |
| --- |
| Exchange 2003 servers use the global catalog exclusively when looking up addresses. Therefore, in addition to causing Active Directory client search problems, the condition of a global catalog server being advertised before it receives all partial replicas can cause Address Book lookup and mail delivery problems for Exchange clients.<br><br>The Name Service Provider Interface (NSPI) must be running on a global catalog server to enable MAPI access to Active Directory. To enable NSPI, you must restart the global catalog server after replication of the partial directory partitions is complete, or after occupancy requirements are met. |

### Administrative Credentials

To perform this procedure you must be a member of the Domain Admins group in Active Directory.

**To monitor global catalog replication progress**

1. Open a Command Prompt.
2. Type the following command and then press ENTER:

   **dcdiag /v /s:** *servername***| find "%"**

   | Value | Description |
   | --- | --- |
   | *servername* | Specifies the name of the new global catalog server. |

3. Repeat this command periodically to monitor progress. If the test shows no output, then replication has completed.

# Determining Global Catalog Readiness

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After replication of the partial domain directory partitions, the domain controller advertises as a global catalog server and begins accepting queries. If the domain controller advertises as a global catalog server before it has complete information from all domains in the forest, it might return false information to applications that begin using the server for forest-wide searches. Determine if a domain controller is ready to begin advertising itself as a global catalog server using the procedures for this task.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Ldp.exe
- Nltest.exe
- DNS snap-in

| **Note** |
| --- |
| The global catalog server must be restarted after replication has completed and before readiness is determined. |

To complete this task, perform the following procedures:

1. Verify global catalog readiness
2. Verify global catalog DNS registrations

# Verify global catalog readiness

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When a global catalog server has satisfied replication requirements, the **isGlobalCatalogReady rootDSE** attribute is set to **TRUE** and the global catalog is ready to serve clients.

**Administrative Credentials**

To perform the following procedures you must be a member of the Domain Users group.

**To verify global catalog readiness**

- Using the Windows interface
- Using a command prompt

**Using the Windows interface**

1. Click **Start**, click **Run**, type **Ldp**, and then click **OK**.
2. On the **Connection** menu, click **Connect**.
3. In the **Connect** box, type the name of the server whose global catalog readiness you want to verify.
4. In the **Port** box, if 389 is not showing, type 389.
5. If the **Connectionless** box is selected, clear it, and then click **OK**.
6. In the details pane, verify that the **isGlobalCatalogReady** attribute has a value of **TRUE**.
7. On the **Connection** menu, click **Disconnect**, and then close Ldp.

**Using a command prompt**

1. Open a Command Prompt.
2. Type the following command and then press ENTER:

   **nltest /server:** *servername* **/dsgetdc:** *domainname*

| Value | Description |
|---|---|
| *servername* | Specifies the name of the domain controller you have designated as a global catalog server. |
| *domainname* | Specifies the name of the domain to which the server belongs. |

3. In the **Flags:** line of the output, if GC appears, then the global catalog server has satisfied its replication requirements

# Verify global catalog DNS registrations

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To verify that a server is advertised as a global catalog server, verify the presence of DNS SRV resource records for the server. Restart the global catalog server prior to checking DNS registrations.

**Administrative Credentials**

To perform this procedure you must be a member of the Domain Users group.

**To verify global catalog DNS registrations**

1. Open the DNS snap-in and connect to a domain controller in the forest root domain.
2. Expand **Forward Lookup Zones** and then expand the forest root domain.
3. Click the **_tcp** container.
4. In the details pane, look in the **Name** column for **_gc** and in the **Data** column for the name of the server. The records that begin with **_gc** are global catalog SRV records.

# Removing the Global Catalog

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Removing the global catalog from a domain controller simply requires clearing the Global Catalog check box on the NTDS Settings object properties page. As soon as this is complete, the domain controller stops advertising itself as a global catalog server (Net Logon de-registers the global catalog-related records in DNS) and it immediately stops accepting LDAP requests over ports 3268 and 3269.

**Task Requirements**

The following tool is required to perform the procedures for this task:

- Active Directory Sites and Services

To complete this task, perform the following procedures:

1. Clear the global catalog setting
2. Monitor global catalog removal in Event Viewer

# Clear the global catalog setting

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Clearing the global catalog setting initiates removal of the partial directory partitions from the directory database of the domain controller.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the global catalog server.

**To clear the global catalog setting**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site from which you are removing a global catalog server.
3. Expand the **Servers** container and then expand the **Server** object for the domain controller that you want to remove as a global catalog server.
4. Right-click the **NTDS Settings** object for the target server, and then click **Properties**.
5. If the **Global Catalog** check box is selected, clear the check box, and then click **OK**.

# Monitor global catalog removal in Event Viewer

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To verify that the global catalog has been removed from a domain controller, monitor Event Viewer. The KCC logs Event 1268, when the global catalog has been successfully removed.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To monitor global catalog removal in Event Viewer**

1. Click **Start**, point to **Programs**, **Administrative Tools**, and click **Event Viewer**.
2. Right-click **Event Viewer (Local)**, and then click **Connect to another computer**.
3. In the **Select Computer** dialog box, click **Another computer**, type the name of the server from which you removed the global catalog, and then click **OK**.
4. Under **Event Viewer**, click **Directory Services log**.
5. Look for NTDS KCC event ID 1268, which indicates that the global catalog is removed from the local machine.

# Administering Operations Master Roles

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides information for administering Active Directory operations master roles in the Microsoft Windows Server 2003 operating system.

**In this guide**

# Introduction to Administering Operations Master Roles

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Operations masters keep the directory functioning properly by performing specific tasks that no other domain controllers are permitted to perform.

Three operations master roles exist in each domain:

- The primary domain controller (PDC) emulator. The PDC emulator processes all replication requests from Microsoft Windows NT 4.0 backup domain controllers. It also processes all password updates for clients not running Active Directory–enabled client software, plus any other directory write operations.
- The relative identifier (RID) master. The RID master allocates RID pools to all domain controllers to ensure that new security principals can be created with a unique identifier.
- The infrastructure master. The infrastructure master for a given domain maintains a list of the security principals for any linked-value attributes.

In addition to the three domain-level operations master roles, two operations master roles exist in each forest:

- The schema master, which governs all changes to the schema.
- The domain naming master, which adds and removes domains and application partitions to and from the forest.

To perform these functions, the domain controllers hosting these operations master roles must be consistently available and be located in areas where network reliability is high. Careful placement of your operations masters becomes more important as you add more domains and sites to build your forest.

**Guidelines for Role Placement**

By improperly placing operations master role holders, you might prevent clients from changing their passwords or being able to add domains and new objects, such as Users and Groups. You might also be unable to make changes to the schema. In addition, name changes might not properly appear within group memberships that are displayed in the user interface.

As your environment changes, you must avoid the problems associated with improperly placed operations master role holders. Eventually, you might need to reassign the roles to other domain controllers.

Although you can assign the forest-level and domain-level operations master roles to any domain controller in the forest and domain respectively, improperly placing the infrastructure master role can cause it to function improperly. Other improper configurations can increase administrative overhead.

Although you can assign the operations master roles to any domain controller, follow these guidelines to minimize administrative overhead and ensure the performance of Active Directory. If a domain controller that is hosting operations master roles fails, following these guidelines also simplifies the recovery process. Guidelines for role placement include:

Leave the two forest-level roles on a domain controller in the forest root domain.

- Place the three domain-level roles on the same domain controller.
- Do not place the domain-level roles on a global catalog server.
- Place the domain-level roles on a higher performance domain controller.
- Adjust the workload of the operations master role holder, if necessary.
- Choose an additional domain controller as the standby operations master for the forest-level roles and choose an additional domain controller as the standby for the domain-level roles.

**Forest-level role placement in the forest root domain**

The first domain controller created in the forest is assigned the schema master and domain naming master roles. To ease administration and backup and restore procedures, leave these roles on the original forest root domain controller. Moving the roles to other domain controllers does not improve performance. Separating the roles creates additional administrative overhead when you must identify the standby operations masters and when you implement a backup and restore policy.

Unlike the PDC emulator role, forest-level roles rarely place a significant burden on the domain controller. Keep these roles together to provide easy, predictable management.

**Forest-level role placement on a Global Catalog server**

In addition to hosting the schema master and domain naming master roles, the first domain controller created in a forest also hosts the global catalog.

**Domain-level role placement on the same domain controller**

The three domain-level roles are assigned to the first domain controller created in a new domain. Except for the forest root domain, leave the roles at that location. Keep the roles together unless the workload on your operations master justifies the additional management burden of separating the roles.

Because all clients prior to Active Directory submit updates to the PDC emulator, the domain controller holding that role uses a higher number of RIDs. Place the PDC emulator and RID master roles on the same domain controller so that these two roles interact more efficiently.

If you must separate the roles, you can still use a single standby operations master for all three roles. However, you must ensure that the standby is a replication partner of all three of the role holders.

Backup and restore procedures also become more complex if you separate the roles. Special care must be taken to restore a domain controller that hosted an operations master role. By hosting the roles on a single computer, you minimize the steps that are required to restore a role holder.

**Domain-level role absence on a Global Catalog server**

Do not host the infrastructure master on a domain controller that is acting as a global catalog server.

The infrastructure master updates the names of security principals for any domain-named linked attributes. For example, if a user from one domain is a member of a group in a second domain and the user's name is changed in the first domain, then the second domain is not notified that the user's name must be updated in the group's membership list. Because domain controllers in one domain do not replicate security principals to domain controllers in another domain, the second domain never becomes aware of the change. The infrastructure master constantly monitors group memberships, looking for security principals from other domains. If it finds one, it checks with the security principal's domain to verify that the information is updated. If the information is out of date, the infrastructure master performs the update and then replicates the change to the other domain controllers in its domain.

Two exceptions apply to this rule. First, if all the domain controllers are global catalog servers, the domain controller that hosts the infrastructure master role is insignificant because global catalogs do replicate the updated information regardless of the domain to which they belong. Second, if the forest has only one domain, the domain controller that hosts the infrastructure master role is not needed because security principals from other domains do not exist.

Because it is best to keep the three domain-level roles together, avoid putting any of them on a global catalog server.

**Domain-level role placement on a higher performance domain controller**

Host the PDC emulator role on a powerful and reliable domain controller to ensure that it is available and capable of handling the workload. Of all the operations master roles, the PDC emulator creates the most overhead on the server that is hosting the role. It has the most intensive daily interaction with other systems on the network. The PDC emulator has the greatest potential to affect daily operations of the directory.

Domain controllers can become overloaded while attempting to service client requests on the network, manage their own resources, and handle any specialized tasks such as performing the various operations master roles. This is especially true of the domain controller holding the PDC emulator role. Again, clients prior to Active Directory and domain controllers running Windows NT 4.0 rely more heavily on the PDC emulator than Active Directory clients and Windows 2000 Server domain controllers. If your networking environment has clients and domain controllers prior to Active Directory, you might need to reduce the workload of the PDC emulator.

If a domain controller begins to indicate that it is overloaded and its performance is affected, you can reconfigure the

environment so that some tasks are performed by other, less-used domain controllers. By adjusting the domain controller's weight in the DNS environment, you can configure the domain controller to receive fewer client requests than other domain controllers on your network. Optionally, you can adjust the domain controller's priority in the DNS environment so that it processes client requests only if other DNS servers are unavailable. With fewer DNS client requests to process, the domain controller can use more resources to perform operations master services for the domain.

#### Guidelines for Role Transfer

Role transfer is the preferred method to move an operations master role from one domain controller to another. During a role transfer, the two domain controllers replicate to ensure that no information is lost. After the transfer completes, the previous role holder reconfigures itself so that it no longer attempts to perform as the operations master while the new domain controller assumes those duties. This prevents the possibility of duplicate operations masters existing on the network at the same time, which can lead to corruption in the directory.

Reasons for moving the operations master role(s) include inadequate service performance, failure or decommission of a domain controller hosting an operations master role, or if dictated by configuration changes made by an administrator.

#### Inadequate level of service

The PDC emulator is the operations master role that most impacts the performance of a domain controller. For clients that do not run Active Directory client software, the PDC emulator processes requests for password changes, replication, and user authentication. While providing support for these clients, the domain controller continues to perform its normal services, such as authenticating Active Directory–enabled clients. As the network grows, the volume of client requests can increase the workload for the domain controller that hosts the PDC emulator role and its performance can suffer. To solve this problem, you can transfer all or some of the master operations roles to another, more powerful domain controller. Alternately, you may choose to transfer the role to another domain controller, upgrade the hardware on the original domain controller, and then transfer the role back again.

#### Master operations role holder failure

In the event of a failure, you must decide if you need to relocate the operations master roles to another domain controller or wait for the domain controller to be returned to service. Base that determination on the role that the domain controller hosts and the expected downtime.

#### Decommissioning of the domain controller

Before permanently taking a domain controller offline, transfer any operations master roles held by the domain controller to another domain controller.

When you use the Active Directory Installation Wizard to decommission a domain controller that currently hosts one or more operations master roles, the wizard reassigns the roles to a different domain controller. When the wizard is run, it determines whether the domain controller currently hosts any operations master roles. If it detects any operations master roles, it queries the directory for other eligible domain controllers and transfers the roles to a new domain controller. A domain controller is eligible to host the domain-level roles if it is a member of the same domain. A domain controller is eligible to host a forest-level role if it is a member of the same forest.

#### Configuration changes

Configuration changes to domain controllers or the network topology can result in the need to transfer master operations roles. Except for the infrastructure master, you can assign operations master roles to any domain controller regardless of any other tasks that the domain controller performs. Do not host the infrastructure master role on a domain controller that is also acting as a global catalog server unless all of the domain controllers in the domain are global catalog servers or unless only one domain is in the forest. If the domain controller hosting the infrastructure master role is configured to be a global catalog server, you must transfer the infrastructure master role to another domain controller. Changes to the network topology can result in the need to transfer operations master roles in order to keep them in a particular site.

You can reassign an operations master role by transfer or, as a last resort, by seizure.

| **Important** |
| --- |
| If you must seize an operations master role, never reattach the previous role holder to the network without following the procedures in this guide. Incorrectly reattaching the previous role holder to the network can result in invalid data and corruption of data in the directory. |

# Managing Operations Master Roles

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Operations masters keep the directory functioning properly by performing specific tasks that no other domain controllers are permitted to perform.

The following tasks for managing operations master roles are described in this objective:

- Designating a standby operations master
- Transferring an operations master role
- Seizing an operations master role
- Reducing the workload on the PDC emulator master

# Designating a standby operations master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A standby operations master is a domain controller that you identify as the computer that assumes the operations master role if the original computer fails. A single domain controller can act as the standby operations master for all of the operations master roles in a domain, or you can designate a separate standby for each operations master role.

No utilities or special steps are required to designate a domain controller as a standby operations master. However, the current operations master and the standby should be well connected. This means that the network connection between them must support at least a 10-megabit transmission rate and be available at all times. In addition, configure the current role holder and the standby as direct replication partners by manually creating a Connection object between them.

Configuring a replication partner can save some time if you must reassign any operations master roles to the standby operations master. Before transferring a role from the current role holder to the standby operations master, ensure that replication between the two computers is functioning properly. Because they are replication partners, the new operations master is as updated as the original operations master, thus reducing the time required for the transfer operation.

During role transfer, the two domain controllers exchange any unreplicated information to ensure that no transactions are lost. If the two domain controllers are not direct replication partners, a substantial amount of information might need to be replicated before the domain controllers completely synchronize with each other. The role transfer requires extra time to replicate the outstanding transactions. If the two domain controllers are direct replication partners, fewer outstanding transactions exist and the role transfer operation completes sooner.

Designating a domain controller as a standby also minimizes the risk of role seizure. By making the operations master and the standby direct replication partners, you reduce the chance of data loss in the event of a role seizure, thereby reducing the chances of introducing corruption into the directory.

When you designate a domain controller as the standby, follow all recommendations that are discussed in Guidelines for Role Placement in Introduction to Administering Operations Master Roles. To designate a standby for the forest-level roles, choose a global catalog server so it can interact more efficiently with the domain naming master. To designate a standby for the domain-level roles, ensure that the domain controller is not a global catalog server so that the infrastructure master continues to function properly if you must transfer the roles.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Active Directory Sites and Services
- Repadmin.exe

To complete this task, perform the following procedures:

1. Determine whether a domain controller is a global catalog server
2. Create a connection object on the current operations master
3. Create a connection object on the standby operations master
4. Verify successful replication to a domain controller

# Determine whether a domain controller is a global catalog server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the setting on the NTDS Settings object to indicate whether a domain controller is designated as a global catalog server.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group in Active Directory.

**To determine whether a domain controller is a global catalog server**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container, expand the site of the domain controller you want to check, expand the **Servers** container, and then expand the **Server** object.
3. Right-click the **NTDS Settings** object, and then click **Properties**.
4. On the **General** tab, if the **Global Catalog** box is selected, the domain controller is designated as a global catalog server.

# Create a connection object on the current operations master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To help ensure that the current role holder and the standby operations master are replication partners, you can manually create a Connection object between the two domain controllers. Even if a Connection object is generated automatically, it is recommended that you manually create one. The system can alter automatically created Connection objects at any time. Manually created connections remain the same until an administrator changes them.

You must know the current operations master role holder to perform the following procedure. To determine the current operations master role holders, see View the current operations master role holders.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To create a connection object on the current operations master**

1. Open **Active Directory Sites and Services**.
2. Expand the site name in which the standby operations master is located to display the **Servers** folder.
3. Expand the **Servers** folder to see a list of the servers in that site.
4. Expand the name of the server that is currently hosting the operations master role to display its NTDS Settings.
5. Right-click **NTDS Settings**, click **New**, and then click **Connection**.
6. In the **Find Domain Controllers** dialog box, select the name of the standby operations master, and then click **OK**.
7. In the **New Object-Connection** dialog box, enter an appropriate name for the Connection object or accept the default name, and click **OK**.

# Create a connection object on the standby operations master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To help ensure that the current role holder and the standby operations master are replication partners, you can manually create a Connection object between the two domain controllers. Even if a Connection object is generated automatically, it is recommended that you manually create one. The system can alter automatically created Connection objects at any time. Manually created connections remain the same until an administrator changes them.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To create a Connection object on the standby operations master**

1. Open **Active Directory Sites and Services**.
2. Expand the site name in which the standby operations master is located to display the **Servers** folder.
3. Expand the **Servers** folder to see a list of the servers in that site.
4. Expand the name of the server that you want to be the standby operations master to display its NTDS Settings.
5. Right-click **NTDS Settings**, click **New**, and then click **Connection**.
6. In the **Find Domain Controllers** dialog box, select the name of the current role holder, and then click **OK**.
7. In the **New Object-Connection** dialog box, enter an appropriate name for the Connection object or accept the default name, and click **OK**.

# Verify successful replication to a domain controller

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **repadmin /showrepl** command to verify successful replication to a specific domain controller. If you are not running Repadmin on the domain controller whose replication you are checking, you can specify a destination domain controller in the command. Repadmin lists INBOUND NEIGHBORS for the current or specified domain controller. INBOUND NEIGHBORS shows the distinguished name of each directory partition for which inbound directory replication has been attempted, the site and name of the source domain controller, and whether replication succeeded or not, as follows:

- Last attempt @ YYYY-MM-DD HH:MM.SS was successful.
- Last attempt @ [Never] was successful.

If @ [Never] appears in the output for a directory partition, replication of that directory partition has never succeeded from the identified source replication partner over the listed connection.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the destination domain controller.

**To verify successful replication to a domain controller**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl** *servername* **/u:** *domainname* **** *username* **/pw:***

   | Term | Definition |
   | --- | --- |
   | *servername* | Specifies the name of the destination domain controller. |
   | *domainname* | Specifies the single-label name of the domain of the destination domain controller. (You do not have to use a fully qualified Domain Name System (DNS) name.) |
   | *username* | Specifies the name of an administrative account in that domain. |

3. When you are prompted for a password, type the password for the user account that you provided, and then press ENTER.

You can also use Repadmin to generate the details of replication to and from all replication partners in a spreadsheet. The spreadsheet displays data in the following columns:

Showrepl_COLUMNS

Destination DC Site

Destination DC

Naming Context

Source DC Site

Source DC

Transport Type

Number of Failures

Last Failure Time

Last Success Time

Last Failure Status

The following procedure shows how to create this spreadsheet and set column headers for improved readability.

**To generate a repadmin /showrepl spreadsheet for all replication partners**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl * /csv >showrepl.csv**
3. Open Microsoft Excel.
4. On the **File** menu, click **Open**, navigate to showrepl.csv, and then click **Open**.
5. Hide or delete column **A** as well as the **Transport Type** column, as follows:
6. Select a column that you want to hide or delete.
   - To hide the column, on the **Format** menu, click **Column**, and then click **Hide**.

     Or

   - To delete the column, right-click the selected column, and then click **Delete**.
7. Select row 1 beneath the column heading row, and then, on the **Window** menu, click **Freeze Panes**.
8. Select the entire spreadsheet. On the **Data** menu, click **Filter**, and then click **AutoFilter**.
9. In the **Last Success Time** column, click the down arrow, and then click **Sort Ascending**.
10. In the **Source DC** column, click the down arrow, and then click **Custom**.
11. In the **Custom AutoFilter** dialog box, under **Show rows where**, click **does not contain**. In the adjacent text box, type **del** to eliminate from view the results for deleted domain controllers.
12. Repeat step 10 for the **Last Failure Time** column, but use the value **does not equal**, and type the value **0**.
13. Resolve replication failures.

The last successful attempt should agree with the replication schedule for intersite replication, or the attempt should be within the last hour for intrasite replication.

If Repadmin reports any of the following conditions, see Troubleshooting Active Directory Replication Problems:

- The last successful intersite replication was prior to the last scheduled replication.
- The last intrasite replication was longer than one hour ago.
- Replication was never successful.

Troubleshooting Active Directory Replication Problems

# Transferring an operations master role

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you create a new domain, the Active Directory Installation Wizard automatically assigns all of the domain-level operations master roles to the first domain controller that is created in that domain. When you create a new forest, the wizard also assigns the two forest-level operations master roles to the first domain controller. After the domain is created and functioning, you might transfer various operations master roles to different domain controllers to optimize performance and simplify administration.

The transfer of forest-level and domain-level operations master roles is performed as needed and is governed by the guidelines for placing operations master roles. Before you transfer an operations master role, ensure that replication between the current role holder and the domain controller assuming the role is updated.

In addition, you must determine if the domain controller that you intend to assume an operations master role is a global catalog server. However, the infrastructure master for each domain must not host the global catalog.

Do not change the global catalog configuration on the domain controller that you intend to assume an operations master role unless your IT management authorizes that change. Changing the global catalog configuration can cause changes that can take days to complete, and the domain controller might not be available during that period. Instead, transfer the operations master roles to a different domain controller that is already properly configured.

**Transferring to a standby ops master**

By following the recommendations for operations master role placement, the standby operations master is a direct replication partner and is ready to assume the roles. Remember to designate a new standby for the domain controller that assumes the roles.

**Transferring an ops master role when no standby is ready**

If you do not follow the recommendations for role placement and you have not designated a standby operations master, you must properly prepare a domain controller to which you intend to transfer the operations master roles. Preparing the future role holder is the same process as preparing a standby operations master. You must manually create a Connection object to ensure that it is a replication partner with the current role holder and that replication between the two domain controllers is updated.

In addition, you must determine whether the domain controller intended to assume an operations master role is a global catalog server. The infrastructure master for each domain must not host the global catalog.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Repadmin.exe
- Active Directory Sites and Services
- Active Directory Domains and Trusts
- Active Directory Schema snap-in
- Active Directory Users and Computers
- Ntdsutil.exe

To complete this task, perform the following procedures:

1. Verify successful replication to a domain controller
2. Determine whether a domain controller is a global catalog server

3. Install the Schema snap-in
4. Transfer the schema master
5. Transfer the domain naming master
6. Transfer the domain-level operations master roles
7. View the current operations master role holders

# Verify successful replication to a domain controller

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **repadmin /showrepl** command to verify successful replication to a specific domain controller. If you are not running Repadmin on the domain controller whose replication you are checking, you can specify a destination domain controller in the command. Repadmin lists INBOUND NEIGHBORS for the current or specified domain controller. INBOUND NEIGHBORS shows the distinguished name of each directory partition for which inbound directory replication has been attempted, the site and name of the source domain controller, and whether replication succeeded or not, as follows:

- Last attempt @ YYYY-MM-DD HH:MM.SS was successful.
- Last attempt @ [Never] was successful.

If @ [Never] appears in the output for a directory partition, replication of that directory partition has never succeeded from the identified source replication partner over the listed connection.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the destination domain controller.

**To verify successful replication to a domain controller**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl** *servername* **/u:** *domainname* **** *username* **/pw:***

   | Term | Definition |
   | --- | --- |
   | *servername* | Specifies the name of the destination domain controller. |
   | *domainname* | Specifies the single-label name of the domain of the destination domain controller. (You do not have to use a fully qualified Domain Name System (DNS) name.) |
   | *username* | Specifies the name of an administrative account in that domain. |

3. When you are prompted for a password, type the password for the user account that you provided, and then press ENTER.

You can also use Repadmin to generate the details of replication to and from all replication partners in a spreadsheet. The spreadsheet displays data in the following columns:

Showrepl_COLUMNS

Destination DC Site

Destination DC

Naming Context

Source DC Site

Source DC

Transport Type

Number of Failures

Last Failure Time

Last Success Time

Last Failure Status

The following procedure shows how to create this spreadsheet and set column headers for improved readability.

**To generate a repadmin /showrepl spreadsheet for all replication partners**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl * /csv >showrepl.csv**
3. Open Microsoft Excel.
4. On the **File** menu, click **Open**, navigate to showrepl.csv, and then click **Open**.
5. Hide or delete column **A** as well as the **Transport Type** column, as follows:
6. Select a column that you want to hide or delete.
   - To hide the column, on the **Format** menu, click **Column**, and then click **Hide**.

     Or

   - To delete the column, right-click the selected column, and then click **Delete**.
7. Select row 1 beneath the column heading row, and then, on the **Window** menu, click **Freeze Panes**.
8. Select the entire spreadsheet. On the **Data** menu, click **Filter**, and then click **AutoFilter**.
9. In the **Last Success Time** column, click the down arrow, and then click **Sort Ascending**.
10. In the **Source DC** column, click the down arrow, and then click **Custom**.
11. In the **Custom AutoFilter** dialog box, under **Show rows where**, click **does not contain**. In the adjacent text box, type **del** to eliminate from view the results for deleted domain controllers.
12. Repeat step 10 for the **Last Failure Time** column, but use the value **does not equal**, and type the value **0**.
13. Resolve replication failures.

The last successful attempt should agree with the replication schedule for intersite replication, or the attempt should be within the last hour for intrasite replication.

If Repadmin reports any of the following conditions, see Troubleshooting Active Directory Replication Problems:

- The last successful intersite replication was prior to the last scheduled replication.
- The last intrasite replication was longer than one hour ago.
- Replication was never successful.

# Determine whether a domain controller is a global catalog server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the setting on the NTDS Settings object to indicate whether a domain controller is designated as a global catalog server.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group in Active Directory.

**To determine whether a domain controller is a global catalog server**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container, expand the site of the domain controller you want to check, expand the **Servers** container, and then expand the **Server** object.
3. Right-click the **NTDS Settings** object, and then click **Properties**.
4. On the **General** tab, if the **Global Catalog** box is selected, the domain controller is designated as a global catalog server.

# Install the Schema snap-in

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to install the Active Directory Schema snap-in.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory.

**To install the Active Directory Schema snap-in**

1. Open a Command Prompt.
2. Type the following command and then press ENTER:

   **Regsvr32 schmmgmt.dll**

   This command will register schmmgmt.dll on your computer.
3. Click **Start**, click **Run**, type **mmc /a**, and then click **OK**.
4. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
5. Under **Available Standalone Snap-ins**, double-click **Active Directory Schema**, click **Close**, and then click **OK**.
6. To save this console, on the **File** menu, click **Save**.
7. In **Save in**, point to the *systemroot***system32** directory.
8. In **File** name, type **schmmgmt.msc**, and then click **Save**.
9. To create a shortcut on your Start menu:
   a. Right-click **Start**, click **Open All Users**, double-click the **Programs** folder, and then double-click the **Administrative Tools** folder.
   b. On the **File** menu, point to **New**, and then click **Shortcut**.
   c. In the **Create Shortcut Wizard**, in **Type the location of the item**, type schmmgmt.msc, and then click **Next**.
   d. On the **Select a Title for the Program** page, in **Type a name for this shortcut**, type **Active Directory Schema**, and then click **Finish**.

| ⚠Caution |
| --- |
| Modifying the schema is an advanced operation best performed by experienced programmers and system administrators. For detailed information about modifying the schema, see the Active Directory programmer's Guide at the Microsoft Web site. |

# Transfer the schema master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the schema operations master role. The schema master is a forest-wide operations master role. Before you can use the Active Directory Schema snap-in for the first time, you must register it with the system. If you have not yet prepared the Active Directory Schema snap-in, see Install the Schema snap-in before you begin this procedure.

| **Note** |
| --- |
| This procedure is performed by using the Microsoft Management Console (MMC), although you can also transfer this role by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a Schema Administrator in Active Directory.

#### Transfer the schema master

1. Open the Active Directory Schema snap-in.
2. In the console tree, right-click **Active Directory Schema**, and click **Change Domain Controller**.
3. In the **Change Domain Controller** dialog box, click **Specify Name**. Then, in the text box, type the name of the server to which you want to transfer the schema master role. Click **OK**.
4. In the console tree, right-click **Active Directory Schema**. Click **Operations Master**. The **Change Schema Master** box displays the name of the server that is currently holding the role. The targeted domain controller is listed in the second box.
5. Click **Change**. Click **Yes** to confirm your choice. The system confirms the operation. Click **OK** again to confirm that the operation succeeded.
6. Click **Close** to close the **Change Schema Master** dialog box.

| **Note** |
| --- |
| Hosting the infrastructure master on a global catalog server is not recommended. If you attempt to transfer the infrastructure master role to a domain controller that is a global catalog, the system displays a warning stating that this is not recommended. |

# Transfer the domain naming master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the domain naming operations master role. The domain naming master is a forest-wide operations master role.

| **Note** |
| --- |
| This procedure is performed by using the Microsoft Management Console (MMC), although you can also transfer this role by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

#### To transfer the domain naming master

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click **Active Directory Domains and Trusts**, and then click **Connect to Domain Controller**.
3. Ensure that the proper domain name is entered in the **Domain** box.

   The available domain controllers from this domain are listed.
4. In the **Name** column, click the domain controller (to select it) to which you want to transfer the role. Click **OK**.
5. Right-click **Active Directory Domains and Trusts**, and then click **Operations Master**.
6. The name of the current domain naming master appears in the first text box. The server to which you want to transfer the role should appear in the second text box. If this is not the case, repeat steps 1 through 4.
7. Click **Change**. To confirm the role transfer, click **Yes**. Click **OK** again to close the message box indicating the transfer took place. Click **Close** to close the **Change Operations Master** dialog box.

# Transfer the domain-level operations master roles

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the three domain-level operations master roles: the PDC emulator, the RID master, and the infrastructure master. You can transfer all of these roles by using the Active Directory Users and Computers console.

| **Note** |
| --- |
| These procedures are performed by using MMC, although you can also transfer these roles by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer the operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To transfer a domain-level operations master role**

1. Open Active Directory Users and Computers.
2. At the top of the console tree, right-click **Active Directory Users and Computers**. Click **Connect to Domain Controller**.
3. In the list of **available domain controllers**, click the name of the server to which you want to transfer the role, and then click **OK**.
4. At the top of the console tree, right-click **Active Directory Users and Computers**, point to **All Tasks**, and then click **Operations Masters**.

   The name of the current operations master role holder appears in the **Operations master** box. The name of the server to which you want to transfer the role appears in the lower box.
5. Click the tab for the role you want to transfer: **RID**, **PDC**, or **Infrastructure**. Verify the computer names that appear and then click **Change**. Click **Yes** to transfer the role, and then click **OK**.
6. Repeat steps 4 and 5 for each role that you want to transfer.

# View the current operations master role holders

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Once an operations master role has been transferred, it should be verified that the transfer has occurred successfully throughout the domain. The change must be replicated to all relevant domain members in order to truly take effect.

To view the current operations master role holders, use Ntdsutil.exe with the roles option. This option displays a list of all current role holders.

**Administrative Credentials**

To perform this procedure, you must be logged on as a User or an Administrator.

**To view the current operations master role holder**

1. Click **Start**, click **Run**, type **ntdsutil**, and then press ENTER.
2. At the **ntdsutil:** prompt, type **roles** and press ENTER.
3. At the **fsmo maintenance:** prompt, type **connections** and press ENTER.
4. At the **server connections:** prompt, type **connect to server** *servername* (where *servername* is the name of the domain controller that belongs to the domain containing the operations masters).
5. After receiving confirmation of the connection, type **quit** and press ENTER to exit this menu.
6. At the **fsmo maintenance:** prompt, type **select operation target** and press ENTER.
7. At the **select operations target:** prompt, type **list roles for connected server** and press ENTER.

   The system responds with a list of the current roles and the Lightweight Directory Access Protocol (LDAP) name of the domain controllers currently assigned to host each role.
8. Type **quit** and press ENTER to exit each prompt in Ntdsutil.exe. Type **quit** and press ENTER at the **ntdsutil:** prompt to close the window.

# Seizing an operations master role

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Role seizure is the act of assigning an operations master role to a new domain controller without the cooperation of the current role holder (usually because it is offline due to a hardware failure). During role seizure, a new domain controller assumes the operations master role without communicating with the current role holder.

Role seizure can create two conditions that can cause problems in the directory. It is for this reason that role seizure should be performed only as a last resort. First, the new role holder starts performing its duties based on the data located in its current directory partition. The new role holder might not receive changes that were made to the previous role holder before it went offline if replication did not complete prior to the time when the original role holder went offline. This can cause data loss or introduce data inconsistency into the directory database.

To minimize the risk of losing data to incomplete replication, do not perform a role seizure until enough time has passed to complete at least one complete end-to-end replication cycle across your network. Allowing enough time for complete end-to-end replication ensures that the domain controller that assumes the role is as up-to-date as possible.

Second, the original role holder is not informed that it is no longer the operations master role holder, which is not a problem if the original role holder stays offline. However, if it comes back online (for example, if the hardware is repaired or the server is restored from a backup), it might try to perform the operations master role that it previously owned. This can result in two domain controllers performing the same operations master role simultaneously. Depending on the role that was seized, the severity of duplicate operations master roles varies from no visible effect to potential corruption of the Active Directory database. Seize the operations master role to a domain controller that has the most recent updates from the current role holder to minimize the impact of the role seizure.

**Task Requirements**

- Repadmin.exe
- Ntdsutil.exe

To complete this task, perform the following procedures:

1. Verify successful replication to a domain controller

   This needs to be the domain controller that will be seizing the role.

2. Seize the operations master role

3. View the current operations master role holders

# Verify successful replication to a domain controller

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **repadmin /showrepl** command to verify successful replication to a specific domain controller. If you are not running Repadmin on the domain controller whose replication you are checking, you can specify a destination domain controller in the command. Repadmin lists INBOUND NEIGHBORS for the current or specified domain controller. INBOUND NEIGHBORS shows the distinguished name of each directory partition for which inbound directory replication has been attempted, the site and name of the source domain controller, and whether replication succeeded or not, as follows:

- Last attempt @ YYYY-MM-DD HH:MM.SS was successful.
- Last attempt @ [Never] was successful.

If @ [Never] appears in the output for a directory partition, replication of that directory partition has never succeeded from the identified source replication partner over the listed connection.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the destination domain controller.

**To verify successful replication to a domain controller**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl** *servername* **/u:** *domainname* **** *username* **/pw:***

   | Term | Definition |
   | --- | --- |
   | *servername* | Specifies the name of the destination domain controller. |
   | *domainname* | Specifies the single-label name of the domain of the destination domain controller. (You do not have to use a fully qualified Domain Name System (DNS) name.) |
   | *username* | Specifies the name of an administrative account in that domain. |

3. When you are prompted for a password, type the password for the user account that you provided, and then press ENTER.

You can also use Repadmin to generate the details of replication to and from all replication partners in a spreadsheet. The spreadsheet displays data in the following columns:

Showrepl_COLUMNS

Destination DC Site

Destination DC

Naming Context

Source DC Site

Source DC

Transport Type

Number of Failures

Last Failure Time

Last Success Time

Last Failure Status

The following procedure shows how to create this spreadsheet and set column headers for improved readability.

**To generate a repadmin /showrepl spreadsheet for all replication partners**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl * /csv >showrepl.csv**
3. Open Microsoft Excel.
4. On the **File** menu, click **Open**, navigate to showrepl.csv, and then click **Open**.
5. Hide or delete column **A** as well as the **Transport Type** column, as follows:
6. Select a column that you want to hide or delete.
   - To hide the column, on the **Format** menu, click **Column**, and then click **Hide**.

     Or

   - To delete the column, right-click the selected column, and then click **Delete**.
7. Select row 1 beneath the column heading row, and then, on the **Window** menu, click **Freeze Panes**.
8. Select the entire spreadsheet. On the **Data** menu, click **Filter**, and then click **AutoFilter**.
9. In the **Last Success Time** column, click the down arrow, and then click **Sort Ascending**.
10. In the **Source DC** column, click the down arrow, and then click **Custom**.
11. In the **Custom AutoFilter** dialog box, under **Show rows where**, click **does not contain**. In the adjacent text box, type **del** to eliminate from view the results for deleted domain controllers.
12. Repeat step 10 for the **Last Failure Time** column, but use the value **does not equal**, and type the value **0**.
13. Resolve replication failures.

The last successful attempt should agree with the replication schedule for intersite replication, or the attempt should be within the last hour for intrasite replication.

If Repadmin reports any of the following conditions, see Troubleshooting Active Directory Replication Problems:

- The last successful intersite replication was prior to the last scheduled replication.
- The last intrasite replication was longer than one hour ago.
- Replication was never successful.

# Seize the operations master role

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Ntdsutil.exe command-line tool allows you to transfer and seize any operations master role. You must use Ntdsutil.exe to seize the schema master, domain naming master, and RID master roles. When you use Ntdsutil.exe to seize an operations master role, it first attempts a transfer from the current role owner. If the current role owner is unavailable, it performs the seizure.

When using Ntdsutil.exe to seize an operations master role, the procedure is nearly identical for all roles. For more information about using Ntdsutil.exe, type **?** at the Ntdsutil.exe command prompt.

**Administrative Credentials**

To perform this procedure, you must be a member of either the Domain Admins group or the Enterprise Admins group in Active Directory.

**To seize an operations master role**

1. Click **Start**, click **Run**, type **ntdsutil**, and then press ENTER.
2. At the **ntdsutil:** prompt, type **roles** and press ENTER.
3. At the **fsmo maintenance:** prompt, type **connections** and press ENTER.
4. At the **server connections:** prompt, type **connect to server** *servername* (where *servername* is the name of the domain controller that will assume the operations master role), and press ENTER.
5. After you receive confirmation of the connection, type **quit** and press ENTER\.
6. Depending on the role you want to seize, at the **fsmo maintenance:** prompt, type the appropriate command and press ENTER.

| Role | Credentials | Command |
|---|---|---|
| Domain naming master | Enterprise Admins | Seize domain naming master |
| Schema master | Enterprise Admins | Seize schema master |
| Infrastructure master | Domain Admins | Seize infrastructure master |
| PDC emulator | Domain Admins | Seize pdc |
| RID master | Domain Admins | Seize rid master |

The system asks for confirmation. It then attempts to transfer the role. When the transfer fails, some error information appears and the system proceeds with the seizure. After the seizure is complete, a list of the roles and the LDAP name of the server that currently holds each role appears.

During seizure of the RID master, the current role holder attempts to synchronize with its replication partners. If it cannot establish a connection with a replication partner during the seizure operation, it displays a warning and confirms that you want the role seizure to proceed. Click **Yes** to proceed.

7. Type **quit** and press ENTER. Type **quit** again and press ENTER to exit Ntdsutil.exe.

# View the current operations master role holders

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Once an operations master role has been transferred, it should be verified that the transfer has occurred successfully throughout the domain. The change must be replicated to all relevant domain members in order to truly take effect.

To view the current operations master role holders, use Ntdsutil.exe with the roles option. This option displays a list of all current role holders.

**Administrative Credentials**

To perform this procedure, you must be logged on as a User or an Administrator.

**To view the current operations master role holder**

1. Click **Start**, click **Run**, type **ntdsutil**, and then press ENTER.
2. At the **ntdsutil:** prompt, type **roles** and press ENTER.
3. At the **fsmo maintenance:** prompt, type **connections** and press ENTER.
4. At the **server connections:** prompt, type **connect to server** *servername* (where *servername* is the name of the domain controller that belongs to the domain containing the operations masters).
5. After receiving confirmation of the connection, type **quit** and press ENTER to exit this menu.
6. At the **fsmo maintenance:** prompt, type **select operation target** and press ENTER.
7. At the **select operations target:** prompt, type **list roles for connected server** and press ENTER.

   The system responds with a list of the current roles and the Lightweight Directory Access Protocol (LDAP) name of the domain controllers currently assigned to host each role.
8. Type **quit** and press ENTER to exit each prompt in Ntdsutil.exe. Type **quit** and press ENTER at the **ntdsutil:** prompt to close the window.

# Reducing the workload on the PDC emulator master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In addition to processing normal domain controller load from clients, the PDC emulator must also process password changes. In order to mitigate some of the load that is caused by normal domain controller traffic, the PDC can be protected, so the load is distributed to other domain controllers that are capable of processing the requests.

You can configure DNS so that a domain controller is queried less frequently than others. Reducing the number of client requests helps reduce the workload on a domain controller, giving it more time to function as an operations master, and is especially important for the PDC emulator. Of all the operations master roles, the PDC role has the highest impact on the domain controller hosting that role.

To receive information from the domain, a client uses DNS to locate a domain controller and then sends the request to that domain controller. By default, DNS performs rudimentary load balancing and randomizes the distribution of client requests so they are not always sent to the same domain controller. If too many client requests are sent to a domain controller while it attempts to perform other duties, such as those of the PDC emulator, it can become overloaded, which has a negative impact on performance. To reduce the number of client requests that are processed by the PDC emulator, you can adjust its weight or its priority in the DNS environment.

**Adjusting the Weight for DNS SRV Records in the Registry**

Adjusting the weight of a domain controller to a value less than that of other domain controllers reduces the number of clients that DNS refers to that domain controller. The value is stored in the LdapSrvWeight registry entry. The default value is 100, but it can range from 0 through 65535. By reducing this value, DNS refers clients to a domain controller less frequently based on the proportion of this value to the value of other domain controllers. For example, to configure the system so that the domain controller hosting the PDC emulator role receives requests only half as many times as the other domain controllers, configure the weight of the domain controller hosting the PDC emulator role to be 50. DNS determines the weight ratio for that domain controller to be 50/100 (50 for that domain controller and 100 for the other domain controllers). After you reduce this ratio to 1/2, DNS refers clients to the other domain controllers twice as often as it refers to the domain controller with the reduced weight setting. By reducing client referrals, the domain controller receives fewer client requests and has more resources for other tasks, such as performing the role of PDC emulator.

**Adjusting the Priority for DNS SRV Records in the Registry**

Adjusting the priority of the domain controller also reduces the number of client referrals. However, rather than reducing it proportionally to the other domain controllers, changing the priority causes DNS to stop referring all clients to this domain controller unless all domain controllers with a lower priority setting are unavailable.

To prevent clients from sending all requests to a single domain controller, the domain controllers are assigned a priority value. Clients always send requests to the domain controller that has the lowest priority value. If more than one domain controller has the same value, the clients randomly choose from the group of domain controllers with the same value. If no domain controllers with the lowest priority value are available, then the clients send requests to the domain controller with the next highest priority.

A domain controller's priority value is stored in its registry. When the domain controller starts, the Net Logon service registers with the DNS server. The priority value is registered with the rest of its DNS information. When a client uses DNS to discover a domain controller, the priority for a given domain controller is returned to the client with the rest of the DNS information. The client uses the priority value to help determine to which domain controller to send requests.

The value is stored in the **LdapSrvPriority** registry entry. The default value is 0, but it can range from 0 through 65535.

| **Note** |
| --- |
| A lower value that is entered for **LdapSrvPriority** indicates a higher priority. Clients will attempt to use a domain controller with an **LdapSrvPriority** setting of 0 before a domain controller with an **LdapSrvPriority** setting of 1, just as domain controllers with **LdapSrvPriority** settings of 1 would be used before domain controllers with **LdapSrvPriority** settings of 2. |

**Task Requirements**

The following tool is required to perform the procedures for this task:

- Regedit.exe

To complete this task, perform the following procedures:

1. Change the weight for DNS SRV records in the registry

2. Change the priority for DNS SRV records in the registry

# Change the weight for DNS SRV records in the registry

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to reduce the workload on the PDC emulator master by changing the weight for DNS SRV records in the registry.

| ⚠Caution |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Administering Active Directory Backup and Restore. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

#### To change the weight for DNS SRV records in the registry

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.
2. In the Registry Editor, navigate to **HKLM\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**
3. Click **Edit**, click **New**, and then click **DWORD** value.
4. For the new value name, type **LdapSrvWeight**, and press ENTER.
5. Double-click the value name that you just typed to open the Edit DWORD Value dialog box.
6. Enter a value from 0 through 65535. The default value is 100.
7. Choose **Decimal** as the **Base** option, and then click **OK**.
8. Click **File**, and then click **Exit** to close the Registry Editor.

# Change the priority for DNS SRV records in the registry

Updated: March 2, 2005

Editor: Jim Becker

# Introduction to Administering Active Directory Backup and Restore

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Active Directory backup must be incorporated into your operations schedule for a set of domain controllers that you identify and on which you perform routine backup operations.

Active Directory restore is not performed routinely as an operations task; it is performed only when indicated by a failure or other condition from which a domain controller can recover only by restoring the directory to a previous state.

**System State Components**

Active Directory is backed up as part of system state, a collection of system components that depend on each other. All system state components must be backed up and restored together.

The system state components on a domain controller include the following:

- System startup (boot) files. These files are required for Windows Server 2003 to start.
- System registry
- Class registration database of component services. The Component Object Model (COM) is a binary standard for writing component software in a distributed systems environment.
- System volume (SYSVOL). SYSVOL provides a default location for files that must be shared for common access throughout a domain. The SYSVOL folder on a domain controller contains the following:
    - Net Logon shared folders. These folders usually host user logon scripts and policy settings for network clients that are running pre–Windows 2000 operating systems.
    - User logon scripts for Active Directory–enabled clients
    - System policies
    - Group Policy settings
    - File system junctions
    - File Replication service (FRS) staging directories and files that are required to be available and synchronized between domain controllers
- Active Directory, including the following:
    - The Active Directory database (Ntds.dit)
    - The checkpoint file (Edb.chk)
    - The transaction logs, each 10 megabytes (MB) in size (Edb*.log)
    - Reserved transaction logs (Res1.log and Res2.log)

If you installed Windows Clustering or Certificate Services on your domain controller, they are also backed up as part of system state. Details of these components are not discussed in this guide.

**Purpose of Performing Regular Backups**

You need a current, verified, and reliable backup to:

- Restore Active Directory data that becomes lost. By using an authoritative restore process, you can restore individual objects or sets of objects (containers or directory partitions) from their deleted state.

- Recover a domain controller that cannot start up or operate normally because of software failure or hardware failure.

- Install Active Directory from backup media (using the **dcpromo /adv** command). You can use this installation option of Dcpromo to install Active Directory on a server running Windows Server 2003 to make that server an additional domain controller. Use this method to quickly add a domain controller to a domain that has a large database or that is located in sites that are separated by slow network links.

- Perform a forest recovery if forest-wide failure occurs.

**Restore Requirements and Recommendations**

The tombstone lifetime value in an Active Directory forest defines the default number of days that a domain controller preserves knowledge of deleted objects. This value also defines the useful life of a system state backup that is used for disaster recovery or installation from backup media. Active Directory protects itself from restoring data that is older than the tombstone lifetime by disallowing the restore.

The tombstone lifetime is stored in the **tombstoneLifetime** attribute of the object CN=Directory Service,CN=Windows NT,CN=Services,CN-Configuration,DC=*ForestRootDomain*. In a forest that is created on a domain controller that is running Windows Server 2003 without Service Pack 1 (SP1), the default tombstone lifetime is 60 days. In a forest that is created on a domain controller that is running Windows Server 2003 with SP1, Windows Server 2003 with Service Pack 2 (SP2), or Windows Server 2003 R2, the default tombstone lifetime is 180 days. Because the tombstone lifetime can be changed administratively, do not assume the default value. Be sure that you are aware of the tombstone lifetime that is in effect in your forest.

| **Important** |
| --- |
| You should not modify system clocks in an attempt to improperly extend the useful life of a system state backup. |

System state restore should be undertaken as a last resort, not as primary method of recovering from an error or failure condition.

**Backup Guidelines**

The following guidelines for backup include the performance of appropriate backups to ensure redundancy of Active Directory data:

- Perform normal backup. Normal backup is the only type of backup that is available and supported for Active Directory. The Backup tool in Windows Server 2003 supports multiple types of backup: normal, copy, incremental, differential, and daily. You must use normal backup because Active Directory is backed up as part of system state.

- Perform daily backups of each unique partition on at least two unique domain controllers, with special emphasis on single-domain controller forests, single-domain controller domains, and empty root domains.

- Where partitions exist in only one site, you can ship backup files offsite to a secure location so that no backup file of a unique directory partition exists in only one physical site at any point in time. This provides an extra level of redundancy.

- Make sure your backups are stored in a secure location at all times.

- Back up Domain Name System (DNS) zones. You must be aware of the location of DNS zones and back up DNS servers accordingly. If you use Active Directory-integrated DNS, DNS zone data is captured as part of system state on domain controllers that are also DNS servers.

  If you do not use Active Directory-integrated DNS, you must back up the zone file directories on a representative set of DNS servers for each DNS zone to ensure fault tolerance for the zone.

| **Note** |
| --- |

The DNS server stores settings in the registry, so system state backup is required for DNS regardless of whether the zone data is Active Directory-integrated or stored in the file system.

- If you have application partitions in your forest, make sure that you take a backup of the domain controllers that hold those application partitions.
- Create additional backups in every geographic location where:
  - Mission-critical work is performed.
  - A wide area network (WAN) outage would disrupt business.
  - The elapsed time that it takes to perform either of the following tasks would be cost-prohibitive because of slow link speeds, the size of the directory database, or both:

    To create a domain controller in its intended domain over the network.

    Or

    To copy or transport a system state backup from a site where a backup exists to a site that has no backup, for the purpose of performing an installation from backup media.

**Note**

A backup can be used to restore only the domain controller on which the backup was generated or to create a new additional domain controller in the same domain by installing from backup media. A backup cannot be used to restore a different domain controller or to restore a domain controller onto different hardware. Likewise, a backup that is made on a domain controller running Windows 2000 Server cannot be used to restore a domain controller running Windows Server 2003.

**Backup Frequency**

Backup frequency depends on criteria that vary for individual environments. In most Active Directory environments, users, computers, and administrators make daily changes to directory objects. For example, computer accounts, including domain controller accounts, change their passwords every 30 days by default. Therefore, every day a percentage of computer passwords changes for domain controllers. Rolling the computer password of a domain controller back to a former state affects authentication and replication. A percentage of user passwords might also expire on a daily basis, and if they are lost as a result of domain controller failure, they must be reset manually. Generally, no record of these changes exists except in Active Directory. Therefore, the more frequently you back up domain controllers, the fewer problems you will encounter if you need to restore.

The more Active Directory objects and domain controllers you have, the more frequent your backups should be. For example, in a large organization, to recover from the inadvertent deletion of a large organizational unit (OU) by restoring the domain from a backup that is days or weeks old, you might have to re-create hundreds of accounts that were created in that OU since the backup was taken. To avoid re-creating accounts and potentially performing large numbers of manual password resets, ensure that recent system state backups are always available to recover recent Create, Modify, and Delete operations.

**Frequency Criteria**

Use the following criteria to assess backup frequency:

- Small environments with a single domain controller in the forest, or domains that exist in a single physical location (that is, that have a single point of failure): create backups at least daily.
- Medium (10 to 49 domain controllers) and large environments (50 to 1,000 or more domain controllers): Create backups of each unique directory partition in the forest on two different computers at least daily with an emphasis on backing up application directory partitions, empty root domains, domain partitions in a single geographic site, and sites that have large populations of users or that host mission-critical work.

Make backups with increasing frequency until you are confident that if you were to lose the objects that were created or modified since the last backup, the loss would not create an operational disruption. For this reason, major changes to the environment should always be immediately followed by a new system state backup.

| **Note** |
| --- |
| It is always recommended that you have at least two domain controllers in each domain of your Active Directory forest |

**Immediate Backup**

In addition to regularly scheduled backups, perform an immediate backup when:

- You have moved the Active Directory database, log files, or both to a different location on a disk.
- A domain controller is upgraded from Windows 2000 Server to Windows Server 2003 or there are any other operating system upgrades.
- A Service Pack is installed.
- A hotfix is installed that makes changes to the Active Directory database.
- A current backup is required for installing from backup media for a new domain controller.
- The tombstone lifetime is changed administratively.

**Backup Latency Interval**

On domain controllers running Windows Server 2003 with Service Pack 1 (SP1), Windows Server 2003 with Service Pack 2 (SP2), or Windows Server 2003 R2, event ID 2089 provides the backup status of each directory partition that a domain controller stores, including application directory partitions. Specifically, event ID 2089 is logged in the Directory Service event log when partitions in the Active Directory forest are not backed up within a backup latency interval. The value for the backup latency interval is stored as a **REG_DWORD** value in the **Backup Latency Threshold (days)** entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters**.

| **Note** |
| --- |
| An initial backup must be performed before event ID 2089 will be logged. If no backup is ever performed on a domain controller, this event does not provide warnings of backup latency. |

By default, the value of Backup Latency Threshold (days) is half the value of the tombstone lifetime of the forest. In a forest that is created on a domain controller that is running Windows Server 2003 without Service Pack 1 (SP1), half the default tombstone lifetime is 30 days. In a forest that is created on a domain controller that is running Windows Server 2003 with SP1, Windows Server 2003 with Service Pack 2 (SP2), or Windows Server 2003 R2, half the default tombstone lifetime is 90 days. However, we recommend that you make backups at a much higher frequency than half the tombstone lifetime. By setting a minimum backup frequency, changing **Backup Latency Threshold (days)** to reflect that frequency, and monitoring Event ID 2089, you ensure the backup frequency that is established in your organization.

To set a different **Backup Latency Threshold (days)** value, use Registry Editor (Regedit.exe) to create the entry as a **REG_DWORD** and provide the appropriate number of days.

# Managing Active Directory Backup and Restore

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks for managing Active Directory backup and restore are described in this objective:

- Backing Up Active Directory Components
- Performing a Nonauthoritative Restore of a Domain Controller
- Performing an Authoritative Restore of Active Directory Objects
- Performing an Authoritative Restore of an Application Directory Partition
- Performing an Authoritative Restore of a Group Policy Object
- Restoring a Domain Controller Through Reinstallation and Subsequent Restore from Backup
- Restoring a Domain Controller Through Reinstallation

# Backing Up Active Directory Components

Updated: April 15, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Active Directory is backed up as part of Microsoft Windows system state. For more information about all Microsoft Windows system state components and Active Directory components, see Introduction to Administering Active Directory Backup and Restore.

**Naming Backup Files**

To ensure the proper use of backup files, the .bkf file should have a file name that includes the following information:

- The fully qualified computer name that includes the domain name of the domain controller on which the backup was performed
- Whether the backup domain controller is a global catalog server
- Whether the backup domain controller contains MD5 checksum data to source the Sysvol tree
- The date that the backup was performed

For example, you might use a file name format that is similar to the following:

X:*Fully_Qualified_Computer_Name.Build_Number.Service_Pack_Revision*. [No]GC.[No]MD5.*TSL.YYYYMMDD*.bkf

where

- *Fully_Qualified_Computer_Name* is the host name and the domain name of the domain controller. This must be the domain name of the domain where the system state was backed up.
- *Build Number* is the build number of the operating system that was backed up.
- *Service_Pack_Revision* is the service pack build number and the service pack version for the operating system that was backed up.
- [No]GC indicates whether the backup originated from a global catalog or not.
- [No]MD5 indicates whether the system state backup contains MD5 checksum data for the files and folders in the SYSVOL tree. For more information about the need for MD5 data, see Preparing a Server Computer for Shipping and Installation from Backup Media.
- *TSL* is the value in days for the **tombstoneLifetime attribute** when the backup was performed. The **tombstoneLifetime** attribute for the forest determines both the useful life of a system state backup and how frequently garbage collection occurs. (Garbage collection removes tombstones from the directory permanently when their tombstone lifetime expires.)
- *YYYYMMDD* is the year, month, and day that the backup was performed.

For example, suppose that you create a system state backup of a global catalog domain controller on July 1, 2005. The domain controller is in the Contoso.com domain, and its name is DC1. The value of the tombstone lifetime is 60 days, and MD5 data is included in the backup. In this scenario, you might use a file name that is similar to the following:

DC1.CONTOSO.COM.3790.SP0.GC.MD5.60.2005.07.01.BKF

A system state backup that you make of DC1 on July 1, 2005, remains valid until August 29, 2005. For the next 60 days, you can use the backup to restore an existing domain controller or to install an additional domain controller in the Contoso.com domain.

You can save the .bkf file to a local volume or to a network share. The network share can be on a server computer that can be installed later as a domain controller by using the restored backup. For more information about using restored backup media for installing domain controllers, see Installing a Domain Controller in an Existing Domain Using Restored Backup Media.

**Task requirements**

The following tools are required to perform the procedures for this task:

- Backup or Restore Wizard (Ntbackup)
- Tape drive or other backup media

To complete this task, perform one of the following procedures, depending on your backup needs:

- Back up system state
- Back up system state and the system disk

Adding Domain Controllers in Remote Sites

# Back up system state

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Ntbackup.exe provides simple and advanced options for backing up Active Directory components. When you back up system state, you can choose to include or exclude system-protected boot files. System-protected boot files are not used for installations from restored backup media. When the backup file that you create is to be used for additional domain controller installations, you can clear the advanced option to back up system-protected files. Clearing this option decreases the size of the .bkf file, as well as the time required to back up, restore, and copy the system state files.

Use these procedures to back up the system state only. These procedures do not back up the system disk or any other data on the domain controller except for the system-protected files.

Use the first procedure, "To back up system state including system-protected files," for routine system state backup. Use the second procedure, "To back up system state excluding system-protected files," if you want to create a smaller backup that is effective for installing domain controllers from restored backup media.

| **Note** |
| --- |
| To back up system state, you must log on locally to the domain controller, or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

- To perform the following two procedures, you must be a member of the Domain Admins group or a member of the Backup Operators group.

#### To back up system state including system-protected files

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.

   This procedure provides steps for backing up in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.

2. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
3. Select **Back up files and settings**, and then click **Next**.
4. Select **Let me choose what to back up**, and then click **Next**.
5. In the **Items to Back Up** window, double-click **My Computer**.
6. In the expanded list below **My Computer**, check **System State**, and then click **Next**.
7. Select a location to store the backup:

   - If you are backing up to a file, type the path and file name for the backup (.bkf) file (or click **Browse** to find a folder or file).

   - If you are backing up to a tape unit, choose the tape that you want to use.

     | **Note** |
     | --- |
     | You should not store the backup on the local hard drive. Instead, store it in a location, such as a tape drive, away from the computer that you are backing up. |

8. Type a name for this backup according to the recommendations in Backing Up Active Directory Components, and then click **Next**.
9. On the last page of the wizard, click **Advanced**.

10. Do not change the default options for **Type of Backup**. **Normal** should be selected, and the check box for **Backup migrated remote storage data** should remain cleared. Click **Next**.
11. Select **Verify data after backup**, and then click **Next**.
12. In the **Backup Options** dialog box, select a backup option, and then click **Next**.
13. If you are replacing the existing backups, select the option to allow only the owner and administrator access to the backup data and to any backups that are appended to this medium, and then click **Next**.
14. In the **When to back up** box, select the appropriate option for your needs, and then click **Next**.
15. If you are satisfied with all of the options that are selected, click **Finish** to perform the backup operation according to your selected schedule.

| **Note** |
| --- |
| The system state can also be backed up by using Ntbackup from a command line with appropriate parameters. For more information, at a command prompt type **ntbackup /?**. |

The following procedure produces a smaller .bkf file that does not include system boot files. By using this procedure, you can reduce the time that is required to perform the backup and subsequent restore, as well as the amount of disk space that is required. This method is recommended when the restored backup is to be used for installing additional domain controllers.

**To back up system state excluding system-protected files**

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.
2. On the **Welcome to the Backup or Restore Wizard** page, click **Advanced Mode**, and then click the **Backup** tab.
3. In the console tree, select the **System State** check box.
4. In **Backup media or file name**, type a name for this backup according to the recommendations in Backing Up Active Directory Components.
5. Click **Start Backup**, and then click **Advanced**.
6. Clear the **Automatically back up System Protected Files with the System State** check box, and then click **OK**.
7. Click **Start Backup**.

Create a Remote Desktop Connection

# Back up system state and the system disk

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to back up both the system state and the system disk.

| **Note** |
| --- |
| To back up system state and the system disk, you must log on locally to the domain controller or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

To perform this procedure, you must be a member of the Domain Admins group or a member of the Backup Operators group.

**To back up system state and the system disk**

1. To start the Windows Server 2003 backup utility, click **Start**, point to **Programs**, **Accessories**, **System Tools**, and then click **Backup**.

   This procedure requires Backup Utility Advanced Mode. If the Welcome to the Backup or Restore Wizard appears when you click **Backup** in step 1, clear **Always start in wizard mode**, close the wizard, and then repeat step 1.
2. On the **Welcome to the Backup Utility Advanced Mode** page, click the **Backup Wizard (Advanced)** button.
3. On the **Welcome to the Backup Wizard** page, click **Next**.
4. On the **What to Back Up** page, click **Back up selected files, drives, or network data**, and then click **Next**.
5. In **Items to Back Up**, select the **System State** check box. Then, locate the drive letter containing the system files, click the check box for it, and then click **Next**.
6. In **Backup Type, Destination, and Name**, select the backup media type by choosing one of the following options:
   - In the **Select the backup type** box, click **File** if you want to back up to a file. If you do not have a tape backup unit installed, **File** is selected automatically.

     Or

   - Select a tape device if you want to back up to tape.
7. In the **Choose a place to save your backup** box, select one of the following options, and then click **Next**:
   - If you are backing up to a file, if you want to change the current backup file location, click **Browse** to find a folder or file. If the destination folder or file does not exist, the system creates it.

     Or

   - If you are backing up to a tape unit, select the tape that you want to use.
8. On the **Completing the Backup Wizard** page, click **Advanced**. Do not change the default options for **Type of Backup**. **Normal** should be selected, and the check box should remain cleared for **Backup migrated remote storage data**. Click **Next**.
9. Click **Verify data after backup**, and then click **Next**.
10. In the **Backup Options** dialog box, select a backup option, and then click **Next**.
11. If you are replacing the existing backups, select the option to allow only the owner and administrator access to the backup data and to any backups that are appended to this medium, and then click **Next**.
12. In the **When to back up** box, select the appropriate option for your needs, and then click **Next**.

13. If you are satisfied with all of the options that are selected, click **Finish** to perform the backup operation according to your selected schedule.

# Performing a Nonauthoritative Restore of a Domain Controller

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A nonauthoritative restore is the default method for restoring Active Directory. To perform a nonauthoritative restore, you must be able to start the domain controller in Directory Services Restore Mode. After you restore the domain controller from backup, replication partners use the standard replication protocols to update Active Directory and associated information on the restored domain controller.

A nonauthoritative restore returns the domain controller to its state at the time of backup and then allows normal replication to overwrite that state with any changes that occurred after the backup was taken. After you restore the system state, the domain controller queries its replication partners. The replication partners replicate any changes to the restored domain controller, ensuring that the domain controller has an accurate and updated copy of the Active Directory database.

A nonauthoritative restore allows the entire directory to be restored on a domain controller, without reintroducing or changing objects that have been modified since the backup. The most common use of a nonauthoritative restore is to bring an entire domain controller back, often after catastrophic or debilitating hardware failures. It is uncommon for data corruption to drive a nonauthoritative restore, unless the corruption is local and the database cannot be successfully loaded.

If you intend to restore a deleted object (or objects), see Performing an Authoritative Restore of Active Directory Objects.

You can perform a nonauthoritative restore on a Windows Server 2003 system that is a stand-alone server, member server, or domain controller. You must start a server in Directory Services Restore Mode to perform a nonauthoritative restore.

| **Note** |
| --- |
| By performing a nonauthoritative restore on Active Directory, you automatically perform a nonauthoritative restore of the system volume (SYSVOL); no additional steps are required. |

**Task requirements**

The following tool is required to perform the procedures for this task:

- NTBackup.exe

To complete this task, perform the following procedures:

1. Restart the domain controller in Directory Services Restore Mode by using one of the following methods:

   - Restart the domain controller in Directory Services Restore Mode locally
   - Restart the domain controller in Directory Services Restore Mode Remotely

   | **Note** |
   | --- |
   | In cases in which you have to reinstall the operating system, before you restore the directory, you do not have to perform a nonauthoritative restore in Directory Services Restore Mode. After you reinstall the operating system, you can perform a restore after the computer boots normally. |

2. Restore Active Directory from backup

3. Verify Active Directory restore

# Restart the domain controller in Directory Services Restore Mode locally

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have physical access to a domain controller, you can restart the domain controller in Directory Services Restore Mode locally. Restarting in Directory Services Restore Mode takes the domain controller offline. In this mode, the server is not functioning as a domain controller.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode locally**

1. Restart the domain controller.
2. When the screen for selecting an operating system appears, press F8.
3. On the **Windows Advanced Options** menu, select **Directory Services Restore Mode**.
4. When you are prompted, log on as the local administrator.

**Concepts**
Restart the domain controller in Directory Services Restore Mode Remotely

# Restart the domain controller in Directory Services Restore Mode Remotely

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If Remote Desktop is enabled on a domain controller, you can use Remote Desktop Connection to connect to the domain controller remotely. Remote Desktop Connection (formerly known as the Terminal Services client) is installed by default on all Windows Server 2003 family operating systems.

If you use Remote Desktop Connection to connect to a domain controller remotely and you want to restart the domain controller in Directory Services Restore Mode, you must first modify the Boot.ini file on the remote server so that you do not lose the connection when the domain controller restarts.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode remotely**

1. Use Remote Desktop Connection to connect to the domain controller that you want to restart in Directory Services Restore Mode.
2. Right-click **My Computer**, click **Properties**, and then click the **Advanced** tab.
3. Click **Settings for startup and recovery**.
4. Click the **Edit** button to edit the startup options file.
5. Modify the default entry to include the **/SAFEBOOT:DSREPAIR** switch, as shown in the following example:

   **multi(0)disk(0)rdisk(0)partition(2)\WINNT="W2K DC ** *your server name* **" /fastdetect /SAFEBOOT:DSREPAIR**

   | **Note** |
   | --- |
   | The **/SAFEBOOT:DSREPAIR** switch works for domain controllers running Windows 2000 Server and Windows Server 2003. |

6. Save the modified Boot.ini file, and then close Notepad.
7. On the **Start** menu, click **Shut Down**, and then click **Restart**. During the restart process, the Terminal Services client reports that the session is disconnected.

   | **Caution** |
   | --- |
   | Be sure to click **Restart** and not **Shut Down** at this step. If you click **Shut Down**, you cannot restart the domain controller remotely. |

8. Wait until the restart process completes on the remote domain controller, and then reconnect the client session.
9. When the client session is reconnected, log on as the local administrator.
10. Right-click **My Computer**, click **Properties**, and then click the **Advanced** tab.
11. Click **Settings for startup and recovery**.
12. Click the **Edit** button to edit the startup options file.
13. Delete the **/SAFEBOOT:DSREPAIR** switch from the default entry in the Boot.ini file, save the file, and then close Notepad.

| **Important** |
| --- |
| If you restart the domain controller before you modify the Boot.ini file, the domain controller remains offline. |

The Boot.ini file is now returned to its original state, which starts the domain controller normally.

Restart the domain controller in Directory Services Restore Mode locally

# Restore Active Directory from backup

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To restore the server, use a good backup containing the system state or the system state and system disk.

| **Note** |
| --- |
| To restore from backup, you must log on locally to the domain controller or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restore Active Directory from backup**

1. Start the computer in Directory Services Restore Mode.
2. To start the Windows Server 2003 backup utility, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

   This procedure provides steps for restoring from backup in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.
3. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
4. Click **Restore files and settings**, and then click **Next**.
5. Select **System State**, and then click **Next**.
6. On the **Completing the Backup or Restore Wizard** page, click **Advanced**.
7. In **Restore files to**, click **Original Location**, and then click **Next**.
8. Click **Leave existing files (Recommended)**, and then click **Next**.
9. In **Advanced Restore Options**, select the following check boxes, and then click **Next**:
   - **Restore security settings**
   - **Restore junction points, but not the folders and file data they reference**
   - **Preserve existing volume mount points**
10. For a primary restore of SYSVOL, also select the following check box: **When restoring replicated data sets, mark the restored data as the primary data for all replicas**.

    A primary restore is required only if the domain controller that you are restoring is the only domain controller in the domain. A primary restore is required on the first domain controller that is being restored in a domain if you are restoring the entire domain or forest.
11. Click **Finish**.
12. When the restore process is complete, click **Close**, and then do one of the following:
    - If you do not want to authoritatively restore any objects, click **Yes** to restart the computer. The system will restart and replicate any new information that is received since the last backup with its replication partners.
    - If you want to authoritatively restore any objects or if you want to create an LDAP Data Interchange Format (LDIF) file to restore back-links on this domain controller, click **No** to remain in Directory Services Restore Mode. For information about how to proceed with authoritative restore, see Performing an Authoritative Restore of Active

Directory Objects.

Performing an Authoritative Restore of Active Directory Objects

# Verify Active Directory restore

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After the restore is completed, use this procedure to restart the server and perform basic verification.

**Administrative credentials**

To verify Active Directory restore, you must be a member of the Domain Admins group.

**To verify Active Directory restore**

1. After the restore operation completes, restart the computer in **Start Windows Normally** mode. Active Directory and Certificate Services automatically detect that they have been recovered from a backup. They perform an integrity check and re-index the database.
2. After you are able to log on to the system, browse Active Directory. Verify that all of the User objects and Group objects that were present in the directory prior to backup are restored. Similarly, verify that files that were members of a File Replication service (FRS) replica set and certificates that were issued by the Certificate Services are present.

# Performing an Authoritative Restore of Active Directory Objects

Updated: April 10, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

On the domain controller that is being restored, an authoritative restore process returns a designated object or container of objects to its state at the time of the backup. For example, you might need to perform an authoritative restore if an administrator inadvertently deletes an organizational unit (OU) containing a large number of users. If you restore the server from backup, the normal, nonauthoritative restore process does not restore the inadvertently deleted OU because the restored domain controller is updated following the restore process to the current status of its replication partners, which have deleted the OU. Recovering the deleted OU requires authoritative restore. You can use authoritative restore to mark the OU as authoritative and let the replication process restore it to all the other domain controllers in the domain.

| **Note** |
| --- |
| If you can isolate a domain controller in the domain that has not received replication of the deletion, the preliminary, nonauthoritative restore from backup is not necessary. For more information, see Recovering Deletions Without Restoring from Backup later in this topic. |

You can restore objects in domain directory partitions, application directory partitions, and the configuration directory partition, as follows:

- Domain directory partitions: You must restore the objects on a domain controller in the domain.
- Application directory partitions: You must restore the objects on a domain controller that hosts the application directory partition. If you delete an entire application directory partition, you must restore the domain naming operations master to recover the application directory partition.
- Configuration directory partitions: You can restore objects on any domain controller in the forest.

When an object is marked for authoritative restore, its version number is changed so that it is higher than the existing version number of the (deleted) object in the Active Directory replication system. This change ensures that any data that you restore authoritatively is replicated from the restored domain controller to other domain controllers in the forest.

An authoritative restore should not be used to restore an entire domain controller, nor should it be used as part of a change-control infrastructure. Proper delegation of administration and change enforcement will optimize data consistency, integrity, and security.

It is important to ensure successful recovery of the information that is being restored. Group membership is particularly sensitive and can be affected greatly by the procedures that you perform during an authoritative restore.

**Important Preliminary Download Requirement for Windows Server 2003**
Before you perform an authoritative restore on a domain controller that is running Windows Server 2003, you must install an update that fixes problems that can cause unexpected results that follow authoritative restore procedures. The required update is available in Knowledge Base article ID 943576 (http://go.microsoft.com/fwlink/?LinkID=123945). Review the information and use the links in the article to install the hotfix. For more information, see Known Issues for Authoritative Restore.

**Selecting Objects to Restore**
When you select objects that you want to replicate authoritatively, it is important to select the object that is lowest in the directory subtree as possible that you can still use to recover the deleted objects. In this way, you avoid reverting objects that are not related to the deletion. Objects other than the deleted objects might have been modified after the backup was created.

When you restore an OU, any changes that are made up to the time that a backup is restored are rolled back to their values at the time of the backup. For any user accounts, computer accounts, and security groups in the restored OU that were not among the deletions being restored, this rollback might mean the loss of the most recent changes to passwords, home directory, profile path, location and container information, group membership, and any security descriptors that are defined on those objects and attributes.

For example, if an object with a password, such as a user or computer or trust account, is authoritatively restored, the password

value of the restored object reverts to the password value at the time of the backup. In this case, user, computer, and service accounts that have a record of only the current password cannot log on because they have no record of the password that existed when the backup was created. In this way, group membership or other data can also be lost. Updates to the password are blocked because the restored value is authoritative during replication. To minimize the impact of rolling unrelated objects back in time, target as few objects as possible. If you have relatively few deletions to restore, you might be able to restore each object individually.

If you have a relatively large number of deleted objects to restore, use the container object that contains most of the deleted objects. Ideally, the container that you restore will contain all the objects that you need to recover.

**Group Membership Restoration Following Authoritative Restore**

When a user object is inadvertently deleted, you can restore it by marking the user object as authoritative during an authoritative restore procedure. However, depending on the functional level of the forest at the time that any groups to which the user belongs were created (or the forest functional level at the time that the user was added to the group, if they are different), the user's group memberships might not be restored in the process. Multiply this condition by hundreds or thousands of users when an OU is deleted. In this case, additional steps are required to restore the group memberships of user accounts that are restored.

**LVR and Restoration of Group Memberships**

Restoration of group memberships for user objects that are deleted and restored authoritatively differs, depending on whether the group was created (or its membership was updated) before or after the implementation of Windows Server 2003 functionality called linked-value replication (LVR). LVR is a feature that is available when the forest has a functional level of Windows Server 2003 interim or Windows Server 2003. In groups that are created before LVR is in effect, the member attribute is replicated as a single value. Therefore, any change to the group's membership results in replication of the entire member attribute. In groups that are created after LVR is in effect, or in groups that are created before LVR but that are updated after LVR is in effect, updates to the member attribute are replicated separately. In this case, group memberships are restored when you use Ntdsutil to authoritatively restore a user, group, or computer object.

The **memberOf** attribute (or any back-link attribute) is generated only because of its link to the **member** attribute (or any corresponding forward-link attribute). For this reason, restoring the membership on a user object necessarily involves updating the **member** attribute on the group object to include the distinguished name of the restored user.

| **Note** |
| --- |
| Only the forward-link attribute value can be updated and replicated. The back-link attribute value is generated only when it is accessed. It is not stored on the object, and it is not replicated. |

When you use the Ntdsutil command-line tool to authoritatively restore a subtree or single object, the ability of Ntdsutil to restore the group memberships of an object that is authoritatively restored depends on whether the group was created before or after LVR was implemented. For example, if a user object is restored and the user belongs to group G1 that was created before LVR was implemented and the user belongs to group G2 that was created after LVR was implemented (the functional level of the forest was raised to Windows Server 2003 interim or Windows Server 2003), the **member** attribute of G2 is updated during authoritative restore (and, therefore, the **memberOf** attribute of the restored user is updated), but the **member** attribute of G1 is not updated.

However, improvements in the version of Ntdsutil that was introduced in Windows Server 2003 with Service Pack 1 (SP1) provide the ability to also restore the memberships of groups that were created before LVR was implemented.

**Authoritative Restore Improvements Introduced in Windows Server 2003 SP1**

Beginning with Windows Server 2003 with SP1, during an authoritative restore, Ntdsutil creates a text file that identifies the authoritatively restored objects and uses this file to create an LDAP Data Interchange Format (LDIF) file. The LDIF file can be used to regenerate all back-links on the restored objects in a forest where LVR is not in effect.

If you need to restore a large number of users (for example, if you delete an OU) in domain X and your forest also contains domain Y and domain Z, authoritative restore requires the restoration of domain X and then the use of Ntdsutil to generate and run the LDIF file against a domain controller in each additional domain.

In most cases, you begin the authoritative restore process by performing a nonauthoritative restore from backup. If you can identify a global catalog server that has not received replication of the deletions and you can isolate it before replication occurs, you can perform the authoritative restore without first restoring from backup. For information about using a latent global catalog server for authoritative restore, see Recovering deletions without restoring from backup. In either case, you then perform the additional steps to restore group memberships, if necessary. The steps that you perform are different if you are restoring the objects on a domain controller running a version of Windows Server beginning with Windows Server 2003 with SP1.

**Files for Recovering Group Memberships Following Authoritative Restore**
When you perform authoritative restore on a domain controller that is running Windows Server 2003 with SP1, Ntdsutil creates the following files that you can use to recover group memberships:

- ar_*YYYYMMDD-HHMMSS*_links_*Domain*.ldf, which is an LDIF file that is generated for the domain in which you perform the authoritative restore procedure. This file contains back-link information for the restored objects. If you perform the procedure on a global catalog server, a separate .ldf file is created for each domain in the forest. You can use this file with the Ldifde command-line tool to import the back-links to recover universal and global group memberships in environments that include pre-LVR groups. For environments that do not include pre-LVR groups, the Ntdsutil tool recovers group memberships automatically in the recovery domain and in the forest (for universal groups) if the recovery domain controller is a global catalog server. If the restore includes security principals that can have memberships in domain local groups in other domains, a text file that is also generated during authoritative restore is required to restore the memberships in the additional domains.

- ar_*YYYYMMDD-HHMMSS*_objects.txt, which is a text file that contains a list of the authoritatively restored objects. This file is generated for each individual object or container that you mark as authoritative. You can use this file to generate an .ldf file that you can use to recover memberships in domain local groups and universal groups (if you are not restoring a global catalog server) in other domains. This file is created on any domain controller that you authoritatively restore. Global catalog servers do not store the **member** attribute of domain local groups. Therefore, even if you perform the restore on a global catalog server, you must always use this file to generate an .ldf file in any domain where there are domain local groups of which restored security principals might be members. You must create a separate .ldf file for each object or container that you mark as authoritative.

**Using a Global Catalog Server for Authoritative Restore**
If possible, perform the authoritative restore on a global catalog server in the domain where the objects were deleted to recover security principals and group memberships. Global catalog servers store a single, writable domain and a partial, read-only replica of all other domains in the forest. A partial replica means that the global catalog stores all objects, but with a limited set of attributes on each object. Check the properties of the NTDS Settings object of the server object in Active Directory Sites and Services to confirm that a domain controller is a global catalog server.

**Global Catalog and Group Memberships**
In relation to the three types of security groups—global groups, domain local groups, and universal groups—global catalog servers are best suited for recovering group memberships after an authoritative restore procedure because they store memberships of all universal groups in the forest and all global groups in the domain.

Security group memberships are restored on a global catalog server as follows:

- **Global groups**: Security principals (users, groups, and computers) can be members of only the global groups that are created in the same domain. Global catalog servers store a writable domain directory partition. Therefore, they can restore global group memberships for the recovery domain.

- **Universal groups:** Security principals can be members of universal groups that are created in any domain. However, the **member** attribute is among the attributes that are stored on the read-only universal group objects in the global catalog. Therefore, a global catalog server can recover universal group memberships for all domains in the forest. A domain controller that is not a global catalog server stores only universal group objects that are created in its own domain.

- **Domain local groups**: Security principals can be members of domain local groups that are created in any domain. Memberships in domain local groups in the recovery domain are restored automatically during authoritative restore. However, the global catalog does not store the **member** attribute for read-only domain local group objects. Therefore, for restored security principals that have memberships in domain local groups in other domains, you must recover these memberships by performing follow-up procedures in each additional domain. The follow-up procedures are described in Create an LDIF file for recovering back-links for authoritatively restored objects.

**Recovering Deletions Without Restoring from Backup**
If you can isolate a global catalog server (or any domain controller, but preferably a global catalog server) in the domain where the deletion occurred before the server receives replication of the deletion, you might be able to avoid performing a preliminary restore from backup (nonauthoritative restore) and having to extend the restore process to other domains. Use the **repadmin /showrepl** command to determine the date and time of the latest inbound replication of the domain directory partition where the deletions occurred.

Global catalog servers often have greater replication latency than ordinary domain controllers, and they are better restore candidates in general because they store universal group memberships. If you can stop inbound replication on a latent global catalog server, you can perform authoritative restore on the global catalog server to recover the deleted memberships for all groups in the domain and for all universal groups in other domains.

If you want to use a latent global catalog server for restoring deleted objects, you must take steps to stop inbound replication immediately. You can use one of the following methods to stop replication:

- Use the Services snap-in to stop AD DS. In this case, other services continue to operate.
- Take the global catalog service offline by restarting it in Directory Services Restore Mode (DSRM). In this case, all other directory-related services are stopped in addition to AD DS.
- Use Repadmin.exe to stop inbound replication. In this case, the domain controller continues to operate but does not receive replication updates.

**Retention (Merge) of New Group Memberships or Other Attributes Following Authoritative Restore**

The authoritative restore procedure results in a merge of authoritatively restored objects and attributes and existing objects and attributes. For example, do not expect that users that have been added to a group (after the backup that is used to restore the deleted group) will be removed by an authoritative restore of the group object. Instead, new attributes of objects that are specified in the authoritative restore are preserved during replication. Therefore, authoritative restore does not remove group memberships that were added between the time of the backup that is used for authoritative restore and the time of the restore procedure.

Objects and attributes are preserved during authoritative restore as follows:

- If an object exists in the backup, before inbound replication occurs, the post-restore directory partition contains the version of the object that exists in the restored backup.
- If an object was created after the backup was made and there are additional domain controllers that store the directory partition, after inbound replication occurs, the restored directory partition also includes the set of objects that were created after the backup.
- If an object contains new attributes that are not contained in the backup but that exist in the directory partition of an additional domain controller in the domain at the time of the restore, after inbound replication the version of the object and attributes as they existed in the backup—plus any new attributes that were added to the object after the backup—are preserved.

Authoritative restore affects only the objects and attributes that existed at the time of the backup. This functionality applies to objects with linked attributes and nonlinked attributes alike. For example, if you are restoring an object that has attribute A and attribute B in the backup version and has attributes A′, B′, and C in the current directory, attribute C is retained after authoritative restore. Therefore, a group object that has the **member** value of User1 in the backup and has both User1 and User2 in the current directory includes both of those memberships after authoritative restore of the group object. Any post-backup **memberOf** or **member** attribute values that were added to a user or group, respectively, are not affected by replication updates after the restore procedure.

If you want to remove group memberships—or any other unwanted object attribute—complete the following steps:

1. Delete the object whose updates you do not want to retain.
2. Allow the deletion to replicate throughout the forest.
3. Back up a domain controller that has received the deletion.
4. Authoritatively restore the object that you deleted from the backup that does not contain the unwanted values.

**Procedures for Domain Controllers Running Windows Server 2003 with SP1, Windows Server 2003 with SP2, or Windows Server 2003 R2**

These procedures include the use of an LDIF file to restore group memberships following authoritative restore of the objects. If

you are restoring objects that can belong to groups in more than one domain, additional steps are required.

**Task requirements**

The following tools are required to perform the procedures for this task:

- Ntbackup.exe
- Ntdsutil.exe
- Repadmin.exe

To complete this task, perform procedures according to the conditions in your environment:

- Procedures for restoring after deletions have replicated
- Procedures for restoring before deletions have replicated
- Procedures for recovering group memberships (and any other back-link attributes) in other domains

**Procedures for Restoring After Deletions Have Replicated**
If you are performing authoritative restore on a domain controller that has already received replication of the deletions, perform the following procedures on the recovery domain controller:

1. If you do not have a current backup of the recovery domain controller, Back up system state. You can use this backup if your recovery is not successful and you can try again.

2. Restart the domain controller in Directory Services Restore Mode locally

   Or

   Restart the domain controller in Directory Services Restore Mode Remotely

3. Restore Active Directory from backup. Be sure to use a backup that contains the deleted objects.

   Restore system state backup to return the domain controller to its state at the time of the backup so that any groups that are being restored, or whose members are being restored, are present in the directory with their pre-deletion membership intact.

   To ensure that replication does not occur, click **No** at the end of the procedure so that the domain controller does not restart.

4. Mark the object or objects authoritative

   Mark the object or objects that you want to restore so that replication does not overwrite them when you restart the domain controller.

5. Restart the domain controller normally.

6. Synchronize replication with all partners

   For the newly restored object to become available and be instantiated in its restored form on all domain controllers, successful replication must occur between the domain controller that originates the restored changes and its partners.

   Make sure that all domain controllers in the domain and all global catalog servers in the forest have received the restored objects.

7. Use the following procedure to run the LDIF file that was created in step 2 on this domain controller to add the missing

group memberships in the domain that you have just restored:

Run an LDIF file to recover back-links in this domain. This procedure updates the group memberships of a restored security principal object or container of objects in the recovery domain. Perform this procedure for each individual object or container that you marked as authoritative.

8. Back up system state on the recovered domain controller.

9. If the .ldf file shows back-links for objects in other domains, perform the procedures in Procedures for recovering group memberships (and any other back-link attributes) in other domains.

**Procedures for Restoring Before Deletions Have Replicated**

If you have identified a global catalog server or other domain controller that has not received replication of the deletions and for which you have a recent backup, you do not have to perform a preliminary restore from backup. Perform the following procedures on the recovery domain controller:

1. Turn off inbound replication.

2. If you do not have a current backup of the recovery domain controller, Back up system state. You can use this backup if your recovery is not successful and you can try again.

3. Restart the domain controller in Directory Services Restore Mode locally.

   Or

   Restart the domain controller in Directory Services Restore Mode Remotely.

4. Mark the object or objects authoritative.

5. Restart the domain controller normally.

6. Synchronize replication with all partners.

7. Run an LDIF file to recover back-links in this domain.

8. Turn on inbound replication.

9. Back up system state on the recovered domain controller.

10. If the .ldf file shows back-links for objects in other domains, perform the procedures in Procedures for recovering group memberships (and any other back-link attributes) in other domains.

**Procedures for Recovering Group Memberships (and Any Other Back-Link Attributes) in Other Domains**

You can recover group memberships in other domains either by adding the members manually to the respective groups or by using the text file from the original authoritative restore procedure to generate one or more .ldf files that you can use to recover back-links in other domains. Be aware that restored objects might have back-links other than group memberships.

If you have restored security principal objects or other objects that have back-link attributes in a forest that has more than one domain and you do not want to restore the back-links manually, and if the .ldf file generated during authoritative restore shows back-links for objects in other domains, perform the following steps on a domain controller in each additional domain:

| **Note** |
| --- |
| For restored security principals, these steps are required only if the restored security principals have memberships in domain local or universal groups in a different domain from the recovery domain. If you restored the security principals on a global catalog server, you need to recover only domain local group memberships in other domains. In some cases, these accounts might be few enough that you can manually recreate the memberships instead of following these procedures. |

1. Restart the domain controller in Directory Services Restore Mode locally

2. Restore Active Directory from backup.

   When the group members were deleted, the **member** attribute (forward link) on any group of which they were members was removed from the group object. This procedure is required to restore the **member** attribute on group objects for those group members that were deleted. This attribute is required to regenerate the **memberOf** attribute value on the restored group members.

3. While still in Directory Services Restore Mode, use Ntdsutil to Create an LDIF file for recovering back-links for authoritatively restored objects

   In this procedure, you must specify the location of the .txt file that was generated by Ntdsutil during the authoritative restore procedure.

4. Restart the domain controller normally (not in Directory Services Restore Mode).

5. Run an LDIF file to recover back-links in this domain on a domain controller other than the domain controller that you restored from backup and on which you created the LDIF file. Because you have just restored the domain controller on which you created the LDIF file from backup, perform this procedure on a different domain controller to be sure that the group objects you update are current. This procedure updates the group memberships of a restored security principal object or container of objects. Perform this procedure for each individual object or container that you marked as authoritative.

**Procedures for Domain Controllers Running Windows Server 2003 with No Service Pack Installed**
To complete this task, perform the following procedures in order:

| **Note** |
| --- |
| If the objects that were deleted do not include group objects, you do not have to perform steps 3 through 10. In addition, if the groups that were deleted do not have members among the list of deleted objects, you do not have to perform steps 3 through10. |

1. Restore Active Directory from backup

   Restore system state to return the domain controller to its state at the time of the backup. To ensure that replication does not occur, click **No** at the end of the procedure so that the domain controller does not restart.

2. Mark the object or objects authoritative

   Mark the object or objects that you want to restore so that replication does not overwrite them when you restart the domain controller.

3. Restart the computer normally, but in isolation. This step allows you to control replication so that inbound replication does not update any restored object before forcing outbound replication. You cannot turn off inbound replication in Directory Services Restore Mode.

   The most common way to start a computer in isolation is to remove the network connection from the domain controller by physically removing the network cable. Alternative methods may be possible, depending on your network hardware and enterprise practices.

   It is important to prevent the domain controller from communicating with any other domain controller in the domain or forest. You should also isolate the domain controller from any clients that might change an object in the directory.

4. Turn off inbound replication

   This step is required only if the domain or forest functional level is Windows 2000 native or earlier. By turning off

inbound replication, you ensure that no changes replicate in to the domain controller and alter group membership.

5. Reconnect the computer to the network.

   After you turn off inbound replication, it is safe to reconnect the domain controller to the network.

   If you isolated your computer by removing the network cable or by disconnecting the network connection from the domain controller, reconnect it to bring the domain controller back onto the network.

   If you followed other procedures based on your enterprise network equipment, follow the equipment's recommendations for reconnecting the domain controller to the network.

6. Synchronize replication with all partners

   For the newly restored object to become available and be instantiated in its restored form on all domain controllers, successful replication must occur between the domain controller that originates the restored changes and its partners.

   Make sure that all domain controllers in the domain and all global catalog servers in the forest have received the restored objects.

7. Restart the domain controller in Directory Services Restore Mode locally

8. Mark the object or objects authoritative

   One of the challenges of restoring objects, and their group memberships, is the fact that the membership and object may replicate in different orders. If the membership replicates before a user is restored, the receiving domain controller will not update the membership because the user does not exist. To overcome the effects of this behavior, it is necessary to mark the objects that have been restored as authoritative a second time and once again have the information replicated out.

9. Restart the computer normally (not in Directory Services Restore Mode).

   After the authoritative restore of the object or objects has completed a second time, you can restart the domain controller in normal mode.

10. Turn on inbound replication

# Restore Active Directory from backup

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To restore the server, use a good backup containing the system state or the system state and system disk.

| **Note** |
| --- |
| To restore from backup, you must log on locally to the domain controller or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restore Active Directory from backup**

1. Start the computer in Directory Services Restore Mode.
2. To start the Windows Server 2003 backup utility, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

   This procedure provides steps for restoring from backup in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.
3. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
4. Click **Restore files and settings**, and then click **Next**.
5. Select **System State**, and then click **Next**.
6. On the **Completing the Backup or Restore Wizard** page, click **Advanced**.
7. In **Restore files to**, click **Original Location**, and then click **Next**.
8. Click **Leave existing files (Recommended)**, and then click **Next**.
9. In **Advanced Restore Options**, select the following check boxes, and then click **Next**:
   - **Restore security settings**
   - **Restore junction points, but not the folders and file data they reference**
   - **Preserve existing volume mount points**
10. For a primary restore of SYSVOL, also select the following check box: **When restoring replicated data sets, mark the restored data as the primary data for all replicas**.

    A primary restore is required only if the domain controller that you are restoring is the only domain controller in the domain. A primary restore is required on the first domain controller that is being restored in a domain if you are restoring the entire domain or forest.
11. Click **Finish**.
12. When the restore process is complete, click **Close**, and then do one of the following:
    - If you do not want to authoritatively restore any objects, click **Yes** to restart the computer. The system will restart and replicate any new information that is received since the last backup with its replication partners.
    - If you want to authoritatively restore any objects or if you want to create an LDAP Data Interchange Format (LDIF) file to restore back-links on this domain controller, click **No** to remain in Directory Services Restore Mode. For information about how to proceed with authoritative restore, see Performing an Authoritative Restore of Active

Directory Objects.

Performing an Authoritative Restore of Active Directory Objects

# Mark the object or objects authoritative

Updated: May 28, 2014

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In this procedure, you select which objects are to be marked authoritative to have them replicate to other domain controllers. You must have completed a nonauthoritative restore procedure, following which the domain controller has not been restarted and remains in Directory Services Restore Mode. To complete this procedure, you must know the full distinguished name of the object or objects that you want to restore.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To mark a subtree or individual object authoritative**

1. In Directory Services Restore Mode, click **Start**, click **Run**, type **ntdsutil**, and then press ENTER.
2. At the **ntdsutil:** prompt, type **authoritative restore**, and then press ENTER.
3. To restore a subtree or individual object, type one of the following commands, as appropriate, and then press ENTER:

   To restore a subtree (for example, an organizational unit and all child objects):

   **restore subtree** *DistinguishedName*

   To restore a single object:

   **restore object** *DistinguishedName*

   ***DistinguishedName***
   The distinguished name of the subtree or object that is to be marked authoritative

4. Click **Yes** in the message box to confirm the command.

   For example, if you want to restore a deleted organizational unit named Marketing NorthAm in the corp.contoso.com domain, type:

   **restore subtree "OU=Marketing NorthAm,DC=corp,DC=contoso,DC=com"**

   (Always enclose the distinguished name in quotes when there is a space or other special characters within the distinguished name.)

   Ntdsutil attempts to mark the object as authoritative. The output message indicates the status of the operation. The most common cause of failure is an incorrectly specified distinguished name or a backup for which the distinguished name does not exist (which occurs if you try to restore a deleted user that was created after the backup).

   | **Note** |
   | --- |
   | If the object is marked authoritative and the restore did not work as expected and then the same backup is used to restore the Active Directory database again, the attribute version numbers of the object to be restored authoritatively must be increased higher than the default of 100000 or the object will not replicate out after the second restore. The syntax below is needed to script an increased version number higher than 100000 (default): ntdsutil "authoritative restore" "restore object \"CN=Smith\, John,OU=sales,DC=contoso,DC=com\" verinc 150000\"" q q<br><br>If the script prompts for confirmation on each object being restored you can turn off the prompts. The syntax to turn off the prompts is: ntdsutil "popups off" "authoritative restore" "restore object \"CN=John Smith,OU=sales,DC=contoso,DC=com\" verinc 150000\"" q q |

   If you are running this command on a domain controller running Windows Server 2003 with Service Pack 1 (SP1), Ntdsutil provides output that indicates whether a restored object has back-links that must be restored. If objects that have back-links are found, Ntdsutil generates a set of files that you can use to restore the back-links in this domain and in other domains, if necessary.

   The following sample output on a domain controller running Windows Server 2003 with SP1 shows that Ntdsutil created a text file (.txt) and an LDAP Data Interchange Format (LDIF) file (.ldf) when the marked object was found to have back-

links:

```
Successfully updated 3 records.

The following text file with a list of authoritatively restored
objects has been created in the current working directory:
ar_20050209-091249_objects.txt

One or more specified objects have back-links in this domain. The
following LDIF files with link restore operations have been created
in the current working directory:
        ar_20050209-091249_links_Test1.com.ldf

Authoritative Restore completed successfully.
```

5. Make a note of the location of the .txt and .ldf files, if any. You will use the .ldf file to restore back-links in this domain. You will use the .txt file to generate an LDIF file to restore back-links in a different domain, if necessary. If you have other domains in which you want to restore back-links for this restored object, make a copy of this .txt file to use on a domain controller in another domain. For more information, see Procedures for Recovering Group Memberships (and Any Other Back-Link Attributes) in Other Domains.

   While still in Directory Services Restore Mode, use Ntdsutil to Create an LDIF file for recovering back-links for authoritatively restored objects. In this procedure, you must specify the location of the .txt file that was generated by Ntdsutil during the authoritative restore procedure.

6. At the **authoritative restore:** and **ntdsutil:** prompts, type **quit**, and then press ENTER.

7. Restart the domain controller in normal operating mode, as follows:

   a. For a domain controller running Windows Server 2003 with no service pack installed: Disconnect the domain controller from the network, and then restart normally. Follow the instructions in "Procedures for Domain Controllers Running Windows Server 2003 with No Service Pack Installed" as described in Performing an Authoritative Restore of Active Directory Objects.

   b. For a domain controller running Windows Server 2003 with SP1: Restart the domain controller normally, and then follow the instructions in "Procedures for Domain Controllers Running Windows Server 2003 with SP1" as described in Performing an Authoritative Restore of Active Directory Objects.

# Synchronize replication with all partners

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to synchronize replication with all replication partners of a domain controller.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the selected domain controller or the Enterprise Admins group in the forest, or you must have been delegated the appropriate authority. If you want to synchronize the configuration and schema directory partitions on a domain controller in a child domain, you must have Domain Admins credentials in the forest root domain or Enterprise Admins credentials in the forest.

**To synchronize replication with all partners**

1. At a command prompt, type the following command, and then press ENTER:

   **repadmin /syncall** *DCName* **/e /d /A /P /q**

| Term | Definition |
|---|---|
| *DCName* | The Domain Name System (DNS) name of the domain controller on which you want synchronize replication with all partners |
| **/e** | Enterprise; includes partners in all sites. |
| **/d** | Identifies servers by distinguished name in messages. |
| **/A** | All; synchronizes all directory partitions that are held on the home server. |
| **/P** | Pushes changes outward from the home server. |
| **/q** | Runs in quiet mode; suppresses callback messages. |

2. Check for replication errors in the output of the command in the previous step. If there are no errors, replication is successful. For replication to complete, any errors must be corrected.

**Concepts**
Verify successful replication to a domain controller

# Run an LDIF file to recover back-links

Updated: April 10, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Ntdsutil in Windows Server 2003 Service Pack 1 (SP1) provides new functionality for performing authoritative restore of objects that have back-links.

The output of the authoritative restore procedure includes the name of an LDAP Data Interchange Format (LDIF) (.ldf) file that contains the forward-links that are required so that the group memberships (back-links) of any restored user, group, or computer objects can be recovered. For each object or subtree that you restore, you must run the LDIF file on a domain controller in each domain that might have group objects that are required to recover back-links on the restored objects.

| **Note** |
| --- |
| This procedure is critical for recovering group memberships for deleted users, groups, or computers, but it applies to any restored objects that have back-link attributes. |

### Administrative credentials

To perform this procedure, you must be a member of the Domain Admins group in the domain of the domain controller on which you run the command.

**To run an LDIF file to recover back-links following authoritative restore**

1. Open a command prompt and change directories, if necessary, to the directory of the .ldf file and its respective log files.
2. At the command prompt, type the following command, and then press ENTER:

   **ldifde -i -k -f** *FileName*

   ***FileName***
   The name of the .ldf file that you want to run, for example, ar_20050609-174604_links_corp.contoso.com.ldf

Create an LDIF file for recovering back-links for authoritatively restored objects

# Restart the domain controller in Directory Services Restore Mode locally

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have physical access to a domain controller, you can restart the domain controller in Directory Services Restore Mode locally. Restarting in Directory Services Restore Mode takes the domain controller offline. In this mode, the server is not functioning as a domain controller.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode locally**

1. Restart the domain controller.
2. When the screen for selecting an operating system appears, press F8.
3. On the **Windows Advanced Options** menu, select **Directory Services Restore Mode**.
4. When you are prompted, log on as the local administrator.

Restart the domain controller in Directory Services Restore Mode Remotely

# Create an LDIF file for recovering back-links for authoritatively restored objects

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have authoritatively restored objects that have back-links in another domain, you can use this procedure to create an LDAP Data Interchange Format (LDIF) file that you can run against a domain controller in that domain to restore the back-links. Perform this procedure on a domain controller in the domain that has the back-links.

Before you perform this procedure, you must:

- Copy the .txt file that Ntdsutil created during the authoritative restore procedure, which you performed on the first domain controller, to a location on this domain controller or a network share.
- Restore this domain controller from backup media.

After you restore this domain controller from backup media, perform this procedure while the domain controller is still running in Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To create an LDIF file for restoring back-links for authoritatively restored objects**

1. In Directory Services Restore Mode, click **Start**, click **Run**, type **ntdsutil**, and then press ENTER.
2. At the **ntdsutil: prompt**, type **authoritative restore**, and then press ENTER.
3. At the **authoritative restore:** prompt, type the following command, and then press ENTER:

   **create ldif files from** *TextFilePath*

   where *TextFilePath* is the location and file name of the .txt file that Ntdsutil created during the initial authoritative restore of the object whose back-links you want to restore, for example, d:\ldif\ar_20050609_091558_objects.txt.

   Ntdsutil displays a message stating that one or more specified objects have back-links in this domain and an LDIF file has been created in the current working directory.
4. At the **authoritative restore:** and **ntdsutil:** prompts, type **quit**.

# Turn off inbound replication

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to turn off inbound replication so that objects on a domain controller cannot be updated by replication from another domain controller.

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group in the domain of the domain controller whose replication you are disabling, or you must be a member of the Enterprise Admins group.

**To turn off inbound replication**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /options** *ServerName* **+DISABLE_INBOUND_REPL**

   where *ServerName* is the network basic input/output system (NetBIOS) name of the domain controller.
3. Verify that the option is set. The following message should appear:

   **New DC Options: DISABLE_INBOUND_REPL**

**See Also**
**Concepts**
Turn on inbound replication

# Turn on inbound replication

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to turn on inbound replication after it has been turned off manually.

**Administrative credentials**

To complete this procedure, you must be a member of the Domain Admins group in the domain of the domain controller whose replication you are enabling, or you must be a member of the Enterprise Admins group.

**To turn on inbound replication**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /options** *ServerName* **-DISABLE_INBOUND_REPL**

   where *ServerName* is the network basic input/output system (NetBIOS) name of the domain controller.
3. Verify that the option is set. The following message should appear:

   **Current DC options: DISABLE_INBOUND_REPL**

   **New DC Options: <none>**

   Current DC Options displays the conditions that were in effect at the time that you ran the command. New DC Options shows the effect of the command, which is that the option to disable replication is not set.

**Concepts**
Turn off inbound replication

# Performing an Authoritative Restore of an Application Directory Partition

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Restoration of an application partition will mark all data that is present in the application partition as authoritative for the replica set. Information that is contained within an application partition will replicate to all domain controllers in the forest that were previously present in the replica set. You should have a current valid backup of the application partition prior to restoring, in the event that particular object changes are lost because of changes since backup.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Backup.exe
- Ntdsutil.exe

To complete this task, perform the following procedures:

1. Restore Active Directory from backup
2. Mark the application directory partition as authoritative
3. Restart the computer

   Once the authoritative restore of the object or objects has been completed a second time, the domain controller can be restarted in normal mode.

# Restore Active Directory from backup

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To restore the server, use a good backup containing the system state or the system state and system disk.

| **Note** |
| --- |
| To restore from backup, you must log on locally to the domain controller or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restore Active Directory from backup**

1. Start the computer in Directory Services Restore Mode.
2. To start the Windows Server 2003 backup utility, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

   This procedure provides steps for restoring from backup in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.
3. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
4. Click **Restore files and settings**, and then click **Next**.
5. Select **System State**, and then click **Next**.
6. On the **Completing the Backup or Restore Wizard** page, click **Advanced**.
7. In **Restore files to**, click **Original Location**, and then click **Next**.
8. Click **Leave existing files (Recommended)**, and then click **Next**.
9. In **Advanced Restore Options**, select the following check boxes, and then click **Next**:
   - **Restore security settings**
   - **Restore junction points, but not the folders and file data they reference**
   - **Preserve existing volume mount points**
10. For a primary restore of SYSVOL, also select the following check box: **When restoring replicated data sets, mark the restored data as the primary data for all replicas**.

    A primary restore is required only if the domain controller that you are restoring is the only domain controller in the domain. A primary restore is required on the first domain controller that is being restored in a domain if you are restoring the entire domain or forest.
11. Click **Finish**.
12. When the restore process is complete, click **Close**, and then do one of the following:
    - If you do not want to authoritatively restore any objects, click **Yes** to restart the computer. The system will restart and replicate any new information that is received since the last backup with its replication partners.
    - If you want to authoritatively restore any objects or if you want to create an LDAP Data Interchange Format (LDIF) file to restore back-links on this domain controller, click **No** to remain in Directory Services Restore Mode. For information about how to proceed with authoritative restore, see Performing an Authoritative Restore of Active

Directory Objects.

**See Also**

Restart the domain controller in Directory Services Restore Mode Remotely
Restore system state to an alternate location
Performing an Authoritative Restore of Active Directory Objects

# Mark the application directory partition as authoritative

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can select which application directory partitions are to be marked authoritative so that you can have them replicated to other domain controllers. To perform this procedure, you must have completed a nonauthoritative restore procedure. After that procedure is complete, the domain controller is not restarted, and it remains in Directory Services Restore Mode.

**Administrative credentials**

To complete this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To mark an application directory partition as authoritative**

1. In Directory Services Restore Mode, open a Command Prompt.
2. Type the following command, and then press ENTER:

   **ntdsutil**

3. At the **ntdsutil:** prompt, type **authoritative restore**, and then press ENTER. For assistance with the Ntdsutil command line-tool, type **help** at any time.
4. Type **List NC CRs**, and then press ENTER.

   Ntdsutil displays a list of the application directory partitions that are available after the restore, along with the associated cross-references. Note the cross-reference distinguished name and application directory partition distinguished name that correspond to the application directory partition that you want to restore.

5. Type **restore subtree** *App Partition DN*, where *App Partition DN* is the distinguished name of the application directory partition that you want to restore.
6. In the confirmation dialog box, click **Yes**.

   The output message indicates the status of the operation. There should be no failures.

7. Type **restore object** *Cross Ref DN* (where *Cross Ref DN* is the distinguished name of the application directory partition cross-reference that you want to restore), and then press ENTER.
8. In the confirmation dialog box, click **Yes**.

   The output message indicates the status of the operation. There should be no failures.

9. Quit the Ntdsutil tool.

# Performing an Authoritative Restore of a Group Policy Object

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Restoring a Group Policy Object (GPO) restores the GPO to a previous state. A restore operation can be used in both of the following cases: the GPO was backed up but has since been deleted, or the GPO is live and you want to roll back to a known previous state. A restore operation retains the original GPO GUID even if the restore is recreating a deleted GPO. This is a key difference between the restore operation and the import or copy operations discussed in later sections of this guide.

A restore operation replaces the following components of a GPO:

- GPO settings
- ACLs on the GPO
- WMI filter links (but not the filters themselves)

The restore operation does not restore links to a SOM (Scope of Management). Any existing links will continue to be used—for example, when restoring an existing GPO to a previous state. However, if the user has deleted a GPO and all links to the GPO, the user must recreate these links after restoring the GPO. To facilitate recreating these links, you can view the report in the backup to identify all links in the domain of the GPO.

For more information, see Administering Group Policy with the GPMC on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=17528).

**Task Requirements**

The following tool is required to perform the procedures for this task:

- Group Policy Management Console

To complete this task, perform the following procedure:

- Restore a Group Policy Object

# Restore a Group Policy Object

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to perform an authoritative restore of a Group Policy object.

**Administrative credentials**

To perform this procedure, you must have edit, delete , and modify permissions on the specific Group Policy object.

**To restore a Group Policy object**

1. Open Group Policy Management Console (GPMC).
2. In the console tree, double-click **Domains** to expand the list of domains.
3. Double-click the desired domain to expand the contents of that domain.
4. Right-click **Group Policy Objects**, and select **Manage Backups**.
5. Right-click the object to be restored, and select **Restore from Backup**.
6. Select the backup location, click the policy backup to be restored, and then click **Restore**.
7. Click **OK** to restore the selected GPO backup.

# Restoring a Domain Controller Through Reinstallation and Subsequent Restore from Backup

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you cannot restart a domain controller in Directory Services Restore Mode, you can restore it through reinstallation of the operating system and subsequent restore of Active Directory from backup.

After you reinstall Windows Server 2003, perform a nonauthoritative restore of the system state and the system disk. You do not need to join the computer to the domain before performing the restore procedure. During the restore, the computer account is reestablished automatically.

| **Note** |
| --- |
| The restore procedure must be performed by using the same backup tool with which the backup was made. Procedures in this task describe using Ntbackup to restore Active Directory, but you must use the tool that you used to create the backup file if it is not Ntbackup. |

Restore a domain controller through reinstallation and restore the system state from backup if the following conditions exist:

- A domain controller has failed and you cannot restart in Directory Services Restore Mode. If the failure was caused by a hardware failure, you have resolved the hardware problem (for example, by replacing the disk).
- You have a previous backup for the failed domain controller that is not older than the tombstone lifetime for the forest.
- The domain controller is running other server services such as Exchange, or it contains other data that you must restore from a backup.
- You have the following information about the failed domain controller:
    - Disk configuration. You need a record of the volumes and sizes of the disks and partitions. In the case of a complete disk failure, use this information to recreate the disk configuration. Windows Server 2003 must be reinstalled to the same drive letter and with at least the same amount of physical drive space. Before you restore the system state, you must recreate all disk configurations. Failure to recreate all disk configurations can cause the restore process to fail and can prevent you from starting the domain controller after the restore.
    - Computer name. You need the computer name to restore a domain controller of the same name and avoid changing client configuration settings.
    - Password for the local computer Administrator account. You must know the local Administrator password that was used when the backup was created. The local Administrator password is also required to restore the system state on a domain controller.

**Task requirements**

The following tool is required to perform the procedures for this task:

- Ntbackup.exe

To complete this task, perform the following procedures:

1. Install Windows Server 2003.

| **Note** |
| --- |
| This guide does not provide information for the installation of Windows Server 2003. |

2. Restore Active Directory from backup

    a. Begin with step 2 of this procedure. You cannot start the server in Directory Services Restore Mode because Active Directory is not installed.

    b. This operation requires that you log on as the local Administrator, not the Administrator for Directory Services Restore Mode.

    c. Restore the System State as described, but in normal mode.

    d. When you are prompted to restart the server after you complete the restore operation, click **Yes** to restart the server normally.

3. Verify Active Directory restore

# Restore Active Directory from backup

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To restore the server, use a good backup containing the system state or the system state and system disk.

| **Note** |
| --- |
| To restore from backup, you must log on locally to the domain controller or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restore Active Directory from backup**

1. Start the computer in Directory Services Restore Mode.
2. To start the Windows Server 2003 backup utility, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

   This procedure provides steps for restoring from backup in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.
3. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
4. Click **Restore files and settings**, and then click **Next**.
5. Select **System State**, and then click **Next**.
6. On the **Completing the Backup or Restore Wizard** page, click **Advanced**.
7. In **Restore files to**, click **Original Location**, and then click **Next**.
8. Click **Leave existing files (Recommended)**, and then click **Next**.
9. In **Advanced Restore Options**, select the following check boxes, and then click **Next**:
   - **Restore security settings**
   - **Restore junction points, but not the folders and file data they reference**
   - **Preserve existing volume mount points**
10. For a primary restore of SYSVOL, also select the following check box: **When restoring replicated data sets, mark the restored data as the primary data for all replicas**.

    A primary restore is required only if the domain controller that you are restoring is the only domain controller in the domain. A primary restore is required on the first domain controller that is being restored in a domain if you are restoring the entire domain or forest.
11. Click **Finish**.
12. When the restore process is complete, click **Close**, and then do one of the following:
    - If you do not want to authoritatively restore any objects, click **Yes** to restart the computer. The system will restart and replicate any new information that is received since the last backup with its replication partners.
    - If you want to authoritatively restore any objects or if you want to create an LDAP Data Interchange Format (LDIF) file to restore back-links on this domain controller, click **No** to remain in Directory Services Restore Mode. For information about how to proceed with authoritative restore, see Performing an Authoritative Restore of Active

Directory Objects.

Performing an Authoritative Restore of Active Directory Objects

# Verify Active Directory restore

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After the restore is completed, use this procedure to restart the server and perform basic verification.

**Administrative credentials**

To verify Active Directory restore, you must be a member of the Domain Admins group.

**To verify Active Directory restore**

1. After the restore operation completes, restart the computer in **Start Windows Normally** mode. Active Directory and Certificate Services automatically detect that they have been recovered from a backup. They perform an integrity check and re-index the database.
2. After you are able to log on to the system, browse Active Directory. Verify that all of the User objects and Group objects that were present in the directory prior to backup are restored. Similarly, verify that files that were members of a File Replication service (FRS) replica set and certificates that were issued by the Certificate Services are present.

# Restoring a Domain Controller Through Reinstallation

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Restoring a domain controller through reinstallation is the same process as creating a new domain controller. It does not involve restoring from backup media. This method relies on Active Directory replication to restore a domain controller to a working state, and it is valid only if another healthy domain controller exists in the same domain. This method is normally used on computers that function only as a domain controller.

Restoring through reinstallation is the only method by which a domain controller that is not part of the backup set can be restored. In addition, you might choose to use this method instead of a nonauthoritative restore because backup media is inaccessible or because this method is more convenient. Restoring a domain controller through reinstallation should not be a substitute for regular backup routines.

This method of restoring a domain controller requires a complete reinstallation of the operating system. It is recommended that before you install the operating system, you format the entire system disk, which will remove all information on the system disk. Ensure that any important or relevant data is moved or backed up before you perform these actions.

Bandwidth is the primary consideration for restoring a domain controller through reinstallation. The bandwidth that is required is directly proportional to the size of the Active Directory database and the time in which the domain controller is required to be in a functioning state. Ideally, the existing functional domain controller should be located in the same Active Directory site as the replicating domain controller (the new domain controller) to reduce the impact on the network and the time that the reinstallation takes to complete.

| **Note** |
| --- |
| Before you restore a domain controller through reinstallation, ensure that hardware failure is not the cause of the problem. If faulty hardware is not changed, restoring through reinstallation might not solve the problems with the domain controller. |

**Task requirements**

The following tools are required to perform the procedures for this task:

- Ntdsutil.exe
- Netdiag.exe
- Dcdiag.exe
- Dcpromo.exe

To complete this task, perform the following procedures:

1. If you plan to give the newly reinstalled domain controller the same name as the failed computer, use the following procedure to clean up server metadata to remove the NTDS Settings object of the failed domain controller:

   Clean up server metadata

   If you plan to give the new domain controller a different name, in addition to cleaning up server metadata, perform the following additional procedures:

   Delete a Server object from a site

   Delete a Computer object from the Domain Controllers OU

2. Install Windows Server 2003

   It is assumed that you will perform a fresh installation of Windows Server 2003. Prepare for installation of the operating system by partitioning or reformatting your hard disk drive, if necessary.

3. Verify DNS registration and functionality

4. Verify communication with other domain controllers

5. Verify the availability of the operations masters

6. Install Active Directory

   During the installation process, replication occurs, which ensures that the domain controller has an accurate and up-to-date copy of Active Directory. You have the option to use the same information for this domain controller as the domain controller that it is replacing: site placement, domain controller name, and domain membership should remain the same. If you plan to install the domain controller under a different name, see Installing a Domain Controller in an Existing Domain.

7. Verifying Active Directory Installation

# Clean up server metadata

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You perform the metadata cleanup process by using Ntdsutil.exe, a command-line tool that is automatically installed on all domain controllers. Metadata cleanup removes data from Active Directory that identifies a domain controller to the replication system. This procedure is required only for Active Directory domain controllers that were not successfully demoted using Dcpromo. This procedure does not have to be performed for domain member servers or client computers. On a domain controller that is running Windows Server 2003 with Service Pack 1 (SP1), metadata cleanup also removes File replication service (FRS) connections and attempts to transfer or seize any operations master roles (also known as flexible single master operations or FSMO roles) that the retired domain controller holds. These additional processes are performed automatically.

You can also use a script to clean up server metadata on most Windows operating systems. For information about using this script, see Remove Active Directory Domain Controller Metadata on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkID=123599).

**Administrative credentials**

- To complete this procedure, you must be a member of the Enterprise Admins group.

**To clean up server metadata**

1. Open a command prompt.
2. Type the following command, and then press ENTER:

   **ntdsutil**

3. At the **ntdsutil:** prompt, type:

   **metadata cleanup**

4. Perform metadata cleanup as follows:

   - If you are performing metadata cleanup by using the version of Ntdsutil.exe that is included with Windows Server 2003 SP1, at the **metadata cleanup:** prompt, type:

     **remove selected server** *ServerName*

     Or

     **remove selected server** *ServerName1* **on** *ServerName2*

     | Value | Definition |
     |---|---|
     | *ServerName, ServerName1* | The distinguished name of the domain controller whose metadata you want to remove, in the form cn=*ServerName*,cn=Servers,cn=*SiteName*, cn=Sites,cn=Configuration,dc=*ForestRootDomain* |
     | *ServerName2* | The DNS name of the domain controller to which you want to connect and from which you want to remove server metadata |

   - If you are performing metadata cleanup by using the version of Ntdsutil.exe that is included with Windows Server 2003 with no service pack, perform metadata cleanup as follows:

     a. At the **metadata cleanup:** prompt, type:

     **connection**

     b. At the **server connections:** prompt, type:

**connect to server** *Server*

c. At the **server connections:** prompt, type:

**quit**

d. At the **metadata cleanup:** prompt, type:

**select operation target**

e. At the **select operation target:** prompt, type:

**list sites**

A numbered list of sites appears.

f. At the **select operation target:** prompt, type:

**select site** *SiteNumber*

g. At the **select operation target:** prompt, type:

**list domains in site**

A numbered list of domains in the selected site appears.

h. At the **select operation target:** prompt, type:

**select domain** *DomainNumber*

i. At the **select operation target:** prompt, type:

**list servers in site**

A numbered list of servers in a domain and site appears.

j. At the **select operation target:** prompt, type:

**select server** *ServerNumber*

k. At the **select operation target:** prompt, type:

**quit**

l. At the **metadata cleanup:** prompt, type:

**remove selected server**

| Value | Description |
|---|---|
| *Server* | The DNS name of a domain controller that you want to connect to |
| *SiteNumber* | The number associated with the site of the server that you want to clean up that appears in the list |

| | |
|---|---|
| *DomainNumber* | The number associated with the domain of the server that you want to clean up that appears in the list |
| *ServerNumber* | The number associated with the server that you want to clean up that appears in the list |

At this point, Active Directory confirms that the domain controller was removed successfully. If you receive an error message that indicates that the object cannot be found, Active Directory might have already removed the domain controller.

5. To verify that the server was removed, type **list servers in site**, and then press ENTER. Ensure that the domain controller that you wanted to be removed is no longer displayed in the command output.
6. At the **metadata cleanup:** and **ntdsutil:** prompts, type **quit**.

| **Important** |
|---|
| If the domain controller that was removed was also a DNS server, ensure that references to it are removed from the **Name Servers** tab in the DNS console. To do this, open the DNS console using another DNS server in the domain (dnsmgmt.msc), and then click the domain name under **Forward Lookup Zones**. Remove any references to the domain controller that was removed from the domain. |

# Delete a Server object from a site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When no Child objects are visible below the Server object in Active Directory Sites and Services, you can remove the Server object.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To delete a server object from a site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site from which you want to delete a Server object.
3. If no Child objects appear below the Server object, right-click the Server object, and then click **Delete**.

| **Important** |
| --- |
| Do not delete a Server object that has a Child object. If an NTDS Settings or other Child object appears below the Server object you want to delete, either replication on the domain controller on which you are viewing the Configuration container has not occurred, or the server whose Server object you are removing has not been properly decommissioned. |

4. Click **Yes** to confirm your choice.

# Delete a Computer object from the Domain Controllers OU

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to delete the Computer object for a failed domain controller. If a domain controller fails and you cannot use the Dcpromo command to remove Active Directory, you must forcefully remove Active Directory and then clean up server metadata. When you perform Dcpromo normally, server metadata, the Computer object, and the Server object for the domain controller are deleted automatically. After you forcefully remove Active Directory, you must clean up server metadata for the failed domain controller and then delete the Server object and Computer object manually.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the domain controller that you are removing. O

**To delete a Computer object from the Domain Controllers organizational unit (OU)**

1. Open Active Directory Users and Computers.
2. Click the **Domain Controllers OU**.
3. In the details pane, right-click the Computer object that is associated with the failed domain controller, click **Delete**, and then click **Yes**.

Delete a Server object from a site

# Verify DNS registration and functionality

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that Domain Name System (DNS) is functioning so that other domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify DNS registration and functionality**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **dcdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If DNS is functioning, the last line of the response for all operating system versions is **DNS Test.....: Passed**. The verbose option lists specific information about what was tested. This information can help with troubleshooting if the test fails.

   If the test fails, do not attempt any additional steps until you determine and fix the problem that prevents proper DNS functionality.

# Verify communication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

**To verify communication with other domain controllers**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dsgetdc**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If domain controllers are successfully located, the last line of the response is **DC discovery test.....: Passed.** The verbose option lists the specific domain controllers that are located.

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **nltest /dclist:** <*domain name*>

   If domain controllers are successfully located, the last line of the response is **The command completed successfully**.

   If the tests fail on any of the operating system versions, do not attempt any additional steps until you determine and fix the problem that prevents communication with other domain controllers.

# Verify the availability of the operations masters

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that the operations masters can be located and that they are online and responding.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

| **Note** |
| --- |
| You can use these tests prior to installing Active Directory as well as afterward. To perform the test prior to installing Active Directory, you must use the **/s** option to indicate the name of a domain controller to use. You do not need the **/s** option to perform the test after installing Active Directory. The test automatically runs on the local domain controller where you are performing the test. The commands listed in this procedure show the **/s** option. If you are performing this test after installing Active Directory, omit the **/s** option. For a more detailed response from this command, you can use the verbose option by adding **/v** to the end of the command to see the detailed response. |

**To verify the availability of the operations masters**

1. Open a Command Prompt.
2. Type the following command to ensure that the operations masters can be located and then press ENTER:

   **dcdiag /s:** *domaincontroller* **/test:knowsofroleholders /verbose**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of the screen, a message confirms that the test succeeded. If you use the verbose option, look carefully at the bottom part of the displayed output. The test confirmation message appears immediately after the list of operations masters. Press ENTER.
3. Type the following command to ensure that the operations masters are functioning properly and are available on the network:

   **dcdiag /s:** *domaincontroller* **/test:fsmocheck**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of your screen, a message confirms that the test succeeded. Press ENTER.

   If these tests fail, do not attempt any additional steps until you determine and fix the problem that prevents locating operations masters and verifying that they are functioning properly.

# Install Active Directory

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the Active Directory Installation Wizard to install Active Directory on a member server in your domain to create an additional domain controller in an existing domain.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To install Active Directory**

1. Click **Start**, click **Run**, type **dcpromo** and then press ENTER.
2. The Active Directory Installation Wizard appears. At the Welcome screen, click **Next**.
3. For **Domain Controller Type**, select **Additional domain controller for an existing domain**. Click **Next**.
4. For **Network Credentials**, enter the user name, password, and domain for the user account that has permission to add this new domain controller to the domain. Click **Next**.
5. Enter the name of the domain that you want the new domain controller to host. Click **Next**.
6. For **Database and Log Locations**, enter the paths for the locations of the directory database (Ntds.dit) and the log files. For better performance, store the database and log files on separate physical disk drives. Click **Next**.
7. For **Shared System Volume**, enter the path where you want to locate the system volume (SYSVOL). Click **Next**.
8. Under **Directory Services Restore Mode Administrator Password**, enter the password that you want to use when you need to start Directory Services Restore Mode. Click **Next**.
9. The **Summary** screen displays a list of the items you chose. Verify that the information is correct, and then click **Next** to proceed with the installation.
10. The wizard proceeds to install Active Directory. When it finishes, the wizard displays a summary screen listing the domain and site in which the new domain controller is a member. Verify that this information is correct. Click **Finish** to close the wizard.
11. Click **Restart** to restart the domain controller.
12. Let the domain controller restart. If any message indicates that one or more services has failed to start, restart the domain controller one more time. If the initial replication cycles have not had enough time to complete during the first restart on a new domain controller, some services may be unable to start successfully. If the message appears during additional restarts, examine the event logs in Event Viewer to determine the cause of the problem.

# Administering Intersite Replication

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides information for administering intersite replication in the Microsoft Windows Server 2003 operating system.

**In this guide**

- Introduction to Administering Intersite Replication
- Managing Intersite Replication

# Introduction to Administering Intersite Replication

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An Active Directory Site object represents a collection of Internet Protocol (IP) subnets, usually constituting a physical local area network (LAN). Multiple sites are connected for replication by Site Link objects.

Sites are used in Active Directory to:

- Enable clients to discover network resources (published shares, domain controllers) that are close to the physical location of the client, reducing network traffic over wide area network (WAN) links.
- Optimize replication between domain controllers.

Managing sites in Active Directory involves adding new subnet, site, and site link objects when the network grows, as well as configuring a schedule and cost for site links. You can modify the site link schedule, cost, or both, to optimize intersite replication. When conditions no longer require replication to a site, or clients no longer require the sites to discover network resources, you can remove the site and associated objects from Active Directory.

| **Note** |
| --- |
| Managing large hub-and-spoke topology or using the SMTP intersite replication transport is beyond the scope of this documentation. |

Managing sites:

- Enables clients to discover network resources (printers, published shares, domain controllers) that are close to the physical location of the client, reducing network traffic over wide area network (WAN) links.
- Optimizes replication between domain controllers.

**The KCC and Replication Topology**

The Knowledge Consistency Checker (KCC) uses site link configuration information to enable and optimize replication traffic by generating a least-cost replication topology. Within a site, for each directory partition, the KCC builds a ring topology that tries to set a maximum number of hops (3) between any two domain controllers. Between sites, the KCC creates a spanning tree of all intersite connections. Therefore, adding sites and domains increases the processing that is required by the KCC. Before adding to the site topology, be sure to consider the guidelines discussed in “Adding a new site” later in this document.

Significant changes to site topology can affect domain controller hardware requirements. For more information about domain controller hardware requirements, see Planning Domain Controller Capacity on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42682).

### Bridgehead Server Selection

By default, bridgehead servers are automatically selected by the intersite topology generator (ISTG) in each site. Alternatively, you can use Active Directory Sites and Services to select preferred bridgehead servers. However, it is recommended for Windows 2000 deployments that you do not select preferred bridgehead servers.

Selecting preferred bridgehead servers limits the bridgehead servers that the KCC can use to those that you have selected. If you use Active Directory Sites and Services to select any preferred bridgehead servers at all in a site, you must select as many as possible and you must select them for all domains that must be replicated to a different site. If you select preferred bridgehead servers for a domain and all preferred bridgehead servers for that domain become unavailable, replication of that domain to and from that site does not occur.

If you have selected one or more bridgehead servers, removing them all from the bridgehead servers list restores the automatic selection functionality to the ISTG.

# Managing Intersite Replication

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks for managing intersite replication are described in this objective:

- Adding a New Site
- Linking Sites for Replication
- Changing Site Link Properties
- Moving a Domain Controller to a Different Site
- Removing a Site

# Adding a New Site

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Design teams or network architects might want to add sites as part of ongoing deployment. Although you typically create subnets to accommodate all address ranges in the network, you do not need to create sites for every location. Generally, sites are required for those locations that have domain controllers or other servers that run applications that depend on site topology, such as Distributed File System (DFS).

When the need for a site arises, the design team typically provides details about the placement and configuration of site links for the new site, as well as subnet assignments or creation if subnets are needed.

If a new range of Internet Protocol (IP) addresses is added to the network, create a Subnet object in Active Directory to correspond to the range of IP addresses. When you create a new Subnet object, you must associate it with a Site object. You can either associate the subnet with an existing site or create a new site first and then create the subnet and associate it with the new site.

**Task requirements**

The following tool is required to perform the procedures for this task:

- Active Directory Sites and Services

To complete this task, perform the following procedures:

1. Create a site object and add it to an existing site link
2. Associate a range of IP addresses with the site by using either of the following methods:
    - Create a subnet object or objects and associate them with the new site
    - Associate an existing subnet object with the new site
3. If you are creating both a new site and a new site link, after you create the new site and add it to an existing site link, Create a site link object and add the appropriate sites. Then, remove the site from the first site link that you added it to when you created the site, if appropriate.
4. Remove the site from the site link

# Create a site object and add it to an existing site link

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To create a new site, you must create a Site object and add it to a site link.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

**To create a site object and add it to an existing site link**

1. Open Active Directory Sites and Services.
2. Right-click the **Sites** container and then click **New Site**.
3. In the **Name** box, type the name of the site.
4. In the **Link Name** list, click a site link for this site, and then click **OK**.
5. In the **Active Directory** message box, read the information, and then click **OK**.

# Create a subnet object or objects and associate them with the new site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Create a Subnet object or objects and associate them with the new site you must have the following information:

- The site to which the subnet is to be associated.
- The network address or any IP address in the range.
- The subnet mask.

Active Directory Sites and Services converts this information into the subnet address.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

**To create a subnet object or objects and associate them with the new site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, right-click **Subnets**, and then click **New Subnet**.
3. In the **New Object - Subnet** dialog box, in the **Address** box, type the network address or any IP address within the range of IP addresses for the subnet.
4. In the **Mask** box, type the subnet mask.
5. In the **Site Name** box, click the site to which this subnet is being associated, and then click **OK**.

# Associate an existing subnet object with the new site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Associate an existing subnet with a site under the following conditions:

- When you are removing the site to which the subnet was associated.
- When you have temporarily associated the subnet with a different site and want to associate it with its permanent site.

### Administrative Credentials

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

**To associate an existing subnet object with the new site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then click the **Subnets** container.
3. In the details pane, right-click the subnet with which you want to associate the site, and then click **Properties**.
4. In the **Site** box, click the site with which to associate the subnet, and then click **OK**.

# Create a site link object and add the appropriate sites

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to create a Site Link object in the IP container and add the appropriate sites. To link sites for replication, create a Site Link object in the container for the intersite transport that will replicate the site, and add the sites to it.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group.

**To create a site link object**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and then the **Inter-Site Transports** container.
3. Right-click **IP**, and then click **New Site Link**.
4. In the **Name** box, type a name for the site link.
5. In the **Sites not in this site link** box, click a site that you want to add to the site link. Hold down the SHIFT key to click a second site that is adjacent in the list, or the CTRL key to click a second site that is not adjacent in the list.
6. After selecting all of the sites that you want added to the site link, click **Add**, and then click **OK**.

# Remove the site from the site link

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use Site Link properties to remove a site from a site link.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

**To remove a site from a site link**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and then the **Inter-Site Transports** container.
3. Click **IP**. In the details pane, right-click the site link from which you want to remove a site, and then click **Properties**.
4. In the **Sites in this site link** box, click the site you want to remove from the site link.
5. Click **Remove**, and then click **OK**.

# Linking Sites for Replication

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To link sites for replication, create a Site Link object in the IP transport container and add two or more sites to the link. Use a naming convention that includes the sites that you are linking. For example, if you want to link the site named Seattle to the site named Boston, you might name the site link SEA-BOS.

After you add two or more site names to a Site Link object, the bridgehead servers in the respective sites replicate between the sites according to the replication schedule, cost, and interval settings on the Site Link object. For information about modifying the default settings, see Changing Site Link Properties.

At least two sites must exist when you create a site link. If you are adding a site link to connect a new site to an existing site, create the new site first and then create the site link. For information about creating a site, see Adding a New Site.

**Task Requirements**

The following tool is required to perform the procedures for this task:

- Active Directory Sites and Services

To complete this task, perform the following procedures:

1. Create a site link object and add the appropriate sites
2. By default, the KCC runs every 15 minutes to generate the replication topology. To generate the intersite topology immediately, perform the following two procedures:
    - Determine the ISTG role owner for a site
    - Generate the replication topology on the ISTG

# Create a site link object and add the appropriate sites

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to create a Site Link object in the IP container and add the appropriate sites. To link sites for replication, create a Site Link object in the container for the intersite transport that will replicate the site, and add the sites to it.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group.

**To create a site link object**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and then the **Inter-Site Transports** container.
3. Right-click **IP**, and then click **New Site Link**.
4. In the **Name** box, type a name for the site link.
5. In the **Sites not in this site link** box, click a site that you want to add to the site link. Hold down the SHIFT key to click a second site that is adjacent in the list, or the CTRL key to click a second site that is not adjacent in the list.
6. After selecting all of the sites that you want added to the site link, click **Add**, and then click **OK**.

# Determine the ISTG role owner for a site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to view the NTDS Site Settings object properties and determine the Intersite Topology Generator (ISTG) role owner for the site.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To determine the ISTG role owner for a site**

1. Open Active Directory Sites and Services.
2. Click the site object whose ISTG you want to determine.
3. In the details pane, right-click the **NTDS Site Settings** object, and then click **Properties**. The current role owner appears in the **Server** box under **Inter-Site Topology Generator**.

# Generate the replication topology on the ISTG

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Knowledge Consistency Checker (KCC) runs by default every 15 minutes. If you want to initiate topology regeneration immediately, you can force the KCC to run as follows:

- To generate the intersite replication topology, run the KCC on the domain controller in the site that holds the ISTG role.
- To generate the intrasite replication topology, run the KCC on any domain controller in the site that does not hold the ISTG role.

| **Note** |
| --- |
| To generate the replication topology on the ISTG, you must first complete the procedure: Determine the ISTG role owner for a site. |

### Administrative Credentials

To perform this procedure, you must be a member of the Enterprise Admins group.

**To generate the replication topology on the ISTG**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site that contains the server on which you want to run the KCC.
3. Expand the **Servers** container, and then click the **Server** object for the ISTG.
4. In the details pane, right-click **NTDS Settings**, click **All Tasks**, and then click **Check Replication Topology**.
5. In the **Check Replication Topology** message box, click **OK**.

# Changing Site Link Properties

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To control which sites replicate directly with each other and when, use the cost, schedule, and interval properties on the Site Link object.

These settings control intersite replication as follows:

- **Schedule**: The time during which replication can occur (the default setting allows replication at all times).
- **Interval**: The number of minutes between replication polling by intersite replication partners within the open schedule window (default is every 180 minutes).
- **Cost**: The relative priority of the link (default is 100). Lower relative cost increases the priority of the link over other higher-cost links.

Consult your design documentation for information about values to set for site link properties.

**Task Requirements**

The following tool is required to perform the procedures for this task:

- Active Directory Sites and Services

To complete this task, perform the following procedures:

1. Configure the site link schedule to identify times during which intersite replication can occur
2. Configure the site link interval to identify how often replication polling can occur during the schedule window
3. Configure the site link cost to establish a priority for replication routing
4. Generate the intersite topology by performing the following two procedures:
    - Determine the ISTG role owner for a site
    - Generate the replication topology on the ISTG

# Configure the site link schedule to identify times during which intersite replication can occur

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the properties on the Site Link object to define when replication is allowed. Obtain the schedule from your design team.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

**To configure the site link schedule**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and the **Inter-Site Transports** container, and then click the **IP** container.
3. In the details pane, right-click the Site Link object you want to configure, and then click **Properties**.
4. In the **SiteLinkName Properties** dialog box, click **Change Schedule**.
5. In the **Schedule for SiteLinkName** dialog box, select the block of days and hours during which you want replication to occur or not occur (available or not available), and then click the appropriate option.
6. Click **OK** twice.

# Configure the site link interval to identify how often replication polling can occur during the schedule window

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the properties on the Site Link object to determine how often during the available replication schedule you want bridgehead servers to poll their intersite replication partners for changes. Obtain the interval value from your design team.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

**To configure the site link interval**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and the **Inter-Site Transports** container, and then click the **IP** container.
3. In the details pane, right-click the Site Link object you want to configure, and then click **Properties**.
4. In the **Replicate every _____ minutes** box, specify the number of minutes for the intervals at which replication polling occurs during an open schedule, and then click **OK**.

# Configure the site link cost to establish a priority for replication routing

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When creating or modifying site links, use the object properties to configure the relative cost of using the site link.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

**To configure the site link cost**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and the **Inter-Site Transports** container, and then click the **IP** container.
3. In the details pane, right-click the Site Link object you want to configure, and then click **Properties**.
4. In the **Cost** box, specify the number for the comparative cost of using the site link, and then click **OK**.

# Determine the ISTG role owner for a site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to view the NTDS Site Settings object properties and determine the Intersite Topology Generator (ISTG) role owner for the site.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To determine the ISTG role owner for a site**

1. Open Active Directory Sites and Services.
2. Click the site object whose ISTG you want to determine.
3. In the details pane, right-click the **NTDS Site Settings** object, and then click **Properties**. The current role owner appears in the **Server** box under **Inter-Site Topology Generator**.

# Generate the replication topology on the ISTG

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Knowledge Consistency Checker (KCC) runs by default every 15 minutes. If you want to initiate topology regeneration immediately, you can force the KCC to run as follows:

- To generate the intersite replication topology, run the KCC on the domain controller in the site that holds the ISTG role.
- To generate the intrasite replication topology, run the KCC on any domain controller in the site that does not hold the ISTG role.

| **Note** |
| --- |
| To generate the replication topology on the ISTG, you must first complete the procedure: Determine the ISTG role owner for a site. |

### Administrative Credentials

To perform this procedure, you must be a member of the Enterprise Admins group.

**To generate the replication topology on the ISTG**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site that contains the server on which you want to run the KCC.
3. Expand the **Servers** container, and then click the **Server** object for the ISTG.
4. In the details pane, right-click **NTDS Settings**, click **All Tasks**, and then click **Check Replication Topology**.
5. In the **Check Replication Topology** message box, click **OK**.

# Moving a Domain Controller to a Different Site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you change the IP address or the subnet-to-site association of a domain controller after Active Directory is installed on the server, the Server object does not change sites automatically. You must move it to the new site manually. When you move the Server object, the Net Logon service on the domain controller registers DNS SRV resource records for the appropriate site.

**TCP/IP Settings**

When you move a domain controller to a different site, if an IP address of the domain controller is statically configured, then you must change the TCP/IP settings accordingly. The IP address of the domain controller must map to a Subnet object that is associated with the site to which you are moving the domain controller. If the IP address of a domain controller does not match the site in which the Server object appears, the domain controller might be forced to communicate over a potentially slow WAN link to locate resources rather than locating resources in its own site.

Prior to moving the domain controller, ensure that the following TCP/IP client values are appropriate for the new location:

- IP address, including the subnet mask and default gateway
- DNS server addresses
- WINS server addresses (if appropriate)

If the domain controller that you are moving is a DNS server, you must also:

- Change the TCP/IP settings on any clients that have static references to the domain controller as the preferred or alternate DNS server.
- Determine whether the parent DNS zone of any zone that is hosted by this DNS server contains a delegation to this DNS server. If yes, update the IP address in all such delegations. For information about creating DNS delegations, see Verifying Active Directory Installation.

**Preferred Bridgehead Server Status**

Before moving any Server object, check the Server object to see whether it is acting as a preferred bridgehead server for the site. This condition has ISTG implications in both sites, as follows:

- Site to which you are moving the server: If you move a preferred bridgehead server to a different site, it becomes a preferred bridgehead server in the new site. If preferred bridgehead servers are not currently in use in this site, the ISTG behavior in this site changes to support preferred bridgehead servers. For this reason, you must either configure the server to not be a preferred bridgehead server (recommended), or select additional preferred bridgehead servers in the site (not recommended).

Site from which you are moving the server: If the server is the last preferred bridgehead server in the original site for its domain, and if other domain controllers for the domain are in the site, the ISTG selects a bridgehead server for the domain. If you use preferred bridgehead servers, always select more than one server as the preferred bridgehead server for the domain. If, after the removal of this domain controller from the site, multiple domain controllers remain that are hosting the same domain and only one of them is configured as a preferred bridgehead server, either configure the server to not be a preferred bridgehead server (recommended), or select additional preferred bridgehead servers hosting the same domain in the site (not recommended).

| **Note** |
| --- |
| If you select preferred bridgehead servers and all selected preferred bridgehead servers for a domain are unavailable in the site, the ISTG does not select a new bridgehead server. In this case, replication of this domain to and from other sites does not occur. However, if no preferred bridgehead server is selected for a domain or transport (through administrator error or as the result of moving the only preferred bridgehead server to a different site), the ISTG automatically selects a preferred bridgehead server for the domain and replication proceeds as scheduled. |

**Task Requirements**

- My Network Places
- DNS snap-in
- Active Directory Sites and Services
- Adsiedit.msc

To complete this task, perform the following procedures in order:

1. Change the static IP address of a domain controller
2. Create a delegation for a domain controller

   If the parent DNS zone of any zone that is hosted by this DNS server contains a delegation to this DNS server, use this procedure to update the IP address in all such delegations.

   If your forest root domain has a parent DNS domain, perform this procedure on a DNS server in the parent domain. If you just added a new domain controller to a child domain, perform this procedure on a DNS server in the DNS parent domain. By following recommended practices, the parent domain is the forest root domain.

3. Verify that an IP address maps to a subnet and determine the site association
4. Determine whether the server is a preferred bridgehead server
5. Configure the server to not be a preferred bridgehead server
6. Move the Server object to the new site

# Change the static IP address of a domain controller

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure includes changing all appropriate TCP/IP values, including preferred and alternate Domain Name System (DNS) servers, as well as Windows Internet Name Service (WINS) servers (if appropriate). Obtain these values from the design team.

| **Note** |
| --- |
| If you change the static IP address of a domain controller, you must also change related TCP/IP settings accordingly. This includes changing the TCP/IP settings for all client computers that rely on the domain controller for related services, such as DNS services. If the affected client computers are configured with static IP addresses, the procedures for changing them should be covered in the operating system help. As an example, see Change TCP/IP settings (http://go.microsoft.com/fwlink/?LinkId=130602). If a Dynamic Host Configuration Protocol (DHCP) server is used to distribute DNS server IP addresses, you may have to modify DHCP server options. For a list of options, see DHCP Options Supported by Clients (http://go.microsoft.com/fwlink/?LinkId=130603). For specific instructions about changing DHCP options, see Modify an option (http://go.microsoft.com/fwlink/?LinkId=130604). |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in the domain of the domain controller whose IP address you are changing.

**To change the static IP address of a domain controller**

1. Log on locally (also known as interactively) to the system console of the domain controller whose IP address you want to change. If you are not able to log on to the domain controller by using the domain, you may have to start the domain controller in Directory Services Restore Mode (DSRM). For more information, see Restart the domain controller in Directory Services Restore Mode locally (http://go.microsoft.com/fwlink/?LinkId=140599).
2. On the desktop, right-click **My Network Places**, and then click **Properties**.
3. In the **Network Connections** dialog box, right-click **Local Area Connection**, and then click **Properties**.
4. In the **Local Area Connection Properties** dialog box, double-click **Internet Protocol (TCP/IP)**.
5. In the **Internet Protocol (TCP/IP) Properties** dialog box, in the **IP address** box, type the new address.
6. In the **Subnet mask** box, type the subnet mask.
7. In the **Default gateway** box, type the default gateway.
8. In the **Preferred DNS server** box, type the address of the DNS server that this computer contacts.
9. In the **Alternate DNS server** box, type the address of the DNS server that this computer contacts if the preferred server is unavailable.
10. If this domain controller uses WINS servers, click **Advanced** and then, in the **Advanced TCP/IP Settings** dialog box, click the **WINS** tab.
11. If an address in the list is no longer appropriate, click the address, and then click **Edit**.
12. In the **TCP/IP WINS Server** dialog box, type the new address, and then click **OK**.
13. Repeat steps 11 and 12 for all addresses that need to be changed, and then click **OK** twice to close the **TCP/IP WINS Server** dialog box and the **Advanced TCP/IP Settings** dialog box.
14. Click **OK** to close the **Internet Protocol (TCP/IP) Properties** dialog box.

After you change the IP address of a domain controller, you should run the **ipconfig /registerdns** command to register the host record and **dcdiag /fix** command to ensure that service records are appropriately registered with DNS. For more information, see Dcdiag Overview and subordinate topics for additional information about the Dcdiag tool (http://go.microsoft.com/fwlink/?LinkId=130605).

Changing the IP settings of a server does not affect the share resources or shared permissions on that server, if the name

resolution structure DNS and WINS settings are correctly configured. However, if network drives or passive connections (connections that are made manually from a command prompt or run line) are mapped using the IP address, an update is required. For example, if a client computer has G: drive mapped using the following command **net use g: \\192.168.0.199\data** and the IP address of the server that hosts the Data shared folder is changed from 192.168.0.199 to 192.168.1.200, the new G: drive mapping command should be changed to **net use g: \\192.168.1.200\data**. A better solution would be to ensure that DNS name resolution is working properly and to use the server name, as opposed to the IP address, in the command. For example, if the server name is DC1, the command to map a G: drive to the Data share on the server is **net use g: \\dc1\data**. It changes only if the server name changes; it is not affected if the IP address of the server changes.

# Create a delegation for a domain controller

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to create a delegation for a new domain controller that is also a DNS server in the parent DNS domain.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To create a delegation for a domain controller**

1. Open the DNS snap-in.
2. Navigate to C*hildDomain* (where C*hildDomain* is the name of the child domain) in the console tree.
3. In the console tree, right-click C*hildDomain*, and then click **Properties**.
4. In the C*hildDomain* **Properties** sheet, on the **Name Servers** tab, click **Add**.
5. In the **New Resource Record** dialog box, in the **Server fully qualified domain name (FQDN)** box, type *ChildDC.ChildDomain.ParentDomain* (where *ChildDC* is the name of the new domain controller, *ChildDomain* is the name of the child domain, and *ParentDomain* is the name of the parent domain).
6. In the **New Resource Record** dialog box, in the **IP address** box, type *IPAddress* (where *IPAddress* is the IP address of the child domain controller), click **Add**, and then click **OK**.

# Verify that an IP address maps to a subnet and determine the site association

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to determine the site to which you want to add a Server object prior to installing Active Directory, or to verify the appropriate site prior to moving a Server object to it.

To be associated with a site, the IP address of a domain controller must map to a Subnet object that is defined in Active Directory. The site to which the subnet is associated is the site of the domain controller.

The subnet address, which is computed from the IP network address and the subnet mask, is the name of a Subnet object in Active Directory. When you know the subnet address, you can locate the Subnet object and determine the site to which the subnet is associated.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To verify that an IP address maps to a subnet and determine the site association**

1. Log on locally or open a Terminal Services connection to the server for which you want to check the IP address.
2. On the desktop, right-click **My Network Places**, and then click **Properties**.
3. In the **Network Connections** dialog box, right-click **Local Area Connection**, and then click **Properties**.
4. Double-click **Internet Protocol (TCP/IP)**.
5. Use the values in **IP address** and **Subnet mask** to calculate the subnet address and then click **OK**.
6. Click **OK** again and close the **Network Connections** dialog box.
7. Open Active Directory Sites and Services.
8. Expand the **Sites** container, and then click the **Subnets** container.
9. In the **Name** column in the details pane, find the Subnet object that matches the subnet address.
10. In the **Site** column, note the site to which the IP subnet address is associated.

    If the site that appears in the **Site** box is not the appropriate site, contact a supervisor and find out whether the IP address is incorrect or whether to move the Server object to the site indicated by the subnet.

# Determine whether the server is a preferred bridgehead server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Preferred bridgehead servers are distinguished by a property on the Server object that adds the server to the preferred bridgehead server list for the IP transport.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To view the list of preferred bridgehead servers**

1. Click **Start**, click **Run**, type the following command and then press ENTER:

   **adsiedit.msc**

2. In ADSI Edit, expand the **Configuration Container** and then expand **CN=Configuration,DC=***ForestRootDomainName,* **CN=Sites, and CN=Inter-Site Transports**.
3. Right-click **CN=IP** and then click **Properties**.
4. In the **Attributes** box, double-click **bridgeheadServerListBL**.
5. If any preferred bridgehead servers are selected in any site in the forest, the **Values** box displays the distinguished name for each server object that is currently selected as a preferred bridgehead server.

# Configure the server to not be a preferred bridgehead server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the Server object properties to remove a preferred bridgehead server from the IP transport.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To configure the server to not be a preferred bridgehead server**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site of the preferred bridgehead server.
3. Expand the **Servers** node to display the list of domain controllers currently configured for that site.
4. Right-click the server you want to remove, and then click **Properties**.
5. If **IP** appears in the list that marks this server as a bridgehead server for the IP transport, click **IP**, click **Remove**, and then click **OK**.

# Move the Server object to the new site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Moving a Server object requires that the IP address of the domain controller maps to the site to which you are moving the Server object. Before performing this procedure, verify that the IP address maps to the target site.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group.

**To move the server object to the new site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and the site in which the server object resides.
3. Expand the **Servers** container to display the domain controllers that are currently configured for that site.
4. Right-click the Server object you want to move, and then click **Move**.
5. In the **Site Name** box, click the destination site, and then click **OK**.
6. Expand the Site object to which you moved the server, and then expand the **Servers** container.
7. Verify that an object for the server you moved exists.
8. Expand the Server object and verify that an NTDS Settings object exists.

Within an hour, the Net Logon service on the domain controller registers the new site information in DNS. Wait an hour and then open Event Viewer and connect to the domain controller whose Server object you moved. Review the System log for Net Logon errors regarding registration of SRV resource records in DNS that have occurred within the last hour. The absence of errors indicates that Net Logon has updated DNS with site-specific SRV resource records. Net Logon event ID 5774 indicates that the registration of DNS resource records has failed. If this error occurs, contact a supervisor and pursue DNS troubleshooting.

# Removing a Site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If domain controllers are no longer needed in a network location, you can remove them from the site and then delete the Site object. Before deleting the site, you must remove domain controllers from the site either by removing it entirely or by moving it to a new location.

- To remove the domain controller, remove Active Directory from the server and then delete the Server object from the site in Active Directory.
- To retain the domain controller in a different location, move the domain controller to a different site and then move the Server object to the respective site in Active Directory.

Domain controllers can host other applications that depend on site topology and publish objects as Child objects of the respective Server object. For example, when MOM or Message Queuing is running on a domain controller, these applications create Child objects beneath the Server object. In addition, a server running Message Queuing that is not a domain controller and is configured to be a routing server running Message Queuing creates a Server object in the Sites container. Removing the application from the server automatically removes the Child object below the respective Server object. However, the Server object is not removed automatically.

When all applications have been removed from the server (no Child objects appear beneath the Server object), you can remove the Server object. After the application is removed from the server, a replication cycle might be required before Child objects are no longer visible below the Server object.

After you delete or move the Server objects but before you delete the Site object, reconcile the following objects:

IP addresses:

- If the addresses are being reassigned to a different site, associate the Subnet object or objects with that site. Any clients using the addresses for the decommissioned site will thereafter be assigned automatically to the other site.
- If the IP addresses will no longer be used on the network, delete the corresponding Subnet object or objects.

Site Link objects:

- If the site you are removing is added to a site link containing only two sites, delete the Site Link object.
- If the site you are removing is added to a site link that contains more than two sites, do not delete this Site Link object.

Before removing a site, you need to consider the implications. If the site you are removing is added to more than one site link, it might be an interim site between other sites that are added to this site link. Deleting the site might disconnect the outer sites from each other. In this case, the site links must be reconciled according to the instructions of the design team.

**Task Requirements**

The following tool is required to perform the procedures for this task:

- Active Directory Sites and Services

To complete this task, perform the following procedures:

1. Determine whether a Server object has child objects
2. Delete a Server object from a site
3. Delete the Site Link object

4. Associate the subnet or subnets with the appropriate site

5. Delete the Site object

6. To avoid replication errors on bridgehead servers in other sites that received replication from the site that has been removed, generate the intersite topology in those sites by performing the following two procedures:

    - Determine the ISTG role owner for a site

    - Generate the replication topology on the ISTG

# Determine whether a Server object has child objects

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After Active Directory is properly installed on a domain controller, the Server object for the domain controller will have a Child NTDS-Settings object. Other applications that are running on domain controllers can also publish Child objects.

Prior to deleting a Server object from the Servers container for a site, verify that the Server object has no Child objects. If a Child object appears, do not delete the Server object.

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Users group.

**To determine whether a server object has child objects**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and expand the site of the Server object.
3. Expand the **Servers** container, and then expand the Server object to view any Child objects.

# Delete a Server object from a site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When no Child objects are visible below the Server object in Active Directory Sites and Services, you can remove the Server object.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To delete a server object from a site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site from which you want to delete a Server object.
3. If no Child objects appear below the Server object, right-click the Server object, and then click **Delete**.

| **Important** |
| --- |
| Do not delete a Server object that has a Child object. If an NTDS Settings or other Child object appears below the Server object you want to delete, either replication on the domain controller on which you are viewing the Configuration container has not occurred, or the server whose Server object you are removing has not been properly decommissioned. |

4. Click **Yes** to confirm your choice.

# Delete the Site Link object

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the following procedure to delete a Site Link object.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group.

**To delete a site link object**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and the **Inter-Site Transports container**, and then click the **IP container**.
3. In the details pane, right-click the Site Link object you want to delete, and then click **Delete**.
4. Click **Yes** to confirm your choice.

# Associate the subnet or subnets with the appropriate site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Associate an existing subnet with a site under the following conditions:

- When you are removing the site to which the subnet was associated.
- When you have temporarily associated the subnet with a different site and want to associate it with its permanent site.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group.

**To associate the subnet or subnets with the appropriate site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then click the **Subnets** container.
3. In the details pane, right-click the subnet with which you want to associate the site, and then click **Properties**.
4. In the **Site** box, click the site with which to associate the subnet, and then click **OK**.

   If the IP addresses are no longer in use, delete the Subnet object or objects with which the addresses are associated.

# Delete the Site object

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Delete a Site object only after you have removed all Server objects from the site and have reassociated the subnets with a different site. The Servers container is deleted when you delete the site.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group.

**To delete the site object**

1. Open Active Directory Sites and Services and click the **Sites** container.
2. In the details pane, right-click the site you want to delete, and then click **Delete**.
3. Click **Yes** to confirm your choice.
4. In the Active Directory message box, read the information, and then click **Yes** to delete the site and its Servers container object.

# Determine the ISTG role owner for a site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to view the NTDS Site Settings object properties and determine the Intersite Topology Generator (ISTG) role owner for the site.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To determine the ISTG role owner for a site**

1. Open Active Directory Sites and Services.
2. Click the site object whose ISTG you want to determine.
3. In the details pane, right-click the **NTDS Site Settings** object, and then click **Properties**. The current role owner appears in the **Server** box under **Inter-Site Topology Generator**.

# Generate the replication topology on the ISTG

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Knowledge Consistency Checker (KCC) runs by default every 15 minutes. If you want to initiate topology regeneration immediately, you can force the KCC to run as follows:

- To generate the intersite replication topology, run the KCC on the domain controller in the site that holds the ISTG role.
- To generate the intrasite replication topology, run the KCC on any domain controller in the site that does not hold the ISTG role.

| **Note** |
| --- |
| To generate the replication topology on the ISTG, you must first complete the procedure: Determine the ISTG role owner for a site. |

### Administrative Credentials

To perform this procedure, you must be a member of the Enterprise Admins group.

**To generate the replication topology on the ISTG**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site that contains the server on which you want to run the KCC.
3. Expand the **Servers** container, and then click the **Server** object for the ISTG.
4. In the details pane, right-click **NTDS Settings**, click **All Tasks**, and then click **Check Replication Topology**.
5. In the **Check Replication Topology** message box, click **OK**.

# Administering the Active Directory Database

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides information for administering the Active Directory database in the Microsoft Windows Server 2003 operating system.

**In this guide**

# Introduction to Administering the Active Directory Database

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Active Directory is stored in the Ntds.dit database file. In addition to this file, the directory uses log files, which store transactions prior to committing them to the database file. For best performance, store the log files and the database on separate hard drives.

The Active Directory database is a self-maintained system and requires no daily maintenance, other than regular backup, during ordinary operation. However, it may need to be managed if the following conditions occur:

- Low disk space
- Pending or current hardware failure
- A need to recover physical space following bulk deletion or removal of the global catalog

Monitor free disk space on the partition or partitions that store the directory database and logs. The following are the recommended parameters for free space:

- Ntds.dit partition: The greater of 20 percent of the Ntds.dit file size or 500 megabytes (MB).
- Log file partition: The greater of 20 percent of the combined log files size or 500 MB.
- Ntds.dit and logs on the same volume: The greater of 1 gigabyte (GB) or 20 percent of the combined Ntds.dit and log files sizes.

During ordinary operation, the customer will delete objects from Active Directory. When an object is deleted, it results in white space (or unused space) being created in the database. On a regular basis, the database will consolidate this white space through a process called defragmentation, and this white space will be reused when new objects are added (without adding any size to the file itself). This automatic online defragmentation redistributes and retains white space for use by the database, but does not release it to the file system. Therefore, the database size does not shrink, even though objects might be deleted. In cases where the data is decreased significantly, such as when the global catalog is removed from a domain controller, white space is not automatically returned to the file system. Although this condition does not affect database operation, it does result in large amounts of white space in the database. You can use offline defragmentation to decrease the size of the database file by returning white space from the database file to the file system.

Managing the Active Directory database also allows you to upgrade or replace the disk on which the database or log files are stored or to move the files to a different location, either permanently or temporarily.

Prior to performing any procedures that affect the directory database, be sure that you have a current system state backup. For information about performing system state backup, see Back up system state.

To manage the database file itself, you must take the domain controller offline by restarting in Directory Services Restore Mode, and then use Ntdsutil.exe to manage the file.

| **Note** |
| --- |
| NTFS disk compression is not supported for the database and log files. |

# Managing the Active Directory Database

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks for managing the Active Directory database are described in this objective:

- Relocating Active Directory Database Files
- Returning Unused Disk Space from the Active Directory Database to the File System
- Guarding Against Accidental Bulk Deletions in Active Directory

# Relocating Active Directory Database Files

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following conditions require moving database files:

- Hardware maintenance: If the physical disk on which the database or log files are stored requires upgrading or maintenance, the database files must be moved, either temporarily or permanently.
- Low disk space: When free disk space is low on the logical drive that stores the database file (Ntds.dit), the log files, or both, first verify that no other files are causing the problem. If the database file or log files are the cause of the growth, then provide more disk space by taking one of the following actions:
- Expand the partition on the disk that currently stores the database file, the log files, or both. This procedure does not change the path to the files and does not require updating the registry.
- Use Ntdsutil.exe to move the database file, the log files, or both to a larger existing partition. If you are not using Ntdsutil.exe when moving files to a different partition, you will need to manually update the registry.

If the path to the database file or log files will change as a result of moving the files, be sure that you:

- Use Ntdsutil.exe to move the files (rather than copying them) so that the registry is updated with the new path. Even if you are moving the files only temporarily, use Ntdsutil.exe to move files locally so that the registry remains current.
- Perform a system state backup as soon as the move is complete so that the restore procedure uses the correct path.
- Verify that the correct permissions are applied on the destination folder following the move. Revise permissions to those that are required to protect the database files, if needed.

The registry entries that Ntdsutil.exe updates when you move the database file are as follows:

In **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS**

**Parameters**:

- Database backup path
- Digital Signature Algorithm (DSA) database file
- DSA working directory

The registry entry that Ntdsutil.exe updates when you move the log files is as follows:

In **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS**

**Parameters**:

- Database log files path

**Disk space requirements for relocating Active Directory database files**

**Temporary location**. Free space on the destination drive equivalent to at least the current size of the database file, the combined log files, or both, depending on which files you are moving.

**Permanent location**. Free space on the destination NTFS drive equivalent to at least the size specified below, plus space to accommodate anticipated growth, depending on which file or files you are moving.

**Caution**

| |
|---|
| The drive that is the permanent location of the database file or log files must be formatted as NTFS. |

- Database file only: The size of the database file plus 20 percent of the Ntds.dit file or 500 MB, whichever is greater.
- Log files only: The size of the combined log files plus 20 percent of the combined logs or 500 MB, whichever is greater.
- Database and logs. If the database and log files are stored on the same partition, free space should be at least 20 percent of the combined Ntds.dit and log files, or 1 GB, whichever is greater.

| **Important** |
|---|
| The preceding levels are minimum recommended levels. Therefore, adding additional space according to anticipated growth is recommended. |

**Task Requirements**

The following tools are required to perform the procedures for this task:

- net use
- dir
- xcopy
- Ntdsutil.exe
- Backup software
- Windows Explorer

| **Note** |
|---|
| If you replace or reconfigure a drive that stores the SYSVOL folder, you must first move the SYSVOL folder manually. For information about moving SYSVOL manually, see Relocating SYSVOL Manually. |

To complete this task, perform the following procedures:

| **Note** |
|---|
| The domain controller will not be available during the time in which files are being moved and until the move is verified. Ensure that alternate domain controllers are available during the file relocation to handle the capacity. |

1. Determine the size and location of the Active Directory database by using one of the following procedures:
   - Determine the database size and location online
   - Determine the database size and location offline
2. Compare the size of the directory database files to the volume size
3. Back up system state

System state includes the database file and log files as well as SYSVOL and Net Logon shared folders, among other things. Always ensure that you have a current backup prior to moving database files.

4. Restart the domain controller in Directory Services Restore Mode by using one of the following methods:

   - Restart the domain controller in Directory Services Restore Mode locally
   - Restart the domain controller in Directory Services Restore Mode Remotely

5. Move or copy the directory database and log files by performing one of the following procedures:

   - Move the directory database and log files to a local drive
   - Copy the directory database and log files to a remote share

     The shared folder on a remote drive must have enough free space to hold the database file (Ntds.dit) and log files. Create separate subdirectories for copying the database file and the log files.

6. Back up system state

# Determine the database size and location online

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When determining the database size and location online, the size is reported in bytes. If you must manage the database file, the log files, or both, first determine the location and size of the files. By default, the database file and associated log files are stored in the *%systemroot%*\NTDS directory.

| **Important** |
| --- |
| Be sure to use the same method to check file sizes when you compare them. The size is reported differently, depending on whether the domain controller is online or offline. For information about determining database size offline, see Determine the database size and location offline. |

You can also use the Search command on the Start menu to locate the database file (Ntds.dit) or the edb*.log file for the location of the database and log files, respectively.

If you have set garbage collection logging to report free disk space, then event ID 1646 in the Active Directory service log also reports the size of the database file: "Total allocated hard disk space (megabytes):"

Alternatively, you can determine the size of the database file by listing the contents of the directory that contains the files.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To determine the database size and location online**

1. On the domain controller on which you want to manage database files, open a command prompt and change directories to the directory containing the files you want to manage.
2. Run the dir command to examine the database size. In the following example, Ntds.dit file and the log files are stored in the same directory. In the example, the files take up 58,761,216 bytes of disk space.

   **H:\NTDS>dir**

   **Volume in drive H has no label.**

   **Volume Serial Number is 003D-0E9E**

   **Directory of H:\NTDS**

   **01/29/2002 11:04 AM <DIR> .**

   **01/29/2002 11:04 AM <DIR> ..**

   **01/28/2002 03:03 PM <DIR> Drop**

   **01/29/2002 10:29 AM 8,192 edb.chk**

   **01/29/2002 10:29 AM 10,485,760 edb.log**

   **01/29/2002 10:29 AM 10,485,760 edb00001.log**

   **01/29/2002 10:29 AM 14,696,448 ntds.dit**

   **01/28/2002 02:54 PM 10,485,760 res1.log**

   **01/28/2002 02:54 PM 10,485,760 res2.log**

   **7 File(s) 58,761,216 bytes**

   **3 Dir(s) 779,284,480 bytes free**

# Determine the database size and location offline

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When determining the database size and location offline, the size is reported in megabytes (MB). Use this method if the domain controller is already started in Directory Services Restore Mode.

| **Important** |
| --- |
| Be sure to use the same method to check file sizes when you compare them. The size is reported differently, depending on whether the domain controller is online or offline. For information about determining database size online, see Determine the database size and location online. |

You can also use the Search command on the Start menu to locate the database file (Ntds.dit) or the edb*.log file for the location of the database and log files, respectively.

If you have set garbage collection logging to report free disk space, then event ID 1646 in the Active Directory service log also reports the size of the database file: "Total allocated hard disk space (megabytes):"

Alternatively, you can determine the size of the database file by listing the contents of the directory that contains the files.

**Administrative Credentials**

To perform this procedure, you must provide the Directory Services Restore Mode password for the local administrator account.

**To determine the database size and location offline**

1. With the domain controller in Directory Services Restore Mode, open a command prompt, type **ntdsutil** and then press ENTER
2. At the **ntdsutil:** prompt, type **files** and then press ENTER.
3. At the **file maintenance:** prompt, type **info** and press ENTER.
4. At the **file maintenance:** prompt, type **quit** and then press ENTER. Type **quit** and then press ENTER again to quit Ntdsutil.exe.

# Compare the size of the directory database files to the volume size

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before moving any files in response to low disk space, verify that no other files on the volume are responsible for the condition of low disk space.

You might need to relocate the database file, the log files, or both, if disk space on the volume on which they are stored becomes low. Before moving the database file or log files, examine the size of the database folder, logs folder, or both, if they are stored in the same location, relative to the size of the volume to verify that these files are the cause of low disk space. Include the size of the SYSVOL folder if it is on the same partition.

**Administrative Credentials**

If you are online when comparing the size of the directory database files, you must be a member of the Domain Admins group. If you are offline, you must provide the Directory Services Restore Mode password for the local administrator account.

**To compare the size of the directory database files to the volume size**

1. In Windows Explorer, click **My Computer**.
2. On the **View** menu, click **Details**.
3. In the **Name** column in the details pane, locate the volume. Make a note of the value in the **Total Size** column.
4. Navigate to the folder that stores the database file, the log files, or both.
5. Right-click the folder, and then click **Properties**. Make a note of the value in **Size on disk**.
6. If the volume includes **SYSVOL**, navigate to that folder and repeat step 5.
7. Compare the sizes. If the combined size of the relevant database files and SYSVOL files (if appropriate) is significantly smaller than the volume size, then check the contents of the volume for other files.
8. If other files are present, move those files and reassess the disk space on the volume.

# Back up system state

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Ntbackup.exe provides simple and advanced options for backing up Active Directory components. When you back up system state, you can choose to include or exclude system-protected boot files. System-protected boot files are not used for installations from restored backup media. When the backup file that you create is to be used for additional domain controller installations, you can clear the advanced option to back up system-protected files. Clearing this option decreases the size of the .bkf file, as well as the time required to back up, restore, and copy the system state files.

Use these procedures to back up the system state only. These procedures do not back up the system disk or any other data on the domain controller except for the system-protected files.

Use the first procedure, "To back up system state including system-protected files," for routine system state backup. Use the second procedure, "To back up system state excluding system-protected files," if you want to create a smaller backup that is effective for installing domain controllers from restored backup media.

| **Note** |
| --- |
| To back up system state, you must log on locally to the domain controller, or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

- To perform the following two procedures, you must be a member of the Domain Admins group or a member of the Backup Operators group.

#### To back up system state including system-protected files

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.

   This procedure provides steps for backing up in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.

2. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
3. Select **Back up files and settings**, and then click **Next**.
4. Select **Let me choose what to back up**, and then click **Next**.
5. In the **Items to Back Up** window, double-click **My Computer**.
6. In the expanded list below **My Computer**, check **System State**, and then click **Next**.
7. Select a location to store the backup:

   - If you are backing up to a file, type the path and file name for the backup (.bkf) file (or click **Browse** to find a folder or file).

   - If you are backing up to a tape unit, choose the tape that you want to use.

     | **Note** |
     | --- |
     | You should not store the backup on the local hard drive. Instead, store it in a location, such as a tape drive, away from the computer that you are backing up. |

8. Type a name for this backup according to the recommendations in Backing Up Active Directory Components, and then click **Next**.
9. On the last page of the wizard, click **Advanced**.

10. Do not change the default options for **Type of Backup**. **Normal** should be selected, and the check box for **Backup migrated remote storage data** should remain cleared. Click **Next**.
11. Select **Verify data after backup**, and then click **Next**.
12. In the **Backup Options** dialog box, select a backup option, and then click **Next**.
13. If you are replacing the existing backups, select the option to allow only the owner and administrator access to the backup data and to any backups that are appended to this medium, and then click **Next**.
14. In the **When to back up** box, select the appropriate option for your needs, and then click **Next**.
15. If you are satisfied with all of the options that are selected, click **Finish** to perform the backup operation according to your selected schedule.

| **Note** |
| --- |
| The system state can also be backed up by using Ntbackup from a command line with appropriate parameters. For more information, at a command prompt type **ntbackup /?**. |

The following procedure produces a smaller .bkf file that does not include system boot files. By using this procedure, you can reduce the time that is required to perform the backup and subsequent restore, as well as the amount of disk space that is required. This method is recommended when the restored backup is to be used for installing additional domain controllers.

**To back up system state excluding system-protected files**

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.
2. On the **Welcome to the Backup or Restore Wizard** page, click **Advanced Mode**, and then click the **Backup** tab.
3. In the console tree, select the **System State** check box.
4. In **Backup media or file name**, type a name for this backup according to the recommendations in Backing Up Active Directory Components.
5. Click **Start Backup**, and then click **Advanced**.
6. Clear the **Automatically back up System Protected Files with the System State** check box, and then click **OK**.
7. Click **Start Backup**.

# Restart the domain controller in Directory Services Restore Mode locally

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have physical access to a domain controller, you can restart the domain controller in Directory Services Restore Mode locally. Restarting in Directory Services Restore Mode takes the domain controller offline. In this mode, the server is not functioning as a domain controller.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode locally**

1. Restart the domain controller.
2. When the screen for selecting an operating system appears, press F8.
3. On the **Windows Advanced Options** menu, select **Directory Services Restore Mode**.
4. When you are prompted, log on as the local administrator.

**Concepts**
Restart the domain controller in Directory Services Restore Mode Remotely

# Restart the domain controller in Directory Services Restore Mode Remotely

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If Remote Desktop is enabled on a domain controller, you can use Remote Desktop Connection to connect to the domain controller remotely. Remote Desktop Connection (formerly known as the Terminal Services client) is installed by default on all Windows Server 2003 family operating systems.

If you use Remote Desktop Connection to connect to a domain controller remotely and you want to restart the domain controller in Directory Services Restore Mode, you must first modify the Boot.ini file on the remote server so that you do not lose the connection when the domain controller restarts.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode remotely**

1. Use Remote Desktop Connection to connect to the domain controller that you want to restart in Directory Services Restore Mode.
2. Right-click **My Computer**, click **Properties**, and then click the **Advanced** tab.
3. Click **Settings for startup and recovery**.
4. Click the **Edit** button to edit the startup options file.
5. Modify the default entry to include the **/SAFEBOOT:DSREPAIR** switch, as shown in the following example:

   **multi(0)disk(0)rdisk(0)partition(2)\WINNT="W2K DC ** *your server name* **" /fastdetect /SAFEBOOT:DSREPAIR**

   | **Note** |
   | --- |
   | The **/SAFEBOOT:DSREPAIR** switch works for domain controllers running Windows 2000 Server and Windows Server 2003. |

6. Save the modified Boot.ini file, and then close Notepad.
7. On the **Start** menu, click **Shut Down**, and then click **Restart**. During the restart process, the Terminal Services client reports that the session is disconnected.

   | **Caution** |
   | --- |
   | Be sure to click **Restart** and not **Shut Down** at this step. If you click **Shut Down**, you cannot restart the domain controller remotely. |

8. Wait until the restart process completes on the remote domain controller, and then reconnect the client session.
9. When the client session is reconnected, log on as the local administrator.
10. Right-click **My Computer**, click **Properties**, and then click the **Advanced** tab.
11. Click **Settings for startup and recovery**.
12. Click the **Edit** button to edit the startup options file.
13. Delete the **/SAFEBOOT:DSREPAIR** switch from the default entry in the Boot.ini file, save the file, and then close Notepad.

| **Important** |
| --- |
| If you restart the domain controller before you modify the Boot.ini file, the domain controller remains offline. |

The Boot.ini file is now returned to its original state, which starts the domain controller normally.

Create a Remote Desktop Connection

Restart the domain controller in Directory Services Restore Mode locally

# Move the directory database and log files to a local drive

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Move the files to a temporary destination if you need to reformat the original location, or to a permanent location if you have additional disk space. Moving the files can be performed locally by using Ntdsutil.exe or remotely (temporarily) by using a file copy.

If you need to reformat the partition that currently stores the database file, the log files, or both, then you must move the files temporarily while you reformat the original drive. After you reformat the drive, use the same procedure to move the files back. Even if you are moving the files only temporarily, use Ntdsutil.exe so that the registry is always current.

**Administrative Credentials**

To perform this procedure, you must provide the Directory Services Restore Mode password for the local administrator account.

**To move the directory database and log files to a local drive**

1. In Directory Services Restore Mode, open a command prompt and change directories to the current location of the directory database file (Ntds.dit) or the log files, whichever you are moving.
2. Run the **dir** command and make a note of the current size and location of the Ntds.dit file.
3. At the command prompt, type **ntdsutil** and then press ENTER.
4. At the **ntdsutil:** prompt, type **files** and then press ENTER.
5. To move the database file, at the file maintenance: prompt, use the following commands:
   - To move the Ntds.dit file, type:

     **move db to** *drive:\directory*

   - To move the log files, type:

     **move logs to** *drive:\directory*

   where *Drive:\directory* specifies the path to the new location. If the directory does not exist, then Ntdsutil.exe creates it.

   | **Note** |
   | --- |
   | If the directory path contains any spaces, the entire path must be surrounded by quotation marks (for example, move db to "*g:\new folder*"). |

6. After the move completes, at the **file maintenance:** prompt, type **quit** and press ENTER. Type **quit** again and press ENTER to quit Ntdsutil.exe.
7. Change to the destination directory and then run the **dir** command to confirm the presence of the files. If you have moved the database file, then check the size of the Ntds.dit file against the file size you noted in step 2 to be sure that you are focused on the correct file.
8. If you are moving the database file or log files permanently, go to step 9.

   If you are moving the database file or log files temporarily, you can now perform any required updates to the original drive. After you update the drive, repeat steps 1 through 7 to move the files back to the original location.

   If the path to the database file or log files has not changed, go to step 10.
9. If the path to the database file or log files has changed from the original location, check permissions on the database folder or logs folder while still in Directory Services Restore Mode, as follows:
   a. In Windows Explorer, right-click the folder to which you have moved the database file or log files, and then click

**Properties**.

b. Click the **Security** tab, and verify that the permissions are:

   **Administrators** group has **Allow Full Control**.

   **System** has **Allow Full Control**.

   **Inheritable permissions are not allowed** (checkbox is cleared).

   **No Deny permissions** are selected.

c. If the permissions in step 9b are in effect, then go to step 10. If permissions other than those described in step 9b are in effect, then perform steps 9d through 9k.

d. If **Allow inheritable permissions from parent to propagate to this object** is selected, click to clear it.

e. When prompted, click **Copy** to copy previously inherited permissions to this object.

f. If **Administrators** or **SYSTEM**, or both, are not in the **Name** list, click **Add**.

g. On the **Select Users or Groups** page, in the **Look in:** box, be sure the name of the local computer is selected.

h. In the **Name** list, click **System** if needed, and then click **Add**. Repeat to add Administrators, if needed, and then click **OK**.

i. On the **Security** tab, click **System** and then in the **Allow** column, click **Full Control**. Repeat for Administrators.

j. In the **Name** box, click any name that is not SYSTEM or Administrators, and then click **Remove**. Repeat until the only remaining accounts are Administrators and SYSTEM, and then click **OK**.

| **Note** |
| --- |
| Some accounts might appear in the form of security identifiers (SIDs). Remove any such accounts. |

k. Click **OK** to close **Properties**.

10. At the command prompt, type **ntdsutil** and then press ENTER.
11. At the **ntdsutil:** prompt, type **files** and then press ENTER.
12. At the **file maintenance:** prompt, type **integrity** and then press ENTER.

    If the integrity check fails, perform semantic database analysis with a fixup record.
13. If the integrity check succeeds, type **quit** and press ENTER to quit the **file maintenance:** prompt. Type **quit** again and press ENTER to quit Ntdsutil.exe.
14. Restart the domain controller normally. If you are performing this procedure remotely over a Terminal Services connection, be sure that you have modified the Boot.ini file for normal restarting before you restart the domain controller.

    If errors appear when you restart the domain controller:

    a. Restart the domain controller in Directory Services Restore Mode.

    b. Check the errors in Event Viewer.

If the following events are logged in Event Viewer on restarting the domain controller, address the events as follows:

- Event ID 1046. “The Active Directory database engine caused an exception with the following parameters.” In this case, Active Directory cannot recover from this error and you must restore from backup media.

- Event ID 1168. “Internal error: An Active Directory error has occurred.” In this case, information is missing from the registry and you must restore from backup media.

# Copy the directory database and log files to a remote share

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When copying any database files from the local computer, always copy both the database file and the log files.

If you need to move the database file or the log files while you reconfigure the drive on which they are currently stored, and you do not have sufficient space to move the files locally, then you can use the xcopy command to copy the files to a remote shared folder temporarily, and then use the same procedure to copy them back to the original drive. You can use this method as long as the path to the files does not change.

| **Important** |
| --- |
| When relocating any database files (the database file or the log files) off the local computer, always copy both the database file and the log files so that all of the files necessary to restore the directory service are maintained. |

### Administrative Credentials

To perform this procedure, you must provide the Directory Services Restore Mode password for the local administrator account.

**To copy the directory database and log files to a remote share and back to the local computer**

1. In Directory Services Restore Mode, open a command prompt and change directories to the current location of the database file (Ntds.dit) or the log files. If the database file and log files are in different locations, perform step 2 for each directory.
2. Run the **dir** command and make a note of the current size and location of the Ntds.dit file and the log files.
3. Establish a network connection to a shared folder, as shown below. Because you are logged on as the local administrator, unless permissions on the shared folder include the built-in Administrator account, you must provide a domain name, user name, and password for an account that has Write permissions on the shared folder.

   In the example below, **\\SERVER1\NTDS** is the name of the shared folder. K: is the drive that you have mapped to the shared folder. Example text that describes information that you type is shown in bold. After typing the first line and pressing ENTER, you are prompted for the password. Type the password and then press ENTER.

   **H:\>net use K: \\SERVER1\NTDS /user:** *domainName\userName* *

   Type the password for **\\SERVER1\NTDS:**

   Drive K: is now connected to **\\SERVER1\NTDS**

   The command completed successfully.
4. Use the xcopy command to copy the database file and log files to the location you established in step 3. In the example where the database file is located in H:\WINNT\NTDS and the share has the subdirectory database, the text you type is shown in bold:

   **H:>xcopy WINNT\NTDS K:\DB**

   The command copies the contents of WINNT\NTDS to the subfolder database in the shared folder described as drive K:. If the database file and log files are in different locations, repeat the xcopy command for the log files, specifying the subfolder for the log files.
5. Change drives to the new location and run the **dir** command to compare the file sizes to those listed in step 2. Use this step to ensure that you copy the correct set of files back to the local computer.
6. At this point, you can safely destroy data on the original local drive.
7. After the destination drive is prepared, re-establish a connection to the network drive as described in step 3, if necessary.
8. Copy the database and log files from the remote shared folder back to the original location on the domain controller.
9. At the command prompt, type **ntdsutil** and then press ENTER.

10. At the **ntdsutil:** prompt, type **files** and then press ENTER.
11. At the **file maintenance:** prompt, type **integrity** and then press ENTER.
12. If the integrity check fails, perform semantic database analysis with a fixup record.
13. If the integrity check succeeds, type **quit** and press ENTER to quit the **file maintenance:** prompt. Type **quit** again and press ENTER to quit Ntdsutil.exe.
14. Restart the domain controller normally. If you are performing this procedure remotely over a Terminal Services connection, be sure that you have modified the Boot.ini file for normal restarting before you restart the domain controller.

If errors appear when you restart the domain controller:

1. Restart the domain controller in Directory Services Restore Mode.

2. Check the errors in Event Viewer.

   If the following events are logged in Event Viewer on restarting the domain controller, respond to the events as follows:

   - Event ID 1046. "The Active Directory database engine caused an exception with the following parameters." In this case, Active Directory cannot recover from this error and you must restore from backup media.

   - Event ID 1168. "Internal error: An Active Directory error has occurred." In this case, information is missing from the registry and you must restore from backup media.

# Returning Unused Disk Space from the Active Directory Database to the File System

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

During ordinary operation, the white space in the Active Directory database file becomes fragmented. Each time garbage collection runs (every 12 hours, by default), white space is automatically defragmented online to optimize its use within the database file. The unused disk space is thereby maintained for the database; it is not returned to the file system.

Only offline defragmentation can return unused disk space from the directory database to the file system. When database contents have decreased considerably through a bulk deletion (for example, you remove the global catalog from a domain controller), or if the size of the database backup is significantly increased due to the white space, use offline defragmentation to reduce the size of the Ntds.dit file.

You can determine how much free disk space is recoverable from the Ntds.dit file by setting the garbage collection logging level in the registry. Changing the garbage collection logging level from the default value of **0** to a value of **1** results in event ID 1646 being logged in the directory service log. This event describes the total amount of disk space used by the database file as well as the amount of free disk space that is recoverable from the Ntds.dit file through offline defragmentation.

At garbage collection logging level 0, only critical events and error events are logged in the directory service log. At level 1, high-level events are logged as well. Events can include one message for each major task that is performed by the service. At level 1, the following events are logged for garbage collection:

- Event IDs 700 and 701: report when online defragmentation begins and ends, respectively.
- Event ID 1646: reports the amount of free space available in the database out of the amount of allocated space.

| **Caution** |
| --- |
| Setting the value of entries in the Diagnostics subkey to greater than 3 can degrade server performance and is not recommended. |

Following offline defragmentation, perform a database integrity check. The integrity command in Ntdsutil.exe detects binary-level database corruption by reading every byte in the database file. The process ensures that the correct headers exist in the database itself and that all of the tables are functioning and consistent. Therefore, depending upon the size of your Ntds.dit file and the domain controller hardware, the process might take considerable time. In testing environments, the speed of 2 GB per hour is considered to be typical. When you run the command, an online graph displays the percentage completed.

**Task requirements**

The following tools are required to perform the procedures for this task:

- Regedit.exe
- Backup software
- Ntdsutil.exe

To complete this task, perform the following procedures:

1. Change the garbage collection logging level to 1
2. Back up system state
3. Use one of the following procedures:
    - Restart the domain controller in Directory Services Restore Mode locally

If you are logged on to the domain controller locally, restart the domain controller in Directory Services Restore Mode.

- Restart the domain controller in Directory Services Restore Mode Remotely

  If you are using Remote Desktop Connection for remote administration, you can restart the domain controller remotely in Directory Services Restore Mode after modifying the Boot.ini file on the remote server.

4. Compact the directory database file (offline defragmentation)

   As part of the offline defragmentation procedure, check directory database integrity.

5. If database integrity check fails, perform semantic database analysis with fixup

# Change the garbage collection logging level to 1

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Check the directory service event log for event ID 1646, which reports the amount of disk space that you can recover by performing offline defragmentation.

The garbage collection logging level is an NTDS diagnostics setting in the registry.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group.

| ⚠**Caution** |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Introduction to Administering Active Directory Backup and Restore. |

**To change the garbage collection logging level**

1. Click **Start**, click **Run**, type **regedit** and then press ENTER.
2. In Registry Editor, navigate to the **Garbage Collection** entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Diagnostics**
3. Double-click **Garbage Collection**, and for the **Base**, click **Decimal**.
4. In the **Value data** box, type **1**, and then click **OK**.

# Back up system state

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Ntbackup.exe provides simple and advanced options for backing up Active Directory components. When you back up system state, you can choose to include or exclude system-protected boot files. System-protected boot files are not used for installations from restored backup media. When the backup file that you create is to be used for additional domain controller installations, you can clear the advanced option to back up system-protected files. Clearing this option decreases the size of the .bkf file, as well as the time required to back up, restore, and copy the system state files.

Use these procedures to back up the system state only. These procedures do not back up the system disk or any other data on the domain controller except for the system-protected files.

Use the first procedure, "To back up system state including system-protected files," for routine system state backup. Use the second procedure, "To back up system state excluding system-protected files," if you want to create a smaller backup that is effective for installing domain controllers from restored backup media.

| **Note** |
| --- |
| To back up system state, you must log on locally to the domain controller, or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

- To perform the following two procedures, you must be a member of the Domain Admins group or a member of the Backup Operators group.

#### To back up system state including system-protected files

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.

   This procedure provides steps for backing up in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.

2. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
3. Select **Back up files and settings**, and then click **Next**.
4. Select **Let me choose what to back up**, and then click **Next**.
5. In the **Items to Back Up** window, double-click **My Computer**.
6. In the expanded list below **My Computer**, check **System State**, and then click **Next**.
7. Select a location to store the backup:

   - If you are backing up to a file, type the path and file name for the backup (.bkf) file (or click **Browse** to find a folder or file).

   - If you are backing up to a tape unit, choose the tape that you want to use.

     | **Note** |
     | --- |
     | You should not store the backup on the local hard drive. Instead, store it in a location, such as a tape drive, away from the computer that you are backing up. |

8. Type a name for this backup according to the recommendations in Backing Up Active Directory Components, and then click **Next**.
9. On the last page of the wizard, click **Advanced**.

10. Do not change the default options for **Type of Backup**. **Normal** should be selected, and the check box for **Backup migrated remote storage data** should remain cleared. Click **Next**.
11. Select **Verify data after backup**, and then click **Next**.
12. In the **Backup Options** dialog box, select a backup option, and then click **Next**.
13. If you are replacing the existing backups, select the option to allow only the owner and administrator access to the backup data and to any backups that are appended to this medium, and then click **Next**.
14. In the **When to back up** box, select the appropriate option for your needs, and then click **Next**.
15. If you are satisfied with all of the options that are selected, click **Finish** to perform the backup operation according to your selected schedule.

| **Note** |
| --- |
| The system state can also be backed up by using Ntbackup from a command line with appropriate parameters. For more information, at a command prompt type **ntbackup /?**. |

The following procedure produces a smaller .bkf file that does not include system boot files. By using this procedure, you can reduce the time that is required to perform the backup and subsequent restore, as well as the amount of disk space that is required. This method is recommended when the restored backup is to be used for installing additional domain controllers.

**To back up system state excluding system-protected files**

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.
2. On the **Welcome to the Backup or Restore Wizard** page, click **Advanced Mode**, and then click the **Backup** tab.
3. In the console tree, select the **System State** check box.
4. In **Backup media or file name**, type a name for this backup according to the recommendations in Backing Up Active Directory Components.
5. Click **Start Backup**, and then click **Advanced**.
6. Clear the **Automatically back up System Protected Files with the System State** check box, and then click **OK**.
7. Click **Start Backup**.

# Restart the domain controller in Directory Services Restore Mode locally

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have physical access to a domain controller, you can restart the domain controller in Directory Services Restore Mode locally. Restarting in Directory Services Restore Mode takes the domain controller offline. In this mode, the server is not functioning as a domain controller.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode locally**

1. Restart the domain controller.
2. When the screen for selecting an operating system appears, press F8.
3. On the **Windows Advanced Options** menu, select **Directory Services Restore Mode**.
4. When you are prompted, log on as the local administrator.

Restart the domain controller in Directory Services Restore Mode Remotely

# Restart the domain controller in Directory Services Restore Mode Remotely

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If Remote Desktop is enabled on a domain controller, you can use Remote Desktop Connection to connect to the domain controller remotely. Remote Desktop Connection (formerly known as the Terminal Services client) is installed by default on all Windows Server 2003 family operating systems.

If you use Remote Desktop Connection to connect to a domain controller remotely and you want to restart the domain controller in Directory Services Restore Mode, you must first modify the Boot.ini file on the remote server so that you do not lose the connection when the domain controller restarts.

When you start Windows Server 2003 in Directory Services Restore Mode, the local Administrator account is authenticated by the local Security Accounts Manager (SAM) database. Therefore, logging on requires that you use the local administrator password, not an Active Directory domain password. This password is set during Active Directory installation when you provide the password for Directory Services Restore Mode.

**Administrative credentials**

To perform this procedure, you must provide the Administrator password for Directory Services Restore Mode.

**To restart the domain controller in Directory Services Restore Mode remotely**

1. Use Remote Desktop Connection to connect to the domain controller that you want to restart in Directory Services Restore Mode.
2. Right-click **My Computer**, click **Properties**, and then click the **Advanced** tab.
3. Click **Settings for startup and recovery**.
4. Click the **Edit** button to edit the startup options file.
5. Modify the default entry to include the **/SAFEBOOT:DSREPAIR** switch, as shown in the following example:

   **multi(0)disk(0)rdisk(0)partition(2)\WINNT="W2K DC ** *your server name* **" /fastdetect /SAFEBOOT:DSREPAIR**

   | **Note** |
   | --- |
   | The **/SAFEBOOT:DSREPAIR** switch works for domain controllers running Windows 2000 Server and Windows Server 2003. |

6. Save the modified Boot.ini file, and then close Notepad.
7. On the **Start** menu, click **Shut Down**, and then click **Restart**. During the restart process, the Terminal Services client reports that the session is disconnected.

   | **Caution** |
   | --- |
   | Be sure to click **Restart** and not **Shut Down** at this step. If you click **Shut Down**, you cannot restart the domain controller remotely. |

8. Wait until the restart process completes on the remote domain controller, and then reconnect the client session.
9. When the client session is reconnected, log on as the local administrator.
10. Right-click **My Computer**, click **Properties**, and then click the **Advanced** tab.
11. Click **Settings for startup and recovery**.
12. Click the **Edit** button to edit the startup options file.
13. Delete the **/SAFEBOOT:DSREPAIR** switch from the default entry in the Boot.ini file, save the file, and then close Notepad.

| **Important** |
| --- |
| If you restart the domain controller before you modify the Boot.ini file, the domain controller remains offline. |

The Boot.ini file is now returned to its original state, which starts the domain controller normally.

Restart the domain controller in Directory Services Restore Mode locally

# Compact the directory database file (offline defragmentation)

Updated: September 16, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| **Note** |
| --- |
| This procedure is for Windows Server 2003. For the Windows Server 2008 version of this procedure, see Compact the Directory Database File (Offline Defragmentation) (http://go.microsoft.com/fwlink/?LinkID=93225). |

As part of the offline defragmentation procedure, check directory database integrity.

Performing offline defragmentation creates a new, compacted version of the database file in a different location. This location can be either on the same computer or a network-mapped drive. However, to avoid potential problems related to network issues, perform this procedure using a local mass storage device. You can use locally attached external mass storage devices, such as Universal Serial Bus (USB), IEEE 1394, and Serial Advanced Technology Attachment (SATA), to provide additional disk space for defragmentation of the database.

After you compact the file to the temporary location, copy the compacted Ntds.dit file back to the original location. If possible, maintain a copy of the original database file that you have either renamed in its current location or copied to an archival location.

| **Note** |
| --- |
| To perform this procedure, the domain controller must be started in Directory Services Restore Mode (DSRM). |

### Administrative Credentials

To perform this procedure, you must provide the Directory Services Restore Mode password for the local administrator account. At the remote location, you must have Read and Write permissions on the destination drive and the shared folder.

### Disk Space

- **Current database drive**. Free space (on the drive that contains the Active Directory database file) equivalent to at least 15 percent of the current size of the database (Ntds.dit) for temporary storage during the index rebuild process.

- **Destination database drive**. Free space equivalent to at least the current size of the database for storage of the compacted database file.

| **Note** |
| --- |
| These disk space requirements mean that if you compress the Active Directory database on a single drive, you should have free space equivalent to at least 115 percent of the space that the current Active Directory database uses on that drive. |

#### To perform offline defragmentation of the directory database

1. In DSRM, compact the database file to a local directory or remote shared folder, as follows:

    - **Local directory:** Go to step 2.

    - **Remote directory:** If you are compacting the database file to a shared folder on a remote computer, establish a network connection to the shared folder as shown below. Because you are logged on as the local administrator, unless permissions on the shared folder include the built-in Administrator account, you must provide a domain name, user name, and password for a domain account that has Write permissions on the shared folder. In the example below, \\SERVER1\NTDS is the name of the shared folder, and K: is the drive that you are mapping to the shared folder. After typing the first line and pressing ENTER, you are prompted for the password. Type the password and then press ENTER.

        **H:\>net use K: \\SERVER1\NTDS /user:***domainName******userName* ***

Type the password for **\\SERVER1\NTDS:**

Drive K: is now connected to **\\SERVER1\NTDS**

The command completed successfully.

2. Type the following command at a command prompt, and then press ENTER:

   **ntdsutil**

3. At the **ntdsutil:** prompt, type **files**, and then press ENTER.
4. At the **file maintenance:** prompt, type **compact to** *drive:\ LocalDirectoryPath* (where *drive:\ LocalDirectoryPath* is the path to a location on the local computer), and then press ENTER.

   If you have mapped a drive to a shared folder on a remote computer, type the drive letter only (for example, **compact to K:**).

   | **Note** |
   | --- |
   | When compacting to a local drive, you must provide a path. If the path contains any spaces, enclose the entire path in quotation marks (for example, compact to "c:\new folder"). If the directory does not exist, Ntdsutil.exe creates it and creates the file named Ntds.dit in that location. |

5. If defragmentation completes successfully, type **quit**, and then press ENTER to quit the **file maintenance:** prompt. Type **quit** again, and then press ENTER to quit Ntdsutil.exe. Go to step 6. If defragmentation completes with errors, go to step 9.

   | **Caution** |
   | --- |
   | Do not overwrite the original Ntds.dit file or delete any log files. |

6. If defragmentation succeeds with no errors, follow the Ntdsutil.exe onscreen instructions to:

   a. Delete all of the log files in the log directory by typing:

      **del** *drive***:***pathToLogFiles****.log**

      | **Note** |
      | --- |
      | You do not have to delete the Edb.chk file. |

   b. You should make a copy of the existing Ntds.dit file if at all possible, even if you have to store that copy to a secured network drive. If the compaction of the database does not work properly, you can then easily restore the database by copying it back to the original location. Do not delete the copy of the Ntds.dit file until you have at least verified that the domain controller starts properly. If space allows, you can rename the original Ntds.dit file to preserve it or else copy it to a different location. Avoid overwriting the original Ntds.dit file.

   c. Manually copy the compacted database file to the original location, as follows:

      **copy** *temporaryDrive***:\ntds.dit** *originalDrive***:***pathToOriginalDatabaseFile***\ntds.dit**

7. Type **ntdsutil** and then press ENTER.
8. At the **ntdsutil:** prompt, type **files** and then press ENTER.
9. At the **file maintenance:** prompt, type **integrity** and then press ENTER.

   If the integrity check fails, the likely cause is that an error occurred during the copy operation in step 6.c. Repeat steps 6.c through step 9. If the integrity check fails again:

   - Contact Microsoft Product Support Services.

-or-

- Copy the original version of the Ntds.dit file that you preserved in step 6.b. to the original database location and repeat the offline defragmentation procedure.

10. If the integrity check succeeds, proceed as follows:

    - If the initial compact to command failed, go back to step 4 and perform steps 4 through 9.

    - If the initial compact to command succeeded, type **quit** and press ENTER to quit the **file maintenance:** prompt, and then type **quit** and press ENTER again to quit Ntdsutil.exe.

11. Restart the domain controller normally. If you are connected remotely through a Terminal Services session, be sure that you have modified the Boot.ini file for normal restarting before you restart the domain controller.

If errors appear when you restart the domain controller:

1. Restart the domain controller in Directory Services Restore Mode.

2. Check the errors in Event Viewer.

   If the following events are logged in Event Viewer on restarting the domain controller, respond to the events as follows:

   - Event ID 1046. "The Active Directory database engine caused an exception with the following parameters." In this case, Active Directory cannot recover from this error and you must restore from backup media.

   - Event ID 1168. "Internal error: An Active Directory error has occurred." In this case, information is missing from the registry and you must restore from backup media.

3. Check database integrity and then proceed as follows:

   If the integrity check fails, try repeating step 6.c through step 9 above, and then repeat the integrity check. If the integrity check fails again:

   - Contact Microsoft Product Support Services.

     -or-

   - Copy the original version of the Ntds.dit file that you preserved in step 6.2. to the original database location and repeat the offline defragmentation procedure.

     If the integrity check succeeds, perform semantic database analysis with fixup.

4. If semantic database analysis with fixup succeeds, quit Ntdsutil.exe and restart the domain controller normally.

If semantic database analysis with fixup fails, contact Microsoft Product Support Services.

# If database integrity check fails, perform semantic database analysis with fixup

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you run semantic database analysis with the Go Fixup command instead of the Go command, errors are written into Dsdit.dmp.xx log files. A progress indicator reports the status of the check.

| **Note** |
| --- |
| To perform this procedure, the domain controller must be started in Directory Services Restore Mode. |

### Administrative Credentials

To perform this procedure, you must provide the Directory Services Restore Mode password for the local administrator account.

**To perform semantic database analysis with fixup**

1. In Directory Services Restore Mode, open a Command Prompt.
2. Type the following command and then press ENTER:

   **ntdsutil:**
3. At the **ntdsutil:** prompt, type **semantic database analysis** and then press ENTER.
4. At the **semantic checker:** prompt, type **verbose on** and then press ENTER.
5. At the **semantic checker:** prompt, type **go fixup** and then press ENTER.

   - If errors are reported during the semantic database analysis Go Fixup phase, perform directory database recovery.

     | **Caution** |
     | --- |
     | Do not confuse the recover command with the repair command. Never use the repair command in Ntdsutil.exe. Forest-wide data loss can occur. |

   - If semantic database analysis with fixup succeeds, type **quit** and then type **quit** again to close Ntdsutil.exe, and then restart the domain controller normally. If you are performing this procedure remotely over a Terminal Services connection, be sure that you have modified the Boot.ini file for normal restarting before you restart the domain controller.

# Guarding Against Accidental Bulk Deletions in Active Directory

Updated: August 25, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2

Although bulk deletions are rare, they are disruptive events that you can guard against by removing the Delete and the Delete Subtree permissions in Active Directory. To guard against accidental deletions, you should remove the Delete and Delete Subtree permissions on organizational units (OUs) that contain user accounts, computer accounts, and security groups in Active Directory. You should also remove the Delete All Child Objects permission on the parent container of an OU that you want to protect.

**Types of deletions**

IT administrators have used Active Directory Users and Computers (dsa.msc) and other Active Directory management tools to accidentally delete objects from Active Directory. Two types of deletions are most common:

- Leaf-node deletions, which occur when an administrator or delegated user selects and deletes one or more leaf objects. A leaf object is an object that does not have subordinate objects. User and group objects are examples of leaf objects.

- OU deletion, which occurs when an administrator or delegated user selects and deletes a container that has subordinate objects.

| **Note** |
| --- |
| Although the remainder of this task refers to using dsa.msc, the explanations and guidelines apply to any tool that you use to perform the deletion, including the Active Directory Sites and Services snap-in (dssite.msc) if you use it to perform bulk deletions of configuration partition data. |

A leaf-node deletion has the following characteristics:

- The domain controller that is targeted for the operation checks whether the user has delete permissions on each selected object as dsa.msc tries to delete it.

- Dsa.msc displays a progress bar that is updated as each object is deleted.

- Because of the round-trip communication that takes place between the client and server, you can cancel or close dsa.msc from the workstation session that initiated the operation to stop the deletion while it is still in progress.

An OU deletion has the following characteristics:

- When you delete an OU, dsa.msc checks for subordinate objects and whether the subtree contains any critical objects. A critical object is an object for which the **isSystemCriticalObject** attribute is set to **True**. If critical objects are in the subtree, dsa.msc stops the operation. If there are no critical objects, dsa.msc displays a warning about deleting an object. You must click **Yes** to continue. Dsa.msc then displays a second warning about deleting child objects and containers. You must click **Yes** again to continue.

- The domain controller that is targeted for the operation performs a single-access check on the top-most OU that you are deleting. If the user has the Delete Subtree advanced permission (the symbolic name for this permission is **RIGHT_DS_DELETE_TREE**), the top OU and all subordinate containers are deleted, regardless of what access control lists (ACLs) are defined on subordinate containers. Administrators are implicitly granted the Delete and Delete Subtree advanced permissions if they have Full Control on a container. You can also explicitly grant the Delete and Delete Subtree advanced permissions to any user.

- The domain controller continues its server-side deletion and does not communicate with dsa.msc again until it reaches the maximum threshold of object deletions, which is 16,384 objects. The deletions are not performed in a particular order.

When dsa.msc reaches the maximum threshold of object deletions, it reissues the delete tree operation request until the operation succeeds or some other error is returned. When you cancel dsa.msc or stop it, either by logging off the session or by rebooting the administrative workstation, the deletion ends after the current batch of 16,384 objects is deleted on the server.

You can stop the server-side deletion only by restarting the domain controller that is targeted for the operation or by removing network connectivity from that domain controller if additional domain controllers exist in the domain.

- Dsa.msc does not display a progress bar during OU deletions.

- Because no round-trip communication occurs between the client and server, the OU deletion operation completes more quickly than leaf-node deletion.

For any OU that you want to protect from accidental deletion, you can add explicit Deny Delete and Deny Delete Subtree advanced permissions to the Everyone group on that container object. To further protect the OU, you can add the explicit Deny Delete All Child Objects permission on the parent container of the OU that you want to protect. The explicit Deny access control entries (ACEs) take precedence over any Allow permissions that the user might have on the container, including inherited permissions.

| **Note** |
| --- |
| To prevent accidental deletion in Windows Server 2008, you can select the **Protect object against accidental deletion** check box when you create a new object or you can select this check box on the **Object** tab of the **Properties** property sheet for an existing object. This feature is available for all objects that appear either in Active Directory Users and Computers or Active Directory Sites and Services. |

**Task requirements**

The following tool is required if you want to perform the procedures for this task by using the Windows interface. For more information about performing this task by using Dsacls.exe at the command line or by using a script, see Script to Protect Organizational Units (OUs) from Accidental Deletion (http://go.microsoft.com/fwlink/?LinkId=162623).

- Active Directory Users and Computers (dsa.msc).

To complete this task by using the Windows interface, perform the following procedures as needed:

- Protect an Organizational Unit from Accidental Deletion

- Remove Protection Against Accidental Organizational Unit Deletion

# Protect an Organizational Unit from Accidental Deletion

Updated: January 7, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to add the following access control entries (ACEs):

- On the organizational unit (OU) that you want to protect, add explicit Deny ACEs for the Delete and Delete Subtree advanced permissions for the Everyone group.
- On the parent container of the OU that you want to protect, add an explicit Deny ACE for the Delete All Child Objects permission for the Everyone group.

This protects an OU from accidental deletion. When a user tries to delete the protected object, the operation returns an error that indicates access is denied.

To remove the protection, remove the Deny ACEs that you added for the Everyone group. For more information, see Remove Protection Against Accidental Organizational Unit Deletion.

Although bulk deletions are not common in the configuration partition data that you can view with the Active Directory Sites and Services snap-in, you can apply the same method to protect objects in the configuration partition by using adsiedit.msc.

Membership in the Domain Admins group, or equivalent, is required to complete this procedure.

**To protect an OU from accidental bulk deletion**

1. Log on to the computer as a member of the Domain Admins group.
2. Open Active Directory Users and Computers.
3. Click **View**, and then click **Advanced Features**.
4. First, apply permissions on the OU that you want to protect. To do this, right-click the OU that you want to protect, and then click **Properties**.
5. In *OU* **Properties**, click the **Security** tab, and then click **Advanced**.
6. On **Advanced Security Settings**, click **Add**, type **Everyone**, and then click **OK**.
7. In **Permission Entry**, in **Permissions**, select the **Deny** check boxes for **Delete** and **Delete subtree**.
8. Select the check box for **Apply these permissions to objects and/or containers within this container only**.
9. Click **OK** to close **Permission Entry**.
10. On **Advanced Security Settings**, click **Apply**.
11. Review the Windows Security warning, and then click **Yes** to continue.
12. Click **OK** to close the **Advanced Security Settings**, and then click **OK** to close *OU* **Properties**.
13. Second, apply permissions to the parent container of the OU that you want to protect. To do this, right-click the parent container, and then click **Properties**.
14. In *Container***Properties**, click the **Security** tab.
15. Click **Add**, type **Everyone**, and then click **OK**.
16. In **Permissions for Everyone**, select the **Deny** check box for **Delete All Child Objects**, and then click **Apply**.
17. Review the Windows Security warning, and then click **Yes** to continue.
18. Click **OK** to close *Container* **Properties**.

# Remove Protection Against Accidental Organizational Unit Deletion

Updated: January 7, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to remove the following access control entries (ACEs):

- On the organizational unit (OU) for which you are removing protection, remove explicit Deny ACEs for the Delete and Delete Subtree advanced permissions for the Everyone group.

- On the parent container of the OU for which you are removing protection, remove an explicit Deny ACE for the Delete All Child Objects permission for the Everyone group.

This removes protection that prevents an OU from accidental deletion. Consequently, you may have to remove these permissions to be able to perform bulk deletions of objects in Active Directory.

To add the protection back again, you can reselect the **Deny** check boxes for the Delete and Delete Subtree advanced permissions for the Everyone group for the OU and the Delete All Child Objects permission for the Everyone group on the parent container. For more information, see Protect an Organizational Unit from Accidental Deletion.

Membership in the Domain Admins group, or equivalent, is required to complete this procedure.

**To remove protection that prevents an OU from accidental deletion**

1. Log on to the computer as a member of the Domain Admins group.
2. Open Active Directory Users and Computers.
3. Click **View**, and then click **Advanced Features**.
4. First, clear permissions on the OU for which you want to remove protection. To do this, right-click the OU, and then click **Properties**.
5. In *OU* **Properties**, click the **Security** tab, and then click **Advanced**.
6. In **Permission Entries**, select the **Deny** entry for the **Everyone** group, and then click **Remove**.
7. Click **OK** to close the **Advanced Security Settings**, and then click **OK** to close *OU* **Properties**.
8. Second, clear permissions on the parent container of the OU for which you want to remove protection. To do this, right-click the parent container, and then click **Properties**.
9. In *Container***Properties**, click the **Security** tab.
10. In Group or user names, select the **Everyone** group, and then clear the **Deny** check box for **Delete All Child Objects**, and then click **OK** to close *Container* **Properties**.

# Administering Domain Controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides information for administering Active Directory domain controllers in the Microsoft Windows Server 2003 operating system.

**In this guide**

- Introduction to Administering Domain Controllers
- Managing Domain Controllers

# Introduction to Administering Domain Controllers

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Although installed domain controllers require little management, your overall operations environment might require change-related tasks such as adding or removing domain controllers, including managing the preparation and shipment of domain controllers to remote sites. During your day-to-day operations, you might need to do some or all of the following:

- Install and remove Active Directory
- Rename domain controllers
- Add domain controllers to remote sites

**Installing and Removing Active Directory**

To create a new domain controller, install Active Directory on a computer that is running Windows Server 2003 or Windows Server 2003 with Service Pack 1 (SP1). Installing domain controllers to create a forest and new domains is a deployment task that you perform when you initially deploy your forest, and it is beyond the scope of this guide. However, as your forest grows, you might need to add more domain controllers to existing domains.

There are several reasons for adding a new domain controller. Additional applications (which are Active Directory–integrated as opposed to running on domain controllers) might be required to meet increased capacity requirements, provide upgrades and fault tolerance, and reduce failures. You might add a new site where users require a domain controller for logging on to the domain. For more information about criteria and best practices for deploying domain controllers, see Designing and Deploying Directory and Security Services on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45801).

When a domain controller is no longer needed, remove Active Directory. The process of removing Active Directory involves steps similar to the steps for installation. You run many of the same tests before you remove the directory as you ran before you installed the directory. These tests ensure that the process occurs without any problems. In the event that a domain controller suffers a hardware failure and you plan to never return it to service, you must use a procedure that forces Active Directory removal and then take additional steps to remove the server object and its metadata from the directory.

**Renaming Domain Controllers**

You often need to rename a domain controller for organizational or administrative reasons or when the computer hardware must be replaced. Renaming a domain controller requires that Domain Name System (DNS) resource records be updated with the new Internet Protocol (IP)-to-host name mappings and that service principal names (SPNs) replicate to all domain controllers in the domain. You must also update File Replication service (FRS) objects.

**Adding Domain Controllers to Remote Sites**

If enough directory users are employed in a remote site, especially in a site that has slow connectivity to the hub site, you might need to add a domain controller to the site to provide directory access for logons and searches. Specifically, you can either install a domain controller in the hub site and ship it to the site or install the domain controller in the remote site. When you install the domain controller in the remote site, Active Directory must be sourced in one of two ways:

- By Active Directory replication over the wide area network (WAN) link
- Directly from restored backup media

Assuming that the remote site is connected to a hub site by a WAN link and does not contain a domain controller for the domain, you might want to avoid the additional time and the performance impact of replicating the full replica of Active Directory over the WAN when you add a new domain controller to the remote site. In this case, you can use backup media to install Active Directory.

If you want to install a domain controller from backup media, both the source of the backup and the target server that is to be promoted to a domain controller must be running Windows Server 2003 or Windows Server 2003 with SP1, and the operating system of the source of the backup and the target server must be the same. The hardware platform (32-bit or 64-bit) of the two computers must also match. Restoring from backup media eliminates the need to use replication to create the Active Directory replica on the new domain controller.

# Managing Domain Controllers

Updated: April 15, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Managing domain controllers involves the following tasks:

- Create an additional domain controller in an existing domain. This task involves preparation steps of gathering information and configuring the TCP/IP and Domain Name System (DNS) client settings. You can use the following methods to install Active Directory to create an additional domain controller in an existing domain:
    - Run the Active Directory Installation Wizard, and use Active Directory replication to create the Active Directory replica and File Replication Service (FRS) replication to create the System Volume (Sysvol) replicas.
    - Run the Active Directory Installation Wizard, and use restored system state backup media to create the Active Directory and Sysvol replicas.
    - Create an answer file and use the Unattend.txt file to provide the information that the Active Directory Installation Wizard requires.
- Perform tests to verify that Active Directory is properly installed and the domain controller is functioning.
- Add domain controllers to remote sites. When you prepare and ship an additional domain controller to a remote site, you can either install the domain controller before shipping or install the domain controller in the remote site.
    - When you install a domain controller in a hub site or staging site before shipment, you must disconnect the domain controller for a period, which requires careful preparation. When you reconnect the domain controller, Active Directory replication brings the domain controller up to date.
    - When you install the domain controller in the remote site, you can use a restored system state backup to avoid having to replicate Active Directory over a wide area network (WAN) link.
- Remove Active Directory from (decommission) a properly functioning domain controller. This task includes first removing operations master roles (also known as flexible single-master operation (FSMO) roles) and the global catalog, if necessary.
- Force the removal of a nonfunctioning domain controller from a domain. If a domain controller is not functioning properly on the network, the Active Directory Installation Wizard cannot contact other domain controllers and DNS servers that are required for Active Directory removal. In this case, a special version of the wizard can be invoked to forcefully remove objects that represent the server as a domain controller from Active Directory.
- Rename a domain controller. You can now rename a domain controller without removing Active Directory. New functionality is available in the Netdom tool when the domain functional level is Windows Server 2003. This new functionality provides better preparation for DNS and service recognition of the new domain controller name. You can also use System Properties, which does not require a domain functional level and does not provide the same preparation, but which relies solely on replication to update the domain controller DNS name and service principal name (SPN). This method can result in a longer delay before clients can use the renamed domain controller.

In addition, to protect domain controllers from infection by viruses that can corrupt directory data or cause software or hardware failure, an integral step in installing any domain controller is to install antivirus software.

**Managing Antivirus Software on Domain Controllers**

Because domain controllers provide critical services to their clients, it is crucial to minimize the risk of disruption of these services caused by malicious code.

Antivirus software is the generally accepted way to mitigate the risk of such malevolent activity. However, one cannot simply install the antivirus software (from any vendor) on a domain controller and tell it to scan everything. Instead, it must be

installed in a manner that mitigates the risk to the highest possible level while not interfering with the performance of the domain controllers in performing their directory service duties.

Installing effective antivirus software on domain controllers minimizes the risk that their activities will be disrupted by malicious code.

**Guidelines for Managing Antivirus Software on Domain Controllers**
Follow the guidelines established by your antivirus software vendor.

| **Note** |
| --- |
| Verify that the antivirus software you are adding is confirmed to work on domain controllers. |

The following recommendations are general and should not be construed as more important than the specific antivirus software vendor's own recommendations. These guidelines must be followed for correct Active Directory and FRS operation.

| **Note** |
| --- |
| Test the chosen antivirus software solution thoroughly in a lab environment to ensure that the software does not compromise the stability of the system. |

- Antivirus software must be installed on all domain controllers in the enterprise. Ideally, such software should also be installed on all other server and client systems that have to interact with the domain controllers. Catching the virus at the earliest point, at the firewall, or the client system on which the virus is first introduced is best—that will prevent the virus from ever reaching the infrastructure systems upon which all clients depend.

- Use a version of antivirus software that is confirmed to work with Active Directory and uses the correct APIs for accessing files on the server. Older versions of most vendors' software inappropriately modified file metadata as it was scanned, causing the FRS replication engine to think the file was changed and to schedule it for replication. Newer versions prevent this problem. For more information about antivirus software versions and FRS, see article 815263, "Antivirus, backup, and disk optimization programs that are compatible with the File Replication Service" in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkID=4441), and see the vendor-specific sites for compliant versions.

- Prevent the use of domain controller systems as general workstations. Users should not be using a domain controller to surf the Web or perform any other activities that could allow the introduction of malicious code.

- When possible, do not use the domain controller as a file sharing server. Virus scanning software must be run against all files in those shares and could place an unsatisfactory load on the processor and memory resources of the server.

**Known Issues with McAfee VirusScan 8.0 Antivirus Software**
McAfee VirusScan version 8.0 is known to cause problems when it is installed on a domain controller. Patching levels for McAfee VirusScan might also affect domain controller performance. If you have installed McAfee VirusScan version 8.0 on a domain controller, make the following changes:

1. Disable the **Buffer Overflow Protection** feature in the **VirusScan Console**. Buffer Overflow Protection is intended to be used on workstations only and might cause problems if used on a server role computer with a high IO load.

2. Disable the following driver:

   File name and location: C:\Windows\System32\Drivers\mfetdik.sys

   Company name: McAfee, Inc.

   File description: Anti-Virus Mini-Firewall Driver

   The driver is known to cause system crashes. To reduce complexity and increase system reliability, perform the following steps to disable the Anti-Virus Mini-Firewall Driver MVSDTi5x.SYS on servers:

a. In Registry Editor, navigate to HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\naiavtdi1.

b. Set **Start** to a value of **4**, which is disabled.

**Files Not at Risk of Infection**

Exclude the following files and folders from being scanned. These files are not at risk of infection and including them could cause serious performance problems due to file locking and excessive replication between domain controllers. Furthermore, they may cause Active Directory and FRS to work improperly, causing Active Directory or FRS data loss. Where a specific set of files is identified by name, exclude only those files rather than the entire folder. In some cases, the entire folder must be excluded.

Do not exclude any of these based on the file name extension (that is, do not exclude all files with a .dit extension). Microsoft has no control over other files that might choose to use the same extension as those shown here. AV software must not modify any data files in the logs, database, and/or DSA working directories specified below.

- Main NTDS database files. The location of these files is specified in:

  **HKEY_LOCAL_MACHINE \System\CurrentControlSet\Services\NTDS\Parameters\DSA Database File**

  Default location is %windir%\ntds

  The file to exclude is: **NTDS.dit**

- Active Directory transaction log files. The log directory on any given server is specified in:

  **HKEY_LOCAL_MACHINE \System\CurrentControlSet\Services\NTDS\Parameters\Database Log Files Path**

  Default location is %windir%\ntds.

  The specific files to exclude are:

  - EDB*.log (notice the wildcard—there can be several)
  - RES1.log
  - RES2.log

- NTDS Working folder specified in:

  **HKEY_LOCAL_MACHINE \System\CurrentControlSet\Services\NTDS\Parameters\DSA Working Directory**

  Specific files to exclude are:

  - TEMP.edb
  - EDB.chk

- SYSVOL. Use the following table for folders and files to scan or exclude:

| Folder or File | Scan or Exclude |
|---|---|
| %systemroot%\SYSVOL | Exclude |
| %systemroot%\SYSVOL\domain | Scan |
| %systemroot%\SYSVOL\domain\DO_NOT_REMOVE_NtFrs_PreInstall_Directory | Exclude |
| %systemroot%\SYSVOL\domain\policies | Scan |

| | |
|---|---|
| %systemroot%\SYSVOL\domain\scripts | Scan |
| %systemroot%\SYSVOL\staging | Exclude |
| %systemroot%\SYSVOL\staging areas | Exclude |
| %systemroot%\SYSVOL\sysvol | Exclude |

- FRS Working Directory specified in:

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Working Directory**

  Files to exclude:

  - <FRS Working Directory>\jet\sys\edb.chk
  - <FRS Working Directory>\jet\ntfrs.jdb
  - <FRS Working Directory>\jet\log*.log

- FRS Database Log files specified in:

  **HKEY_LOCAL_MACHINE\system\currentcontrolset\services\NtFrs\Parameters\DB Log File Directory**

  Default location is %windir%\ntds.

  Files to exclude:

  - <FRS Working Directory>\jet\log*.log (if registry entry is not set)
  - <DB Log File Directory>\log*.log (if registry entry is set)

- FRS Replica_root files specified in:

  **HKEY_LOCAL_MACHINE\system\currentcontrolset\services\NtFrs\Parameters\Replica Sets\GUID\Replica Set Root**

- Staging directory found in:

  **HKEY_LOCAL_MACHINE\system\currentcontrolset\services\NtFrs\Parameters\Replica Sets\GUID\Replica Set Stage**

- FRS Preinstall directory located at:

  **<Replica_root>\DO_NOT_REMOVE_NtFrs_PreInstall_Directory**.

  The Preinstall directory is always open exclusively when FRS is running.

The following tasks for managing domain controllers are described in this objective:

- Preparing for Active Directory Installation
- Installing a Domain Controller in an Existing Domain
- Adding Domain Controllers in Remote Sites
- Installing a Domain Controller in an Existing Domain Using Restored Backup Media

- Performing an Unattended Installation of Active Directory
- Verifying Active Directory Installation
- Renaming a Domain Controller
- Decommissioning a Domain Controller
- Forcing the Removal of a Domain Controller

# Preparing for Active Directory Installation

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Properly preparing for the installation of Active Directory decreases the chances of problems occurring during the installation process and helps you quickly complete the operation.

There are a number of requirements for installing Active Directory on a new domain controller in an existing domain. This task addresses general requirements with respect to Domain Name System (DNS) configuration, placement of the domain controller in a site, and connectivity for the Active Directory Installation Wizard.

After you have gathered all the information that you need to run the Active Directory Installation Wizard and you have performed the tests to verify that all the necessary domain controllers are available, you are ready to install Active Directory on your server and create an additional domain controller in the domain.

Preparation includes installing and configuring DNS and gathering information that you need for the installation.

**Configuring DNS**
The DNS client is always present on a server running Windows Server 2003. A DNS server must be present in the forest that stores DNS data for the server. You should properly configure both the DNS client and the DNS server to ensure that name resolution and related dependencies will function as expected during the installation of Active Directory.

Ensure that any required configuration, forwarders, or zones are present and accessible prior to installation. For more information about DNS configuration best practices, see Designing the Active Directory Logical Structure on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=25466).

**Site Placement**
During installation, the Active Directory Installation Wizard attempts to place the new domain controller in the appropriate site. The appropriate site is determined by the domain controller's IP address and subnet mask. The wizard uses the IP information to calculate the subnet address of the domain controller and checks to see if a Subnet object exists in the directory for that subnet address. If the Subnet object exists, the wizard uses it to place the new Server object in the appropriate site. If not, the wizard places the new Server object in the same site as the domain controller that is being used as a source to replicate the directory database to the new domain controller. Make sure the Subnet object has been created for the desired site prior to running the wizard.

A site is allocated according to the following rules:

1. If you specify a site in the Unattended text file that is used to create the new domain controller, the domain controller will be placed directly into that site when it is built.

2. If no site is specified in the Unattended text file when the new domain controller is built, then by default the domain controller will be placed in a site based on its IP address.

3. If you specify a replica partner in the Unattended text file but do not specify a site, the new domain controller should be placed in the replica partner's site.

4. If the replica partner or site is not specified, then the allocation of the site is random. It will depend on the replica partner selected for initial replication.

**Domain Connectivity**
During the installation process, the Active Directory Installation Wizard needs to communicate with other domain controllers to join the new domain controller to the domain. The wizard needs to communicate with a member of the domain to receive the initial copy of the directory database for the new domain controller. It communicates with the domain naming master for domain installs only, so that the new domain controller can be added to the domain. The wizard also needs to contact the relative ID (RID) master so that the new domain controller can receive its RID pool, and it needs to communicate with another domain controller in order to populate the SYSVOL shared folder on the new domain controller. All of this communication depends on proper DNS installation and configuration. By using Netdiag.exe and Dcdiag.exe, you can test all of these connections prior to starting the Active Directory Installation Wizard.

## Task requirements

During the installation process, the wizard needs to communicate with other domain controllers to add this new domain controller to the domain and get the appropriate information into the Active Directory database. To maintain security, you must provide credentials that allow administrative access to the directory.

Before you begin your installation, the following conditions must exist in your environment:

- Your Active Directory forest root domain must already exist.
- If you are installing a new domain controller in a child domain, there should be at least two properly functioning domain controllers in the forest root domain.
- DNS must be functioning properly. In this guide, it is assumed that you are using Active Directory–integrated DNS zones. You must have configured at least one domain controller as a DNS server.

Creating or removing a domain or forest is beyond the scope of this guide.

The following information and tools are necessary to complete this task:

- The Active Directory Installation Wizard asks for the following specific configuration information before it begins installing Active Directory:
    - A domain administrator's user name and password
    - A location to store the directory database and log files
    - A location to store the shared system volume files (SYSVOL)
    - The password to use for Directory Services Restore Mode
    - The fully qualified DNS name of the domain to which the new domain controller will be added
- My Network Places
- Adsiedit.msc
- Netdiag.exe
- Active Directory Sites and Services
- Dcdiag.exe

To complete this task, perform the following procedures:

1. Install the DNS Server service
2. Verify DNS registration and functionality
3. Verify that an IP address maps to a subnet and determine the site association
4. Verify communication with other domain controllers
5. Verify the availability of the operations masters

| **Caution** |
| --- |
| If any verification test fails, do not continue until you determine what went wrong and fix the problems. If these tests fail, the installation is also likely to fail. |

# Install the DNS Server service

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Assign a static IP address, rather than a dynamically-assigned IP address, to any computer that acts as a DNS server. To perform this procedure, your DNS infrastructure must already exist, function properly, and be configured to use Active Directory-integrated zones. This procedure describes the steps to add an additional DNS server into the DNS infrastructure.

**Administrative Credentials**

To perform this procedure, you must be a member of either the Domain Admins group or the Enterprise Admins group.

**To install the DNS server service**

1. Ensure that the computer is using a static IP address by right-clicking **My Network Places** and then clicking **Properties**.
2. In the **Network Connections** dialog box, right-click the connection that represents the connection this computer uses to attach to your network. The default label is Local Area Connection, but this can be changed, so it might not be labeled the same on your computer. Click **Properties**.
3. In the **Local Area Connection Properties** dialog box, click once on **Internet Protocol (TCP/IP)** to highlight it (be sure that you do not clear the check box in front of it), and then click **Properties**.
4. In the **Internet Protocol (TCP/IP) Properties** dialog box, ensure that **Use the following IP address:** is selected and that a valid IP address, subnet mask, and default gateway appear. Click **OK** to close the dialog box. Click **OK** again to return to your desktop.
5. In **Control Panel**, click **Add or Remove Programs**. Click **Add/Remove Windows Components.**
6. Scroll down to **Networking Services**. Highlight it and click **Details**.
7. In the **Networking Services** dialog box, select the check box in front of **Domain Name System (DNS)**. Click **OK**.
8. Click **Next**. Provide the location of the installation files, if necessary. After the installation is complete, click **Finish** to end the wizard, and then click **Close** to exit **Add or Remove Programs**.

# Verify DNS registration and functionality

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that Domain Name System (DNS) is functioning so that other domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify DNS registration and functionality**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **dcdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If DNS is functioning, the last line of the response for all operating system versions is **DNS Test.....: Passed**. The verbose option lists specific information about what was tested. This information can help with troubleshooting if the test fails.

   If the test fails, do not attempt any additional steps until you determine and fix the problem that prevents proper DNS functionality.

# Verify that an IP address maps to a subnet and determine the site association

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to determine the site to which you want to add a Server object prior to installing Active Directory, or to verify the appropriate site prior to moving a Server object to it.

To be associated with a site, the IP address of a domain controller must map to a Subnet object that is defined in Active Directory. The site to which the subnet is associated is the site of the domain controller.

The subnet address, which is computed from the IP network address and the subnet mask, is the name of a Subnet object in Active Directory. When you know the subnet address, you can locate the Subnet object and determine the site to which the subnet is associated.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To verify that an IP address maps to a subnet and determine the site association**

1. Log on locally or open a Terminal Services connection to the server for which you want to check the IP address.
2. On the desktop, right-click **My Network Places**, and then click **Properties**.
3. In the **Network Connections** dialog box, right-click **Local Area Connection**, and then click **Properties**.
4. Double-click **Internet Protocol (TCP/IP)**.
5. Use the values in **IP address** and **Subnet mask** to calculate the subnet address and then click **OK**.
6. Click **OK** again and close the **Network Connections** dialog box.
7. Open Active Directory Sites and Services.
8. Expand the **Sites** container, and then click the **Subnets** container.
9. In the **Name** column in the details pane, find the Subnet object that matches the subnet address.
10. In the **Site** column, note the site to which the IP subnet address is associated.

    If the site that appears in the **Site** box is not the appropriate site, contact a supervisor and find out whether the IP address is incorrect or whether to move the Server object to the site indicated by the subnet.

# Verify communication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

**To verify communication with other domain controllers**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dsgetdc**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If domain controllers are successfully located, the last line of the response is **DC discovery test.....: Passed.** The verbose option lists the specific domain controllers that are located.

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **nltest /dclist:** <*domain name*>

   If domain controllers are successfully located, the last line of the response is **The command completed successfully**.

   If the tests fail on any of the operating system versions, do not attempt any additional steps until you determine and fix the problem that prevents communication with other domain controllers.

# Verify the availability of the operations masters

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that the operations masters can be located and that they are online and responding.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

| **Note** |
| --- |
| You can use these tests prior to installing Active Directory as well as afterward. To perform the test prior to installing Active Directory, you must use the **/s** option to indicate the name of a domain controller to use. You do not need the **/s** option to perform the test after installing Active Directory. The test automatically runs on the local domain controller where you are performing the test. The commands listed in this procedure show the **/s** option. If you are performing this test after installing Active Directory, omit the **/s** option. For a more detailed response from this command, you can use the verbose option by adding **/v** to the end of the command to see the detailed response. |

**To verify the availability of the operations masters**

1. Open a Command Prompt.
2. Type the following command to ensure that the operations masters can be located and then press ENTER:

   **dcdiag /s:** *domaincontroller* **/test:knowsofroleholders /verbose**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of the screen, a message confirms that the test succeeded. If you use the verbose option, look carefully at the bottom part of the displayed output. The test confirmation message appears immediately after the list of operations masters. Press ENTER.
3. Type the following command to ensure that the operations masters are functioning properly and are available on the network:

   **dcdiag /s:** *domaincontroller* **/test:fsmocheck**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of your screen, a message confirms that the test succeeded. Press ENTER.

   If these tests fail, do not attempt any additional steps until you determine and fix the problem that prevents locating operations masters and verifying that they are functioning properly.

# Installing a Domain Controller in an Existing Domain

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This task covers the installation of Active Directory onto a Windows Server 2003 system that will become a domain controller in an existing Active Directory domain. To ensure successful installation of a new domain controller, you should verify that all critical services that Active Directory depends on are configured following Microsoft best practices. For more information about best practices for planning, testing, and deploying Active Directory, see Designing and Deploying Directory and Security Services on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=27638).

**Task Requirements**

The following tool is required to perform the procedure for this task:

Dcpromo.exe

To complete this task, perform the following procedure:

- Install Active Directory

**Note**

By default, when a domain controller account is added to the existing Active Directory domain, it is assigned an "Account Ops-FC" access control entry (ACE) that gives members of the Account Operators group full control over this domain controller account, which is not a recommended configuration. For example, members of Account Operators group will be able to reset this domain controller's password. Because the Account Operators group has significant power in the domain, we recommend that you add members to it with caution. For a detailed description of the Account Operators group, see Default groups (http://go.microsoft.com/fwlink/?LinkID=131422). To modify permissions for Account Operators on a computer account, you can use the Active Directory Users and Computers snap-in and complete the following steps:

1. To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
2. In the console tree, right-click the affected domain controller account and then click **Properties**.
3. On the **Security** tab, select **Account Operators** in the **Group or user names** list, and then modify permissions according to the specifications of your environment.

You can also install Active Directory from installation media or by performing an unattended installation. For information about completing each of these tasks, see the following:

Installing a Domain Controller in an Existing Domain Using Restored Backup Media

Performing an Unattended Installation of Active Directory

# Install Active Directory

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the Active Directory Installation Wizard to install Active Directory on a member server in your domain to create an additional domain controller in an existing domain.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To install Active Directory**

1. Click **Start**, click **Run**, type **dcpromo** and then press ENTER.
2. The Active Directory Installation Wizard appears. At the Welcome screen, click **Next**.
3. For **Domain Controller Type**, select **Additional domain controller for an existing domain**. Click **Next**.
4. For **Network Credentials**, enter the user name, password, and domain for the user account that has permission to add this new domain controller to the domain. Click **Next**.
5. Enter the name of the domain that you want the new domain controller to host. Click **Next**.
6. For **Database and Log Locations**, enter the paths for the locations of the directory database (Ntds.dit) and the log files. For better performance, store the database and log files on separate physical disk drives. Click **Next**.
7. For **Shared System Volume**, enter the path where you want to locate the system volume (SYSVOL). Click **Next**.
8. Under **Directory Services Restore Mode Administrator Password**, enter the password that you want to use when you need to start Directory Services Restore Mode. Click **Next**.
9. The **Summary** screen displays a list of the items you chose. Verify that the information is correct, and then click **Next** to proceed with the installation.
10. The wizard proceeds to install Active Directory. When it finishes, the wizard displays a summary screen listing the domain and site in which the new domain controller is a member. Verify that this information is correct. Click **Finish** to close the wizard.
11. Click **Restart** to restart the domain controller.
12. Let the domain controller restart. If any message indicates that one or more services has failed to start, restart the domain controller one more time. If the initial replication cycles have not had enough time to complete during the first restart on a new domain controller, some services may be unable to start successfully. If the message appears during additional restarts, examine the event logs in Event Viewer to determine the cause of the problem.

# Installing a Domain Controller in an Existing Domain Using Restored Backup Media

Updated: December 5, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you install Active Directory from restored backup media, you can reduce the replication traffic that is initiated during the installation of an additional domain controller in an Active Directory domain. Reducing the replication traffic reduces the time necessary to install the additional domain controller.

The procedures in this task are particularly useful for installing domain controllers in remote sites. By using these procedures, you can avoid having to either replicate the entire Active Directory replica over a wide area network (WAN) link or disconnect an existing domain controller while it is being shipped to the remote site. If you are installing additional domain controllers in remote sites and you want to minimize the Active Directory and SYSVOL replication that is required during the installation from backup media, use the information in this topic in conjunction with the information in Adding Domain Controllers in Remote Sites.

When the domain controller that you are installing will be a Domain Name System (DNS) server and you are using Active Directory–integrated DNS zones, the DomainDNSZones and ForestDNSZones application directory partitions are not included in the restored backup media by default. If you want to include application directory partitions in the restored backup media that is used to install Active Directory, additional procedures are required to complete the installation task. Follow the instructions for including application directory partitions in the installation media.

**Task requirements**

To begin the task to install a domain controller from restored backup media without application directory partitions, ensure that the following requirements are met:

- A Windows Server 2003–based domain controller must be running in each domain where you will be performing installations from backup media.
- The restored system state backup that is used to create additional domain controllers must be taken from a domain controller in the same domain as the new additional domain controller.
- The server that is being installed as a domain controller must be running Windows Server 2003, and the version must be the same as the domain controller from which the backup was taken. For example, you cannot use backup media from a domain controller running Windows Server 2003 to create a domain controller running Windows Server 2003 with Service Pack 1 (SP1). The reverse is also true.
- The restored system state backup that is used to create additional domain controllers must be taken on a domain controller that matches the processor type of the new domain controller. System state backups that are taken on a domain controller that has a 32-bit processor cannot be used to install a domain controller that has a 64-bit processor. The reverse is also true.
- During Active Directory installation, Dcpromo checks that the value of the tombstone lifetime in the restored system state backup matches the value on an existing domain controller. If you plan to change the value of the tombstone lifetime, change this value before you create the backup.
- If the domain controller that you are creating is to be a global catalog server, the system state backup that you restore must be taken from an existing global catalog server in the domain.

On servers that are running Windows Server 2003 with SP1, you can use restored backup media to install a domain controller that is a DNS server (stores the DomainDNSZones and ForestDNSZones application directory partitions) or that stores other application directory partitions. In addition to the previous requirements, to begin the task to install a domain controller from restored backup media that includes application directory partitions, ensure that the following requirements are met:

- The forest functional level has been raised to Windows Server 2003.
- The domain controller on which you created the system state backup is running Windows Server 2003 with SP1.

- The domain controller on which you created the system state backup contains the application directory partitions that you want to include.
- The server computer that you are installing is running Windows Server 2003 with SP1.
- You have created an answer file that contains the distinguished names (or * for all names) of the application directory partitions that you want to include.

The following tools are required to perform the procedures for this task:

- Ntbackup.exe
- Dcpromo.exe
- Ref.chm or Unattend.txt file, or both, for installations that include application directory partitions.

To complete this task, perform the procedures for the following methods:

1. Back up system state

   Back up the system state of an existing domain controller according to the requirements described above.

2. As an option, before you restore the backup, copy the .bkf file to a CD, DVD, or other removable media from which you will subsequently restore the backup to an alternate location on the local hard drive of the server on which Active Directory is being installed. You can use this media to restore the same backup to any number of servers that will be installed as domain controllers. With this method, you restore the backup for each domain controller that you install. Compare this method to method 3.2, in which you restore the backup only once and copy the restored files to the removable media.

3. Restore system state to an alternate location

   Select the location for the system state backup that you will use to install a new domain controller. Use one of the following locations for restoring the system state backup:

   - Restore the .bkf file to a volume on the server that will be installed as a domain controller. We recommend restoring to a folder named \NTDSRESTORE on the volume that will host the Ntds.dit file when Dcpromo is run, if space permits. Otherwise, restore to a folder named \NTDSRESTORE on a volume that has sufficient free space. For additional criteria regarding the volume on which you restore the backup, see Adding Domain Controllers in Remote Sites.
   - Restore the .bkf file to the local hard drive of any computer, and then burn the expanded restore tree to a CD, DVD, or other removable storage media. Install Active Directory directly from this media. You can use this media to directly install any number of domain controllers. With this method, you restore the backup only once.

4. Install Active Directory from media.

   Install the domain controller from the system state backup that you restored in step 3 by using one of the following methods:

   - Install Active Directory from restored backup media to create a new domain controller that does not include application directory partitions.
   - Include application directory partitions in an Active Directory installation from backup media to create a new domain controller that contains application directory partitions. (See the special requirements described earlier in

this section.) This method uses an answer file to specify the application directory partitions to include in the Active Directory installation. To use this method, you must first Create an answer file for domain controller installation. You can also include instructions to install the DNS Server service in the answer file.

Create an answer file for domain controller installation

# Back up system state

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Ntbackup.exe provides simple and advanced options for backing up Active Directory components. When you back up system state, you can choose to include or exclude system-protected boot files. System-protected boot files are not used for installations from restored backup media. When the backup file that you create is to be used for additional domain controller installations, you can clear the advanced option to back up system-protected files. Clearing this option decreases the size of the .bkf file, as well as the time required to back up, restore, and copy the system state files.

Use these procedures to back up the system state only. These procedures do not back up the system disk or any other data on the domain controller except for the system-protected files.

Use the first procedure, "To back up system state including system-protected files," for routine system state backup. Use the second procedure, "To back up system state excluding system-protected files," if you want to create a smaller backup that is effective for installing domain controllers from restored backup media.

| **Note** |
| --- |
| To back up system state, you must log on locally to the domain controller, or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

- To perform the following two procedures, you must be a member of the Domain Admins group or a member of the Backup Operators group.

#### To back up system state including system-protected files

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.

   This procedure provides steps for backing up in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.

2. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
3. Select **Back up files and settings**, and then click **Next**.
4. Select **Let me choose what to back up**, and then click **Next**.
5. In the **Items to Back Up** window, double-click **My Computer**.
6. In the expanded list below **My Computer**, check **System State**, and then click **Next**.
7. Select a location to store the backup:

   - If you are backing up to a file, type the path and file name for the backup (.bkf) file (or click **Browse** to find a folder or file).

   - If you are backing up to a tape unit, choose the tape that you want to use.

     | **Note** |
     | --- |
     | You should not store the backup on the local hard drive. Instead, store it in a location, such as a tape drive, away from the computer that you are backing up. |

8. Type a name for this backup according to the recommendations in Backing Up Active Directory Components, and then click **Next**.
9. On the last page of the wizard, click **Advanced**.

10. Do not change the default options for **Type of Backup**. **Normal** should be selected, and the check box for **Backup migrated remote storage data** should remain cleared. Click **Next**.
11. Select **Verify data after backup**, and then click **Next**.
12. In the **Backup Options** dialog box, select a backup option, and then click **Next**.
13. If you are replacing the existing backups, select the option to allow only the owner and administrator access to the backup data and to any backups that are appended to this medium, and then click **Next**.
14. In the **When to back up** box, select the appropriate option for your needs, and then click **Next**.
15. If you are satisfied with all of the options that are selected, click **Finish** to perform the backup operation according to your selected schedule.

| **Note** |
| --- |
| The system state can also be backed up by using Ntbackup from a command line with appropriate parameters. For more information, at a command prompt type **ntbackup /?**. |

The following procedure produces a smaller .bkf file that does not include system boot files. By using this procedure, you can reduce the time that is required to perform the backup and subsequent restore, as well as the amount of disk space that is required. This method is recommended when the restored backup is to be used for installing additional domain controllers.

**To back up system state excluding system-protected files**

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.
2. On the **Welcome to the Backup or Restore Wizard** page, click **Advanced Mode**, and then click the **Backup** tab.
3. In the console tree, select the **System State** check box.
4. In **Backup media or file name**, type a name for this backup according to the recommendations in Backing Up Active Directory Components.
5. Click **Start Backup**, and then click **Advanced**.
6. Clear the **Automatically back up System Protected Files with the System State** check box, and then click **OK**.
7. Click **Start Backup**.

Create a Remote Desktop Connection

# Restore system state to an alternate location

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Perform this procedure to create media for installing a domain controller from restored backup media or to allow an authoritative restore of SYSVOL. After the domain controller installation is complete, delete the files in the alternate location.

You can restore the system state backup to an alternate location on the domain controller from which the backup was made, a location on another computer, or a location on the computer that you want to install as a domain controller.

**Administrative credentials**

To perform this procedure, you must be a member of the Backup Operators group, as follows:

- Restore system state on a member or workgroup server: Backup Operators group on the local computer
- Restore system state on a domain controller: Backup Operators group in the domain

**To restore system state to an alternate location**

1. Log on to the server that has the alternate location to which you are restoring system state backup files.
2. Click **Start**, click **Run**, type **ntbackup**, and then click **OK**.
3. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
4. Click **Restore Files and settings**, and then click **Next**.
5. On the **What to Restore** page, click **Browse**, and then, in the **Open Backup File** dialog box, click **Browse** again.
6. Navigate to the .bkf file that you want to restore to an alternate location. The .bkf file can be located in a folder on the current computer, in a shared folder on the backup computer or other network computer, or on an external drive that contains removable media.
7. In the **Select file for catalog** dialog box, click the .bkf file that you want to restore, and then click **Open**.
8. In the **Open Backup File** dialog box, click **OK**.
9. In **Items to restore**, double-click **File**, and then double-click the .bkf file that you want to restore.
10. Below the .bkf file that you want to restore, select the **System State** check box, and then click **Next**. (You do not need to restore the system disk to an alternate location.)
11. On the **Completing the Backup or Restore Wizard** page, click **Advanced**.
12. In the **Restore Files to** drop-down list, click **Alternate Location**.
13. In **Alternate Location**, type the path (or browse) to the local folder to which you are restoring the backup, and then click **Next**. We recommend restoring to a folder named NTDSRESTORE, if space permits, on the volume that will host the Ntds.dit file when Dcpromo is run. Otherwise, restore to a folder named \NTDSRESTORE on another volume that has sufficient free space.
14. On the **How to Restore** page, accept the default selection **Leave existing files (Recommended)**, and then click **Next**.
15. On the **Advanced Restore Option**s page, accept the default selections **Restore security settings** and **Preserve existing volume mount points**, and then click **Next**.
16. On the **Completing the Backup or Restore Wizard** page, click **Finish**.

# Install Active Directory from restored backup media

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to install Active Directory from backup media to create an additional domain controller in an existing domain.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain into which you are installing the additional domain controller.

**To install Active Directory from restored backup media**

1. Click **Start**, click **Run**, type **dcpromo /adv**, and then press ENTER.
2. In the Active Directory Installation Wizard, select **Additional domain controller for existing domain**.
3. Select **From these restored backup files**, and point to the same location where you restored the system state data.
4. If the domain controller whose system state backup you are using is a global catalog server, the Active Directory Installation Wizard asks you whether you want this server to also be a global catalog server.
5. Give appropriate credentials for the operation.
6. Enter the domain of the new domain controller. This domain must be the domain of the domain controller whose system state backup you are using.
7. Complete the remaining pages of the Active Directory Installation Wizard.

   Dcpromo.exe will install Active Directory using the data present in the restored files, which eliminates the need to replicate every object from a partner domain controller. However, objects that were modified, added, or deleted since the backup was taken must be replicated. If the backup was recent, the amount of replication required will be considerably less than that required for a regular Active Directory installation.

   After the installation operation completes successfully and the computer is restarted, the folder and subfolders that contain the restored system state can be removed from the local disk.

Restore system state to an alternate location
Include application directory partitions in an Active Directory installation from backup media

# Include application directory partitions in an Active Directory installation from backup media

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to install Active Directory from restored backup media that includes application directory partitions to create an additional domain controller in an existing domain. In this procedure, you edit a domain controller installation answer file to provide instructions for including application directory partitions in the installation. You must have already created the answer file according to the directions in Create an answer file for domain controller installation.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain into which you are installing the additional domain controller.

**To include application directory partitions in an Active Directory installation from backup media**

1. Open the answer file that you created to install the domain controller.
2. To include application directory partitions that are contained in the system state backup, add the following entry to the end of the answer file:

   **ApplicationPartitionsToReplicate=**

3. Provide a value for **ApplicationPartitionsToReplicate** as follows:

   - If you want to include all application directory partitions, use the value *****.

   - If you want to include specific application directory partitions, type the distinguished name of each directory partition. Separate each distinguished name with a space, and enclose the entire list in quotation marks, as shown in the following example:

     **ApplicationPartitionsToReplicate="dc=app1,dc=contoso,dc=com dc=app2,dc=contoso,dc=com"**

4. In the entry **ReplicationSourcePath=**, type the path to the folder that contains the restored system state backup files on the installation computer.
5. If you do not want Dcpromo to prompt the user for passwords, type the password in the **Password=** entry for the account that you will use to install the domain controller, type the password in the **SafeModeAdminPassword=** entry that you will use to provide access to Directory Services Restore Mode, and then save the answer file.

   | **Note** |
   | --- |
   | Passwords are automatically deleted from the answer file when Dcpromo runs. |

6. Open a command prompt, and then change directories to the location of the answer file.
7. At the command prompt, type the following command, and then press ENTER:

   **dcpromo /adv /answer:"** *Drive* **:** *PathToAnswerFile* **** *AnswerFileName* **"**

   Active Directory installation occurs automatically. If you left passwords blank in the answer file, Dcpromo prompts you for your administrative password and for the Directory Services Restore Mode password. If you specified "no" for the **RebootOnSuccess=** entry in the answer file, Dcpromo prompts you to restart the server after installation.

# Adding Domain Controllers in Remote Sites

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can create an additional domain controller in a domain by installing Active Directory on a server computer. When the additional domain controller is being placed in a remote site, you can install Active Directory on the server either before or after shipping it to the remote site, as follows:

- Ship the computer as a workgroup computer, and install Active Directory in the remote site. Enable Remote Desktop on the computer before you ship it so that you can perform the installation remotely. In the remote site, you can either:
    - Install Active Directory from restored backup media that has been shipped to the site on removable media or that has been restored to a location on the server itself before shipping.
    - Install Active Directory over the network.
- Install Active Directory on the server in a hub or staging site, and ship the installed domain controller to the remote site.

Both methods have advantages and disadvantages, and both methods require care to ensure the secure transfer of Active Directory data, whether it is installed or in the form of backup files that are stored on the server or on removable media.

For information about the advantages and disadvantages of shipping a server to a remote site before or after installing Active Directory, see Known Issues for Adding Domain Controllers in Remote Sites.

For information about how best to manage adding domain controllers to remote sites for the method you are using, see Best Practices for Adding Domain Controllers in Remote Sites.

By following the guidelines in this guide, you can decide the best method for your environment of adding domain controllers in remote sites. By following the instructions in this guide, you can safely and securely install domain controllers in remote sites, either locally or remotely.

The following tasks for adding domain controllers in remote sites are described in this objective:

- Preparing a Server Computer for Shipping and Installation from Backup Media
- Preparing an Existing Domain Controller for Shipping and Long-Term Disconnection
- Reconnecting a Domain Controller After a Long-Term Disconnection

# Known Issues for Adding Domain Controllers in Remote Sites

Updated: February 9, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following two methods to add domain controllers in remote sites:

- Ship the member computer to the remote site, and then install Active Directory by using the **dcpromo /adv** option, which uses restored system state backup media as the source for the Active Directory installation in the remote site.
- Install Active Directory in the hub site by using the normal Dcpromo method, and then ship the installed domain controller to the remote site.

You can use the information in this section to determine the method for adding domain controllers in remote sites that is best for your environment. SYSVOL replication issues potentially affect both methods, and each method has advantages and disadvantages that are discussed in this section.

| **Important** |
| --- |
| Do not attempt to perform actions based only on the recommendations that are discussed in this topic. Step-by-step guidance is provided in the task-based topics for all actions that are recommended in this topic. Follow the See Also links to the related task-based topics. |

**SYSVOL Replication**

SYSVOL is a shared folder that stores files that must be available and synchronized among all domain controllers in a domain. SYSVOL contains the NETLOGON share, Group Policy settings, and File Replication service (FRS) staging directories and files. The SYSVOL share is required for Active Directory to function properly.

The primary focus for both methods of installing additional domain controllers in remote sites is to avoid the replication of Active Directory over a wide area network (WAN) between the remote site and the hub site. Each method accomplishes this goal. However, depending on the size of your SYSVOL, you might also be concerned about replication of SYSVOL files over the network. Unless you follow specific instructions, the SYSVOL tree might be created on the new domain controller through replication of the entire tree from an existing domain controller in the domain. Regardless of which method you use to add domain controllers to remote sites, you might want to take additional steps to manage SYSVOL creation on the new domain controller to avoid replicating the full SYSVOL from another domain controller in the domain.

When you install a domain controller from backup media, preliminary steps are required to ensure that SYSVOL is created from the local copy of the restored backup media. Similarly, preliminary steps are required to avoid full SYSVOL synchronization when you ship an installed domain controller and restart it in the remote site. These requirements are discussed for each method respectively in the following topics:

- Preparing a Server Computer for Shipping and Installation from Backup Media
- Preparing an Existing Domain Controller for Shipping and Long-Term Disconnection

**Using Backup Media to Install Active Directory in a Remote Site**

The ability to use restored backup media to install domain controllers is a new feature in Windows Server 2003. The method for using backup media to install domain controllers includes the following general steps:

1. Back up system state on a domain controller in the domain in which you are adding the new domain controller. If you want the additional domain controller to be a global catalog server, back up a global catalog server. If you want the additional domain controller to be a Domain Name System (DNS) server, back up a DNS server.
2. Restore the backup to an alternate location. You can restore the backup directly to the computer that you want to install as a domain controller, or you can transfer it to removable media.
3. Run Dcpromo with the **/adv** option and indicate the restored backup as the source for the Active Directory installation.

This method of installing domain controllers in remote sites has several advantages. One of the primary advantages of this method is that it substantially reduces the network bandwidth requirement compared to network-based installations. This method also has a few issues that mostly affect deployments that have a large number of remote sites. If you deploy more than 100 remote sites, additional considerations might be necessary. For information about large branch office deployments, see the Windows Server 2003 Active Directory Branch Office Guide on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42506).

**Advantages of Using Backup Media to Install Active Directory in a Remote Site**

The following advantages are associated with using backup media to install a domain controller in a remote site:

- You can install many domain controllers from a single source of removable backup media. Although you can restore backup media directly to an alternate location on the server computer that you are going to install as a domain controller, you can also use that media as the source for any number of domain controllers by either copying or restoring the system state backup to removable media. For more information about the effects of copying — as opposed to restoring — a system state backup to removable media, see Preparing a Server Computer for Shipping and Installation from Backup Media.

- You do not have to disconnect the domain controller from the replication topology. Therefore, you can avoid the disadvantages that are associated with a domain controller that does not replicate. For information about the problems that are associated with domain controller disconnection, see Issues with Installing Domain Controllers Before Shipping Them to the Remote Site.

- You avoid replicating the entire Active Directory over a WAN link, particularly a link that requires a dial-up connection.

- If you enable Remote Desktop on the server before you ship it, you do not have to employ an administrator with Domain Admins credentials in the remote site.

**Issues with Using Backup Media to Install Active Directory in Remote Sites**

The following issues are associated with using backup media to install a domain controller in a remote site:

- **Domain Admins credentials and remote installation.** An administrator must have Domain Admins credentials to install Active Directory. Assuming that you do not employ a service administrator with this level of administrative credentials in each branch site, a domain administrator in the hub site must be able to connect remotely to the server to perform the installation. Therefore, you must be sure to enable Remote Desktop on the server before you ship it to the remote site.

- **Time to restore the system state backup.** The installation media is prepared by restoring a system state backup to an alternate location. Therefore, preparing the media requires taking the backup itself and restoring the backup. These tasks add time to the installation of a single domain controller. However, if you take advantage of the ability to transfer the restored backup files to removable media, you perform the preliminary backup and restore processes only once to install any number of domain controllers. In addition, you can follow instructions to prepare a smaller backup file to further decrease the time that is required for restoring and copying backup media. The volume on which you restore the backup on the target server also affects the speed of the installation. Moving the Ntds.dit file is faster than copying it. If you restore the media to the same location that will be used to host the Active Directory database, the Ntds.dit file will be moved (as opposed to being copied) into the new location, eliminating the additional time required to copy the file. For more information about the criteria that affect how long installation from backup media takes, see Preparing a Server Computer for Shipping and Installation from Backup Media.

- **Backup source for application directory partitions.** When DNS zone data is stored in application directory partitions, the replication impact can be significant if application directory partitions must be replicated over the corporate network. System state data that you restore from backup to an alternate location does not include application directory partitions if the backup is performed on servers running Windows Server 2003 with no service pack installed.

  Including application directory partitions in the backup media has the following requirements:

  - The domain controller that you back up and the computer that you intend to install as a domain controller must both be running Windows Server 2003 with Service Pack 1 (SP1).

  - The forest functional level must be set to Windows Server 2003 because linked-value replication is required to

ensure that cross-references are correctly updated for the application directory partition replica set.

- You must use an answer file to install Active Directory because the Dcpromo user interface (UI) does not provide an option for specifying application directory partitions. Use the answer file to provide the distinguished names of the application directory partitions that you want to include in the installation.

For more information about how to include application directory partitions and create a DNS server, see Preparing a Server Computer for Shipping and Installation from Backup Media.

- **Bridgehead server load balancing.** If backup media are sent to many sites and if enough domain controllers are promoted at the same time, you might experience performance issues with the bridgehead servers that are the source for Active Directory and FRS replication.

| **Note** |
| --- |
| These issues are of concern only in situations in which hundreds of domain controllers might be promoted at the same time and their need for bridgehead server resources is very high. If you are deploying hundreds of domain controllers in branch sites, see the Windows Server 2003 Active Directory Branch Office Guide on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42506). |

  - **Active Directory intersite replication.** You cannot load-balance intersite connections to and from the hub site until the domain controller is installed. If a large number of domain controllers are being installed in remote sites (more than 100), manual rebalancing of connections might be required after the domain controllers are installed. For information about how to use the Active Directory Load Balancing (ADLB) tool to rebalance connections, see the Windows Server 2003 Active Directory Branch Office Guide on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42506).

  - **FRS replication.** Because FRS on the source computer uses CPU, memory, and disk resources, the FRS recommendation is to perform a staged update on no more than 10 branch office domain controllers at a time per source hub domain controller. If a single domain controller functions as the source for SYSVOL replication to more than 10 destination domain controllers, performance on the source domain controller can decrease significantly. To balance source domain controllers, you can use an answer file with Dcpromo to specify the source domain controller.

#### Installing Domain Controllers Before Shipping Them to the Remote Site

When you install a domain controller and then disconnect it from the network for a period of time, you interrupt the normal replication activities of other domain controllers on the network. This naturally creates error conditions that result from various failed operations, such as attempts to replicate with the disconnected domain controller. As long as you are aware of the issues that disconnections cause, you can take steps to ensure smooth disconnection and reconnection.

#### Advantages of Installing Domain Controllers Before Shipping Them to the Remote Site

The following advantages are associated with installing domain controllers before shipping them to the remote site:

- **Standardization.** The process for installing domain controllers can be automated and standardized in the hub or staging site, with the one additional step of packing and shipping the domain controller. If you follow the instructions for safe disconnection and reconnection, restarting the domain controller in the remote site is all that is required.

- **Branch site personnel.** The requirement for personnel with Domain Admins credentials is contained within the hub site; that is, intervention by personnel with Domain Admins credentials is not required at the branch site.

#### Issues with Installing Domain Controllers Before Shipping Them to the Remote Site

The following issues are associated with installing domain controllers and then disconnecting them from the network while they are shipped to the remote site:

- **Disconnection error conditions.** After disconnection, online domain controllers in the domain continue to attempt replication with the disconnected domain controller, causing Active Directory and FRS errors to be generated for as long as the domain controller is disconnected.

- **Additional preparation.** Additional preparation is required to ensure smooth reconnection:
    - Preparing for the nonauthoritative restart of SYSVOL.
    - Ensuring an adequate tombstone lifetime to avoid the possibility of objects remaining on the domain controller that have been permanently deleted from the directory on all other domain controllers. The tombstone lifetime is a forest-wide setting that determines how long an object deletion persists in the directory.
- **Protection of existing accounts and metadata.** You must ensure that computer accounts and metadata for the domain controller are not deleted or improperly modified while the domain controller is disconnected.
- **Risk of lingering objects.** A lingering object is an object that remains on a disconnected domain controller after the object has been permanently deleted from Active Directory on all connected domain controllers. Deletion updates are replicated as tombstone objects. These objects have a limited lifetime in Active Directory, which is defined by the tombstone lifetime. After a tombstone is permanently removed from Active Directory, replication of the deletion it represented is no longer possible. Therefore, if you restart a domain controller on which such an object remains, replication does not recognize that object as a deleted object, and it remains in Active Directory on only the reconnected domain controller and nowhere else. If you plan to disconnect a domain controller for longer than the period of time that a domain controller keeps track of object deletions (the tombstone lifetime), you must take additional steps to ensure directory consistency. For more information about lingering objects and their causes and effects, see Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042).

**Maintaining Directory Consistency When Disconnecting a Domain Controller**

Maintaining consistency of Active Directory data involves several related issues. Review the following known issues before disconnecting an installed domain controller:

- Relationship of tombstone lifetime to Active Directory backup
- Protection against lingering object replication
- Availability of operations master roles in the domain and forest
- Up to dateness of Active Directory replication at the time of disconnection
- SYSVOL consistency on reconnection

For procedures to ensure that all of these issues are addressed, see the following topics:

- Preparing an Existing Domain Controller for Shipping and Long-Term Disconnection
- Reconnecting a Domain Controller After a Long-Term Disconnection

**Tombstone Lifetime and Backup**

Active Directory backups are useful for recovering a domain controller for only as long as the tombstone lifetime. When an object is deleted, Active Directory replicates the object as a tombstone, which consists of a small subset of the attributes of the deleted object. The tombstone is retained in Active Directory for 60 days by default in a Windows Server 2003 forest. This default value is changed in Windows Server 2003 with Service Pack 1 (SP1). The tombstone is retained for 180 days by default in a new forest that is created on a domain controller running Windows Server 2003 with SP1. NTBackup.exe, the Windows Server backup utility, will not restore a system state backup that is older than the tombstone lifetime.

The tombstone lifetime value that is in effect when a domain controller is upgraded to Windows Server 2003 SP1 is not changed by the installation of Windows Server 2003 SP1. The existing value is maintained until you change it manually. You can determine the value of the **tombstoneLifetime** attribute by viewing the properties of CN=Directory Service,CN=Windows NT,CN=Services,CN=Configuration,DC=*ForestRootDomain* in ADSI Edit (adsiedit.msc), which is available in Windows Support Tools. A value in **tombstoneLifetime** of **<Not Set**> always indicates that the Windows Server 2003 default value of 60 is in effect. If you create a new forest on a domain controller running Windows Server 2003 with SP1, the default **tombstoneLifetime** value of 180 is displayed in the UI.

When the number of days in the tombstone lifetime has passed, the tombstone is permanently removed. Because a domain controller that is disconnected for a period that is longer than the tombstone lifetime cannot receive deletions that occurred before the beginning of the tombstone lifetime, a backup that is older than the tombstone lifetime cannot be used to restore Active Directory.

When conditions beyond your control cause a domain controller to be disconnected for a period that is longer than the tombstone lifetime, one or more objects that have been deleted from the rest of the directory while the domain controller was offline might remain on the disconnected domain controller.

If planned domain controller disconnections are consistently lasting longer than the number of days in the tombstone lifetime, consider extending the tombstone lifetime for the forest prior to disconnecting any domain controllers.

For more information about the causes and effects of lingering objects, see Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042).

**Protection Against Lingering Object Replication**
Domain controllers that have not performed inbound replication in the previous tombstone lifetime number of days are vulnerable to retaining lingering objects. If a domain controller that has one or more lingering objects is reconnected to the replication topology and a lingering object is subsequently updated on that domain controller, the object might be recreated in Active Directory, depending on how the strict replication consistency registry setting is configured.

A lingering object is made known to the replication system only if it is updated on the domain controller that stores it. In this case, the source domain controller attempts replication of an update to an object that the destination does not store. On destination domain controllers running Windows 2000 Server with Service Pack 3 (SP3) or Service Pack 4 (SP4) and Windows Server 2003, the **strict replication consistency** registry entry (type **REG_DWORD**) in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters**) determines whether replication is allowed to proceed if the domain controller receives a request for an update to an object that it does not have.

The value in the **strict replication consistency** registry entry determines whether replication proceeds or is stopped, as follows:

- **1** (enabled): Inbound replication of the specified directory partition from the source is stopped on the destination. Replication of the directory partition is halted on both the source and destination domain controllers.

- **0** (disabled): The destination requests the full object from the source domain controller and the destination domain controller reanimates a full copy of an object it has previously deleted and permanently removed through garbage collection.

For more information about how to manage the strict replication consistency setting, including its effects and its default values, see Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042).

**Up to Dateness of Active Directory Replication**
Ensure that a domain controller is updated before you disconnect it. Immediately before you disconnect the domain controller, force replication with all replication partners and verify that each directory partition replicates to the domain controller that you are disconnecting. If replication of any directory partition does not succeed, resolve the replication problem before you disconnect the domain controller. By ensuring that replication is up to date, you can maximize the possible safe disconnection period, which cannot exceed the tombstone lifetime for the forest.

**SYSVOL Consistency**
SYSVOL replication cannot be synchronized manually. For this reason, ensuring that SYSVOL is updated before you disconnect the domain controller is more difficult than simply updating SYSVOL when the domain controller is reconnected. Regardless of the length of the disconnection, to ensure that SYSVOL is synchronized when the domain controller is reconnected, prepare the domain controller to perform a nonauthoritative restart of SYSVOL before you disconnect the domain controller. When the domain controller restarts, nonauthoritative restart of SYSVOL occurs automatically.

# Best Practices for Adding Domain Controllers in Remote Sites

Updated: February 15, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By reviewing the information in Known Issues for Adding Domain Controllers in Remote Sites, you can determine the best method to use for installing domain controllers in your remote sites. You can use this topic to learn about the best practices for the method that you decide to use.

| **Important** |
| --- |
| Do not attempt to perform actions based only on the recommendations that are discussed in this topic. Step-by-step guidance is provided in the task-based topics for all actions that are recommended in this topic. Follow the See Also links to the related task-based topics. |

**Using Backup Media to Install Active Directory in the Remote Site**

The primary purpose of using restored backup media to install a domain controller is to provide a local source for the domain, configuration, and schema directory partitions — and, optionally, global catalog partial, read-only directory partitions and Domain Name System (DNS) application directory partitions. The local source is the restored system state backup files that reside on the server that you are installing. Updates to object attributes that occur since the system state backup was made will replicate over the network from an existing domain controller in the domain or forest. Although SYSVOL is part of the system state backup, under some conditions SYSVOL is not sourced from the backup media. Configuring SYSVOL to be sourced from local backup media is more challenging and might not prove worthwhile. For more information about the conditions that determine the need for SYSVOL replication, see Known Issues for Adding Domain Controllers in Remote Sites.

To use restored backup files for installation of one or more additional domain controllers in a domain, you can either:

- Copy ("burn") either the unrestored .bkf file or the restored backup files onto removable media, such as a portable disk drive, CD, or DVD, which can be shipped with the workgroup computer when it leaves the staging site or shipped separately.

- Restore system state backup to the local hard drive of the workgroup computer before it leaves the staging site.

For information about the advantages and disadvantages of these methods, see Preparing a Server Computer for Shipping and Installation from Backup Media.

The **Dcpromo /adv** option in Windows Server 2003 to install a domain controller from backup media eliminates the Windows 2000 Server requirement to either promote the domain controller before shipping it to the remote site or promote the domain controller in the remote site by replicating the entire directory over a wide area network (WAN) connection when another domain controller for the domain is not present in the site.

The following best practices are recommended to optimize data security and consistency when you add domain controllers in remote sites:

- **Upgrade to Windows Server 2003 with Service Pack 1 (SP1).** If you use Active Directory-integrated DNS or if you want other application directory partitions to be included in the domain controller replica, upgrade the server computer to Windows Server 2003 with SP1 before Active Directory installation. When you use restored backup media to install a computer running Windows Server 2003 with no service pack installed, the replica installation does not include application directory partitions. In the case of DNS application directory partitions, the impact of replicating these directory partitions over the WAN might be significant. When you use restored backup media to install a computer running Windows Server 2003 with SP1, you can use an answer file to include application directory partitions in the replica that you install.

- **Back up the type of domain controller that you want to add.** You must back up the type of domain controller that you want to add. If you want to add a global catalog server in the remote site, back up a global catalog server in the domain. If you want to add a DNS server, back up a DNS server in the domain.

- **Take the same security precautions for shipment of removable backup media or a server computer that contains a restored backup as you would take for shipping an installed domain controller.** For information

about securing domain controllers, see Best Practice Guide for Securing Windows Server Active Directory Installations on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=28521).

- **Minimize the time between the backup and installation.** Minimizing this delay reduces the number of updates that will be required to replicate after installation.

- **Install the operating system before shipping the server to the remote site.** Installing the operating system requires expertise that might not be available at branch sites. Ideally, installation routines are available in the staging site to automate the operating system installation process and ensure uniformity for all domain controllers (partition sizes, drive letter assignments, and so on). As part of the operating system installation, apply a standardized set of hotfixes plus any available service packs to ensure service consistency throughout the forest.

- **Ship the server as a member of a workgroup rather than a member server in a domain.** If the server is joined to a domain and then stolen during shipment, information about domain names, DNS suffixes, and number of domains in the forest can aid attackers in attempts to compromise or steal directory data.

- **Ship computers with properly configured Internet Protocol (IP), subnet mask, and default gateway addresses.** Remember to reconfigure the server with TCP/IP settings that are appropriate to the target site, not the staging site. Specifically, the domain controller must not point to itself for DNS.

- **Enable Remote Desktop on the server computer before shipping.** This best practice assumes that you need to be able to install and manage Active Directory remotely rather than employing an administrator with Domain Admins credentials in each remote site.

#### Installing Domain Controllers Prior to Shipping to the Remote Site

When you install Active Directory in the hub or staging site, disconnect the installed domain controller, and then ship the computer to the remote site, you are disconnecting a viable domain controller from the replication topology. The most significant risk from disconnection is that the domain controller will remain offline long enough to exceed the tombstone lifetime and thereby become capable of retaining objects that have been permanently deleted from the directory on all other domain controllers in the domain. Such objects, called lingering objects, cause directory inconsistency and, under certain conditions, can be reintroduced into the directory. For information about the causes and effects of lingering objects and how to avoid them, see Known Issues for Adding Domain Controllers in Remote Sites.

The following best practices reduce the possibility of Active Directory consistency problems due to lingering objects remaining on domain controllers that are disconnected for long periods of time. Take the following precautions to avoid directory consistency problems when you disconnect an existing domain controller and to ensure that if inadvertent long disconnections occur, lingering objects cannot be replicated.

- **Upgrade all Windows 2000 Server domain controllers to Windows Server 2003.** This process requires upgrading the forest schema by using the **adprep /forestprep** command. Thereafter, you can begin upgrading domain controllers to Windows Server 2003. The Windows Server 2003 schema update adds 25 indexed attributes to the schema directory partition. An update of this size can cause replication delays in a large database. For this reason, domain controllers that are running Windows 2000 Server must be running — at a minimum — Windows 2000 Service Pack 2 (SP2) plus all additional Windows updates. However, it is highly recommended that you install Windows 2000 Service Pack 3 (SP3) on all domain controllers before preparing your infrastructure for upgrade to the Windows Server 2003 operating system. For information about upgrading to Windows Server 2003, see "Upgrading from Windows 2000 Domains to Windows Server 2003 Domains" in the Windows Server 2003 Deployment Guide on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=46082).

- **Enable strict replication consistency on all domain controllers.** This registry setting, which stops inbound replication of a directory partition from a source domain controller that is suspected of having a lingering object, should be set for the forest to prevent the reintroduction of a lingering object into the directory. You can use the **Repadmin /regkey** command, which is available in the version of Windows Support Tools that is included with Windows Server 2003 SP1, to enable this setting on a specific domain controller or on all domain controllers in the forest, which eliminates the need to update the registry manually.

- **Monitor the Knowledge Consistency Checker (KCC) topology and replication to ensure that unintended long disconnections are detected.** By monitoring replication, you can detect disconnections that occur as a result of

network failures, service failures, or configuration errors. Use the Active Directory Management Pack or other monitoring application to implement a monitoring solution for your Active Directory deployment. Event IDs to monitor include 1311, 1388, 1925, 1988, 2042, 2087, and 2088.

- **Ship computers with properly configured IP, subnet mask, and default gateway addresses.** Remember to reconfigure the server with TCP/IP settings that are appropriate to the target site, not the staging site. Specifically, the domain controller must not point to itself for DNS.

- **Configure the tombstone lifetime appropriately.** Ensure that the tombstone lifetime is not lowered below the default. The default tombstone lifetime in a forest that was created on a domain controller running Windows 2000 Server or Windows Server 2003 is 60 days. The default tombstone lifetime in a forest that was created on a server running Windows Server 2003 with SP1 is 180 days. If you must disconnect a domain controller for a period of several weeks or months, before you disconnect the domain controller, do the following:

    - **Estimate the anticipated length of disconnection.**

    - **Determine the value of the tombstone lifetime for the forest.** This value is stored in the **tombstoneLifetime** attribute of CN=Directory Service,CN=Windows NT,CN=Services,CN=Configuration,DC=*ForestRootDomain*.

    - **Determine the maximum length of time that the domain controller can be safely disconnected.** From the tombstone lifetime number of days, subtract a generous estimate of the number of days that are required for end-to-end replication latency. The resulting amount of time is the maximum period for which the domain controller can safely be disconnected.

    - **Determine whether to extend the tombstone lifetime for the forest.** If you estimate the maximum time of disconnection to be longer than the tombstone lifetime, you must determine whether to extend the tombstone lifetime or perform the procedure to remove lingering objects from the domain controller after it is reconnected. If you extend the tombstone lifetime, you must also make sure that all domain controllers have adequate disk space to store additional tombstones. In addition, make sure that replication of the tombstone lifetime change has reached all potential source domain controllers before you run Dcpromo to install an additional domain controller.

- **Prepare the registry for automatic nonauthoritative restart of SYSVOL when the domain controller restarts.** SYSVOL cannot be updated manually before disconnection. By editing a registry setting, you can ensure that SYSVOL is updated as soon as the domain controller is restarted.

- **Ensure that the domain controller replicates successfully with all replication partners.** Immediately before you disconnect the domain controller, force replication with its partners. Check that replication has succeeded before you disconnect the domain controller.

- **Label the domain controller.** When you disconnect the domain controller, attach a label to the computer that identifies the date and time of disconnection, the destination, and the IP settings.

- **When you reconnect the domain controller, restore SYSVOL as quickly as possible.** The domain controller does not serve as a domain controller until SYSVOL has been updated through replication. If the site has one or more other domain controllers in the same domain, start the domain controller anytime. If the site contains no other domain controller in the same domain, time the restart of the domain controller to coincide with the beginning of intersite replication.

- **Do not allow an outdated Windows 2000 Server domain controller to replicate.** If a domain controller running any version of Windows 2000 Server has been disconnected for longer than the maximum safe time of disconnection (the tombstone lifetime minus end-to-end replication latency), do not allow the domain controller to replicate. Instead, force the removal of Active Directory, perform metadata cleanup, and then reinstall Active Directory. As an alternative, you can reinstall the domain controller with Windows Server 2003. For more information about completing these tasks, see Reconnecting a Domain Controller After a Long-Term Disconnection.

| Note |
| --- |
| This recommendation applies to additional domain controllers in an existing domain. If the outdated domain controller is the only domain controller in the domain, the recommendation is to reconnect the domain controller and follow the instructions to remove lingering objects in article 314282, "Lingering objects may remain after you bring an out-of-date global catalog server back online," in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=37924). |

- **To avoid time skew issues**, e**nsure that the system clock is synchronized with the domain source on startup.** When you start the domain controller in the remote site, use the following command to set the hardware clock:

  **net time /domain:***DomainName* **/set /y**

# Preparing a Server Computer for Shipping and Installation from Backup Media

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The specific guidelines for installing Active Directory from backup media are provided in the topic Installing a Domain Controller in an Existing Domain Using Restored Backup Media. Be sure to read that topic before performing the procedures that are specified in this topic.

When you want to ship theserver to a remote site and install Active Directory by restoring from backup media in the remote site, you must make certain choices regarding the method that you use to restore the backup. You must also decide whether to use removable media or ship the backup on the server that will become the additional domain controller. You can use the information in this topic to make these decisions and to prepare the server for shipping. Use the information in Installing a Domain Controller in an Existing Domain Using Restored Backup Media to perform the actual backup, restore, and Active Directory installation procedures.

Preparing a computer for installation in a remote site by using restored backup media requires that you perform the following tasks:

- Begin by backing up system state on a domain controller in the domain into which you are installing the domain controller according to the recommendations and requirements in Installing a Domain Controller in an Existing Domain Using Restored Backup Media.

- Determine whether to restore the system state backup onto the computer that will be promoted or use removable media to ship the backup files separately from the computer.

- Determine the volume on which to restore the backup media. If you have a large Ntds.dit file, this decision can affect the amount of time necessary for Active Directory installation. If you have a large SYSVOL, this decision can affect whether full replication of SYSVOL occurs during Active Directory installation. The ability to use the backup media to source SYSVOL depends on various factors. If you want to avoid full replication of SYSVOL, additional preparation is required, as described later in this section.

- Before you ship the server, enable Remote Desktop access on the server so that you can install the domain controller and manage it remotely. You can also enable Remote Desktop remotely by using the registry, but this method should be used only as a fallback measure if, through some oversight, Remote Desktop is not enabled prior to shipping.

- If you are installing a domain controller that is running Windows Server 2003 with Service Pack 1 (SP1) in a forest that has a forest functional level of Windows Server 2003 or Windows Server 2003 interim and you want to include application directory partitions in the installation media, you can do so by creating an answer file that contains the location of the restored backup media and then running an unattended installation of Active Directory.

**Restore the Backup to the Promotion Computer or Ship Removable Media**

When you back up system state for the purpose of creating restored backup media for domain controller installation, you can use various methods to create the media for shipment and installation. You can:

- Before you ship the server, restore the backup directly to a volume on the server that you are shipping. When the server arrives at the remote site, it is ready for installation with no further preparation.

- Copy the .bkf file onto removable media before restoration. Ship the media to the remote site, and then restore the backup from the removable media to an alternate location on each domain controller that you want to install. The advantage of this method is that you retain the potential for SYSVOL to be sourced from the backup media.

- Restore the backup to any location on any server and then copy the restored backup to removable media, such as a CD, DVD, or portable hard drive. The advantage of using this method is that you restore the backup only once; you can install as many domain controllers as necessary from the same media. The disadvantage is that copying the restored files loses the SYSVOL data that is required for sourcing SYSVOL from the restored backup. For more information about ensuring

that SYSVOL is sourced from the restored backup, see "Seeding the SYSVOL tree from restored files during IFM promotion" in article 311078, "How to use the Install from Media feature to promote Windows Server 2003–based domain controllers," on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=37924).

**Determine the Restore Volume**

The volume on which you restore the system state backup has implications for both Active Directory files and SYSVOL files. For faster restore, it is recommended that you restore the backup to the volume that you will designate to host the Ntds.dit file when you run Dcpromo, if space permits. Otherwise, restore the backup to a volume that has sufficient free space. Restoring the backup to the volume that will store Ntds.dit, as opposed to a different volume, affects how files are managed by the system during and after Active Directory installation, as follows:

- **Active Directory files.** The volume to which you restore the Ntds.dit and NTDS log files determines how long installation will take and whether you must delete copied files following installation:

  - If you restore the system state to a location on the same volume (drive letter) that will ultimately host the Ntds.dit and NTDS log files, when you designate the path for the Ntds.dit and NTDS log files during installation, the Active Directory Installation Wizard will move the Ntds.dit and NTDS log files from the restored location to their installed location. Moving the files is much faster than copying the files.

  - If you restore the system state to a different volume than the volume that will ultimately host the Ntds.dit and NTDS log files, the Active Directory Installation Wizard will copy the Ntds.dit and NTDS log files to their final location during installation. In the case of a large Ntds.dit file, the copy process can add significantly to the installation time. In this case, you must manually delete the remaining files and folders in the restored folder after a successful installation. As a best practice, we recommend that you always delete the folder that you use to receive the restored backup, regardless of whether files are copied or moved.

- **SYSVOL replication.** The volume to which you restore the system state backup also determines whether the File Replication service (FRS) can use the restored files as the source for SYSVOL on the new domain controller or whether FRS replicates a new copy of SYSVOL from a different domain controller in the domain. To be able to use the installation media as the source for the SYSVOL data, you must restore the system state backup to the same volume as the drive that you specify in the Active Directory Installation Wizard to host the SYSVOL tree. In addition, you must perform preliminary procedures to pre-seed the SYSVOL data on the installation server. Otherwise, the data will be sourced over the network from a domain controller that is in the same domain as the new domain controller.

  If you store the SYSVOL shared folder on a different volume from the Active Directory files, consider the effect of copying Active Directory files, as described earlier in this topic, as opposed to the effect of replicating the entire contents of the SYSVOL shared folder. If avoiding replication of the SYSVOL shared folder is a goal of the remote installation, restore the backup to a location that is on the same volume as the drive that will contain the SYSVOL share and perform the preliminary SYSVOL pre-seeding procedures.

  In addition to the requirement that you restore the backup to the volume where SYSVOL is to be installed, successful pre-seeding of SYSVOL from the installation media also requires that SYSVOL has been replicated. If only one domain controller is installed in the domain (SYSVOL has not replicated at least once between two domain controllers in the domain), you must configure another domain controller in the domain to prepare the SYSVOL before you perform the system state backup.

| **Note** |
| --- |
| It is recommended that you deploy at least two domain controllers in each domain for redundancy and failover. |

For complete instructions for how to ensure that SYSVOL is sourced from the restored backup, see "Seeding the SYSVOL tree from restored files during IFM promotion" in article 311078, "How to use the Install from Media feature to promote Windows Server 2003–based domain controllers," on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=70809). To assess the effect of replication, as opposed to additional configuration to source SYSVOL from the backup media, test both procedures in a lab environment that mirrors your production environment in terms of wide area network (WAN) speed and replication latency.

**Enable Remote Desktop**

You can use Remote Desktop to connect to the domain controller and manage it as if you were sitting at the console. Remote Desktop is disabled by default in Windows Server 2003 operating systems. To install Active Directory, you must have Domain Admins credentials in the domain into which you are adding the domain controller. This level of service administration might not be available in the remote site. In any case, you will want to be able to install and manage the domain controller from the hub site.

**Create a Domain Controller Installation Answer File**

If you want to include application directory partitions in the restored backup media that you use as the source for an Active Directory installation, you must create a domain controller installation answer file and perform an unattended Active Directory installation. Dcpromo uses the answer file for installation instructions, including the location of restored backup media and instructions to use these files as the source for the installation.

If you are installing a domain controller in a remote site that will also be a DNS server, you might want to include application directory partitions in the installation media rather than replicating them. You can include application directory partitions in the installation media if the following conditions apply:

- The forest has a functional level of Windows Server 2003 or Windows Server 2003 interim.
- The domain controller that you back up and the server that you are installing are both running Windows Server 2003 with SP1.
- For creating a DNS server, your forest uses Active Directory-integrated DNS (DNS zone data is stored in application directory partitions on DNS servers in the forest).
- The domain controller that you back up stores the application directory partitions that you want to include.

Instructions for performing this type of installation are included in this task.

**Task requirements**

The following tools are necessary to complete this task:

- Ntbackup.exe
- System Control Panel
- Dcpromo.exe
- Ref.chm on the Windows Server 2003 installation CD (for unattended installations only)

To complete this task, perform the following procedures:

1. Back up system state on a domain controller in the domain into which you are installing the additional domain controller. The following requirements apply for the backup domain controller and the target server:

    - The backup domain controller and target server must be running the same version of Windows Server 2003. For example, if the domain controller that you back up is running Windows Server 2003 with SP1, you cannot use this backup media to install Active Directory on a server that is running Windows Server 2003 with no service pack installed.
    - The backup domain controller and target server must be running on the same hardware platform (32-bit or 64-bit).
    - To install a domain controller that is a global catalog server, you must back up system state on a global catalog server.
    - To install a domain controller that is a DNS server (that is, a server that stores the DomainDNSZones and ForestDNSZones application directory partitions), you must back up system state on a DNS server that stores these directory partitions.

2. Restore system state to an alternate location. This location can be on the target server or in a different location, from which the backup files can be copied to removable media and then shipped to the remote site separately from the target server. Follow the guidelines described in "Determine the Restore Volume" earlier in this topic.

   As an alternative, you can copy the unrestored .bkf file to removable media and then ship the media to the remote site, where it can be restored to a location on the target server.

   When you restore, you must run Ntbackup on the server that has the alternate location. Therefore, if you are restoring to an alternate location that is not on the server on which the .bkf file is stored, before you run Ntbackup, do the following:

   a. Share the folder that contains the .bkf file.

   b. Map a connection to it from the computer on which you are running Ntbackup.

3. Enable Remote Desktop on the target server.

4. If you are installing a DNS server or a domain controller that will store any application directory partitions, Create an answer file for domain controller installation.

5. Ship the domain controller and any prepared removable media and answer file to the remote site. Ship these items separately and securely.

6. When the server is running in the remote site, install the domain controller as follows:

   - Create a Remote Desktop Connection to the remote server.

   - If you are installing a domain controller that does not require application directory partitions to be included in the installation, Install Active Directory from restored backup media.

   - If you are installing a domain controller that will be a DNS server or that requires other application directory partitions to be included in the installation media, perform the procedure to Include application directory partitions in an Active Directory installation from backup media.

7. If the domain controller is to be a DNS server, Install the DNS Server service after Active Directory has been installed.

Installing a Domain Controller in an Existing Domain Using Restored Backup Media

# Back up system state

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Ntbackup.exe provides simple and advanced options for backing up Active Directory components. When you back up system state, you can choose to include or exclude system-protected boot files. System-protected boot files are not used for installations from restored backup media. When the backup file that you create is to be used for additional domain controller installations, you can clear the advanced option to back up system-protected files. Clearing this option decreases the size of the .bkf file, as well as the time required to back up, restore, and copy the system state files.

Use these procedures to back up the system state only. These procedures do not back up the system disk or any other data on the domain controller except for the system-protected files.

Use the first procedure, "To back up system state including system-protected files," for routine system state backup. Use the second procedure, "To back up system state excluding system-protected files," if you want to create a smaller backup that is effective for installing domain controllers from restored backup media.

| **Note** |
| --- |
| To back up system state, you must log on locally to the domain controller, or Remote Desktop must be enabled on the remote domain controller so that you can connect remotely. |

### Administrative credentials

- To perform the following two procedures, you must be a member of the Domain Admins group or a member of the Backup Operators group.

#### To back up system state including system-protected files

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.

   This procedure provides steps for backing up in Wizard Mode. By default, the **Always Start in Wizard Mode** check box is selected in the Backup or Restore Wizard. If the **Welcome to the Backup Utility Advanced Mode** page appears, click **Wizard Mode** to open the Backup or Restore Wizard.

2. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
3. Select **Back up files and settings**, and then click **Next**.
4. Select **Let me choose what to back up**, and then click **Next**.
5. In the **Items to Back Up** window, double-click **My Computer**.
6. In the expanded list below **My Computer**, check **System State**, and then click **Next**.
7. Select a location to store the backup:

   - If you are backing up to a file, type the path and file name for the backup (.bkf) file (or click **Browse** to find a folder or file).

   - If you are backing up to a tape unit, choose the tape that you want to use.

     | **Note** |
     | --- |
     | You should not store the backup on the local hard drive. Instead, store it in a location, such as a tape drive, away from the computer that you are backing up. |

8. Type a name for this backup according to the recommendations in Backing Up Active Directory Components, and then click **Next**.
9. On the last page of the wizard, click **Advanced**.

10. Do not change the default options for **Type of Backup**. **Normal** should be selected, and the check box for **Backup migrated remote storage data** should remain cleared. Click **Next**.
11. Select **Verify data after backup**, and then click **Next**.
12. In the **Backup Options** dialog box, select a backup option, and then click **Next**.
13. If you are replacing the existing backups, select the option to allow only the owner and administrator access to the backup data and to any backups that are appended to this medium, and then click **Next**.
14. In the **When to back up** box, select the appropriate option for your needs, and then click **Next**.
15. If you are satisfied with all of the options that are selected, click **Finish** to perform the backup operation according to your selected schedule.

| **Note** |
| --- |
| The system state can also be backed up by using Ntbackup from a command line with appropriate parameters. For more information, at a command prompt type **ntbackup /?**. |

The following procedure produces a smaller .bkf file that does not include system boot files. By using this procedure, you can reduce the time that is required to perform the backup and subsequent restore, as well as the amount of disk space that is required. This method is recommended when the restored backup is to be used for installing additional domain controllers.

**To back up system state excluding system-protected files**

1. To start the Windows Server 2003 backup utility, click **Start**, click **Run**, type **ntbackup**, and then click **OK**.
2. On the **Welcome to the Backup or Restore Wizard** page, click **Advanced Mode**, and then click the **Backup** tab.
3. In the console tree, select the **System State** check box.
4. In **Backup media or file name**, type a name for this backup according to the recommendations in Backing Up Active Directory Components.
5. Click **Start Backup**, and then click **Advanced**.
6. Clear the **Automatically back up System Protected Files with the System State** check box, and then click **OK**.
7. Click **Start Backup**.

Create a Remote Desktop Connection

# Restore system state to an alternate location

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Perform this procedure to create media for installing a domain controller from restored backup media or to allow an authoritative restore of SYSVOL. After the domain controller installation is complete, delete the files in the alternate location.

You can restore the system state backup to an alternate location on the domain controller from which the backup was made, a location on another computer, or a location on the computer that you want to install as a domain controller.

**Administrative credentials**

To perform this procedure, you must be a member of the Backup Operators group, as follows:

- Restore system state on a member or workgroup server: Backup Operators group on the local computer
- Restore system state on a domain controller: Backup Operators group in the domain

**To restore system state to an alternate location**

1. Log on to the server that has the alternate location to which you are restoring system state backup files.
2. Click **Start**, click **Run**, type **ntbackup**, and then click **OK**.
3. On the **Welcome to the Backup or Restore Wizard** page, click **Next**.
4. Click **Restore Files and settings**, and then click **Next**.
5. On the **What to Restore** page, click **Browse**, and then, in the **Open Backup File** dialog box, click **Browse** again.
6. Navigate to the .bkf file that you want to restore to an alternate location. The .bkf file can be located in a folder on the current computer, in a shared folder on the backup computer or other network computer, or on an external drive that contains removable media.
7. In the **Select file for catalog** dialog box, click the .bkf file that you want to restore, and then click **Open**.
8. In the **Open Backup File** dialog box, click **OK**.
9. In **Items to restore**, double-click **File**, and then double-click the .bkf file that you want to restore.
10. Below the .bkf file that you want to restore, select the **System State** check box, and then click **Next**. (You do not need to restore the system disk to an alternate location.)
11. On the **Completing the Backup or Restore Wizard** page, click **Advanced**.
12. In the **Restore Files to** drop-down list, click **Alternate Location**.
13. In **Alternate Location**, type the path (or browse) to the local folder to which you are restoring the backup, and then click **Next**. We recommend restoring to a folder named NTDSRESTORE, if space permits, on the volume that will host the Ntds.dit file when Dcpromo is run. Otherwise, restore to a folder named \NTDSRESTORE on another volume that has sufficient free space.
14. On the **How to Restore** page, accept the default selection **Leave existing files (Recommended)**, and then click **Next**.
15. On the **Advanced Restore Option**s page, accept the default selections **Restore security settings** and **Preserve existing volume mount points**, and then click **Next**.
16. On the **Completing the Backup or Restore Wizard** page, click **Finish**.

# Enable Remote Desktop

Updated: February 9, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can enable Remote Desktop on the server that you are installing as a domain controller so that service administrators can manage the domain controller remotely. Remote Desktop is disabled by default in Windows Server 2003 operating systems.

Use this procedure to enable remote desktop prior to shipping the server that will be installed as a domain controller. If you neglected to perform this procedure prior to shipping the server, use the procedure "To enable Remote Desktop remotely by using the registry," later in this topic

**Administrative credentials**

To complete this procedure, you must be a member of the local Administrators group.

**To enable Remote Desktop**

1. Click **Start**, point to **Control Panel**, and then click **System**.
   Or
   Click **Start**, right-click **My Computer**, and then click **Properties**.
2. On the **Remote** tab, under **Remote Desktop**, select the **Allow users to connect remotely to this computer** check box, and then click **OK**.

| **Note** |
| --- |
| On computers running Windows Server 2003 with Service Pack 1 (SP1), on the **Remote** tab, select the **Enable Remote Desktop on this computer** check box. |

If for any reason you neglected to perform this procedure prior to shipping the server, you can enable Remote Desktop remotely by using the registry.

**Administrative credentials**

To complete this procedure, you must be a member of the local Administrators group.

**To enable Remote Desktop remotely by using the registry**

1. On any computer that is running a version of Windows Server 2003 or Windows XP Professional, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. On the **File** menu, click **Connect Network Registry**.
3. In the **Select Computer** dialog box, type the computer name and then click **Check Names**.
4. In the **Enter Network Password** dialog box, provide Domain Admins credentials for the domain of the server, and then click **OK**.
5. After the computer name resolves, click **OK**.
6. In the computer node that appears in the Registry Editor, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server**.
7. In the console tree, click **Terminal Server** and then, in the details pane, double-click **fDenyTSConnections**.
8. In the **Edit DWORD Value** box, in **Value data**, type **0**, and then click **OK**.
9. To implement the change, reboot the server remotely, as follows:

   Open a command prompt, type the following, and then press Enter:

   **shutdown -m ** *DomainControllerName* **-r**

# Create an answer file for domain controller installation

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to create a text file that you can use as the answer file for an unattended installation of a domain controller. The answer file contains sensitive information and should be kept in a secure location.

**Administrative credentials**

To perform this procedure, you must be a member of the Authenticated Users group on the local computer on which you create the answer file.

**To create an answer file for domain controller installation**

1. On a local computer, insert the Windows Server 2003 CD-ROM into the CD-ROM drive or DVD-ROM drive. Press and hold down the SHIFT key as you insert the CD to prevent it from starting automatically.
2. Start Windows Explorer, and then open the Support\Tools folder on the Windows Server 2003 CD-ROM.
3. In the console tree, click **Tools**, and then, in the details pane, double-click **Deploy.cab**.
4. In the details pane, right-click **Ref.chm**, and then click **Extract**.
5. In the **Select a Destination** dialog box, navigate to or create a new folder for the expanded Ref.chm file, and then click **Extract**.
6. In its extracted location, open Ref.chm.
7. On the **Contents** tab in the scope pane, double-click **Unattend.txt**, and then click **[DCInstall]**.
8. In the details pane, scroll to **Sample**, select the entire sample, beginning at **[DCInstall]**, and then copy the sample.
9. Open Notepad, paste the sample into the Notepad file, and save the text file.
10. Edit the text file to contain at least the following entries. For additional examples and parameters, see Ref.chm and article 223757 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=155037).

    **[DCINSTALL]**

    **UserName=** *SAM account name that has Domain Admins credentials in the target domain. This account must be used by the administrator who runs the Dcpromo command.*

    **Password=** *Password for the account name. If you leave this blank, Dcpromo prompts the user during installation. Dcpromo deletes this value following installation.*

    **UserDomain=** *Domain name for the user account in* **UserName** .

    **DatabasePath=** *Location of the Ntds.dit file. (The default is %systemroot%*\ntds*.) If you omit this entry, Dcpromo uses the default location.*

    **LogPath=** *Location of the database log files. (The default is %systemroot%*\ntds*.) If you omit this entry, Dcpromo uses the default location.*

    **SYSVOLPath=** *Location of the shared SYSVOL tree. (The default is %systemroot%*\SYSVOL*.)* If you omit this entry, Dcpromo uses the default location.

    **SafeModeAdminPassword=** *Password for the administrator account that must be used to start the domain controller in Directory Services Restore Mode.* If you leave this blank, Dcpromo prompts the user for the password during installation. Dcpromo deletes this value following installation. Passwords are removed from the answer file when Dcpromo is executed.

    **CriticalReplicationOnly=Yes** *or* **no** *, to specify whether to skip noncritical portions of replication and allow Dcpromo to complete before replication is complete.*

    **SiteName=** *The name of the Active Directory site in which this domain controller will be placed.* This site must be created in advance in the Active Directory Sites and Services snap-in.

    **ReplicaOrNewDomain=** *Specify either* **Replica** *for an additional domain controller in an existing domain or*

**NewDomain** *for the first domain controller in a new domain.*

**ReplicaDomainDNSName=** *The fully qualified domain name of the domain of the new domain controller.*

**ReplicationSourceDC=** *The name of an existing domain controller in the domain to use as the source replication partner during installation.* When you install Active Directory from restored backup media, you can use this entry in conjunction with **ReplicateFromMedia** if you want to specify the domain controller from which Active Directory changes and SYSVOL changes are replicated.

**ReplicateFromMedia=Yes** *for installation from media,* **no** *for installation by replication.*

| **Note** |
| --- |
| For more information on this option, see article 311078 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkID=128859). |

**ReplicationSourcePath=** *When the installation is by replication, the path to the installation CD or network share. When the installation is from restored backup media, the local drive and path to the restored backup files.*

**RebootOnSuccess=Yes** *if you want the domain controller to restart automatically following a successful installation,* **no** *if you want to restart the domain controller manually. If you do not want the domain controller to restart automatically and you do not want to be prompted, use the value* **NoAndNoPromptEither**.

**ApplicationPartitionsToReplicate=** *Comma-separated distinguished names, with the entire string enclosed in quotation marks, of application directory partitions that you want to include when you use restored backup media to install Active Directory (or * to include all application directory partitions).* Using this entry requires Windows Server 2003 with Service Pack 1 (SP1) and Windows Server 2003 forest functional level. For more information about using this entry, see Include application directory partitions in an Active Directory installation from backup media.

| **Note** |
| --- |
| For additional examples and parameters, see Ref.chm and article 223757 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=155037). |

11. Save the answer file to the location on the installation server from which it is to be called by Dcpromo, or save the file to a network shared folder or removable media for distribution.

Include application directory partitions in an Active Directory installation from backup media

# Create a Remote Desktop Connection

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If Remote Desktop is enabled on a server, you can use Remote Desktop Connection to connect to the server and manage it remotely. Remote Desktop is disabled by default in Windows Server 2003 operating systems.

**Administrative credentials**

To complete this procedure, you must have Remote Desktop permissions by being added to the Remote Desktop Users group or you must be a member of the local Administrators group of the computer to which you are connecting. If the computer is a domain controller, you must have the **Allow Logon Locally** right applied in the Default Domain Controllers Policy.

**To create a new Remote Desktop Connection**

1. On the **Start** menu, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
2. In **Computer**, type a computer name or Internet Protocol (IP) address, and then click **Connect**. The computer can be a terminal server, or it can be a computer running Windows XP Professional or a Windows Server 2003 operating system that has Remote Desktop enabled and for which you have Remote Desktop permissions.
3. In the **Log On to Windows** dialog box, type your user name, password, and domain (if required), and then click **OK**.

**Concepts**
Enable Remote Desktop

# Install Active Directory from restored backup media

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to install Active Directory from backup media to create an additional domain controller in an existing domain.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain into which you are installing the additional domain controller.

**To install Active Directory from restored backup media**

1. Click **Start**, click **Run**, type **dcpromo /adv**, and then press ENTER.
2. In the Active Directory Installation Wizard, select **Additional domain controller for existing domain**.
3. Select **From these restored backup files**, and point to the same location where you restored the system state data.
4. If the domain controller whose system state backup you are using is a global catalog server, the Active Directory Installation Wizard asks you whether you want this server to also be a global catalog server.
5. Give appropriate credentials for the operation.
6. Enter the domain of the new domain controller. This domain must be the domain of the domain controller whose system state backup you are using.
7. Complete the remaining pages of the Active Directory Installation Wizard.

   Dcpromo.exe will install Active Directory using the data present in the restored files, which eliminates the need to replicate every object from a partner domain controller. However, objects that were modified, added, or deleted since the backup was taken must be replicated. If the backup was recent, the amount of replication required will be considerably less than that required for a regular Active Directory installation.

   After the installation operation completes successfully and the computer is restarted, the folder and subfolders that contain the restored system state can be removed from the local disk.

Restore system state to an alternate location
Include application directory partitions in an Active Directory installation from backup media

# Include application directory partitions in an Active Directory installation from backup media

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to install Active Directory from restored backup media that includes application directory partitions to create an additional domain controller in an existing domain. In this procedure, you edit a domain controller installation answer file to provide instructions for including application directory partitions in the installation. You must have already created the answer file according to the directions in Create an answer file for domain controller installation.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain into which you are installing the additional domain controller.

**To include application directory partitions in an Active Directory installation from backup media**

1. Open the answer file that you created to install the domain controller.
2. To include application directory partitions that are contained in the system state backup, add the following entry to the end of the answer file:

   **ApplicationPartitionsToReplicate=**

3. Provide a value for **ApplicationPartitionsToReplicate** as follows:

   - If you want to include all application directory partitions, use the value *****.

   - If you want to include specific application directory partitions, type the distinguished name of each directory partition. Separate each distinguished name with a space, and enclose the entire list in quotation marks, as shown in the following example:

     **ApplicationPartitionsToReplicate="dc=app1,dc=contoso,dc=com dc=app2,dc=contoso,dc=com"**

4. In the entry **ReplicationSourcePath=**, type the path to the folder that contains the restored system state backup files on the installation computer.
5. If you do not want Dcpromo to prompt the user for passwords, type the password in the **Password=** entry for the account that you will use to install the domain controller, type the password in the **SafeModeAdminPassword=** entry that you will use to provide access to Directory Services Restore Mode, and then save the answer file.

   | **Note** |
   | --- |
   | Passwords are automatically deleted from the answer file when Dcpromo runs. |

6. Open a command prompt, and then change directories to the location of the answer file.
7. At the command prompt, type the following command, and then press ENTER:

   **dcpromo /adv /answer:"** *Drive* **:** *PathToAnswerFile* **** *AnswerFileName* **"**

   Active Directory installation occurs automatically. If you left passwords blank in the answer file, Dcpromo prompts you for your administrative password and for the Directory Services Restore Mode password. If you specified "no" for the **RebootOnSuccess=** entry in the answer file, Dcpromo prompts you to restart the server after installation.

# Preparing an Existing Domain Controller for Shipping and Long-Term Disconnection

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you ship a domain controller to a remote site, you must disconnect it from the network and, consequently, from the replication topology. If a domain controller must be separated from the replication topology for a period of time that might be longer than a tombstone lifetime, you must take preliminary steps to ensure a smooth reconnection. Otherwise, it is possible that a long-term disconnection can result in a deleted object being reintroduced into the directory. Such deleted objects, when they are retained on a domain controller that has been disconnected for a period that is longer than a tombstone lifetime, are called "lingering objects." Lingering objects that are security principals, such as users or groups, can cause problems with Active Directory searches and e-mail delivery. Lingering objects can also jeopardize security if a user is allowed access to a resource by virtue of membership in a group that has been deleted. For more information about lingering objects, see "Maintaining Directory Consistency When Disconnecting a Domain Controller" in Known Issues for Adding Domain Controllers in Remote Sites.

By taking preliminary precautions, you can ensure that long-term disconnections do not result in directory inconsistency from lingering objects.

To complete this task, perform the following procedures:

1. Determine the anticipated length of the disconnection.

2. Determine the tombstone lifetime for the forest.

3. Determine the maximum safe disconnection period by subtracting a generous estimate of the end-to-end replication latency from the tombstone lifetime. Either find the latency estimate in the design documentation for your deployment or request the information from a member of your design or deployment team.

   - If the anticipated time of disconnection exceeds the maximum safe disconnection period, make a decision about whether to extend the tombstone lifetime. To change the tombstone lifetime, see Determine the tombstone lifetime for the forest and change the value in the **tombstoneLifetime** attribute.

   - If the estimated time of disconnection does not exceed the maximum safe disconnection time, proceed with disconnection.

4. View the current operations master role holders to determine whether the domain controller is an operations master role holder.

5. Transfer the domain-level operations master roles, if appropriate.

6. Transfer the schema master, if appropriate.

7. Transfer the domain naming master, if appropriate.

8. Prepare a domain controller for nonauthoritative SYSVOL restart on the domain controller that you are disconnecting. This process prevents the domain controller from having to reconcile and process deletions and modifications that took place from the time of the last SYSVOL update to the time the domain controller is restarted in the new site, and improves synchronization time.

9. Enable strict replication consistency on the domain controller that you are disconnecting. You can use this command-line procedure as an option to enable strict replication consistency on additional other domain controllers or on all domain controllers in the forest.

10. Synchronize replication with all partners. Update the domain controller with the latest changes just before you

disconnect it.

11. Verify successful replication to a domain controller for the domain controller that you are disconnecting.

12. Label the domain controller with the date and time of disconnection and the maximum safe disconnection period.

# Determine the tombstone lifetime for the forest

Updated: November 12, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 Foundation, Windows Server 2008 R2, Windows Server 2008 R2 Foundation, Windows Server 2012

The tombstone lifetime in an Active Directory forest determines how long a deleted object (called a "tombstone") is retained in Active Directory Domain Services (AD DS). The tombstone lifetime is determined by the value of the **tombstoneLifetime** attribute on the Directory Service object in the configuration directory partition.

You can use this procedure to determine the tombstone lifetime for the forest.

Membership in **Domain Users**, or equivalent, is the minimum required to complete this procedure. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

**To determine the tombstone lifetime for the forest using ADSIEdit**

1. Click **Start**, point to **Administrative Tools**, and then click **ADSI Edit**.
2. In ADSI Edit, right-click **ADSI Edit**, and then click **Connect to**.
3. For **Connection Point**, click **Select a well known Naming Context**, and then click **Configuration**.
4. If you want to connect to a different domain controller, for **Computer**, click **Select or type a domain or server: (Server | Domain [:port])**. Provide the server name or the domain name and Lightweight Directory Access Protocol (LDAP) port (389), and then click **OK**.
5. Double-click **Configuration**, **CN=Configuration,DC=***ForestRootDomainName*, **CN=Services**, and **CN=Windows NT**.
6. Right-click **CN=Directory Service**, and then click **Properties**.
7. In the **Attribute** column, click **tombstoneLifetime**.
8. Note the value in the **Value** column. If the value is **<not set>**, the value is 60 days.

**To determine the tombstone lifetime for the forest using Dsquery**

1. Open a Command Prompt window. To open a command prompt, click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, type the following command, and then press ENTER:

   ```
   dsquery * "cn=directory service,cn=windows nt,cn=services,cn=configuration,dc=
   <forestDN>" -scope base -attr tombstonelifetime
   ```

   Be sure to replace `<forestDN>` with the actual distinguished name of the forest. For example, if your forest name is corp.proseware.com, type the following, and then press ENTER:

   ```
   dsquery * "cn=directory service,cn=windows
   nt,cn=services,cn=configuration,dc=corp,dc=proseware,dc=com" -scope base -attr
   tombstonelifetime
   ```

# View the current operations master role holders

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Once an operations master role has been transferred, it should be verified that the transfer has occurred successfully throughout the domain. The change must be replicated to all relevant domain members in order to truly take effect.

To view the current operations master role holders, use Ntdsutil.exe with the roles option. This option displays a list of all current role holders.

**Administrative Credentials**

To perform this procedure, you must be logged on as a User or an Administrator.

**To view the current operations master role holder**

1. Click **Start**, click **Run**, type **ntdsutil**, and then press ENTER.
2. At the **ntdsutil:** prompt, type **roles** and press ENTER.
3. At the **fsmo maintenance:** prompt, type **connections** and press ENTER.
4. At the **server connections:** prompt, type **connect to server** *servername* (where *servername* is the name of the domain controller that belongs to the domain containing the operations masters).
5. After receiving confirmation of the connection, type **quit** and press ENTER to exit this menu.
6. At the **fsmo maintenance:** prompt, type **select operation target** and press ENTER.
7. At the **select operations target:** prompt, type **list roles for connected server** and press ENTER.

   The system responds with a list of the current roles and the Lightweight Directory Access Protocol (LDAP) name of the domain controllers currently assigned to host each role.
8. Type **quit** and press ENTER to exit each prompt in Ntdsutil.exe. Type **quit** and press ENTER at the **ntdsutil:** prompt to close the window.

# Transfer the domain-level operations master roles

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the three domain-level operations master roles: the PDC emulator, the RID master, and the infrastructure master. You can transfer all of these roles by using the Active Directory Users and Computers console.

| **Note** |
| --- |
| These procedures are performed by using MMC, although you can also transfer these roles by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer the operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To transfer a domain-level operations master role**

1. Open Active Directory Users and Computers.
2. At the top of the console tree, right-click **Active Directory Users and Computers**. Click **Connect to Domain Controller**.
3. In the list of **available domain controllers**, click the name of the server to which you want to transfer the role, and then click **OK**.
4. At the top of the console tree, right-click **Active Directory Users and Computers**, point to **All Tasks**, and then click **Operations Masters**.

   The name of the current operations master role holder appears in the **Operations master** box. The name of the server to which you want to transfer the role appears in the lower box.
5. Click the tab for the role you want to transfer: **RID**, **PDC**, or **Infrastructure**. Verify the computer names that appear and then click **Change**. Click **Yes** to transfer the role, and then click **OK**.
6. Repeat steps 4 and 5 for each role that you want to transfer.

# Transfer the schema master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the schema operations master role. The schema master is a forest-wide operations master role. Before you can use the Active Directory Schema snap-in for the first time, you must register it with the system. If you have not yet prepared the Active Directory Schema snap-in, see Install the Schema snap-in before you begin this procedure.

| **Note** |
| --- |
| This procedure is performed by using the Microsoft Management Console (MMC), although you can also transfer this role by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a Schema Administrator in Active Directory.

#### Transfer the schema master

1. Open the Active Directory Schema snap-in.
2. In the console tree, right-click **Active Directory Schema**, and click **Change Domain Controller**.
3. In the **Change Domain Controller** dialog box, click **Specify Name**. Then, in the text box, type the name of the server to which you want to transfer the schema master role. Click **OK**.
4. In the console tree, right-click **Active Directory Schema**. Click **Operations Master**. The **Change Schema Master** box displays the name of the server that is currently holding the role. The targeted domain controller is listed in the second box.
5. Click **Change**. Click **Yes** to confirm your choice. The system confirms the operation. Click **OK** again to confirm that the operation succeeded.
6. Click **Close** to close the **Change Schema Master** dialog box.

| **Note** |
| --- |
| Hosting the infrastructure master on a global catalog server is not recommended. If you attempt to transfer the infrastructure master role to a domain controller that is a global catalog, the system displays a warning stating that this is not recommended. |

# Transfer the domain naming master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the domain naming operations master role. The domain naming master is a forest-wide operations master role.

| **Note** |
| --- |
| This procedure is performed by using the Microsoft Management Console (MMC), although you can also transfer this role by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

#### To transfer the domain naming master

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click **Active Directory Domains and Trusts**, and then click **Connect to Domain Controller**.
3. Ensure that the proper domain name is entered in the **Domain** box.

   The available domain controllers from this domain are listed.
4. In the **Name** column, click the domain controller (to select it) to which you want to transfer the role. Click **OK**.
5. Right-click **Active Directory Domains and Trusts**, and then click **Operations Master**.
6. The name of the current domain naming master appears in the first text box. The server to which you want to transfer the role should appear in the second text box. If this is not the case, repeat steps 1 through 4.
7. Click **Change**. To confirm the role transfer, click **Yes**. Click **OK** again to close the message box indicating the transfer took place. Click **Close** to close the **Change Operations Master** dialog box.

# Prepare a domain controller for nonauthoritative SYSVOL restart

Updated: April 15, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Initiate a nonauthoritative restore of SYSVOL by modifying the value of the BurFlags (backup/restore flags) registry entry. Changing the value to D2 (hexadecimal) or 210 (decimal) prior to disconnecting a domain controller initiates an automatic nonauthoritative restore of SYSVOL when the domain controller is restarted. This process results in a smaller database size and improved synchronization time because the domain controller does not reconcile and process every deletion and modification that took place from the time of the last SYSVOL update to the time the domain controller is restarted in the new site, thereby improving synchronization time. Instead, it processes only the latest changes.

Separate entries exist for global and replica-set-specific BurFlags, as follows:

- To initiate a nonauthoritative restart of SYSVOL when it is the only replica set that is represented on the domain controller, set the value of the global BurFlags (REG_DWORD) entry under

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Backup/Restore\Process at Startup**

- If other replica sets are represented on the domain controller and you want to update only SYSVOL, set the value of the replica-set-specific BurFlags (REG_DWORD) entry under

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters\Cumulative Replica Sets\SYSVOL GUID**

Modifying the replica-set-specific BurFlags entry requires identifying the SYSVOL GUID in the registry.

| ⚠**Caution** |
| --- |
| The Registry Editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back up system state first. For information about backing up system state, see Administering Active Directory Backup and Restore. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To prepare a domain controller for nonauthoritative SYSVOL restart**

1. Click **Start**, click **Run**, type **regedit** and then click **OK**.
2. Navigate to

   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NtFrs\Parameters**
3. Expand **Parameters**.
4. Modify one of the BurFlags entries as follows:

   To modify the global BurFlags entry:

   a. Expand **Backup/Restore** and then click **Process at Startup**.

   b. In the details pane, right-click **BurFlags** and click **Modify**.

   c. In the **Value data** box, type **D2** hexadecimal or **210** decimal.

   d. Click **OK** and close Registry Editor.

To modify the replica-set-specific BurFlags entry:

a. Expand both **Cumulative Replica Sets** and **Replica Sets**.

b. Match the GUID under **Replica Sets** to the identical GUID under **Cumulative Replica Sets**, and click the matching GUID under **Cumulative Replica Sets**.

c. In the details pane, right click **BurFlags** and click **Modify**.

d. In the **Value data** box, type **D2** hexadecimal or **210** decimal.

e. Click **OK** and close Registry Editor.

# Enable strict replication consistency

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The setting for replication consistency is stored in the registry in the **Strict Replication Consistency** entry in **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters**.

Values for this entry are as follows:

- Value: **1** (**0** to disable)
- Default: **1** (enabled) in a new Windows Server 2003 forest; otherwise **0**.
- Data type: **REG_DWORD**

On domain controllers running Windows Server 2003 with Service Pack 1 (SP1), you do not have to edit the registry directly to enable strict replication consistency. It is best to avoid editing the registry directly if possible. You can use a Repadmin command that enables strict replication consistency on one or all domain controllers in the forest. This command is available only in the version of Repadmin that is included with Windows Support Tools in Windows Server 2003 SP1. This command can be applied only on domain controllers running Windows Server 2003 with SP1.

**Administrative credentials**

- To complete this procedure on a single domain controller, you must be a member of the Domain Admins group in the domain.
- To complete this procedure on all domain controllers, you must be a member of the Enterprise Admins group in the forest.

**Requirements:**

- Operating system: Windows Server 2003 with SP1

| **Note** |
| --- |
| To enable strict replication consistency on a domain controller that is not running Windows Server 2003 with SP1, use a registry editor to set the value in the **Strict Replication Consistency** entry to **1**. |

| **Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

**To enable strict replication consistency**

1. Open a command prompt, type the following command, and then press ENTER:

   **repadmin /regkey** *DC_LIST* **{+|-}** *key*

| Term | Definition |
| --- | --- |
| *DC_LIST* | The name of a single domain controller. (***** applies the change to all domain controllers in the forest.) For the domain controller name, you can use the Domain Name System (DNS) name, the distinguished name of the domain controller computer object, or the distinguished name of the domain controller server object. |

| | |
|---|---|
| **{+\|-}** *key* | **+** to enable and **-** to disable, and *key* is strict. For example, **+strict** enables strict replication consistency; **-strict** disables it. |

2. Repeat step 1 for every domain controller on which you want to enable strict replication consistency.

| **Note** |
|---|
| For more naming options and information about the syntax of the *DC_LIST* parameter, at the command prompt type **repadmin /listhelp**. |

# Synchronize replication with all partners

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to synchronize replication with all replication partners of a domain controller.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the selected domain controller or the Enterprise Admins group in the forest, or you must have been delegated the appropriate authority. If you want to synchronize the configuration and schema directory partitions on a domain controller in a child domain, you must have Domain Admins credentials in the forest root domain or Enterprise Admins credentials in the forest.

**To synchronize replication with all partners**

1. At a command prompt, type the following command, and then press ENTER:

   **repadmin /syncall** *DCName* **/e /d /A /P /q**

| Term | Definition |
|---|---|
| *DCName* | The Domain Name System (DNS) name of the domain controller on which you want synchronize replication with all partners |
| **/e** | Enterprise; includes partners in all sites. |
| **/d** | Identifies servers by distinguished name in messages. |
| **/A** | All; synchronizes all directory partitions that are held on the home server. |
| **/P** | Pushes changes outward from the home server. |
| **/q** | Runs in quiet mode; suppresses callback messages. |

2. Check for replication errors in the output of the command in the previous step. If there are no errors, replication is successful. For replication to complete, any errors must be corrected.

**See Also**
**Concepts**
Verify successful replication to a domain controller

# Verify successful replication to a domain controller

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **repadmin /showrepl** command to verify successful replication to a specific domain controller. If you are not running Repadmin on the domain controller whose replication you are checking, you can specify a destination domain controller in the command. Repadmin lists INBOUND NEIGHBORS for the current or specified domain controller. INBOUND NEIGHBORS shows the distinguished name of each directory partition for which inbound directory replication has been attempted, the site and name of the source domain controller, and whether replication succeeded or not, as follows:

- Last attempt @ YYYY-MM-DD HH:MM.SS was successful.
- Last attempt @ [Never] was successful.

If @ [Never] appears in the output for a directory partition, replication of that directory partition has never succeeded from the identified source replication partner over the listed connection.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the destination domain controller.

**To verify successful replication to a domain controller**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl** *servername* **/u:** *domainname* **** *username* **/pw:***

   | Term | Definition |
   | --- | --- |
   | *servername* | Specifies the name of the destination domain controller. |
   | *domainname* | Specifies the single-label name of the domain of the destination domain controller. (You do not have to use a fully qualified Domain Name System (DNS) name.) |
   | *username* | Specifies the name of an administrative account in that domain. |

3. When you are prompted for a password, type the password for the user account that you provided, and then press ENTER.

You can also use Repadmin to generate the details of replication to and from all replication partners in a spreadsheet. The spreadsheet displays data in the following columns:

Showrepl_COLUMNS

Destination DC Site

Destination DC

Naming Context

Source DC Site

Source DC

Transport Type

Number of Failures

Last Failure Time

Last Success Time

Last Failure Status

The following procedure shows how to create this spreadsheet and set column headers for improved readability.

**To generate a repadmin /showrepl spreadsheet for all replication partners**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl * /csv >showrepl.csv**
3. Open Microsoft Excel.
4. On the **File** menu, click **Open**, navigate to showrepl.csv, and then click **Open**.
5. Hide or delete column **A** as well as the **Transport Type** column, as follows:
6. Select a column that you want to hide or delete.
   - To hide the column, on the **Format** menu, click **Column**, and then click **Hide**.

     Or

   - To delete the column, right-click the selected column, and then click **Delete**.
7. Select row 1 beneath the column heading row, and then, on the **Window** menu, click **Freeze Panes**.
8. Select the entire spreadsheet. On the **Data** menu, click **Filter**, and then click **AutoFilter**.
9. In the **Last Success Time** column, click the down arrow, and then click **Sort Ascending**.
10. In the **Source DC** column, click the down arrow, and then click **Custom**.
11. In the **Custom AutoFilter** dialog box, under **Show rows where**, click **does not contain**. In the adjacent text box, type **del** to eliminate from view the results for deleted domain controllers.
12. Repeat step 10 for the **Last Failure Time** column, but use the value **does not equal**, and type the value **0**.
13. Resolve replication failures.

The last successful attempt should agree with the replication schedule for intersite replication, or the attempt should be within the last hour for intrasite replication.

If Repadmin reports any of the following conditions, see Troubleshooting Active Directory Replication Problems:

- The last successful intersite replication was prior to the last scheduled replication.
- The last intrasite replication was longer than one hour ago.
- Replication was never successful.

Troubleshooting Active Directory Replication Problems

# Reconnecting a Domain Controller After a Long-Term Disconnection

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Assuming that a domain controller has not been disconnected for longer than the maximum safe period for disconnection (tombstone lifetime minus end-to-end replication latency), reconnecting the domain controller to the replication topology requires no special procedures. By default, the Knowledge Consistency Checker (KCC) on a domain controller runs five minutes after the domain controller starts, automatically incorporating the reconnected domain controller into the replication topology.

**Reconnecting an Outdated Domain Controller**

If you plan appropriately for disconnecting and reconnecting domain controllers, no domain controller will be disconnected from the replication topology for longer than a tombstone lifetime. However, if unexpected events result in a domain controller becoming outdated, reconnect the domain controller as follows:

- The disconnected domain controller is running Windows Server 2003, and an authoritative domain controller running Windows Server 2003 is available in this site or a neighboring site: Reconnect the domain controller, and immediately follow the instructions in Use Repadmin to remove lingering objects.

- The disconnected domain controller is running Windows Server 2003, but no other authoritative domain controller running Windows Server 2003 is available in the domain: Reconnect the domain controller, and follow the instructions in article 314282, "Lingering objects may remain after you bring an out-of-date global catalog server back online," in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=37924).

- The disconnected domain controller is running Windows 2000 Server, and another domain controller is available in the domain: Do not reconnect the domain controller. Instead, force Active Directory removal on the disconnected domain controller, perform metadata cleanup, and then reinstall Active Directory. To complete these tasks, follow the instructions in Forcing the Removal of a Domain Controller and Installing a Domain Controller in an Existing Domain.

- The disconnected domain controller is running Windows 2000 Server, and no other domain controller is available in the domain: If you want to recover the domain, reconnect the domain controller, and follow the instructions in article 314282, "Lingering objects may remain after you bring an out-of-date global catalog server back online," in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=37924).

**Updating SYSVOL**

As described in Preparing an Existing Domain Controller for Shipping and Long-Term Disconnection, the recommended practice to ensure consistency of SYSVOL is to modify the registry before disconnecting the domain controller so that SYSVOL is updated automatically when the domain controller is restarted. In addition, if you want to avoid a full synchronization of SYSVOL through intersite replication, you must take preparatory steps before disconnection. For information about how to ensure that SYSVOL is sourced locally and updated over the network only for changes, see "Seeding the SYSVOL tree from restored files during IFM promotion" in article 311078, "How to use the Install from Media feature to promote Windows Server 2003-based domain controllers," in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=37924). To update SYSVOL as soon as possible after reconnecting a domain controller, plan the time that you restart the domain controller to optimize the replication schedule, as follows:

- If the closest replication partner for the domain is in a different site, view site link properties to determine the replication schedule, and then restart the domain controller as soon as possible after replication is scheduled to start.

- If a replication partner for the domain is available within the site, verify replication success on that partner before restarting the domain controller.

**Important**

Do not use file copy utilities, such as Xcopy or Robocopy, to update an outdated SYSVOL. Copying SYSVOL files is recommended only for recreating a nonfunctioning SYSVOL, which requires several preliminary procedures. Copying SYSVOL files from one domain controller to another without following these procedures causes invalid data to be replicated and causes the system volumes on other domain controllers to become inconsistent. For information about how to recreate a nonfunctioning SYSVOL, see Restoring and Rebuilding SYSVOL.

To complete this task, perform the following procedures:

1. Determine the tombstone lifetime for the forest.

2. Determine whether the maximum safe disconnection time has been exceeded. The maximum safe disconnection time should have been established at the time of disconnection, as follows:

   Subtract a generous estimate of the amount of time for end-to-end replication latency from the tombstone lifetime. Either find the latency estimate in the design documentation for your deployment or request the information from a member of your design or deployment team.

3. If the maximum safe disconnection time has not been exceeded, proceed with the reconnection process as follows:

   - If the site in which you are reconnecting the domain controller has one or more other domain controllers that are authoritative for the domain, start the domain controller anytime.

   - If the site in which you are reconnecting the domain controller has no other domain controllers that are authoritative for the domain, proceed as follows:

     Determine when intersite replication is scheduled to begin by viewing the replication properties on the site link that connects this site to the next closest site that includes a domain controller that is authoritative for this domain.

     As soon as possible after the next replication cycle begins, start the domain controller.

   If the maximum safe disconnection time has been exceeded, proceed in the appropriate manner according to the operating system, as described in "Reconnecting an Outdated Domain Controller" earlier in this topic.

4. After replication is complete, Verify successful replication to a domain controller (the reconnected domain controller) of the domain, configuration, and schema directory partitions. If the domain controller is a global catalog server, check for successful replication of all domain directory partitions.

Preparing an Existing Domain Controller for Shipping and Long-Term Disconnection

# Determine when intersite replication is scheduled to begin

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the properties on the site link object to determine when intersite replication between sites is scheduled to begin.

**Administrative Credentials**

To complete this procedure, you must be a member of the Domain Users group.

**To determine when intersite replication is scheduled to begin**

1. Open Active Directory Sites and Services.
2. In the console tree, double-click the **Sites** container, double-click the **Inter-Site Transports** container, and then click the **IP** container.
3. In the details pane, right-click the site link object for which you want to view the schedule, and then click **Properties**.
4. In the *SiteLinkName* **Properties** dialog box, click **Change Schedule**. Note the block of days and hours during which replication is allowed (**Replication Available**), and then click **OK**.
5. In the **Replicate every _____ minutes** box, note the number of minutes for the intervals at which replication polling takes place during an open schedule window, and then click **OK**.

# Use Repadmin to remove lingering objects

Updated: July 12, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use Repadmin to remove lingering objects when you reconnect a domain controller that has been offline for longer than a tombstone lifetime and you want to ensure that lingering objects do not exist or, if they do, that they are removed before they are replicated. You can also use this procedure when event ID 1388 or event ID 1988 is logged on a domain controller. In this case, the information that you need to perform the procedure is provided in the event. For information about removing lingering objects when event ID 1388 or event ID 1988 has been logged, see "Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042)."

If you are running the procedure preemptively, you must gather the following information before beginning the procedure:

- Name of the server that has or might have lingering objects. This name can be the Domain Name System (DNS) name, NetBIOS name, or distinguished name of the domain controller.
- Globally unique identifier (GUID) of the NTDS Settings object of a domain controller that is authoritative for the domain of the domain controller from which you want to remove lingering objects.

If necessary, use the following procedure to determine the GUID of a domain controller.

**Administrative Credentials**

To complete this procedure, you must be a member of the Domain Users group in the domain of the domain controller.

**To determine the GUID of a domain controller**

1. At a command prompt, type the following command, and then press ENTER:

   **repadmin /showrepl***DomainControllerName*

   where *DomainControllerName* is the NetBIOS name of the domain controller whose GUID you want to determine.

2. In the top portion of the output, note the value in **DC object GUID:**

If the destination domain controller and source domain controller are both running Windows Server 2003, you can remove lingering objects by using Repadmin. If either domain controller is running Windows 2000 Server, follow instructions in article 314282, "Lingering objects may remain after you bring an out-of-date global catalog server back online," in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=37924).

**Administrative Credentials**

To complete this procedure, you must be a member of the Domain Admins group in the *DirectoryPartition* domain.

**To use Repadmin to remove lingering objects**

1. At a command prompt, type the following command, and then press ENTER:

| **Important** |
|---|
| There must be connectivity between the server that has or might have lingering objects and the server that has an up-to-date, writable replica of the directory partition. |

**repadmin /removelingeringobjects** *ServerName ServerGUID DirectoryPartition* **/advisory_mode**

| Term | Definition |
|---|---|
| *ServerName* | The DNS name or the distinguished name of the domain controller that has or might have lingering objects. |
| *ServerGUID* | The GUID of a domain controller that has an up-to-date writable replica of the directory partition |

| | |
|---|---|
| *DirectoryPartition* | The distinguished name of the domain directory partition that might have lingering objects. For example, DC=*RegionalDomainName*,DC=*ForestRootDomainName*,DC=com. Also run the command against the configuration directory partition (CN=configuration,DC=*ForestRootDomainName*,DC=com), the schema directory partition (CN=schema,CN=configuration,DC=*ForestRootDomainName*), and any application directory partitions that are hosted on the domain controller you are checking for lingering objects. |

**/advisory_mode** logs the lingering objects that will be removed so that you can review them, but it does not remove them.

2. If lingering objects are found, repeat step 1 without **/advisory_mode** to delete the identified lingering objects from the directory partition.
3. Repeat steps 1 and 2 for every domain controller that might have lingering objects.

| **Note** |
|---|
| The *ServerName* parameter uses the **DC_LIST** syntax for **repadmin**, which allows the use of ***** for all domain controllers in the forest and **gc:** for all global catalog servers in the forest. To see the **DC_LIST** syntax, type **repadmin /listhelp**. |

Fixing Replication Lingering Object Problems (Event IDs 1388, 1988, 2042)

# Verify successful replication to a domain controller

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **repadmin /showrepl** command to verify successful replication to a specific domain controller. If you are not running Repadmin on the domain controller whose replication you are checking, you can specify a destination domain controller in the command. Repadmin lists INBOUND NEIGHBORS for the current or specified domain controller. INBOUND NEIGHBORS shows the distinguished name of each directory partition for which inbound directory replication has been attempted, the site and name of the source domain controller, and whether replication succeeded or not, as follows:

- Last attempt @ YYYY-MM-DD HH:MM.SS was successful.
- Last attempt @ [Never] was successful.

If @ [Never] appears in the output for a directory partition, replication of that directory partition has never succeeded from the identified source replication partner over the listed connection.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the destination domain controller.

**To verify successful replication to a domain controller**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl** *servername* **/u:** *domainname* **** *username* **/pw:***

   | Term | Definition |
   | --- | --- |
   | *servername* | Specifies the name of the destination domain controller. |
   | *domainname* | Specifies the single-label name of the domain of the destination domain controller. (You do not have to use a fully qualified Domain Name System (DNS) name.) |
   | *username* | Specifies the name of an administrative account in that domain. |

3. When you are prompted for a password, type the password for the user account that you provided, and then press ENTER.

You can also use Repadmin to generate the details of replication to and from all replication partners in a spreadsheet. The spreadsheet displays data in the following columns:

Showrepl_COLUMNS

Destination DC Site

Destination DC

Naming Context

Source DC Site

Source DC

Transport Type

Number of Failures

Last Failure Time

Last Success Time

Last Failure Status

The following procedure shows how to create this spreadsheet and set column headers for improved readability.

**To generate a repadmin /showrepl spreadsheet for all replication partners**

1. Open a Command Prompt.
2. Type the following command, and then press ENTER:

   **repadmin /showrepl * /csv >showrepl.csv**
3. Open Microsoft Excel.
4. On the **File** menu, click **Open**, navigate to showrepl.csv, and then click **Open**.
5. Hide or delete column **A** as well as the **Transport Type** column, as follows:
6. Select a column that you want to hide or delete.
   - To hide the column, on the **Format** menu, click **Column**, and then click **Hide**.

     Or

   - To delete the column, right-click the selected column, and then click **Delete**.
7. Select row 1 beneath the column heading row, and then, on the **Window** menu, click **Freeze Panes**.
8. Select the entire spreadsheet. On the **Data** menu, click **Filter**, and then click **AutoFilter**.
9. In the **Last Success Time** column, click the down arrow, and then click **Sort Ascending**.
10. In the **Source DC** column, click the down arrow, and then click **Custom**.
11. In the **Custom AutoFilter** dialog box, under **Show rows where**, click **does not contain**. In the adjacent text box, type **del** to eliminate from view the results for deleted domain controllers.
12. Repeat step 10 for the **Last Failure Time** column, but use the value **does not equal**, and type the value **0**.
13. Resolve replication failures.

The last successful attempt should agree with the replication schedule for intersite replication, or the attempt should be within the last hour for intrasite replication.

If Repadmin reports any of the following conditions, see Troubleshooting Active Directory Replication Problems:

- The last successful intersite replication was prior to the last scheduled replication.
- The last intrasite replication was longer than one hour ago.
- Replication was never successful.

Troubleshooting Active Directory Replication Problems

# Performing an Unattended Installation of Active Directory

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Running an unattended install simplifies the process of setting up Active Directory on multiple computers. The unattended install feature uses an "answer file" to provide answers to the questions that are asked during a normal setup. This way, the installation process can proceed from start to completion without user intervention. This method works best when Active Directory is installed with identical options on many computers. This method is required if you want to include application directory partitions in Active Directory installations from restored backup media.

**Task requirements**

The following tool is required to complete this task:

- Dcpromo.exe

The following files are required to complete this task:

- Ref.chm (in the Support\Tools folder on the Windows Server 2003 operating system CD)
- Unattend.txt
- Domain controller answer file

To complete this task, perform the following procedures:

1. Create an answer file for domain controller installation
2. Install Active Directory using an answer file

**See Also**
**Concepts**
Include application directory partitions in an Active Directory installation from backup media

# Create an answer file for domain controller installation

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to create a text file that you can use as the answer file for an unattended installation of a domain controller. The answer file contains sensitive information and should be kept in a secure location.

**Administrative credentials**

To perform this procedure, you must be a member of the Authenticated Users group on the local computer on which you create the answer file.

**To create an answer file for domain controller installation**

1. On a local computer, insert the Windows Server 2003 CD-ROM into the CD-ROM drive or DVD-ROM drive. Press and hold down the SHIFT key as you insert the CD to prevent it from starting automatically.
2. Start Windows Explorer, and then open the Support\Tools folder on the Windows Server 2003 CD-ROM.
3. In the console tree, click **Tools**, and then, in the details pane, double-click **Deploy.cab**.
4. In the details pane, right-click **Ref.chm**, and then click **Extract**.
5. In the **Select a Destination** dialog box, navigate to or create a new folder for the expanded Ref.chm file, and then click **Extract**.
6. In its extracted location, open Ref.chm.
7. On the **Contents** tab in the scope pane, double-click **Unattend.txt**, and then click **[DCInstall]**.
8. In the details pane, scroll to **Sample**, select the entire sample, beginning at **[DCInstall]**, and then copy the sample.
9. Open Notepad, paste the sample into the Notepad file, and save the text file.
10. Edit the text file to contain at least the following entries. For additional examples and parameters, see Ref.chm and article 223757 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=155037).

    **[DCINSTALL]**

    **UserName=** *SAM account name that has Domain Admins credentials in the target domain. This account must be used by the administrator who runs the Dcpromo command.*

    **Password=** *Password for the account name. If you leave this blank, Dcpromo prompts the user during installation. Dcpromo deletes this value following installation.*

    **UserDomain=** *Domain name for the user account in* **UserName** .

    **DatabasePath=** *Location of the Ntds.dit file. (The default is %systemroot%*\ntds*.) If you omit this entry, Dcpromo uses the default location.*

    **LogPath=** *Location of the database log files. (The default is %systemroot%*\ntds*.) If you omit this entry, Dcpromo uses the default location.*

    **SYSVOLPath=** *Location of the shared SYSVOL tree. (The default is %systemroot%*\SYSVOL*.)* If you omit this entry, Dcpromo uses the default location.

    **SafeModeAdminPassword=** *Password for the administrator account that must be used to start the domain controller in Directory Services Restore Mode.* If you leave this blank, Dcpromo prompts the user for the password during installation. Dcpromo deletes this value following installation. Passwords are removed from the answer file when Dcpromo is executed.

    **CriticalReplicationOnly=Yes** *or* **no** *, to specify whether to skip noncritical portions of replication and allow Dcpromo to complete before replication is complete.*

    **SiteName=** *The name of the Active Directory site in which this domain controller will be placed.* This site must be created in advance in the Active Directory Sites and Services snap-in.

    **ReplicaOrNewDomain=** *Specify either* **Replica** *for an additional domain controller in an existing domain or*

**NewDomain** *for the first domain controller in a new domain.*

**ReplicaDomainDNSName=** *The fully qualified domain name of the domain of the new domain controller.*

**ReplicationSourceDC=** *The name of an existing domain controller in the domain to use as the source replication partner during installation.* When you install Active Directory from restored backup media, you can use this entry in conjunction with **ReplicateFromMedia** if you want to specify the domain controller from which Active Directory changes and SYSVOL changes are replicated.

**ReplicateFromMedia=Yes** *for installation from media,* **no** *for installation by replication.*

| **Note** |
| --- |
| For more information on this option, see article 311078 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkID=128859). |

**ReplicationSourcePath=** *When the installation is by replication, the path to the installation CD or network share. When the installation is from restored backup media, the local drive and path to the restored backup files.*

**RebootOnSuccess=Yes** *if you want the domain controller to restart automatically following a successful installation,* **no** *if you want to restart the domain controller manually. If you do not want the domain controller to restart automatically and you do not want to be prompted, use the value* **NoAndNoPromptEither**.

**ApplicationPartitionsToReplicate=** *Comma-separated distinguished names, with the entire string enclosed in quotation marks, of application directory partitions that you want to include when you use restored backup media to install Active Directory (or * to include all application directory partitions).* Using this entry requires Windows Server 2003 with Service Pack 1 (SP1) and Windows Server 2003 forest functional level. For more information about using this entry, see Include application directory partitions in an Active Directory installation from backup media.

| **Note** |
| --- |
| For additional examples and parameters, see Ref.chm and article 223757 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=155037). |

11. Save the answer file to the location on the installation server from which it is to be called by Dcpromo, or save the file to a network shared folder or removable media for distribution.

Include application directory partitions in an Active Directory installation from backup media

# Install Active Directory using an answer file

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to perform an unattended Active Directory installation by using an answer file.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group in the domain of the domain controller that you are installing.

**To install Active Directory using an answer file**

1. Click **Start**, click **Run**, and then type **dcpromo /answer:***answerfile*

   ***Answerfile***
   The path to the answer file, including the filename.

2. Click **OK**.

Verifying Active Directory Installation

# Verifying Active Directory Installation

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

There are several verification tasks that can be performed on a computer on which Active Directory has been newly installed. Successfully completing the requirements of each verification task will provide a strong indication of a healthy, operational domain controller.

**Task Requirements**

The following tools are recommended to perform the procedures for this task:

- Active Directory Sites and Services
- DNS Manager
- Event Viewer
- Netdiag.exe
- Dcdiag.exe
- Ntdsutil.exe

To complete this task, perform the following procedures:

1. Determine whether a Server object has child objects
2. Verify that an IP address maps to a subnet and determine the site association

   You must ensure that the new domain controller is located in the proper site so that after the installation is complete, the new domain controller can locate replication partners and become part of the replication topology. If the site is not correct, you can use the Active Directory Sites and Services snap-in to move the Server object for the domain controller to the proper site after Active Directory installation is complete.

3. Move the Server object to the new site
4. Configure DNS server forwarders
5. Complete all procedures for the Verifying DNS configuration task.
6. Check the status of the shared SYSVOL
7. Verify DNS registration and functionality
8. Verify domain membership for a new domain controller
9. Verify communication with other domain controllers
10. Verify replication with other domain controllers
11. Verify the availability of the operations masters

# Determine whether a Server object has child objects

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After Active Directory is properly installed on a domain controller, the Server object for the domain controller will have a Child NTDS-Settings object. Other applications that are running on domain controllers can also publish Child objects.

Prior to deleting a Server object from the Servers container for a site, verify that the Server object has no Child objects. If a Child object appears, do not delete the Server object.

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Users group.

**To determine whether a server object has child objects**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and expand the site of the Server object.
3. Expand the **Servers** container, and then expand the Server object to view any Child objects.

# Verify that an IP address maps to a subnet and determine the site association

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to determine the site to which you want to add a Server object prior to installing Active Directory, or to verify the appropriate site prior to moving a Server object to it.

To be associated with a site, the IP address of a domain controller must map to a Subnet object that is defined in Active Directory. The site to which the subnet is associated is the site of the domain controller.

The subnet address, which is computed from the IP network address and the subnet mask, is the name of a Subnet object in Active Directory. When you know the subnet address, you can locate the Subnet object and determine the site to which the subnet is associated.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To verify that an IP address maps to a subnet and determine the site association**

1. Log on locally or open a Terminal Services connection to the server for which you want to check the IP address.
2. On the desktop, right-click **My Network Places**, and then click **Properties**.
3. In the **Network Connections** dialog box, right-click **Local Area Connection**, and then click **Properties**.
4. Double-click **Internet Protocol (TCP/IP)**.
5. Use the values in **IP address** and **Subnet mask** to calculate the subnet address and then click **OK**.
6. Click **OK** again and close the **Network Connections** dialog box.
7. Open Active Directory Sites and Services.
8. Expand the **Sites** container, and then click the **Subnets** container.
9. In the **Name** column in the details pane, find the Subnet object that matches the subnet address.
10. In the **Site** column, note the site to which the IP subnet address is associated.

    If the site that appears in the **Site** box is not the appropriate site, contact a supervisor and find out whether the IP address is incorrect or whether to move the Server object to the site indicated by the subnet.

# Move the Server object to the new site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Moving a Server object requires that the IP address of the domain controller maps to the site to which you are moving the Server object. Before performing this procedure, verify that the IP address maps to the target site.

**Administrative Credentials**

To perform this procedure, you must be a member of the Enterprise Admins group.

**To move the server object to the new site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and the site in which the server object resides.
3. Expand the **Servers** container to display the domain controllers that are currently configured for that site.
4. Right-click the Server object you want to move, and then click **Move**.
5. In the **Site Name** box, click the destination site, and then click **OK**.
6. Expand the Site object to which you moved the server, and then expand the **Servers** container.
7. Verify that an object for the server you moved exists.
8. Expand the Server object and verify that an NTDS Settings object exists.

Within an hour, the Net Logon service on the domain controller registers the new site information in DNS. Wait an hour and then open Event Viewer and connect to the domain controller whose Server object you moved. Review the System log for Net Logon errors regarding registration of SRV resource records in DNS that have occurred within the last hour. The absence of errors indicates that Net Logon has updated DNS with site-specific SRV resource records. Net Logon event ID 5774 indicates that the registration of DNS resource records has failed. If this error occurs, contact a supervisor and pursue DNS troubleshooting.

# Configure DNS server forwarders

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Configure DNS server forwarders based on the forwarders method established on your network.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To configure DNS server forwarders**

1. If your network uses root hints as the forwarders method, you do not need to perform any additional options. Root hints are automatically configured during installation. Do not continue to step 2.
2. If you need to configure forwarders, open the DNS snap-in and continue to step 3.
3. In the console tree, right-click *ComputerName* (where *ComputerName* is the computer name of the domain controller), and then click **Properties**.
4. In the *ComputerName* Properties sheet (where *ComputerName* is the name of the domain controller), on the **Forwarders** tab, select the **Enable forwarders** check box.
5. In the **IP address** box, type *IpAddress* (where *IpAddress* is the IP address of the DNS server or nearest replication partner from which the domain is delegated), click **Add**, and then click **OK**.

# Verifying DNS configuration

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Part of verifying Active Directory installation is verifying that DNS was installed and configured appropriately.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- DNS snap-in
- My Network Places

To complete this task, perform the following procedures:

1. Create a delegation for a domain controller

   If the parent DNS zone of any zone that is hosted by this DNS server contains a delegation to this DNS server, use this procedure to update the IP address in all such delegations.

   If your forest root domain has a parent DNS domain, perform this procedure on a DNS server in the parent domain. If you just added a new domain controller to a child domain, perform this procedure on a DNS server in the DNS parent domain. By following recommended practices, the parent domain is the forest root domain.

2. Configure the DNS client settings

3. Create a secondary zone

# Create a delegation for a domain controller

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to create a delegation for a new domain controller that is also a DNS server in the parent DNS domain.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To create a delegation for a domain controller**

1. Open the DNS snap-in.
2. Navigate to C*hildDomain* (where C*hildDomain* is the name of the child domain) in the console tree.
3. In the console tree, right-click C*hildDomain*, and then click **Properties**.
4. In the C*hildDomain* **Properties** sheet, on the **Name Servers** tab, click **Add**.
5. In the **New Resource Record** dialog box, in the **Server fully qualified domain name (FQDN)** box, type *ChildDC.ChildDomain.ParentDomain* (where *ChildDC* is the name of the new domain controller, *ChildDomain* is the name of the child domain, and *ParentDomain* is the name of the parent domain).
6. In the **New Resource Record** dialog box, in the **IP address** box, type *IPAddress* (where *IPAddress* is the IP address of the child domain controller), click **Add**, and then click **OK**.

# Create a secondary zone

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Perform this procedure only on new domain controllers that are also DNS servers that are located in the child domain, not the forest root domain.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To create a secondary zone**

1. Open the DNS snap-in.
2. In the console tree, right-click the new domain controller and click **New Zone**.
3. In the **New Zone Wizard**, click **Next** to continue.
4. On the **Zone Type** page, select **Secondary zone** and click **Next**.
5. Ensure that **Forward lookup zone** is selected. Click **Next**.
6. For Zone name, type **_msdcs.***forestrootdomain* (where *forestrootdomain* is the fully qualified domain name of the forest root domain), and click **Next**.
7. In the **Master DNS Servers** dialog box, enter the IP addresses of at least two DNS servers in the forest root domain. Click **Next**.
8. Review the settings you defined, and click **Finish** to close the wizard.

# Configure the DNS client settings

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Configure the DNS client settings on the new domain controller.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To configure the DNS client settings**

1. On the desktop, right-click **My Network Places** and click **Properties**.
2. In the **Network Connections** dialog box, right-click the connection that represents the connection this computer uses to attach to your network. The default label is **Local Area Connection**, but this can be changed so it might not be labeled the same on your computer. Click **Properties**.
3. In the **Local Area Connection Properties** dialog box, click once on **Internet Protocol (TCP/IP)** to highlight it (be sure you do not clear the check box in front of it), then click **Properties**.
4. In the **Internet Protocol (TCP/IP) Properties** dialog box, verify that **Use the following DNS server addresses:** is selected.
5. If the new domain controller is located in the forest root domain, set the **Preferred DNS server** IP address to that of another DNS server in the forest root domain. Try to choose a server that is located near the new domain controller. Set the **Alternate DNS server** address to the IP address of the new domain controller (so that it is referencing itself).

   If the new domain controller is located in a child domain, set the **Preferred DNS server** IP address to the IP address of the new domain controller (so that it is referencing itself). Set the **Alternate DNS server** address to that of another DNS server in the same domain. Try to choose a server that is located near the new domain controller.
6. Click **OK** to close the dialog box.

# Check the status of the shared SYSVOL

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure involves checking Event Viewer to make sure that the File Replication service is started properly and then ensuring that the SYSVOL and Net Logon shared folders are created.

| **Note** |
| --- |
| You do not need to perform this procedure on every replication partner, but you need to perform it enough times to be confident that the shared system volumes on the replication partners are healthy. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To check the status of the shared SYSVOL**

1. Open Event Viewer.
2. In the Event Viewer tree, click **File Replication Service** to display the FRS events.
3. Look for an event 13516 with a date and time stamp that corresponds with the recent restart. It can take 15 minutes or more to appear. An event 13508 indicates that FRS is in the process of starting the service. An event 13509 indicates that the service has started successfully. Event 13516 indicates that the service is started, the folders are shared, and the domain controller is functional.
4. To verify the shared folder is created, open a command prompt and type **net share** to display a list of the shared folders on this domain controller, including Net Logon and SYSVOL.
5. At a command prompt, type **dcdiag /test:netlogons** and press ENTER.
6. Look for a message that states *computername* **passed test NetLogons** where *computername* is the name of the domain controller. If you do not see the test passed message, some problem will prevent replication from functioning. This test verifies that the proper logon privileges are set to allow replication to occur. If this test fails, verify the permissions set on the Net Logon and SYSVOL shared folders.

# Verify DNS registration and functionality

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that Domain Name System (DNS) is functioning so that other domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify DNS registration and functionality**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **dcdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If DNS is functioning, the last line of the response for all operating system versions is **DNS Test.....: Passed**. The verbose option lists specific information about what was tested. This information can help with troubleshooting if the test fails.

   If the test fails, do not attempt any additional steps until you determine and fix the problem that prevents proper DNS functionality.

# Verify communication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

**To verify communication with other domain controllers**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dsgetdc**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If domain controllers are successfully located, the last line of the response is **DC discovery test.....: Passed.** The verbose option lists the specific domain controllers that are located.

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **nltest /dclist:** <*domain name*>

   If domain controllers are successfully located, the last line of the response is **The command completed successfully**.

   If the tests fail on any of the operating system versions, do not attempt any additional steps until you determine and fix the problem that prevents communication with other domain controllers.

# Verify replication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The tests performed in this procedure verify that different aspects of the replication topology are working properly. They check to see that objects are replicating and they verify that the proper logon permissions are set to allow replication to occur.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify replication is functioning**

1. Open a Command Prompt.
2. Type the following command, and then press Enter:

   **dcdiag /test:replications**

   | **Note** |
   | --- |
   | For this set of tests, the **/v** option is available. However, it does not display any significant additional information. Messages indicate that the connectivity and replications tests passed. |

3. To verify that the proper permissions are set for replication, type the following command and then press Enter:

   **dcdiag /test:netlogons**

   Messages indicate that the connectivity and netlogons tests passed.

# Verify the availability of the operations masters

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that the operations masters can be located and that they are online and responding.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

| **Note** |
| --- |
| You can use these tests prior to installing Active Directory as well as afterward. To perform the test prior to installing Active Directory, you must use the **/s** option to indicate the name of a domain controller to use. You do not need the **/s** option to perform the test after installing Active Directory. The test automatically runs on the local domain controller where you are performing the test. The commands listed in this procedure show the **/s** option. If you are performing this test after installing Active Directory, omit the **/s** option. For a more detailed response from this command, you can use the verbose option by adding **/v** to the end of the command to see the detailed response. |

**To verify the availability of the operations masters**

1. Open a Command Prompt.
2. Type the following command to ensure that the operations masters can be located and then press ENTER:

   **dcdiag /s:** *domaincontroller* **/test:knowsofroleholders /verbose**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of the screen, a message confirms that the test succeeded. If you use the verbose option, look carefully at the bottom part of the displayed output. The test confirmation message appears immediately after the list of operations masters. Press ENTER.
3. Type the following command to ensure that the operations masters are functioning properly and are available on the network:

   **dcdiag /s:** *domaincontroller* **/test:fsmocheck**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of your screen, a message confirms that the test succeeded. Press ENTER.

   If these tests fail, do not attempt any additional steps until you determine and fix the problem that prevents locating operations masters and verifying that they are functioning properly.

# Verify domain membership for a new domain controller

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This test verifies that a new domain controller has successfully become a member of the domain.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group.

**To verify domain membership for a new domain controller**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:member**

   If the test was successful, you should see the following message: "Domain membership test passed." If you use the **/v** option, it lists the name of the domain controller, its role, the name of the domain, and a number of other statistics about the new domain controller.

   On a **Windows Server 2008** or **Windows Server® 2008 R2** computer, type the following command, and then press ENTER:

   **nltest /dsgetdc:** <*domain name*>

   If the test was successful, you should see the domain name in the list of returned results and the message: "The command completed successfully."

# Renaming a Domain Controller

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The ability to rename domain controllers running Windows Server 2003 (contrary to Windows 2000 Server) provides you with the flexibility to:

- Restructure your network for organizational and business needs.
- Make management and administrative control easier.

Renaming a domain controller is a common operation in many organizations and usually occurs when:

- New hardware is purchased to replace an existing domain controller.
- Domain controllers are decommissioned, or promoted, and renamed to maintain a naming convention.
- Domain controllers are moved or placed in sites.

| **Note** |
| --- |
| It is important to note that domain controller names have a primary impact on administration, rather than client access. Renaming a domain controller is an optional exercise, and the impacts should be well understood prior to renaming. |

Although you can use the System Properties user interface (UI) to rename a domain controller (as you can for any computer), Active Directory and DNS replication latency might temporarily prevent clients from locating or authenticating to the renamed domain controller, or both. To avoid this delay, use the Netdom command-line tool to rename a domain controller.

**Task requirements**

The following tools are required to perform the procedures for this task:

- System Properties or Netdom.exe
- Ldp.exe or Adsiedit.msc

If you want to use Netdom, the domain functional level must be set to Windows Server 2003.

To complete this task, use one of the following two sets of procedures:

1. Rename a domain controller using System Properties
2. Update the FRS member object

Or

1. Rename a domain controller using Netdom
2. Update the FRS member object

# Rename a domain controller using System Properties

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to rename a domain controller by using the System Properties user interface (UI).

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group.

**To rename a domain controller using System Properties**

1. Click **Start**, and then click **Control Panel**.
2. In **Control Panel**, double-click **System Properties**.
3. On the **Computer Name** tab, click **Change**.
4. Click **OK** to acknowledge that renaming the domain controller may cause it to become temporarily unavailable to users and computers. (See note below.)
5. Under **Computer Name**, type the new name.
6. Click **OK** to close the **System Properties** dialog box.
7. If you are prompted, provide the user name and password for an account with Domain Admin or Enterprise Admin credentials.

| **Note** |
| --- |
| Renaming a domain controller in this way may result in Active Directory replication latency, making it more difficult for clients to locate or authenticate the domain controller under its new name. |

**Concepts**
Rename a domain controller using Netdom

# Rename a domain controller using Netdom

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to rename a domain controller by using the Netdom command-line tool.

The **netdom** command updates the service principal name (SPN) attributes in Active Directory for the computer account and registers Domain Name System (DNS) resource records for the new computer name. The SPN value of the computer account must be replicated to all domain controllers in the domain, and the DNS resource records for the new computer name must be distributed to all the authoritative DNS servers for the domain name. If the updates and registrations have not occurred prior to removal of the old computer name, some clients might be unable to locate this computer using the new name or the old name.

**Administrative credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group.

**To rename a domain controller using Netdom**

1. Open a Command Prompt.
2. Type the following command to add the new domain controller name, and then press ENTER:

   **netdom computername** *CurrentComputerName* **/add:** *NewComputerName*

3. Type the following command to designate the new name as the primary computer name, and then press ENTER:

   **netdom computername** *CurrentComputerName* **/makeprimary:** *NewComputerName*

| Term | Definition |
|---|---|
| *CurrentComputerName* | The current, or primary, computer name or Internet Protocol (IP) address of the computer that you are renaming. |
| *NewComputerName* | The new name for the computer. The *NewComputerName* must be a fully qualified domain name (FQDN). The primary DNS suffix that is specified in the FQDN for *NewComputerName* must be the same as the primary DNS suffix of *CurrentComputerName*, or it must match the DNS name of the Active Directory domain that is hosted by this domain controller, or it must be contained in the list of allowed DNS suffixes that is specified in the **msDS-AllowedDNSSuffixes** attribute of the domainDns object. |

4. Restart the computer.
5. After the computer restarts, open a Command Prompt.
6. Type the following command to remove the old domain controller name, and then press ENTER:

   **netdom computername** *NewComputerName* **/remove:** *OldComputerName*

| Term | Definition |
|---|---|
| *NewComputerName* | The new FQDN that you added for the computer in step 2. |
| *OldComputerName* | The old FQDN of the renamed computer. |

Rename a domain controller using System Properties

# Update the FRS member object

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to update the File Replication service (FRS) member object after renaming a domain controller.

For more information about this procedure, see article 316826 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=82821).

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group.

**To update the FRS member object**

1. Using Ldp.exe (or ADSI edit), find the computer object of the renamed domain controller.
2. Do a recursive search for an object of type **nTFRSSubscriber** with the computer name of "**Domain System Volume (SYSVOL share)**" under the Computer object.
3. The search filter is "(&((cn=Domain System Volume (SYSVOL share))(objectclass=ntfrssubscriber)))".
4. Find the **fRSMemberReference** attribute of the object returned by the search.
5. Find the object whose domain name is in the **fRSMemberReference** attribute. This is the **Ntfrsmember** object corresponding to this domain controller.
6. Change the computer name of this **Ntfrsmember** object from the old name of the domain controller to the new name of the domain controller.

# Decommissioning a Domain Controller

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Decommissioning a domain controller effectively removes all Active Directory and related components and returns the domain controller to a member server role.

**Protecting EFS-encrypted files**

If the domain controller to be decommissioned hosts any Encrypting File System (EFS) encrypted files, you must take precautions to protect the private key for the recovery agent for the local EFS-encrypted documents. It is possible for this key to be lost during the demotion when the Security Accounts Manager (SAM) is recreated on the computer. In this case, you are cannot recover encrypted documents on this computer unless the recovery agent is changed to an existing domain account before encryption. To prevent loss of the private key, you must back up (export) the recovery agent private key before you decommission the domain controller. After you remove Active Directory, re-import the private key.

You must be able to ensure that the domain account that serves as the recovery agent for the certificate remains the same after removing Active Directory. If you cannot guarantee that the account will remain the same after the domain controller is decommissioned, or if you removed Active Directory without backing up the certificate and you cannot recover EFS-encrypted files, see article 276239 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=117370).

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Ntdsutil.exe
- Active Directory Domains and Trusts
- Active Directory Users and Computers
- Active Directory Sites and Services
- Netdiag.exe
- Dcdiag.exe

To complete this task, perform the following procedures:

1. View the current operations master role holders

   To avoid problems, transfer any operations master roles prior to running the Active Directory Installation Wizard to decommission a domain controller so that you can control the operations master role placement. If you need to transfer any roles from a domain controller, understand all the recommendations for role placement before performing the transfer.

   | ⚠Caution |
   | --- |
   | During the decommissioning process, the Active Directory Installation Wizard will attempt to transfer any remaining operations master roles to other domain controllers without any user interaction. However, if a failure occurs, the wizard will continue to uninstall Active Directory and leave your domain without roles. Also, you do not have control over which domain controller receives the roles. The wizard transfers the roles to any available domain controller and does not indicate which domain controller hosts them. |

2. Transfer the schema master
3. Transfer the domain naming master
4. Transfer the domain-level operations master roles

5. Determine whether a domain controller is a global catalog server

   If you remove Active Directory from a domain controller that hosts a global catalog, the Active Directory Installation Wizard confirms that you want to continue with removing Active Directory. This confirmation ensures that you are aware that you are removing a global catalog from your environment. Do not remove the last global catalog server from your environment because users cannot log on without an available global catalog server. If you are not sure, do not proceed with removing Active Directory until you know that at least one other global catalog server is available.

6. Verify DNS registration and functionality

7. Verify communication with other domain controllers

   During the removal of Active Directory, contact with other domain controllers is required to ensure:

   - Any unreplicated changes are replicated to another domain controller.
   - Removal of the domain controller from the directory.
   - Transfer of any remaining operations master roles.

   If the domain controller cannot contact the other domain controllers during Active Directory removal, the decommissioning operation fails. As with the installation process, test the communication infrastructure prior to running the installation wizard. When you remove Active Directory, use the same connectivity tests that you used during the installation of Active Directory.

8. Verify the availability of the operations masters

   | **Important** |
   | --- |
   | If any of the verification tests fail, do not continue until you determine and fix the problems. If these tests fail, the uninstallation is also likely to fail. |

9. If the domain controller hosts encrypted documents, perform the following procedure before you remove Active Directory to ensure that the encrypted files can be recovered after Active Directory is removed:

   Export a certificate with the private key (http://go.microsoft.com/fwlink/?LinkId=20039)

10. Uninstall Active Directory

11. If the domain controller hosts encrypted documents and you backed up the certificate and private key before you remove Active Directory, perform the following procedure to re-import the certificate to the server:

    Import a certificate (http://go.microsoft.com/fwlink/?LinkId=20040)

12. Determine whether a Server object has child objects

13. Delete a Server object from a site

    | **Note** |
    | --- |
    | The administrator may not want to remove the Server object if it hosts something in addition to Active Directory—Microsoft Exchange, for example. |

# View the current operations master role holders

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Once an operations master role has been transferred, it should be verified that the transfer has occurred successfully throughout the domain. The change must be replicated to all relevant domain members in order to truly take effect.

To view the current operations master role holders, use Ntdsutil.exe with the roles option. This option displays a list of all current role holders.

**Administrative Credentials**

To perform this procedure, you must be logged on as a User or an Administrator.

**To view the current operations master role holder**

1. Click **Start**, click **Run**, type **ntdsutil**, and then press ENTER.
2. At the **ntdsutil:** prompt, type **roles** and press ENTER.
3. At the **fsmo maintenance:** prompt, type **connections** and press ENTER.
4. At the **server connections:** prompt, type **connect to server** *servername* (where *servername* is the name of the domain controller that belongs to the domain containing the operations masters).
5. After receiving confirmation of the connection, type **quit** and press ENTER to exit this menu.
6. At the **fsmo maintenance:** prompt, type **select operation target** and press ENTER.
7. At the **select operations target:** prompt, type **list roles for connected server** and press ENTER.

   The system responds with a list of the current roles and the Lightweight Directory Access Protocol (LDAP) name of the domain controllers currently assigned to host each role.
8. Type **quit** and press ENTER to exit each prompt in Ntdsutil.exe. Type **quit** and press ENTER at the **ntdsutil:** prompt to close the window.

# Transfer the schema master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the schema operations master role. The schema master is a forest-wide operations master role. Before you can use the Active Directory Schema snap-in for the first time, you must register it with the system. If you have not yet prepared the Active Directory Schema snap-in, see Install the Schema snap-in before you begin this procedure.

| **Note** |
| --- |
| This procedure is performed by using the Microsoft Management Console (MMC), although you can also transfer this role by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a Schema Administrator in Active Directory.

#### Transfer the schema master

1. Open the Active Directory Schema snap-in.
2. In the console tree, right-click **Active Directory Schema**, and click **Change Domain Controller**.
3. In the **Change Domain Controller** dialog box, click **Specify Name**. Then, in the text box, type the name of the server to which you want to transfer the schema master role. Click **OK**.
4. In the console tree, right-click **Active Directory Schema**. Click **Operations Master**. The **Change Schema Master** box displays the name of the server that is currently holding the role. The targeted domain controller is listed in the second box.
5. Click **Change**. Click **Yes** to confirm your choice. The system confirms the operation. Click **OK** again to confirm that the operation succeeded.
6. Click **Close** to close the **Change Schema Master** dialog box.

| **Note** |
| --- |
| Hosting the infrastructure master on a global catalog server is not recommended. If you attempt to transfer the infrastructure master role to a domain controller that is a global catalog, the system displays a warning stating that this is not recommended. |

# Transfer the domain naming master

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the domain naming operations master role. The domain naming master is a forest-wide operations master role.

| **Note** |
| --- |
| This procedure is performed by using the Microsoft Management Console (MMC), although you can also transfer this role by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory.

#### To transfer the domain naming master

1. Open Active Directory Domains and Trusts.
2. In the console tree, right-click **Active Directory Domains and Trusts**, and then click **Connect to Domain Controller**.
3. Ensure that the proper domain name is entered in the **Domain** box.

   The available domain controllers from this domain are listed.
4. In the **Name** column, click the domain controller (to select it) to which you want to transfer the role. Click **OK**.
5. Right-click **Active Directory Domains and Trusts**, and then click **Operations Master**.
6. The name of the current domain naming master appears in the first text box. The server to which you want to transfer the role should appear in the second text box. If this is not the case, repeat steps 1 through 4.
7. Click **Change**. To confirm the role transfer, click **Yes**. Click **OK** again to close the message box indicating the transfer took place. Click **Close** to close the **Change Operations Master** dialog box.

# Transfer the domain-level operations master roles

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to transfer the three domain-level operations master roles: the PDC emulator, the RID master, and the infrastructure master. You can transfer all of these roles by using the Active Directory Users and Computers console.

| **Note** |
| --- |
| These procedures are performed by using MMC, although you can also transfer these roles by using Ntdsutil.exe. For information about using Ntdsutil.exe to transfer the operations master roles, type **?** at the Ntdsutil.exe command prompt. |

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To transfer a domain-level operations master role**

1. Open Active Directory Users and Computers.
2. At the top of the console tree, right-click **Active Directory Users and Computers**. Click **Connect to Domain Controller**.
3. In the list of **available domain controllers**, click the name of the server to which you want to transfer the role, and then click **OK**.
4. At the top of the console tree, right-click **Active Directory Users and Computers**, point to **All Tasks**, and then click **Operations Masters**.

   The name of the current operations master role holder appears in the **Operations master** box. The name of the server to which you want to transfer the role appears in the lower box.
5. Click the tab for the role you want to transfer: **RID**, **PDC**, or **Infrastructure**. Verify the computer names that appear and then click **Change**. Click **Yes** to transfer the role, and then click **OK**.
6. Repeat steps 4 and 5 for each role that you want to transfer.

# Determine whether a domain controller is a global catalog server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the setting on the NTDS Settings object to indicate whether a domain controller is designated as a global catalog server.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Users group in Active Directory.

**To determine whether a domain controller is a global catalog server**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container, expand the site of the domain controller you want to check, expand the **Servers** container, and then expand the **Server** object.
3. Right-click the **NTDS Settings** object, and then click **Properties**.
4. On the **General** tab, if the **Global Catalog** box is selected, the domain controller is designated as a global catalog server.

# Verify DNS registration and functionality

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that Domain Name System (DNS) is functioning so that other domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To verify DNS registration and functionality**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **dcdiag /test:dns**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If DNS is functioning, the last line of the response for all operating system versions is **DNS Test.....: Passed**. The verbose option lists specific information about what was tested. This information can help with troubleshooting if the test fails.

   If the test fails, do not attempt any additional steps until you determine and fix the problem that prevents proper DNS functionality.

# Verify communication with other domain controllers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that domain controllers can be located.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

**To verify communication with other domain controllers**

1. Open a Command Prompt.
2. On a **Windows Server 2003** computer, type the following command, and then press ENTER:

   **netdiag /test:dsgetdc**

   | **Note** |
   | --- |
   | For a more detailed response from this command, add **/v** to the end of the command. |

   If domain controllers are successfully located, the last line of the response is **DC discovery test.....: Passed.** The verbose option lists the specific domain controllers that are located.

   On a **Windows Server 2008** or **Windows Server 2008 R2** computer, type the following command, and then press ENTER:

   **nltest /dclist:** <*domain name*>

   If domain controllers are successfully located, the last line of the response is **The command completed successfully**.

   If the tests fail on any of the operating system versions, do not attempt any additional steps until you determine and fix the problem that prevents communication with other domain controllers.

# Verify the availability of the operations masters

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure verifies that the operations masters can be located and that they are online and responding.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain users group in Active Directory.

| **Note** |
| --- |
| You can use these tests prior to installing Active Directory as well as afterward. To perform the test prior to installing Active Directory, you must use the **/s** option to indicate the name of a domain controller to use. You do not need the **/s** option to perform the test after installing Active Directory. The test automatically runs on the local domain controller where you are performing the test. The commands listed in this procedure show the **/s** option. If you are performing this test after installing Active Directory, omit the **/s** option. For a more detailed response from this command, you can use the verbose option by adding **/v** to the end of the command to see the detailed response. |

**To verify the availability of the operations masters**

1. Open a Command Prompt.
2. Type the following command to ensure that the operations masters can be located and then press ENTER:

   **dcdiag /s:** *domaincontroller* **/test:knowsofroleholders /verbose**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of the screen, a message confirms that the test succeeded. If you use the verbose option, look carefully at the bottom part of the displayed output. The test confirmation message appears immediately after the list of operations masters. Press ENTER.
3. Type the following command to ensure that the operations masters are functioning properly and are available on the network:

   **dcdiag /s:** *domaincontroller* **/test:fsmocheck**

   where *domaincontroller* is the name of a domain controller in the domain in which you want to add the new domain controller. The verbose option provides a detailed list of the operations masters that were tested. Near the bottom of your screen, a message confirms that the test succeeded. Press ENTER.

   If these tests fail, do not attempt any additional steps until you determine and fix the problem that prevents locating operations masters and verifying that they are functioning properly.

# Uninstall Active Directory

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To use the Active Directory Installation Wizard to remove Active Directory, you must know the password to assign to the local Administrator account of the server after Active Directory is removed.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To uninstall Active Directory**

1. Click **Start**, click **Run**, type **dcpromo** and then click **OK**.
2. The Active Directory Installation Wizard appears. Click **Next** at the Welcome screen.
3. You have an option to select **This server is the last domain controller in the domain**. If you select this option, the wizard attempts to remove the domain from the forest. Do not select this option. Click **Next**.
4. At the **Administrative Password** screen, enter and confirm the password that you want to assign to the local Administrator account after Active Directory is removed. Click **Next**.
5. At the **Summary** screen, verify that the information is correct and then click **Next** to proceed with the removal.
6. The wizard proceeds to remove Active Directory. After it finishes, the wizard displays a completion screen. Click **Finish** to close the wizard.
7. Click **Restart** to restart the domain controller.

# Determine whether a Server object has child objects

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After Active Directory is properly installed on a domain controller, the Server object for the domain controller will have a Child NTDS-Settings object. Other applications that are running on domain controllers can also publish Child objects.

Prior to deleting a Server object from the Servers container for a site, verify that the Server object has no Child objects. If a Child object appears, do not delete the Server object.

### Administrative Credentials

To perform this procedure, you must be a member of the Domain Users group.

**To determine whether a server object has child objects**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container and expand the site of the Server object.
3. Expand the **Servers** container, and then expand the Server object to view any Child objects.

# Delete a Server object from a site

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When no Child objects are visible below the Server object in Active Directory Sites and Services, you can remove the Server object.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To delete a server object from a site**

1. Open Active Directory Sites and Services.
2. Expand the **Sites** container, and then expand the site from which you want to delete a Server object.
3. If no Child objects appear below the Server object, right-click the Server object, and then click **Delete**.

| **Important** |
| --- |
| Do not delete a Server object that has a Child object. If an NTDS Settings or other Child object appears below the Server object you want to delete, either replication on the domain controller on which you are viewing the Configuration container has not occurred, or the server whose Server object you are removing has not been properly decommissioned. |

4. Click **Yes** to confirm your choice.

# Forcing the Removal of a Domain Controller

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Forced removal of a domain controller from Active Directory is intended to be used as a last resort to avoid having to reinstall the operating system on a domain controller that has failed and cannot be recovered. When a domain controller can no longer function in a domain (that is, it is offline), you cannot remove Active Directory in the normal way, which requires connectivity to the domain. Forced removal is not intended to replace the normal Active Directory removal procedure in any way. It is virtually equivalent to permanently disconnecting the domain controller.

Active Directory stores a considerable amount of metadata about a domain controller. During the normal process of uninstalling Active Directory on a domain controller, this metadata is removed from Active Directory through a connection to another domain controller in the domain. A forced removal assumes that there is no connectivity to the domain; therefore, it does not attempt any metadata removal (cleanup).

Consequently, forced removal of Active Directory from a domain controller should always be followed by the metadata cleanup procedure, which removes all references to the domain controller from the domain and forest.

Forced demotion should not be performed on the last domain controller in a domain.

**Task Requirements**

The following tools are required to perform the procedures for this task:

- Active Directory Sites and Services
- Dcpromo.exe
- Ntdsutil.exe

To complete this task, perform the following procedures:

1. Identify replication partners. Connect to one of these domain controllers when you clean up server metadata in procedure 3.
2. Force domain controller removal
3. Clean up server metadata

# Identify replication partners

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to examine the Connection objects for a domain controller and determine its replication partners.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group in Active Directory.

**To identify replication partners**

1. Open Active Directory Sites and Services.
2. In the console tree, expand the **Sites** container to display the list of sites.
3. Double-click the site that contains the domain controller for which you want to determine Connection objects.

| **Note** |
| --- |
| If you do not know the site in which the domain controller is located, open a command prompt and type **ipconfig** to get the IP address of the domain controller. Use the IP address to Verify that an IP address maps to a subnet and determine the site association. |

4. Expand the **Servers** folder to display the list of servers in that site.
5. Expand the name of your domain controller to display its NTDS settings.
6. Double-click **NTDSSettings** to display the list of Connection objects in the details pane (these represent inbound connections used for replication). The **From Server** column displays the names of the domain controllers that are the replication partners.

# Force domain controller removal

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to force the removal of Active Directory from a domain controller.

**Administrative Credentials**

To perform this procedure, you must be a member of the Domain Admins group.

**To force domain controller removal**

1. Click **Start**, click **Run**, type the following command and then press ENTER:

   **Dcpromo /forceremoval**

2. At the **Welcome to the Active Directory Installation Wizard** page, click **Next**.
3. At the **Force the Removal of Active Directory** page, click **Next**.
4. In **Administrator Password**, type the password and confirmed password that you want to assign to the Administrator account of the local SAM database, and then click **Next**.
5. In **Summary**, click **Next**.

# Clean up server metadata

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You perform the metadata cleanup process by using Ntdsutil.exe, a command-line tool that is automatically installed on all domain controllers. Metadata cleanup removes data from Active Directory that identifies a domain controller to the replication system. This procedure is required only for Active Directory domain controllers that were not successfully demoted using Dcpromo. This procedure does not have to be performed for domain member servers or client computers. On a domain controller that is running Windows Server 2003 with Service Pack 1 (SP1), metadata cleanup also removes File replication service (FRS) connections and attempts to transfer or seize any operations master roles (also known as flexible single master operations or FSMO roles) that the retired domain controller holds. These additional processes are performed automatically.

You can also use a script to clean up server metadata on most Windows operating systems. For information about using this script, see Remove Active Directory Domain Controller Metadata on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkID=123599).

**Administrative credentials**

- To complete this procedure, you must be a member of the Enterprise Admins group.

**To clean up server metadata**

1. Open a command prompt.
2. Type the following command, and then press ENTER:

   **ntdsutil**

3. At the **ntdsutil:** prompt, type:

   **metadata cleanup**

4. Perform metadata cleanup as follows:

   - If you are performing metadata cleanup by using the version of Ntdsutil.exe that is included with Windows Server 2003 SP1, at the **metadata cleanup:** prompt, type:

     **remove selected server** *ServerName*

     Or

     **remove selected server** *ServerName1* **on** *ServerName2*

     | Value | Definition |
     |---|---|
     | *ServerName, ServerName1* | The distinguished name of the domain controller whose metadata you want to remove, in the form cn=*ServerName*,cn=Servers,cn=*SiteName*, cn=Sites,cn=Configuration,dc=*ForestRootDomain* |
     | *ServerName2* | The DNS name of the domain controller to which you want to connect and from which you want to remove server metadata |

   - If you are performing metadata cleanup by using the version of Ntdsutil.exe that is included with Windows Server 2003 with no service pack, perform metadata cleanup as follows:

     a. At the **metadata cleanup:** prompt, type:

     **connection**

     b. At the **server connections:** prompt, type:

**connect to server** *Server*

c. At the **server connections:** prompt, type:

**quit**

d. At the **metadata cleanup:** prompt, type:

**select operation target**

e. At the **select operation target:** prompt, type:

**list sites**

A numbered list of sites appears.

f. At the **select operation target:** prompt, type:

**select site** *SiteNumber*

g. At the **select operation target:** prompt, type:

**list domains in site**

A numbered list of domains in the selected site appears.

h. At the **select operation target:** prompt, type:

**select domain** *DomainNumber*

i. At the **select operation target:** prompt, type:

**list servers in site**

A numbered list of servers in a domain and site appears.

j. At the **select operation target:** prompt, type:

**select server** *ServerNumber*

k. At the **select operation target:** prompt, type:

**quit**

l. At the **metadata cleanup:** prompt, type:

**remove selected server**

| Value | Description |
|---|---|
| *Server* | The DNS name of a domain controller that you want to connect to |
| *SiteNumber* | The number associated with the site of the server that you want to clean up that appears in the list |

| | |
|---|---|
| *DomainNumber* | The number associated with the domain of the server that you want to clean up that appears in the list |
| *ServerNumber* | The number associated with the server that you want to clean up that appears in the list |

At this point, Active Directory confirms that the domain controller was removed successfully. If you receive an error message that indicates that the object cannot be found, Active Directory might have already removed the domain controller.

5. To verify that the server was removed, type **list servers in site**, and then press ENTER. Ensure that the domain controller that you wanted to be removed is no longer displayed in the command output.
6. At the **metadata cleanup:** and **ntdsutil:** prompts, type **quit**.

| **Important** |
|---|
| If the domain controller that was removed was also a DNS server, ensure that references to it are removed from the **Name Servers** tab in the DNS console. To do this, open the DNS console using another DNS server in the domain (dnsmgmt.msc), and then click the domain name under **Forward Lookup Zones**. Remove any references to the domain controller that was removed from the domain. |

# DNS Operations Guide

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The DNS Operations Guide provides administering and troubleshooting information for Domain Name System (DNS) in the Microsoft® Windows Server™ 2003 with Service Pack 1 (SP1) operating system.

**In this guide**

- Administering DNS Operations
- Troubleshooting Domain Name System
- Additional Resources for Domain Name System

# Administering DNS Operations

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This Domain Name System (DNS) Administering guide provides administering information for DNS in the Microsoft Windows Server 2003 with Service Pack 1 (SP1) operating system.

**In this guide**

- Introduction to Administering DNS Operations
- Managing DNS
- Monitoring DNS
- Optimizing DNS
- Securing DNS

This DNS Administering guide provides detailed procedures for managing DNS servers, clients, and resource records. It also provides procedures for monitoring, optimizing, and securing your DNS infrastructure. For most procedures, this guide provides both a user interface (UI) and a command-line method of performing each procedure. In addition, this guide provides sample scripts for the most frequently used, repetitive tasks.

# Introduction to Administering DNS Operations

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide explains how to administer Microsoft Domain Name System (DNS). These activities are part of the operating phase of the information technology (IT) life cycle. If you are not familiar with this guide, review the following sections of this introduction.

**When to Use This Guide**
You should use this guide when:

- You want to manage DNS servers.
- You want to manage DNS clients.

This guide assumes a basic understanding of what DNS is, how it works, and why your organization uses it for name resolution. You should also have a thorough understanding of how DNS is deployed and managed in your organization. This includes an understanding of the mechanism that your organization uses to configure and manage DNS settings.

This guide can be used by organizations that have deployed Windows Server 2003 Service Pack 1 (SP1). It includes information that is relevant to different roles within an IT organization, including IT operations management and administrators. This guide contains high-level information that is required to plan a DNS operations environment, along with management-level knowledge of the DNS and IT processes that are required to operate it.

In addition, this guide contains more detailed procedures that are designed for operators who have varied levels of expertise and experience. Although the procedures provide operator guidance from start to finish, operators must have a basic proficiency with Microsoft Management Console (MMC) and snap-ins and know how to start administrative programs and access the command line. If operators are not familiar with DNS, it might be necessary for IT planners or managers to review the relevant operations in this guide and provide the operators with parameters or data that must be entered when the operations are performed.

**How to Use This Guide**
The operations areas are divided into the following types of content:

- Objectives are high-level goals for managing, monitoring, optimizing, and securing DNS. Each objective consists of one or more high-level tasks that describe how the objective is accomplished. In this guide, Managing Domain Name System Servers is an example of an objective.
- Tasks are used to group related procedures and provide general guidance for achieving the goals of an objective. In this guide, Modifying an Existing DNS Server is an example of a task.
- Procedures provide step-by-step instructions for completing tasks. In this guide, Change the name-checking method of a DNS server is an example of a procedure.

If you are an IT manager who will be delegating tasks to operators in your organization, you will want to:

- Read through the objectives and tasks to determine how to delegate permissions and whether you need to install tools before operators perform the procedures for each task.
- Before assigning tasks to individual operators, ensure that you have all the tools installed where operators can use them.
- When necessary, create “tear sheets” for each task that operators perform in your organization. Cut and paste the task and its related procedures into a separate document and then either print these documents or store them online, depending on the preference of your organization.

# Managing DNS

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide describes processes and procedures for improving the management of Windows Server 2003 Domain Name System (DNS) in your network infrastructure. Ensuring that DNS is functioning properly helps increase system availability for your users.

The following tasks for managing DNS are described in this objective:

- Managing Domain Name System Servers
- Managing Domain Name System Clients
- Managing Domain Name System Zones
- Managing DNS Resource Records

# Managing Domain Name System Servers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks for managing Domain Name System (DNS) servers are described in this objective:

- Adding a Primary DNS Server to an Existing Zone
- Adding a Secondary DNS Server
- Modifying an Existing DNS Server
- Using Forwarders to Manage DNS Servers
- Removing a DNS Server from the Network
- Using DNS Aging and Scavenging

# Adding a Primary DNS Server to an Existing Zone

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are installing Domain Name System (DNS) with Active Directory, use the Active Directory Installation Wizard option to automatically install and configure a local DNS server. This option installs the DNS Server service on the computer where you are running the wizard, and it configures the computer's preferred DNS server setting to use the new local DNS server. Configure any other computers that join this domain to use this DNS server's Internet Protocol (IP) address as their preferred DNS server.

If you are installing DNS on a member server, use the procedures in this task.

It is recommended that you manually configure the computer to use a static IP address. If the DNS server is configured to use Dynamic Host Configuration Protocol (DHCP)–assigned dynamic addresses, when the DHCP server assigns a new IP address to the DNS server, the DNS clients that are configured to use that DNS server's previous IP address will be unable to resolve the previous IP address and locate the DNS server.

After you install a DNS server, you can decide how to administer it and its zones. Although you can use a text editor to make changes to server boot and zone files, this method is not recommended. The DNS console and the DNS command-line tool, Dnscmd, simplify maintenance of these files, and they should be used whenever possible. After you begin managing these files by using the console or the command line, editing them manually is not recommended.

You can administer DNS zones that are stored in Active Directory by using the DNS console or the Dnscmd command-line tool only. These zones cannot be administered by using a text editor.

If you uninstall a DNS server that hosts Active Directory-integrated zones, these zones are saved or deleted according to their storage type. For all storage types, the zone data is stored on other domain controllers or DNS servers. It is not deleted unless the DNS server that you uninstall is the last DNS server hosting that zone.

If you uninstall a DNS server hosting standard DNS zones, the zone files will remain in the systemroot\system32\Dns directory, but they will not be reloaded if the DNS server is reinstalled. If you create a new zone with the same name as an old zone, the old zone file is replaced with the new zone file.

When they write DNS server boot and zone data to text files, DNS servers use the Berkeley Internet Name Domain (BIND) file format that is recognized by legacy BIND 4 servers, not the more recent BIND 8 format.

Complete this task after you determine that you need to add a primary DNS server to your environment. For more information about planning a DNS infrastructure, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

To complete this task, perform one the following procedures:

- Install a new DNS server
- Configure a DNS server

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Install a new DNS server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to install Domain Name System (DNS) on a member server, which makes that server a DNS server.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

#### Installing a new DNS server

### To install a DNS server

1. Open the Windows Components Wizard.
2. In **Components**, select the **Networking Services** check box, and then click **Details**.
3. In **Subcomponents of Networking Services**, select the **Domain Name System (DNS)** check box, click **OK**, and then click **Next**.
4. If you are prompted to do so, in **Copy files from**, type the full path to the installation location, and then click **OK**.

   Required files are copied to your hard disk.

| **Note** |
| --- |
| To open the Windows Components Wizard, click **Start**, point to **Control Panel**, click **Add or Remove Programs**, and then click **Add/Remove Windows Components**. |

# Configure a DNS server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use these procedures to configure a new Domain Name System (DNS) server. When you finish configuring the server, you may need to complete additional tasks, such as enabling dynamic updates for its zones or adding resource records to its zones. See the other tasks in this guide to determine whether they are appropriate for your environment.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd tool at the command line.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Configuring a DNS server**

- Using the Windows interface
- Using a command line

### To configure a DNS server using the Windows interface

1. Open the DNS snap-in.
2. If necessary, add the applicable server to the console and connect to it.
3. In the console tree, click the applicable DNS server.

   **Where?**

   - DNS/*Applicable DNS server*

4. On the **Action** menu, click **Configure a DNS Server**.
5. Follow the instructions in the Configure a DNS Server Wizard.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To configure a DNS server using the command line

- At a command prompt,type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** {*ZoneName*|**..AllZones**} *Property* {**1**|**0**}

| Value | Description |
|---|---|
| **dnscmd** | Specifies the name of the command-line tool. |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/Config** | Specifies the configuration command. |
| {*ZoneName*\|**..AllZones**} | Specifies the name of the zone to be configured. To apply the configuration for all zones that are hosted by the specified DNS server, type **..AllZones**. |

| | |
|---|---|
| *Property* | Specifies the server property or zone property to be configured. There are different properties available for servers and zones. For a list of the available properties, at a command prompt type: **dnscmd/Config /help**. |
| {**1**\|**0**} | Sets configuration options to either **1** (on) or **0** (off). Note that some server and zone properties must be reset as part of a more complex operation. |

| **Note** |
|---|
| To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**. |

# Adding a Secondary DNS Server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain Name System (DNS) design specifications recommend that at least two DNS servers be used to host each zone. For standard, primary zones, a secondary server is required to add and configure the zone so that it appears to other DNS servers in the network. For directory-integrated, primary zones, secondary servers are supported but not required for this purpose. For example, two DNS servers running on domain controllers can be redundant primary servers for a zone. They can provide the same benefits as adding a secondary server while also providing additional benefits.

Secondary servers can be used to offload DNS query traffic in areas of the network where a zone is heavily queried. In addition, if a primary server is unavailable, a secondary server can provide some name resolution in the zone until the primary server is available.

If you add a secondary server, try to locate it as close as possible to clients that have a high demand for names that are used in the zone. Also, consider placing secondary servers across a router, either on other subnets (if you use a routed local area network (LAN)) or across wide area network (WAN) links. This constitutes a good use of a secondary server as a local backup in scenarios in which an intermediate network link becomes the point of failure between DNS servers and clients that use the zone.

Because a primary server always maintains the master copy of updates and changes to the zone, a secondary server relies on DNS zone transfer mechanisms to obtain its information and keep the information current. Issues such as zone transfer methods — using either full or incremental zone transfers — are more applicable when you use secondary servers.

When you consider the impact of zone transfers that are caused by secondary servers, consider their advantage as a backup source of information, and measure this against the added cost that they impose on your network infrastructure. A simple rule is that for each secondary server that you add, network usage (because of added zone replication traffic) increases, and so does the time that is required to synchronize the zone at all secondary servers.

Secondary servers are used most heavily for forward lookup zones. If you are using reverse lookup zones, it is not necessary to add as many secondary servers for those zones. Typically, a secondary server for a reverse lookup zone is not used outside the network and subnet that correspond to the reverse zone.

To complete this task, perform the following procedure:

- Add a secondary server to a zone

# Add a secondary server to a zone

Published: March 2, 2005

Updated: November 18, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To add a secondary server to an existing zone, you must have network access to the server that acts as the master server for this server and its use of the zone. The master server acts as the source for zone data. It is contacted periodically to assist in renewing the zone and to transfer zone updates whenever they are needed.

You can perform this procedure by using the DNS console or by using the Dnscmd command-line tool. This procedure can be performed on the secondary DNS server, or on a computer with permission to manage the secondary DNS server. To add a secondary server to multiple zones, you must repeat this procedure for each zone.

| **Important** |
| --- |
| Before you add a secondary server to a zone, you must allow zone transfers from the primary to the secondary server. For more information, see Modify DNS zone transfer settings. |

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

#### Adding a secondary server to a zone

- Using the Windows interface
- Using the command line

### To add a secondary server to a zone using the Windows interface

1. Click **Start**, point to **Administrative Tools**, and then click **DNS**.
2. In the console tree, click the applicable Domain Name System (DNS) server.
3. On the **Action** menu, click **New Zone**.
4. Follow the instructions in the New Zone Wizard. When you add the zone, select **Secondary zone** as the zone type.

### To add a secondary server to a zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **Dnscmd** *ServerName* **/ZoneAdd** *ZoneName* **/Secondary** *MasterIPaddress***...** [**/file** *FileName*]

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| *ZoneName* | Specifies the fully qualified domain name (FQDN) of the secondary zone that you are adding. The zone name must be the same as the name of the primary zone from which the secondary zone is created. |
| *MasterIPaddress* | Specifies one or more IP addresses for the secondary zone master servers, from which it copies zone data. |
| *FileName* | Specifies the name of the file to use for creating the secondary zone. |

In the following example, zone transfers are first allowed from the primary DNS server *primarydns.contoso.com* at

*10.0.0.2* to the secondary server *secondarydns.contoso.com* at *11.0.0.2*. Next, the secondary DNS server is added to the zone *secondtest.contoso.com*.

**Dnscmd** *primarydns.contoso.com* **/zoneresetsecondaries** *secondtest.contoso.com* **/securelist** *11.0.0.2*

**Dnscmd** *secondarydns.contoso.com* **/zoneadd** *secondtest.contoso.com* **/secondary** *10.0.0.2*

For more information about using dnscmd, see Dnscmd Syntax.

# Modifying an Existing DNS Server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You may need to modify or update the configuration of your Domain Name System (DNS) servers for various reasons. For example, you may need to change the name-checking method of a DNS server to allow the DNS server to resolve non–Request for Comments (RFC)–compliant names. In addition, you may need to modify or update a DNS server in the process of troubleshooting or optimizing it.

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform one of the following procedures:

- Start, stop, pause, or restart a DNS server
- Manually update DNS server data files
- Clear the DNS server names cache
- Change the boot method of a DNS server
- Change the name-checking method of a DNS server
- Restore DNS server default preferences

**See Also**

Deploying Domain Name System (DNS)

# Start, stop, pause, or restart a DNS server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to start, stop, pause, or restart Domain Name System (DNS).

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To start, stop, pause, or restart a DNS server**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.
3. On the **Action** menu, point to **All Tasks**, and then click one of the following:
   - To start the DNS service on this server, click **Start**.
   - To stop the DNS service on this server, click **Stop**.
   - To interrupt the DNS service on this server, click **Pause**.
   - To stop and then automatically restart the DNS service on this server, click **Restart**.

| **Note** |
| --- |
| To open the DNS management console, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

| **Note** |
| --- |
| If you want to resume the service after you pause or stop it, on the **Action** menu, point to **All Tasks**, and then click **Resume** to immediately resume the service. |

# Manually update DNS server data files

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool. Use the DNS snap-in for standard Domain Name System (DNS) zones and the Dnscmd command-line tool for Active Directory–integrated zones.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Manually updating DNS server data files**

- Using the Windows interface
- Using the command line

**To manually update DNS server data files using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.
3. On the **Action** menu, click **Update Server Data Files**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To manually update DNS server data files using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneUpdateFromDs** *ZoneName*

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName* | Specifies the name of the zone to which you want to set aging and scavenging. |

# Clear the DNS server names cache

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Clearing the DNS server names cache**

- Using the Windows interface
- Using the command line

### To clear the DNS server names cache using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable Domain Name System (DNS) server.
3. On the **Action** menu, click **Clear Cache**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To clear the DNS server names cache using the command line

- At a command prompt, type the following, and then press ENTER:

  **dnscmd** *ServerName* **/clearcache**

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |

# Change the boot method of a DNS server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By default, Domain Name System (DNS) servers use information that is stored in the registry to initialize the service and load any zone data for use at the server. In addition, you can configure the DNS server to boot from a file. Or, in Active Directory environments, you can supplement local registry data with zone data that is retrieved for directory-integrated zones that are stored in the Active Directory database. If you use the file method, the file must be a text file named Boot, which is located on the computer in the %Systemroot%\Windows\System32\Dns folder.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To change the boot method of a DNS server**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable DNS server, and then click **Properties**.
3. Click the **Advanced** tab.
4. In the **Load zone data on startup** list, select one of the following:
    - **From registry**
    - **From file**
    - **From Active Directory and registry**

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Change the name-checking method of a DNS server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The DNS Server service supports three different possible methods for checking the names that it receives and processes during normal operations:

- Strict RFC (ANSI): This method strictly enforces Request for Comments (RFC)–compliant naming rules for all Domain Name System (DNS) names that the server processes. Names that are not RFC compliant are treated as erred data by the DNS server.

- Non RFC (ANSI): This method allows names that are not RFC compliant, such as names that use American Standard Code for Information Interchange (ASCII) characters but are not compliant with RFC host naming requirements, to be used with the DNS server.

- Multibyte (UTF8): This method allows names that use the Unicode 8-bit translation encoding scheme, which is a proposed RFC draft, to be used with the DNS server.

By default, the DNS server uses the Multibyte (UTF8) method to check names.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To change the name-checking method of a DNS server**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable DNS server, and then click **Properties**.
3. Click the **Advanced** tab.
4. In the **Name checking** list, click **Strict RFC (ANSI)**, **Non RFC (ANSI)**, **Multibyte (UTF8)**, or **All names**.

   **All names** enables all three name-checking methods.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Restore DNS server default preferences

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to configure the Domain Name System (DNS) server with the initial configuration settings that it had following installation. These initial configuration settings are listed in the following table.

| Property | Settings |
|---|---|
| Disable recursion | Off |
| BIND secondaries | On |
| Fail on load if bad zone data | Off |
| Enable round robin | On |
| Enable netmask ordering | On |
| Secure cache against pollution | On |
| Name checking | Multibyte (UTF8) |
| Load zone data on startup | From Active Directory and registry |
| Enable automatic scavenging of stale records | Off |

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To restore DNS server default preferences**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable DNS server, then click **Properties**.
3. Click the **Advanced** tab.
4. Click **Reset to Default**, and then click **OK**.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Using Forwarders to Manage DNS Servers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you want to use forwarders to manage the Domain Name System (DNS) traffic between your network and the Internet, configure your network firewall to allow only one DNS server to communicate with the Internet. When you have configured the other DNS servers in your network to forward queries that they cannot resolve locally to that DNS server, it will act as your forwarder.

Consider the following tips for efficient forwarder configuration and use:

- **Keep forwarder configuration uncomplicated.** For every DNS server that is configured with a forwarder, queries can be sent to a number of different places. Each forwarder and each conditional forwarder must be administered for the benefit of DNS client queries, and this process can be time consuming. Use forwarders strategically — where they are needed the most — for example, for resolving offsite queries or for sharing information between namespaces.

- **Avoid chaining your forwarders.** If you have configured a DNS server named server1 to forward queries for wingtiptoys.corp.com to DNS server server2, do not configure server2 to forward queries for wingtiptoys.corp.com to DNS server server3. This is an inefficient resolution process, and it can result in errors if server3 is accidentally configured to forward queries for wingtiptoys.corp.com to server1.

- **Do not concentrate too great a load on forwarders.** The recursive queries that forwarders send to the Internet can require a significant amount of time to answer because of the nature of the Internet. When large numbers of internal DNS servers use these forwarders for Internet queries, the server can experience a substantial concentration of network traffic. If network load is an issue, use more than one forwarder and distribute the load between them.

- **Do not create inefficient resolution by using forwarders.** The DNS server attempts to forward domain names according to the order in which the domain names are configured in the DNS console. For example, a DNS server in Seattle may be incorrectly configured to forward a query to a server in London, instead of another server in Seattle, because the server in London is higher up in the forwarders list. This decreases the efficiency of name resolution on the network. Evaluate your network's forwarding configurations periodically to see if there are similar, inefficient configurations.

To complete this task, perform the following procedure:

- Configure forwarders for a DNS server

# Configure forwarders for a DNS server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you use this procedure to configure a conditional forwarder, note that you cannot use a domain name in a conditional forwarder if the DNS server hosts a primary zone, secondary zone, or stub zone for that domain name. For example, if a DNS server is authoritative for the domain name wingtiptoys.corp.com (that is, it hosts the primary zone for that domain name), you cannot configure that DNS server with a conditional forwarder for wingtiptoys.corp.com.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Configuring forwarders for a DNS server**

- Using the Windows interface
- Using the command line

**To configure forwarders for a DNS server using the Windows graphical user interface**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.
3. On the **Action** menu, click **Properties**.
4. On the **Forwarders** tab, under **DNS domain**, click a domain name.

| **Note** |
| --- |
| To create a new domain name, click **New**, and then, under **DNS domain**, type the domain name. |

5. Under **Selected domain's forwarder IP address list**, type the Internet Protocol (IP) address of a forwarder, and then click **Add**.

| **Note** |
| --- |
| When you specify a conditional forwarder, select a DNS domain name before you enter an IP address. |

6. By default, the DNS server waits five seconds for a response from one forwarder IP address before trying another forwarder IP address. In **Number of seconds before forward queries time out**, you can change the number of seconds that the DNS server waits. If the overall recursion timeout (by default, 15 seconds) is exceeded before all forwarders are exhausted, the DNS server fails the query. If the overall recursion timeout has not been exceeded and the server exhausts all forwarders, it attempts standard recursion.
7. If you want the DNS server to only use forwarders and not attempt any further recursion if the forwarders fail, select the **Do not use recursion for this domain** check box.

| **Note** |
| --- |
| You can disable recursion for the DNS server so that it does not perform recursion on any query. If you disable recursion on the DNS server, you will not be able to use forwarders on the same server. |

| **Note** |
| --- |

To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**.

**To configure forwarders for a DNS server using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneAdd** *ZoneName* **/Forwarder** *MasterIPaddress* **...** [**/TimeOut** *Time*][**/Slave**]

| Value | Description |
|---|---|
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| *ZoneName* | Specifies the fully qualified domain name (FQDN) of the zone. |
| *MasterIPaddress* | Specifies a space-separated list of one or more IP addresses of the DNS servers where queries for ZoneName are forwarded. You can specify a list of space-separated IP addresses. |
| *Time* | Specifies the value for the **/TimeOut** parameter. The value is in seconds. The default timeout is five seconds. |

# Removing a DNS Server from the Network

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To remove a DNS server from the network, perform the following procedures to make changes in zones where the server is configured as an authoritative server for the zone:

1. Use the Delete a resource record procedure to remove the address (A) resource record for the server.

2. Use the Modify an existing resource record procedure to update the name server (NS) records, in zones where the server is configured as authoritative, to no longer include the server by name (as it appeared in the A record that was deleted in procedure 1).

3. If the server is the primary server for a standard zone, use the Modify the SOA record for a zone procedure to revise the owner field of the start of authority (SOA) resource record for the zone to point to the new primary DNS server for the zone. (If the zone is a directory-integrated zone, this procedure is not necessary.)

4. Use the Verify a zone delegation procedure to check the parent zone to ensure that any records (NS or A resource records) that are used for delegation to the zone are revised and that they no longer point to the removed server.

# Delete a resource record

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to delete a resource record from a zone. Pointer (PTR) resource records are deleted automatically if the corresponding address (A) resource record is deleted.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Deleting a resource record**

- Using the Windows interface
- Using the command line

### To delete a resource record using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.
3. In the details pane, right-click the resource record that you want to delete, and then click **Delete**.
4. When you are asked to confirm that you want to delete the selected resource record, click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To delete a resource record using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordDelete** *ZoneName NodeName RRType RRData* [**/f**]

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordDelete** | Required. Deletes a resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| *RRType RRData* | Required. Specifies the type of resource record to add, followed by the data to be contained in the resource record. |

| Resource record type | Resource record data |
|---|---|
| A | *IPAddress* |
| NS,CNAME,MB,MD,PTR,MF,MG,MR | *HostName*\|*DomainName* |
| MX,RT,AFSDB | *PreferenceServerName* |
| SRV | *Priority Weight Port HostName* |
| SOA | *PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL* |
| AAAA | *Ipv6Address* |
| TXT,X25,HINFO,ISDN | *String* [*String*] |
| MINFO,RP | *MailboxName ErrMailboxName* |
| WKS | *Protocol IPAddress Service...* |
| WINS | *MapFlag LookupTimeout CacheTimeout IPAddress...* |
| WINSR | *MapFlag LookupTimeout CacheTimeout RstDomainName* |

| Value | Description |
|---|---|
| *IPAddress* | Specifies a standard IP address, for example, 255.255.255.255. |
| *ipv6Address* | Specifies a standard IPv6 address, for example, 1:2:3:4:5:6:7:8. |
| *Protocol* | Specifies the transmission protocol: UDP or TCP. |
| *Service* | Specifies a standard service, for example, domain, smtp. |
| *HostName*\|*DomainName* | Specifies the FQDN of a resource record that is located in the DNS namespace. |
| **/f** | Specifies that the command is executed without asking for confirmation. If you omit this parameter, you are prompted to confirm the deletion of the resource record. |

# Modify an existing resource record

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to modify an existing resource record in a zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Modifying an existing resource record**

- Using the Windows interface
- Using the command line

**To modify an existing resource record using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.
3. In the details pane, right-click the resource record that you want to modify, and then click **Properties**.
4. In **Properties**, edit the properties that can be modified.

   If necessary, you can view and modify advanced resource record properties with the DNS snap-in. To display advanced properties, on the **View** menu, click **Advanced**.
5. When you have finished modifying the record, click **OK**.

| **Note** |
| --- |
| When advanced view options are enabled, you can modify additional settings for an existing resource record, such as its record-specific Time to Live (TTL). |

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To modify an existing resource record using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName***/RecordAdd***ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] *RRTypeRRData*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordAdd** | Required. Adds a new resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |

| | |
|---|---|
| *RRType RRData* | Required. Specifies the type of resource record to add, followed by the data to be contained in the resource record. |

| **Resource record type** | **Resource record data** |
|---|---|
| A | *IPAddress* |
| NS,CNAME,MB,MD,PTR,MF,MG,MR | *HostName*\|*DomainName* |
| MX,RT,AFSDB | *Preference ServerName* |
| SRV | *Priority Weight Port HostName* |
| SOA | *PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL* |
| AAAA | *Ipv6Address* |
| TXT,X25,HINFO,ISDN | *String* [*String*] |
| MINFO,RP | *MailboxName ErrMailboxName* |
| WKS | *Protocol IPAddress Service...* |
| WINS | *MapFlag LookupTimeout CacheTimeout IPAddress...* |
| WINSR | *MapFlag LookupTimeout CacheTimeout RstDomainName* |

| **Value** | **Description** |
|---|---|
| *IPAddress* | Specifies a standard IP address, for example, 255.255.255.255. |
| *ipv6Address* | Specifies a standard IPv6 address, for example, 1:2:3:4:5:6:7:8. |
| *Protocol* | Specifies the transmission protocol: UDP or TCP. |
| *Service* | Specifies a standard service, for example, domain, smtp. |
| *HostName*\|*DomainName* | Specifies the FQDN of a resource record that is located in the DNS namespace. |

# Modify the SOA record for a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to change settings for the start of authority (SOA) resource record for a zone. The settings that are applied for the SOA record affect how zone transfers are made between servers.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Modifying the SOA record for a zone**

- Using the Windows interface
- Using a command line

### To modify the SOA record for a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. Click the **Start of Authority (SOA)** tab.
4. Modify the properties for the SOA record as needed.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To modify the SOA record for a zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordAdd** *ZoneName NodeName* [**/Aging**] [*Ttl*] **SOA***PrimSvrAdmin Serial#\ Refresh Retry Expire MinTTL*

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/RecordAdd** | Required. Adds or modifies a resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace for which the SOA record is added. You can also type the node name relative to the *ZoneName*, or you can type @, which specifies the zone's root node. |
| **/Aging** | Specifies that this resource record is able to be aged and scavenged. If this parameter is not used, the resource record remains in the DNS database unless it is manually updated or removed. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. The default TTL is defined in SOA resource record. |
| **SOA** | Required. Specifies the type of resource record that you are modifying. |

| | |
|---|---|
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| *PrimSvr* | Required. Specifies the FQDN name of the server that is the primary source for information about the zone, for example, nameserver.place.sales.wingtiptoys.com.. |
| *Admin* | Required. Specifies the name of the DNS administrator for the zone, for example, postmaster.nameserver.place.sales.wingtiptoys.com.. |
| *Serial#* | Required. Specifies the version information for the zone. |
| *Refresh* | Required. Specifies the refresh interval for the zone. The standard setting is 3600 seconds (one hour). |
| *Retry* | Required. Specifies the retry interval for the zone. The standard setting is 600 seconds (10 minutes). |
| *Expire* | Required. Specifies the expire interval for the zone. The standard setting is 86400 seconds (one day). |
| *MinTTL* | Required. Specifies the minimum TTL value. This is the length of time that is used by other DNS servers to determine how long to cache information for a record in the zone before expiring and discarding it. The standard setting is 3600 seconds (one hour). |

**Note**

To modify any specific SOA record's values using Dnscmd, you must specify all the SOA values (*PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL*).

# Verify a zone delegation

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative credentials**

You do not need administrative credentials to perform this task. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

**To verify a zone delegation**

1. At a command prompt, type the following command, and then press ENTER:

   **nslookup** *RootServerIpAddress*

2. Type the following command, and then press ENTER:

   **nslookup**

3. At the next prompt, type the following command, and then press ENTER:

   **set norecurse**

4. At the next prompt, type the following command, and then press ENTER:

   **set q=NS**

5. Type the fully qualified domain name (FQDN) for the failed name.

   Use the trailing period (**.**) when you type the name. If zone delegations are set correctly, a list of name server (NS) resource records for delegated servers is returned in the response.

6. If the NS query response contains no names or Internet Protocol (IP) addresses for delegated servers, type **q=ns**, and then query again using the FQDN for the parent zone of the failed name.

   For example, if the failed name that you used in the previous step was sales.wingtiptoys.com, query for wingtiptoys.com.

7. If the response contains NS resource records, but no host address (A) resource records, type **set recurse**, and then query individually for any of the A resource records of the servers that are listed in the NS resource records.

   If, for each NS resource record that you encounter in a zone, you do not find at least one valid IP address in an A resource record, you have a broken delegation.

8. Either fix the broken delegation or retry the delegation test that is described in the previous step and use a different IP address.

   If more than one A resource record or IP address is found, use it to repeat the delegation test described in the previous step. To fix a delegation, add or update an A resource record in the parent zone with a valid IP address for a correct DNS server for the delegated zone.

| Value | Description |
|---|---|
| *RootServerIpAddress* | The IP address of a valid root server for your network. |
| **set norecursion** | Instructs the root server to not perform recursion on your query. |
| **set q=NS** | Sends the query for NS resource records to the root server. |

# Using DNS Aging and Scavenging

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Aging and scavenging of stale resource records are features of Domain Name System (DNS) that are available when you deploy your server with primary zones.

Where aging and scavenging are available, you can use the DNS snap-in to perform the following related tasks for your DNS servers and any directory-integrated zones that they load:

- Enable or disable the use of scavenging at a DNS server
- Enable or disable the use of scavenging for selected zones at the DNS server
- Modify the no-refresh interval, either as a server default or by specifying an overriding value at selected zones
- Modify the refresh interval, either as a server default or by specifying an overriding value at selected zones
- Specify whether periodic scavenging occurs automatically at the DNS server for any of its eligible zones and how often these operations are repeated
- Manually initiate a single scavenging operation for all eligible zones at the DNS server
- View other related properties, such as the time stamp for individual resource records or the start-scavenging time for a specified zone

**Enabling Scavenging of Stale Resource Records**

By default, aging and scavenging features are disabled on all DNS servers and any of their zones. Before using these features, you should configure the following settings for the applicable server and its directory-integrated zones:

- **Server aging and scavenging properties for determining the use of these features on a server-wide basis.** These settings are used to determine the affect of zone-level properties for any directory-integrated zones that are loaded at the server. For more information, see Set aging and scavenging properties for a DNS server.
- **Zone aging and scavenging properties for determining the use of these features on a per zone basis.** When zone-specific properties are set for a selected zone, these settings apply only to the applicable zone and its resource records. Unless these zone-level properties are otherwise configured, they inherit their defaults from comparable settings that are maintained in server aging and scavenging properties. For more information, see Set aging and scavenging properties for a zone.

  **Caution** Enabling aging and scavenging for use with standard primary zones modifies the format of zone files. This change does not affect zone replication to secondary servers, but the modified zone files cannot be loaded by other versions of DNS servers.

**Modifying No-refresh Intervals**

When the no-refresh interval is in effect for a specific resource record, attempts to dynamically refresh its time stamp are suppressed by the DNS server. This aspect of the aging and scavenging mechanism prevents unnecessary refreshes from being processed by the server for aged resource records. These early refresh attempts, if not handled in this way, might otherwise increase Active Directory replication traffic related to processing DNS zone changes.

To ensure that records do not refresh prematurely, keep the no-refresh interval comparable in length to the current refresh interval for each resource record. For example, if you increase the refresh interval to a higher value, you can similarly increase the no-refresh interval.

In most instances, the default interval of seven days is sufficient and does not need to be changed.

**Modifying Refresh Intervals**

When the refresh interval is in effect for a resource record, attempts to dynamically refresh its time stamp are accepted and processed by the DNS server. When you set this interval, it is important that the length of time used be greater than the maximum possible refresh period for any resource records that are contained in the zone. This period is equal to the maximum amount of time that it might take the record to be refreshed under normal network conditions, based on the specific source generating the record refresh.

For example, the following table shows default refresh periods for various services that are known to register and refresh records dynamically in DNS.

| Service | Default refresh period |
|---|---|
| Net logon | 24 hours |
| Clustering | 24 hours |
| DHCP client | 24 hours<br><br>The DHCP Client service sends dynamic updates for the DNS records. This includes both computers that obtain a leased Internet Protocol (IP) address by using Dynamic Host Configuration Protocol (DHCP) and computers that are configured statically for TCP/IP. |
| DHCP server | Four days (half of the lease interval, which is eight days by default).<br><br>Refresh attempts are made only by DHCP servers that are configured to perform DNS dynamic updates on behalf of their clients, for example, Windows 2000 Server DHCP servers and Windows Server 2003 DHCP servers. The period is based on the frequency in which DHCP clients renew their IP address leases with the server. Typically, this occurs when 50 percent of the scope lease time has elapsed. If the DNS default scope lease duration of eight days is used, the maximum refresh period for records that are updated by DHCP servers on behalf of clients is four days. |

By default, the refresh interval is seven days. In most instances, this value is sufficient and does not need to be changed, unless any resource records in the zone are refreshed less often than once every seven days.

**Automated and Manually Initiated Scavenging**

Although scavenging start time and other factors determine when zones and records are actually eligible for scavenging, you can initiate scavenging by using either of two methods:

- **Automatic scavenging.** Automatic scavenging specifies that aging and scavenging of stale records is to be performed automatically by the server for any eligible zones at a recurring interval that is specified as the scavenging period. When you use automatic scavenging, the default scavenging period is one day, and the minimum allowed value that you can use for the scavenging period is one hour. For more information, see Configure automatic scavenging of stale resource records.

- **Manual scavenging.** Manual scavenging specifies that aging and scavenging of stale records is to be performed as a nonrecurring operation for any eligible zones at the server. For more information, see Start scavenging of stale resource records.

**Modifying Time-Stamp Values**

For resource records that are not added dynamically to DNS zone data, a record time-stamp value of zero is applied, which prevents these records from aging or removal during scavenging.

You can, however, reset record properties manually to enable any statically entered records to qualify for the aging and scavenging process. If you do this, the record will be deleted based on the modified time-stamp value, at which point you might need to re-create a record if it is still needed.

For more information, see Reset aging and scavenging properties for a specific resource record.

To complete this task, perform the following procedures:

1. Set aging and scavenging properties for a DNS server

2. Set aging and scavenging properties for a zone

3. Configure automatic scavenging of stale resource records

4. Start scavenging of stale resource records

5. Reset aging and scavenging properties for a specific resource record

# Set aging and scavenging properties for a DNS server

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The settings for server aging and scavenging properties determine the effect of zone-level properties for any directory-integrated zones that are loaded at the server.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Setting aging and scavenging properties for a DNS server**

- Using the Windows interface
- Using the command line

### To set aging and scavenging properties for a DNS server using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable Domain Name System (DNS) server, and then click **Set Aging/Scavenging for All Zones**.
3. Select the **Scavenge stale resource records** check box.
4. Modify other aging and scavenging properties as needed

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To set aging and scavenging properties for a DNS server using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** {**/ScavengingInterval** *Value*|**/DefaultAgingState** *Value*|**/DefaultNoRefreshInterval** *Value*|**/DefaultRefreshInterval** *Value*}

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *Value* | For **/ScavengingInterval**, type a value in hours. The default is 168 hours (one week). For **/DefaultAgingState**, type **1** to enable aging for new zones when they are created. Type **0** to disable aging for new zones. For **/DefaultNoRefreshInterval**, type a value in hours. The default is 168 hours (one week). For **/DefaultRefreshInterval**, type a value in hours. The default is 168 hours (one week). |

# Set aging and scavenging properties for a zone

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The settings for zone aging and scavenging properties determine the use of these features on a per-zone basis. When you set zone-specific properties for a selected zone, these settings apply only to the applicable zone and its resource records. Unless these zone-level properties are otherwise configured, they inherit their defaults from comparable settings that are maintained in server aging and scavenging properties.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Setting aging and scavenging properties for a zone**

- Using the Windows interface
- Using the command line

### To set aging and scavenging properties for a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, click **Aging**.
4. Select the **Scavenge stale resource records** check box.
5. Modify other aging and scavenging properties as needed.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To set aging and scavenging properties for a zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** {*ZoneName*|**..AllZones**} {**/Aging** *Value*|**/RefreshInterval** *Value*|**/NoRefreshInterval** *Value*}

| Value | Description |
|---|---|
| *ServerName* | Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName*\|**..AllZones** | Specifies the name of the zone to which you want to set aging and scavenging. To apply the operation to all zones, use **..AllZones**. |
| *Value* | For **/Aging**, type **1** to enable aging. Type **0** to disable aging. For **/RefreshInterval**, type a value in hours. The default setting is 168 hours (one week). For **/NoRefreshInterval**, type a value in seconds. The standard setting is 3600 seconds (one hour). |

# Configure automatic scavenging of stale resource records

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To configure automatic scavenging of stale resource records**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable Domain Name System (DNS) server, and then click **Properties**.
3. Click the **Advanced** tab.
4. Select the **Enable automatic scavenging of stale records** check box.
5. To adjust the scavenging period, in **Scavenging period**, select an interval in the drop-down list (either hours or days), and then type a number in the text box.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Start scavenging of stale resource records

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Starting scavenging of stale resource records**

- Using the Windows interface
- Using the command line

**To start scavenging of stale resource records using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable Domain Name System (DNS) server, and then click **Scavenge Stale Resource Records**.
3. When you are prompted to confirm that you want to scavenge all stale resource records on the server, click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To start scavenging of stale resource records using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/StartScavenging**

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |

# Reset aging and scavenging properties for a specific resource record

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is used only for resource records that are registered dynamically. For records that you add to a zone manually, a time-stamp value of zero always applies to the record, which excludes it from the scavenging process.

| **Note** |
| --- |
| Scavenging and aging properties for name server (NS) and start of authority (SOA) resource records are reset in the properties of the zone, not in the properties of the resource record. |

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Resetting aging and scavenging properties for a specific resource record**

- Using the Windows interface
- Using the command line

**To reset aging and scavenging properties for a specific resource record using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.
3. In the details pane, double-click the resource record for which you want to reset scavenging and aging properties.
4. Depending on the how the resource record was originally added to the zone, do one of the following:
   - If the record was added dynamically using dynamic update, clear the **Delete this record when it becomes stale** check box to prevent the record's aging or potential removal during the scavenging process. If dynamic updates to this record continue to occur, the Domain Name System (DNS) server will always reset this check box so that the dynamically updated record can be deleted.
   - If you added the record manually, select the **Delete this record when it becomes stale** check box to permit the record's aging or potential removal during the scavenging process.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To reset aging and scavenging properties for a specific resource record using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** {*ZoneName*|**..AllZones**} **/ScavengingInterval** *Value*

| **Value** | **Description** |
| --- | --- |

| | |
|---|---|
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName*\|**..AllZones** | Specifies the fully qualified domain name (FQDN) of the zone. To configure all zones that are hosted on the specified DNS server to allow dynamic updates, type **..AllZones**. |
| *Value* | The new value for the scavenging interval, specified in hours. The default is 168 hours (one week). |

# Managing Domain Name System Clients

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks are described in this objective:

Configuring DNS Client Settings for DNS Operations

Managing the DNS Client Resolver Cache

Renewing DNS Client Registration

# Configuring DNS Client Settings for DNS Operations

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain Name System (DNS) configuration involves the following tasks when TCP/IP properties are configured for each computer:

- Setting a DNS computer name or host name for each computer. For example, in the fully qualified domain name (FQDN) wkstn1.sales.wingtiptoys.com., the DNS computer name is wkstn1.
- Setting a primary DNS suffix for the computer, which is placed after the computer name or host name to form the FQDN. Using the previous example, the primary DNS suffix is sales.wingtiptoys.com.
- Setting a list of DNS servers for clients to use when resolving DNS names, such as a preferred DNS server, and any alternate DNS servers to use if the preferred server is not available.
- Setting the DNS suffix search list or search method to be used by the client when it performs DNS query searches for short, unqualified domain names.

These tasks are discussed in more detail in each of the following sections.

**Setting Computer Names**

When you set a computer name for DNS, it is useful to think of the name as the leftmost portion of a fully qualified domain name (FQDN). For example, in wkstn1.sales.wingtiptoys.com., wkstn1 is the computer name.

You can configure all Windows DNS clients with a computer name that is based on any of the standard supported characters that are defined in Request for Comments (RFC) 1123, "Requirements for Internet Hosts -- Application and Support." These characters include the following:

- Uppercase letters: A through Z
- Lowercase letters: a through z
- Numbers: 0 through 9
- Hyphens (-)

If you are supporting both network basic input/output system (NetBIOS) and DNS namespaces on your network, you can use a different computer name in each namespace. However, it is recommended that, wherever possible, you try to use computer names that are 15 characters or less and that you follow the RFC 1123 naming requirements described in the previous paragraph.

By default, the leftmost label in the FQDN for clients equals the NetBIOS computer name, unless this label is 16 or more characters, which is the maximum for NetBIOS names. When the computer name exceeds the maximum length for NetBIOS, the NetBIOS computer name is truncated based on the full label that is specified.

Before you configure computers with varying DNS and NetBIOS names, consider the following issues and their implications for your deployment:

If Windows Internet Name Service (WINS) lookup is enabled for zones that are hosted by your DNS servers, you must use the same name for both NetBIOS and DNS computer naming. Otherwise, the results of clients attempting to query and resolve the names of these computers will be inconsistent.

If you have an investment in using NetBIOS names to support legacy Microsoft networking technology, it is recommended that you revise NetBIOS computer names that are used on your network to prepare for migration to a standard DNS-only environment. This prepares your network well for long-term growth and interoperability with future naming requirements. For example, if you use the same computer name for both NetBIOS and DNS resolution, consider converting any special characters such as the underscore (_) in your current NetBIOS names that do not comply with DNS naming standards. While these

characters are permitted in NetBIOS names, they are more often incompatible with traditional DNS host naming requirements and most existing DNS resolver client software.

| **Note** |
| --- |
| Although the use of the underscore (_) in DNS host names or in host address (A) resource records has traditionally been prohibited by DNS standards, the use of underscores in service-related names — such as those used for service locator (SRV) resource records — has been proposed to avoid naming collisions in the Internet DNS namespace. |

In addition to DNS standard naming conventions, Windows Server 2003 DNS supports the use of extended American Standard Code for Information Interchange (ASCII) and Unicode characters. However, because most resolver software that is written for other platforms (such as UNIX) is based on Internet DNS standards, this enhanced character support can be used only in private networks with computers running Windows 2000 or Windows Server 2003 DNS.

The initial setup of DNS and TCP/IP displays a warning to suggest a standard DNS name if a nonstandard DNS name is entered.

By default, computers and servers use DNS to resolve any name that is greater than 15 characters in length. If the name is less than or equal to 15 characters, both NetBIOS and DNS name resolution can be attempted and used to resolve the name.

**Setting Domain Names**

The domain name is used with the client computer name to form the FQDN, which is also known as the full computer name. In general, the DNS domain name is the remainder of the FQDN that is not used as the unique host name for the computer.

For example, the DNS domain name for a client computer can be defined as the following: If the FQDN is wkstn1.sales.wingtiptoys.com, the domain name is the sales.wingtiptoys.com portion of this name.

DNS domain names have two variations: a DNS name and a NetBIOS name. The full computer name (a fully qualified DNS name) is used during querying and location of named resources on your network. For earlier-version clients, the NetBIOS name is used to locate various types of NetBIOS services that are shared on your network.

The Net Logon service is an example of a service that shows the need for both NetBIOS and DNS names. In Windows Server 2003 DNS, the Net Logon service on a domain controller registers its SRV resource records on a DNS server. For Windows NT Server 4.0 and earlier operating systems, domain controllers register a DomainName entry in WINS to perform the same registration and to advertise their availability for providing authentication service to the network.

When a client computer is started on the network, it uses the DNS resolver to query a DNS server for SRV records for its configured domain name. This query is used to locate domain controllers and provide logon authentication for accessing network resources. A client or a domain controller on the network optionally uses the NetBIOS resolver service to query WINS servers, attempting to locate DomainName [1C] entries to complete the logon process.

Your DNS domain names should follow the same standards and recommended practices that apply to DNS computer naming described in the previous section. In general, acceptable naming conventions for domain names include the use of letters A through Z, numerals 0 through 9, and the hyphen (-). The period (.) in a domain name is always used to separate the discrete parts of a domain name, commonly known as labels. Each label corresponds to an additional level that is defined in the DNS namespace tree.

For most computers, the primary DNS suffix that is configured for the computer can be the same as its Active Directory domain name, although the two values can also be different.

| **Important** |
| --- |
| By default, the primary DNS suffix portion of a computer's FQDN must be the same as the name of the Active Directory domain where the computer is located. To allow different primary DNS suffixes, a domain administrator may establish a restricted list of allowed suffixes by creating the **msDS-AllowedDNSSuffixes** attribute in the domain object container. This attribute is created and managed by the domain administrator using Active Directory Service Interfaces (ADSI) or the Lightweight Directory Access Protocol (LDAP). |

**Configuring a DNS Servers List**

For DNS clients to operate effectively, a prioritized list of DNS name servers must be configured for each computer to use when processing queries and resolving DNS names. In most cases, the client computer contacts and uses its preferred DNS server, which is the first DNS server on its locally configured list. The client computer contacts and uses listed alternate DNS servers when the preferred server is not available. For this reason, it is important that the preferred DNS server be appropriate

for continuous client use under normal conditions.

| Note |
| --- |
| For computers running Windows XP, the DNS server list is used by clients only to resolve DNS names. When clients send dynamic updates — for example, when they change their DNS domain name or a configured Internet Protocol (IP) address — they might contact these servers or other DNS servers as needed to update their DNS resource records. |

By default, the DNS client on Windows XP does not attempt dynamic update over a Remote Access Service (RAS) or virtual private network (VPN) connection. To modify this configuration, you can modify the advanced TCP/IP settings of the particular network connection or you can modify the registry.

By default, the DNS client does not attempt dynamic update of top-level domain (TLD) zones. Any zone that is named with a single-label name is considered a TLD zone, for example, com, edu, blank, or my-company. To configure the DNS client to allow the dynamic update of TLD zones, you can use the **Update Top Level Domain Zones** policy setting or you can modify the registry.

When DNS clients are configured dynamically by a Dynamic Host Configuration Protocol (DHCP) server, it is possible to have a larger list of provided DNS servers. To provide an IP address list of DNS servers to your DHCP clients, enable option code 6 on the configured options types that are provided by your DHCP server. For Windows Server 2003 DHCP servers, you can configure a list of up to 25 DNS servers for each client with this option.

To effectively share the load when multiple DNS servers are provided in a DHCP options-specified list, you can configure a separate DHCP scope that rotates the listed order of DNS and WINS servers that are provided to clients.

**Configuring a DNS Suffix Search List**

For DNS clients, you can configure a DNS domain suffix search list that extends or revises their DNS search capabilities. By adding additional suffixes to the list, you can search for short, unqualified computer names in more than one specified DNS domain. Then, if a DNS query fails, the DNS Client service can use this list to append other name suffix endings to your original name and to repeat DNS queries to the DNS server for these alternate FQDNs.

For computers and servers, the following default DNS search behavior is predetermined and used for completing and resolving short, unqualified names.

When the suffix search list is empty or unspecified, the primary DNS suffix of the computer is appended to short, unqualified names, and a DNS query is used to resolve the resultant FQDN. If this query fails, the computer can try additional queries for alternate FQDNs by appending any connection-specific DNS suffix that is configured for network connections.

If no connection-specific suffixes are configured or if queries for these resultant connection-specific FQDNs fail, the client can then begin to retry queries based on systematic reduction of the primary suffix (also known as devolution).

For example, if the primary suffix is sales.wingtiptoys.com, the devolution process is able to retry queries for the short name by searching for it in the wingtiptoys.com and com domains.

When the suffix search list is not empty and it has at least one DNS suffix specified, attempts to qualify and resolve short DNS names are limited to searching only those FQDNs that are made possible by the specified suffix list. If queries for any FQDNs form as a result of appending and trying each suffix in the list, the query process fails, producing a "Name not found" result.

| Note |
| --- |
| If the domain suffix list is used, clients continue to send additional alternate queries based on different DNS domain names when a query is not answered or resolved. After a name is resolved using an entry in the suffix list, unused list entries are not tried. For this reason, it is most efficient to order the list with the most used domain suffixes first. |

**Configuring Multiple Names**

Computers running Windows XP and servers running Windows Server 2003 are given DNS names by default. Each computer can have its DNS names configured using one of two possible methods:

- A primary DNS domain name, which applies as the default, fully qualified, DNS name for the computer and all its configured network connections.

- A connection-specific, DNS domain name, which can be configured as an alternate DNS domain name that applies only for a single network adapter that is installed and configured on the computer.

Although most computers do not need to support or use more than one name in DNS, support for configuring multiple, connection-specific DNS names is sometimes useful. For example, by using multiple names, a user can specify which network connection to use when connecting to a multihomed computer.

To complete these tasks, perform the following procedure:

Configure DNS settings in Network Connections

# Configure DNS settings in Network Connections

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to configure TCP/IP to use Domain Name System (DNS).

**Administrative credentials**

To complete this procedure, you must be a member of the Administrators group or the Network Configuration Operators group on the local computer.

**To configure DNS settings in Network Connections**

1. Open Network Connections.
2. Right-click the network connection that you want to configure, and then click **Properties**.
3. On the **General** tab (for a local area connection) or the **Networking** tab (for all other connections), click **Internet Protocol (TCP/IP)**, and then click **Properties**.
4. If you want to obtain DNS server addresses from a DHCP server, click **Obtain DNS server address automatically**.
5. If you want to configure DNS server addresses manually, click **Use the following DNS server addresses**, and in **Preferred DNS server** and **Alternate DNS server**, type the Internet Protocol (IP) addresses of the preferred DNS server and alternate DNS server.
6. To configure advanced DNS properties, click **Advanced**, click the **DNS** tab, and then do one or more of the following:
   - To configure an additional DNS server IP address:

     a. Under **DNS server addresses**, in order of use, click **Add**.

     b. In **DNS server**, type the IP address of the DNS server, and then click **Add**.

   - To resolve an unqualified name by appending the primary DNS suffix and the DNS suffix of each connection (if configured), click **Append primary and connection specific DNS suffixes**. If you also want to search the parent suffixes of the primary DNS suffix up to the second-level domain, select the **Append parent suffixes of the primary DNS suffix** check box.
   - To resolve an unqualified name by appending the suffixes from a list of configured suffixes, click **Append these DNS suffixes (in order)**, and then click **Add** to add suffixes to the list.
   - To use a DNS dynamic update to register the IP addresses of this connection and the primary domain name of the computer, select the **Register this connection's addresses in DNS** check box. This option is enabled by default. The primary domain name of the computer is the primary DNS suffix appended to the computer name, and it can be viewed as the full computer name on the **Computer Name** tab (which is available in **System** in **Control Panel**).
   - To use a DNS dynamic update to register the IP addresses and the connection-specific domain name of this connection, select the **Use this connection's DNS suffix in DNS registration** check box. This option is disabled by default. The connection-specific domain name of this connection is the DNS suffix for this connection appended to the computer name.
   - To completely disable DNS dynamic update for all names on the computer, clear the **Register this connection's addresses in DNS** and **Use this connection's DNS suffix in DNS registration** check boxes for all connections in Network Connections.

**Note**

To open Network Connections, click **Start**, point to **Control Panel**, and then click **Network Connections**.

# Managing the DNS Client Resolver Cache

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **ipconfig** command to troubleshoot Domain Name System (DNS) problems or to verify DNS settings. To complete this task for troubleshooting or verification, perform the following procedures:

- Preload the DNS client resolver cache
- View a DNS client resolver cache
- Flush and reset a client resolver cache

# Preload the DNS client resolver cache

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Entries that you add with this procedure are always answered first from the local resolver cache. They are not sent to the Domain Name System (DNS) query when queries are made locally to resolve these names to host address (A) resource records.

Every line in the Hosts file contains an Internet Protocol (IP) address, followed by one or more host names. For example, you can add a line, such as the following line, with an IP address (10.0.0.1) that maps to more than one DNS host name:

```
10.0.0.1  host-a  host-a.example.microsoft.com  host-b.example2.microsoft.com
```

Likewise, a single DNS host name can correspond to more than one IP address if each of the addresses is mapped and used in separate lines. For example, you can add lines for the following multihomed or multiaddressable DNS host computer:

```
10.0.0.1  host-a.example.microsoft.com
10.0.0.2  host-a.example.microsoft.com
10.0.0.3  host-a.example.microsoft.com
```

When multiple names or IP addresses are used in the Hosts file, the DNS Client service must be running for all entries to be returned or used in answering queries. If the DNS Client service is not running, only the first entry in the file is used to resolve the query.

**To preload the DNS client resolver cache**

1. At a command prompt, type the following command, and then press ENTER:

   **notepad %systemroot%\system32\drivers\etc\hosts**

2. Using the default entry in the file (a mapping for the local host to the loopback IP address, 127.0.0.1), add additional host name-to-address mappings on separate lines to be preloaded into the resolver cache of the client. For example, you might add:

   10.0.0.1  host-a  host-a.example.microsoft.com

3. On the **File** menu, click **Save**, and then **Exit**.

4. As an option, you can verify that your changes have been updated in the resolver cache by viewing its contents.

# View a DNS client resolver cache

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **ipconfig /displaydns** command to view the contents of the Domain Name System (DNS) client resolver cache, which includes entries that are preloaded from the local Hosts file, as well as any recently obtained resource records for name queries that were resolved by the system. This information is used by the DNS Client service to quickly resolve frequently queried names before it queries its configured DNS servers.

When you use the **ipconfig /displaydns** command to display current resolver cache contents, the resultant output generally includes the local host and loopback Internet Protocol (IP) address (127.0.0.1) mappings. This is because these mappings typically exist in the default (unmodified) contents of the local Hosts file.

**To view a DNS client resolver cache**

- At a command prompt, type the following command, and then press ENTER:

  **ipconfig /displaydns**

# Flush and reset a client resolver cache

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **ipconfig /flushdns** command to flush and reset the contents of the Domain Name System (DNS) client resolver cache. During DNS troubleshooting, if necessary, you can use this procedure to discard negative cache entries from the cache, as well as any other dynamically added entries.

Resetting the cache does not eliminate entries that are preloaded from the local Hosts file. To eliminate those entries from the cache, remove them from this file.

**To flush and reset a client resolver cache**

- At a command prompt, type the following command, and then press ENTER:

  **ipconfig /flushdns**

# Renewing DNS Client Registration

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the **ipconfig /registerdns** command to initiate dynamic registration manually for the Domain Name System (DNS) names and Internet Protocol (IP) addresses that are configured at a computer. This option can assist in troubleshooting a failed DNS name registration or in resolving a dynamic update problem between a client and the DNS server without restarting the client.

By default, the **ipconfig /registerdns** command refreshes all Dynamic Host Configuration Protocol (DHCP) address leases and registers all related DNS names that are configured and used by the client computer.

**To renew DNS client registration**

- At a command prompt, type the following command, and then press ENTER:

  **ipconfig /registerdns**

# Managing Domain Name System Zones

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks for managing Domain Name System (DNS) zones are described in this objective:

Adding and Removing a Zone

Start or pause a zone

Start a zone transfer at a secondary server

Modifying Zone Properties

Configuring Dynamic Updates

Delegating a Zone

Using Stub Zones for DNS Operations

Using WINS Lookup in DNS Zones

# Adding and Removing a Zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A zone starts as a storage database for a single Domain Name System (DNS) domain name. If other domains are added below the domain that is used to create the zone, these domains can either be part of the same zone or belong to another zone. After a subdomain is added, it can then either be:

- Managed and included as part of the original zone records.
- Delegated away to another zone that is created to support the subdomain.

You can use this task after you determine that you need to add or remove a DNS zone from your environment. For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirement:

- Install Dnscmd.

To complete this task, perform one of the following procedures:

- Delete a DNS zone
- Add a new zone

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Delete a DNS zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Although it can also be used to delete a primary zone, the following procedure is most often used to delete a secondary copy of a zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

Deleting a standard primary zone is usually unnecessary, unless you are redesigning your Domain Name System (DNS) namespace and the zone is no longer needed or used. In most cases, you can change the zone type if you only want to modify the zone.

| **Caution** |
| --- |
| Deleting an Active Directory–integrated zone effectively deletes the zone and eliminates its use at all other DNS servers that use the same directory store of zone data. |

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

#### Deleting a DNS zone

- Using the Windows interface
- Using the command line

### To delete a DNS zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.

   Where?

   - DNS/*applicable DNS server*/Forward Lookup Zones (or Reverse Lookup Zones)/*applicable zone*

3. On the **Action** menu, click **Delete**.
4. When you are asked to confirm that you want to delete the zone, click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To delete a DNS zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneDelete** *ZoneName* [**/DsDel**] [**/f**]

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/ZoneDelete** | Required. Specifies the command to delete the zone that is specified by *ZoneName*. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone that you are deleting. |

| | |
|---|---|
| **/DsDel** | Deletes the zone from Active Directory. |
| **/f** | Performs the command without asking for confirmation. If you omit this parameter, you are prompted to confirm the deletion of the resource record. |

# Add a new zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to create a new primary, secondary, stub, or reverse lookup zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Adding a new zone**

- Using the Windows interface
- Using a command line

### To add a new zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click a DNS server, and then click **New Zone** to start the New Zone Wizard.
3. Follow the instructions in the wizard to create a new primary, secondary, stub, or reverse lookup zone.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To add a new zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneAdd** *ZoneName* {**/Primary**|**/DsPrimary**|**/Secondary**|**/Stub**|**/DsStub**} [**/file** *FileName*] [**/load**] [**/a** *AdminEmail*] [**/DP** *FQDN*]

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/ZoneAdd** | Required. Adds a zone. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the in-addr.arpa domain for the zone, for example, **20.1.168.192.in-addr.arpa.** |
| **/Primary**\|**/DsPrimary** | Required. Specifies the type of zone. To specify an Active Directory-integrated zone, type **/DsPrimary**. |
| **/file** | Required for **/Primary**. Specifies a file for the new zone. This parameter is invalid for the **/DsPrimary** zone type. |
| *FileName* | Required for **/Primary**. Specifies the name of the zone file. This parameter is invalid for the **/DsPrimary** zone type. |
| **/load** | Loads an existing file for the zone. If this parameter is not specified, default zone records are created automatically. This parameter does not apply to **/DsPrimary**. |
| **/a** | Adds an administrator e-mail address for the zone. |

| | |
|---|---|
| *AdminEmail* | Specifies the administrator e-mail name for the zone. |
| **/DP** | Adds the zone to an application directory partition. You may also use one of the following:<br>• **/DP /domain** for a domain directory partition (replicates to all DNS servers in the domain).<br>• **/DP /forest** for a forest directory partition (replicates to all DNS server in the forest).<br>• **/DP /legacy** for a legacy directory partition (replicates to all domain controllers in the domain). This setting supports domains using legacy Windows 2000 Server domain controllers. |
| *FQDN* | Specifies the FQDN of the directory partition. |

# Start or pause a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to start or pause a zone. By default, zones are started when they are created or loaded at the server. Only zones that have previously been paused need to be restarted.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Starting or pausing a zone**

- Using the Windows interface
- Using the command line

### To start or pause a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.

   Where?

   - DNS/*applicable DNS server*/Forward Lookup Zones (or Reverse Lookup Zones)/*applicable zone*

3. On the **Action** menu, click **Properties**.
4. On the **General** tab, click **Start** or **Pause**, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To start or pause a zone using the command line

1. Open a command prompt. To start a zone, type the following command, and then press ENTER:

   **dnscmd** *ServerName* **/ZoneResume** *ZoneName*

2. To pause a zone, type the following command, and then press ENTER:

   **dnscmd** *ServerName* **/ZonePause** *ZoneName*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/ZoneResume** | Required. Resumes the hosting of the zone by the DNS server. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone resuming operation. |

# Start a zone transfer at a secondary server

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure checks to see if the start of authority (SOA) resource record in the secondary zone is the most recent version of the SOA resource record in the primary zone. If the SOA resource records are synchronized, there is no zone transfer. If the SOA resource records are not synchronized, there is a zone transfer.

By default, the Domain Name System (DNS) server only allows a zone transfer to authoritative DNS servers that are listed in the name server (NS) resource records for the zone.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Starting a zone transfer at a secondary server**

- Using the Windows interface
- Using the command line

### To start a zone transfer at a secondary server using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Transfer from master**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To start a zone transfer at a secondary server using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneRefresh** *ZoneName*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/ZoneRefresh** | Required. Updates the secondary zone. |
| *ZoneName* | Required. Specifies the name of the secondary zone to update. |

# Modifying Zone Properties

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You might decide to modify certain Domain Name System (DNS) zone properties based on a design or performance evaluation of your network. These settings affect zone transfers and zone types. For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform one of the following procedures:

1. Change the DNS zone type
2. Change a DNS zone file name
3. Change the zone replication scope
4. Modify the SOA record for a zone
5. Modify DNS zone transfer settings
6. Specify DNS servers as authoritative for a zone
7. Change the master server for a secondary zone
8. Create a notify list for a zone
9. Adjust the refresh, retry, or expire intervals for a zone

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Change the DNS zone type

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to change the Domain Name System (DNS) zone type. You can select a primary, secondary, or stub zone. When you select the secondary or stub zone type, you must specify the Internet Protocol (IP) address of another DNS server to be used as the source for obtaining updated information for the zone.

If the DNS server computer is operating as a domain controller, the option to change the zone type to **Active Directory-Integrated** is available. When you select this zone type, zone data is stored and replicated as part of the Active Directory database.

Changing a zone from secondary to primary can affect other zone activities, including the management of dynamic updates and zone transfers and the use of DNS notify lists to notify other servers about changes in the zone. Changing a zone from stub to primary (or the reverse) is not recommended because of the purpose of stub zones. For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Changing the zone type**

- Using the Windows interface
- Using the command line

### To change the zone type using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, note the current zone type, and then click **Change**.
4. In the **Change Zone Type** dialog box, click a zone type other than the current one, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To change the zone type using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneResetType** *ZoneName Property* [*MasterIPaddress...*] [**/file** *FileName*] {**/OverWrite_Mem**|**/OverWrite_Ds**|**/DirectoryPartition** *FQDN*}

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of zone. |

| | |
|---|---|
| *Property* | Required. One of the following zone types:<br>• **/Primary**<br>Standard primary zone. The *FileName* must be required.<br>• **/DsPrimary**<br>Active Directory-integrated primary zone.<br>• **/Secondary**<br>Secondary zone. You must specify at least one *MasterIPaddress...*<br>• **/Stub**<br>Stub zone. You must specify at least one *MasterIPaddress....*<br>• **/DsStub**<br>Active Directory-integrated stub zone. You must specify at least one *MasterIPaddress....* |
| *MasterIPaddress...* | Required for **/Secondary**, **/Stub** and **/DsStub**. Specifies one or more IP addresses for the master servers of the secondary or stub zone, from which it copies zone data. |
| **/file** | Required for **/Primary**. Specifies a file for the new zone. This parameter is invalid for the **/DsPrimary** zone type. |
| *FileName* | Required for **/Primary**. Specifies the name of the zone file. This parameter is invalid for the **/DsPrimary** zone type. |
| **/OverWrite_Mem**\|**/OverWrite_Ds**\|**/DirectoryPartition***FQDN* | **/OverWrite_Mem** overwrites exisiting DNS data using the data in Active Directory.<br>**/OverWrite_Ds** overwrites Active Directory data with data in DNS.<br>**/DirectoryPartition** stores the new zone in the application directory partition that is specified by *FQDN*, such as DomainDnsZones.corp.sales.wingtiptoys.com. |

**Other Resources**
Deploying Domain Name System (DNS)

# Change a DNS zone file name

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you use the following procedure, the name of the zone file changes, not the name of the zone. You can use Windows Explorer to view or verify the new zone file name.

The zone file name is not used for Active Directory-integrated zones because these zones store zone data in the Active Directory database, not a text file on the DNS server computer.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To change a zone file name**

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.

   Where?

   - DNS/*applicable DNS server*/Forward Lookup Zones (or Reverse Lookup Zones)/*applicable zone*

3. On the **Action** menu, click **Properties**.
4. On the **General** tab, in the **Zone file name** text box, type the new file name for this zone, and then click **OK**.

**Caution**

- If the zone file name is changed, be sure to update the zone file name on other DNS servers that maintain this zone. Otherwise, subsequent zone transfers and updates might fail. This can occur in the following situations:

  - The zone type is primary on this server.

  - The zone type is secondary on this server, and this server acts as a source or master server for this zone to other DNS servers that host secondary copies of this zone.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Change the zone replication scope

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to change the replication scope for a zone. Only Active Directory-integrated primary and stub forward lookup zones can change their replication scope. Secondary forward lookup zones cannot change their replication scope.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Changing zone replication scope**

- Using the Windows interface
- Using the command line

### To change zone replication scope using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, note the current zone replication type, and then click **Change**.
4. Select a replication scope for the zone.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To change zone replication scope using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneChangeDirectoryPartition** *ZoneName NewPartitionName*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/ZoneChangeDirectoryPartition** | Required. Changes a zone's replication scope. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NewPartitionName* | Required. The FQDN of the DNS application directory partition where the zone will be stored. |

# Modify the SOA record for a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to change settings for the start of authority (SOA) resource record for a zone. The settings that are applied for the SOA record affect how zone transfers are made between servers.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Modifying the SOA record for a zone**

- Using the Windows interface
- Using a command line

### To modify the SOA record for a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. Click the **Start of Authority (SOA)** tab.
4. Modify the properties for the SOA record as needed.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To modify the SOA record for a zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordAdd** *ZoneName NodeName* [**/Aging**] [*Ttl*] **SOA***PrimSvrAdmin Serial#\ Refresh Retry Expire MinTTL*

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/RecordAdd** | Required. Adds or modifies a resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace for which the SOA record is added. You can also type the node name relative to the *ZoneName*, or you can type @, which specifies the zone's root node. |
| **/Aging** | Specifies that this resource record is able to be aged and scavenged. If this parameter is not used, the resource record remains in the DNS database unless it is manually updated or removed. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. The default TTL is defined in SOA resource record. |
| **SOA** | Required. Specifies the type of resource record that you are modifying. |

| | |
|---|---|
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| *PrimSvr* | Required. Specifies the FQDN name of the server that is the primary source for information about the zone, for example, nameserver.place.sales.wingtiptoys.com.. |
| *Admin* | Required. Specifies the name of the DNS administrator for the zone, for example, postmaster.nameserver.place.sales.wingtiptoys.com.. |
| *Serial#* | Required. Specifies the version information for the zone. |
| *Refresh* | Required. Specifies the refresh interval for the zone. The standard setting is 3600 seconds (one hour). |
| *Retry* | Required. Specifies the retry interval for the zone. The standard setting is 600 seconds (10 minutes). |
| *Expire* | Required. Specifies the expire interval for the zone. The standard setting is 86400 seconds (one day). |
| *MinTTL* | Required. Specifies the minimum TTL value. This is the length of time that is used by other DNS servers to determine how long to cache information for a record in the zone before expiring and discarding it. The standard setting is 3600 seconds (one hour). |

**Note**

To modify any specific SOA record's values using Dnscmd, you must specify all the SOA values (*PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL*).

# Modify DNS zone transfer settings

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to change Domain Name System (DNS) zone transfer settings. To improve the security of your DNS infrastructure, zone transfers should be allowed only for either the DNS servers in the name server (NS) resource records for a zone or for specified DNS servers. If you allow any DNS server to perform a zone transfer, you are allowing internal network information to be transferred to any host that can contact your DNS server.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Modifying DNS zone transfer settings**

- Using the Windows interface
- Using the command line

### To modify DNS zone transfer settings using the Windows interface

1. Open the DNS snap-in.
2. Right-click a DNS zone, and then click **Properties**.
3. On the **Zone Transfers** tab, do one of the following:
   - To disable zone transfers, clear the **Allow zone transfers** check box.
   - To allow zone transfers, select the **Allow zone transfers** check box.
4. If you allowed zone transfers, do one of the following:
   - To allow zone transfers to any server, click **To any server**.
   - To allow zone transfers only to the DNS servers that are listed on the **Name Servers** tab, click **Only to servers listed on the Name Servers tab**.
   - To allow zone transfers only to specific DNS servers, click **Only to the following servers**, and then add the Internet Protocol (IP) address of one or more DNS servers.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To modify DNS zone transfer settings using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneResetSecondaries** *ZoneName* {**/NoXfr**|**/NonSecure**|**/SecureNs**|**/SecureList**[*SecondaryIPAddress*...]}

| Value | Description |
| --- | --- |

| | |
|---|---|
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of zone. |
| **/NoXfr** | Disables zone transfers for the zone. |
| **/NonSecure** | Permits zone transfers to any DNS server. |
| **/SecureNs** | Permits zone transfers only to DNS servers that are listed in the zone using NS resource records. |
| **/SecureList** | Permits zone transfers only to DNS servers that are specified by *SecondaryIPAddress*. |
| *SecondaryIPAddress* | Required if **/SecureList** is specified. A list of one or more IP addresses for DNS servers that are permitted to obtain zone transfers. |

# Specify DNS servers as authoritative for a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain Name System (DNS) servers that you specify with the following procedure are added to those server Internet Protocol (IP) addresses that are already present for the existing name server (NS) resource record for the zone. Typically, you might only need to perform this procedure at the primary zone when you add DNS servers to act as secondary servers and also to specify that these servers are known to be authoritative when they answer queries for zone data.

DNS servers automatically add and perform initial configuration of the NS resource record for each new primary zone that is added to the server.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Specifying DNS servers as authoritative for a zone**

- Using the Windows interface
- Using the command line

### To specify DNS servers as authoritative for a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. Click the **Name Servers** tab.
4. Click **Add**.
5. Specify additional DNS servers by their names and IP addresses, and then click **Add** to add them to the list.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

| **Note** |
|---|
| To add a name server to the list of authoritative servers for the zone, you must specify both the server's IP address and its DNS name. When you enter a name, click **Resolve** to resolve the name to its IP address before adding it to the list. |

### To specify DNS servers as authoritative for a zone using the command line

1. At a command prompt, type the following command, and then press ENTER:

   **dnscmd** *ServerName* **/RecordAdd** *ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] **NS** {*HostName*|*DomainName*}

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/RecordAdd** | Required. Specifies the command to add a resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |

| | |
|---|---|
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace for which the SOA record is added. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| **/Aging** | If this command is used, this resource record is able to be aged and scavenged. If this command is not used, the resource record remains in the DNS database unless it is updated or removed manually. |
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. (The default TTL is defined in the start-of-authority (SOA) resource record). |
| **NS** | Required. Specifies that you are adding a name server (NS) resource record to the zone that is specified in *ZoneName*. |
| *HostName*\|*DomainName* | Required. Specifies the host name or FQDN of the new authoritative server. |

# Change the master server for a secondary zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to specify a new master server for a secondary zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Changing the master server for a secondary zone**

- Using the Windows interface
- Using the command line

### To change the master server for a secondary zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable secondary zone, and then click **Properties**.
3. On the **General** tab, in **IP address**, specify the Internet Protocol (IP) address for a new master server, and then click **Add** to update the list.

| **Note** |
| --- |
| To open DNS, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To change the master server for a secondary zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneResetMasters** *ZoneName* [**/Local**] *MasterIPaddress...*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/ZoneResetMasters** | Required. Updates the master servers for a secondary zone. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone that you are updating. |
| **/Local** | Specifies the local master list for Active Directory-integrated zones. |
| *MasterIPaddress...* | Required. Specifies the IP addresses of the master servers to be used by the DNS server when updating the specified secondary zones. If you do not specify *ServerIPs*, you are requesting the DNS server to reset the value to an empty list. The request may be denied because a zone must always have at least one master server. *MasterIPaddress...* is required to clear the local master list for a zone. |

# Create a notify list for a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to create or change a notify list for a zone. Changes to the notify list properties are available only on primary zones. For secondary zones, these properties are read only.

By default, the DNS server allows a zone transfer only to authoritative DNS servers that are listed in the name server (NS) resource records for the zone.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To create or change a notify list for a zone**

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.

   Where?

   - DNS/*applicable DNS server*/Forward Lookup Zones (or Reverse Lookup Zones)/*applicable zone*

3. On the **Action** menu, click **Properties**.
4. Click the **Zone Transfers** tab.
5. Click **Notify**.
6. Verify that the **Automatically notify** check box is selected.
7. Select the method to be used for creating a list for notifying other DNS servers when changes to the zone occur. Your options are as follows:

   - Use the default, **Servers listed on the Name Servers tab**, to permit only those servers that appear by Internet Protocol (IP) address on the **Name Servers** tab to be included in the notify list.

   - Select **The following servers** if you want to specify a different notify list to be used instead.

8. If you selected **The following servers** in the previous step, add or remove server IP addresses to form the notify list as needed:

   - To add a server to the notify list, type its IP address in the **IP address** box, and then click **Add**.

   - To remove a server from the notify list, click the server IP address in the list box, and then click **Remove**.

| **Note** |
| --- |
| To open DNS, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Adjust the refresh, retry, or expire intervals for a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to change the following intervals for a Domain Name System (DNS) zone:

- **Refresh interval**. Used to determine how often other DNS servers that load and host the zone must attempt to renew the zone.
- **Retry interval**. Used to determine how often other DNS servers that load and host the zone are to retry a request for update of the zone each time that the refresh interval occurs.
- **Expire interval**. Used by other DNS servers that are configured to load and host the zone to determine when zone data expires if it is not renewed.

The default values for each interval are as follows:

- **Refresh interval**: 15 minutes.
- **Retry interval**: 10 minutes.
- **Expire interval**: one day.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Adjusting the refresh, retry, or expire interval for a zone**

- Using the Windows interface
- Using the command line

**To adjust the refresh, retry, or expire interval for a zone using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, verify that the zone type is either **Primary** or **Active Directory-Integrated**.
4. Click the **Start of Authority (SOA)** tab.
5. In **Refresh interval**, **Retry interval**, or **Expires after**, click a time period in minutes, hours, or days, and type a number in the text box.
6. Click **OK** to save the adjusted interval.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To adjust the refresh, retry, or expire interval for a zone using the command line**

- At a command prompt, type the following command, and then press ENTER:

**dnscmd** *ServerName***/RecordAdd** *ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] **SOA** *PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL*

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/RecordAdd** | Required. Adds or modifies a resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace for which the SOA record is added. You can also type the node name relative to the *ZoneName*, or you can type @, which specifies the zone's root node. |
| **/Aging** | Specifies that this resource record is able to be aged and scavenged. If this parameter is not used, the resource record remains in the DNS database unless it is updated or removed manually. |
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. The default TTL is defined in the start-of-authority (SOA) resource record. |
| **SOA** | Required. Specifies the type of resource record that you are modifying. |
| *PrimSvr* | Required. Specifies the FQDN name of the server that is the primary source for information about the zone, for example, nameserver.place.sales.wingtiptoys.com.. |
| *Admin* | Required. Specifies the name of the DNS administrator for the zone, for example, postmaster.nameserver.place.sales.wingtiptoys.com. |
| *Serial#* | Required. Specifies the version information for the zone. |
| *Refresh* | Required. Specifies the refresh interval for the zone. The standard setting is 3600 seconds (one hour). |
| *Retry* | Required. Specifies the retry interval for the zone. The standard setting is 600 seconds (10 minutes). |
| *Expire* | Required. Specifies the expire interval for the zone. The standard setting is 86400 seconds (one day). |
| *MinTTL* | Required. Specifies the minimum TTL value. This is the length of time that is used by other DNS servers to determine how long to cache information for a record in the zone before expiring and discarding it. The standard setting is 3600 seconds (one hour). |

**Note**

To modify any specific SOA resource record's values using Dnscmd, you must specify all the SOA values (*PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL*).

# Configuring Dynamic Updates

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Dynamic update enables Domain Name System (DNS) client computers to register and dynamically update their resource records with a DNS server whenever changes occur. This reduces the need for manual administration of zone records, especially for clients that frequently move or change locations and use Dynamic Host Configuration Protocol (DHCP) to obtain an Internet Protocol (IP) address.

The DNS Server service allows dynamic update to be enabled or disabled on a per-zone basis at each server that is configured to load either a standard primary or directory-integrated zone. By default, the DNS Client service dynamically updates host address (A) resource records in DNS when it is configured for TCP/IP.

Secure dynamic update is available only for zones that are integrated into Active Directory. After you directory-integrate a zone, access control list (ACL) editing features are available in the DNS snap-in. You can use these features to add or remove users or groups from the ACL for a specified zone or resource record.

For more information about planning DNS zones and dynamic updates, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

You can use this task to enable or disable dynamic updates or to allow only secure dynamic updates.

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform one of the following procedures:

- Enable dynamic updates
- Enable secure dynamic updates

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Enable dynamic updates

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to enable dynamic updates for a zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Enabling dynamic updates**

- Using the Windows interface
- Using the command line

### To enable dynamic updates using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, verify that the zone **Type** is either **Primary** or **Active Directory-Integrated**.
4. In **Dynamic updates**, click **Nonsecure and secure**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To enable dynamic updates using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** {*ZoneName*|**..AllZones**} **/AllowUpdate** {**1**|**0**}

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName*\|**..AllZones** | Required. Specifies the fully qualified domain name (FQDN) of the zone. To configure all zones that are hosted on the specified DNS server to allow dynamic updates, type **..AllZones**. |
| **1**\|**0** | Configures dynamic update. To allow dynamic updates, type a value of **1**. To not allow dynamic updates, type a value of **0**. |

# Enable secure dynamic updates

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to allow only secure dynamic updates for a zone. Secure dynamic update is supported only for Active Directory–integrated zones. If the zone type is configured differently, you must change the zone type and directory-integrate the zone before securing it for Domain Name System (DNS) dynamic updates.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Enabling secure dynamic updates**

- Using the Windows interface
- Using the command line

### To enable secure dynamic updates using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, verify that the zone type is **Active Directory-Integrated**.
4. In **Dynamic updates**, click **Secure only**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To enable secure dynamic updates using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** {*ZoneName*|**..AllZones**} **/AllowUpdate 2**

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName*\|**..AllZones** | Required. Specifies the fully qualified domain name (FQDN) of the zone. To configure all zones that are hosted on the specified DNS server to allow dynamic updates, type **..AllZones**. |
| **2** | Required. Configures the server to allow secure dynamic updates. If you exclude the **2**, the zone is set to perform standard dynamic updates only. |

# Delegating a Zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain Name System (DNS) provides the option of dividing up the namespace into one or more zones, which can then be stored, distributed, and replicated to other DNS servers. When deciding whether to divide your DNS namespace to make additional zones, consider the following reasons to use additional zones:

- You want to delegate management of part of your DNS namespace to another location or department in your organization.
- You want to divide one large zone into smaller zones for distributing traffic loads among multiple servers, improving DNS name resolution performance, or creating a more fault-tolerant DNS environment.
- You want to extend the namespace by adding numerous subdomains at once, for example, to accommodate the opening of a new branch or site.

If, for any of these reasons, your network can benefit from delegating zones, it may make sense to restructure your namespace by adding additional zones. When choosing how to structure zones, use a plan that reflects the structure of your organization.

When you delegate zones within your namespace, be aware that for each new zone you create, you will need delegation records in other zones that point to the authoritative DNS servers for the new zone. This is necessary both to transfer authority and to provide correct referral to other DNS servers and clients of the new servers that are being made authoritative for the new zone.

When a standard primary zone is first created, it is stored as a text file that contains all resource record information on a single DNS server. This server acts as the primary master for the zone. Zone information can be replicated to other DNS servers to improve fault tolerance and server performance.

When you structure your zones, there are several good reasons to use additional DNS servers for zone replication:

- Added DNS servers provide zone redundancy, enabling DNS names in the zone to be resolved for clients if a primary server for the zone stops responding.
- Added DNS servers can be placed so as to reduce DNS network traffic. For example, adding a DNS server to the opposing side of a low-speed, wide area network (WAN) link can be useful in managing and reducing network traffic.
- Additional secondary servers can be used to reduce loads on a primary server for a zone.

For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.
- Install Nslookup.

To complete this task, perform one of the following procedures:

- Create a new zone delegation
- Verify a zone delegation

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Create a new zone delegation

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to create a new zone delegation. All domains (or subdomains) that appear as part of the applicable zone delegation must be created in the current zone before you perform delegation as described in this procedure. As necessary, use the DNS snap-in to first add domains to the zone before you perform this procedure. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Creating a new zone delegation**

- Using the Windows interface
- Using the command line

### To create a new zone delegation using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable subdomain, and then click **New Delegation**.
3. Follow the instructions in the New Delegation Wizard to finish creating the new delegated domain.

| **Note** |
|---|
| To open DNS, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To create a new zone delegation using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordAdd** *ZoneName NodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] **NS** {*HostName*|*FQDN*}

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace for which the start-of-authority (SOA) record is added. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| **/Aging** | If this command is used, this resource record is able to be aged and scavenged. If this command is not used, the resource record remains in the DNS database unless it is updated or removed manually. |
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. (The default TTL is defined in the SOA resource record). |
| **NS** | Required. Specifies that you are adding a name server (NS) resource record to the zone that is specified in *ZoneName*. |

| | |
|---|---|
| *HostName\|FQDN* | Required. Specifies the host name or FQDN of the new authoritative server. |

# Verify a zone delegation

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative credentials**

You do not need administrative credentials to perform this task. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

**To verify a zone delegation**

1. At a command prompt, type the following command, and then press ENTER:

   **nslookup** *RootServerIpAddress*

2. Type the following command, and then press ENTER:

   **nslookup**

3. At the next prompt, type the following command, and then press ENTER:

   **set norecurse**

4. At the next prompt, type the following command, and then press ENTER:

   **set q=NS**

5. Type the fully qualified domain name (FQDN) for the failed name.

   Use the trailing period (**.**) when you type the name. If zone delegations are set correctly, a list of name server (NS) resource records for delegated servers is returned in the response.

6. If the NS query response contains no names or Internet Protocol (IP) addresses for delegated servers, type **q=ns**, and then query again using the FQDN for the parent zone of the failed name.

   For example, if the failed name that you used in the previous step was sales.wingtiptoys.com, query for wingtiptoys.com.

7. If the response contains NS resource records, but no host address (A) resource records, type **set recurse**, and then query individually for any of the A resource records of the servers that are listed in the NS resource records.

   If, for each NS resource record that you encounter in a zone, you do not find at least one valid IP address in an A resource record, you have a broken delegation.

8. Either fix the broken delegation or retry the delegation test that is described in the previous step and use a different IP address.

   If more than one A resource record or IP address is found, use it to repeat the delegation test described in the previous step. To fix a delegation, add or update an A resource record in the parent zone with a valid IP address for a correct DNS server for the delegated zone.

| Value | Description |
|---|---|
| *RootServerIpAddress* | The IP address of a valid root server for your network. |
| **set norecursion** | Instructs the root server to not perform recursion on your query. |
| **set q=NS** | Sends the query for NS resource records to the root server. |

# Using Stub Zones for DNS Operations

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use stub zones to:

- **Keep delegated zone information current.** By updating a stub zone for one of its child zones regularly, the Domain Name System (DNS) server that hosts both the parent zone and the stub zone maintains a current list of authoritative DNS servers for the child zone.

- **Improve name resolution.** Stub zones enable a DNS server to perform recursion by using the stub zone's list of name servers, without needing to query the Internet or the internal root server for the DNS namespace.

- **Simplify DNS administration.** By using stub zones throughout your DNS infrastructure, you can distribute a list of the authoritative DNS servers for a zone without using secondary zones. However, stub zones do not serve the same purpose as secondary zones, and they are not a valid alternative to secondary zones with regard to redundancy and load sharing.

When a DNS server loads a stub zone, it queries the master servers, which can be in different locations, for the necessary resource records of the authoritative servers for the zone. The list of master servers may contain a single server or multiple servers, and the list can be changed anytime.

For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform one of the following procedures:

- Reload or transfer stub zones

- Configure a stub zone to use local master servers

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Reload or transfer stub zones

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to reload or transfer stub zones. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Reloading or transferring stub zones**

- Using the Windows interface
- Using the command line

**To reload or transfer stub zones using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable stub zone, and do one of the following:
   - To reload the stub zone from storage, click **Reload**.
   - To have the DNS server determine if the serial number in the stub zone's start-of-authority (SOA) resource record has expired and then perform a zone transfer from the stub zone's master server, click **Transfer from Master**.
   - To perform a zone transfer from the stub zone's master server regardless of the serial number in the stub zone's SOA resource record, click **Reload from Master**.

| **Note** |
| --- |
| To open DNS, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To reload or transfer stub zones using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* {**/ZoneReload**|**/ZoneUpdateFromDs**|**/ZoneRefresh**} *ZoneName*

| **Value** | **Description** |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/ZoneReload** | Reloads the stub zone. |
| **/ZoneUpdateFromDs** | Reloads the stub zone from Active Directory. |
| **/ZoneRefresh** | Refreshes the stub zone. The DNS server determines if the serial number in the stub zone's SOA resource record has expired. If the serial number has expired, the DNS server performs a zone transfer from the stub zone's master server. |
| *ZoneName* | Required. Specifies the name of the stub zone that you want to reload or refresh. |

| **Note** |
| --- |

There is no **dnscmd** command to perform a zone transfer regardless of the SOA resource record's expiration date. To perform this operation, use the Windows interface procedure.

# Configure a stub zone to use local master servers

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to specify local master servers that you want the Domain Name System (DNS) server to use when loading and updating the stub zone.

When modifications to the master servers list are made and applied on a domain controller hosting the stub zone, the list of master servers for the stub zone is updated in Active Directory. If the local list of master servers is cleared at a later date, the master servers list from Active Directory is applied and the local list of master servers is deleted.

The DNS server keeps the master servers list from Active Directory stored in memory.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the DnsAdmins or the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using the **Run as** command to perform this procedure.

**Configuring a stub zone to use local master servers**

- Using the Windows interface
- Using the command line

### To configure a stub zone to use local master servers using the Windows interface

1. Open DNS.
2. In the console tree, right-click the stub zone, and then click **Properties**.
3. On the **General** tab, under **IP address**, modify the list to display the Internet Protocol (IP) addresses of the local master servers that you want the DNS server to use when loading and updating the stub zone.

   Ensure that the IP addresses of the local master servers are for only those authoritative DNS servers that should be queried to update the records of the stub zone on this server.
4. Select the **Use the list above as a local list of masters** check box, and then click **OK**.

| **Note** |
| --- |
| To open DNS, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To configure a stub zone to use local master servers using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneResetMasters** *ZoneName* [**/Local**] [*MasterIPaddress...*]

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| **/Local** | Configures the local master list for Active Directory–integrated zones. |

| | |
|---|---|
| *MasterIPaddress...* | List of one or more IP addresses of master servers for this zone. Master servers may include the server hosting the primary zone or servers hosting other secondary copies for the zone. To clear the local list of masters, type the command without entering any IP addresses. Ensure that the IP addresses of the local master servers are for only those authoritative DNS servers that should be queried to update the records of the stub zone on this server. |

# Using WINS Lookup in DNS Zones

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The DNS Server service provides the ability to use Windows Internet Name Service (WINS) servers to look up names that are not found in the Domain Name System (DNS) domain namespace by checking the network basic input/output system (NetBIOS) namespace that is managed by WINS.

For WINS lookup integration, two special resource record types — the WINS and WINS-R resource records — are enabled and added to a zone. When the WINS resource record is used, DNS queries that fail to find a matched host address (A) resource record in the zone are forwarded to WINS servers that are configured in the WINS resource record. For reverse lookup zones, the WINS-R resource record can be enabled and used to provide a similar benefit for further resolving a reverse query that is not answerable in the reverse in-addr.arpa domain.

For example, you can use WINS lookup when you are using a mixed-mode client environment consisting of UNIX clients that use only DNS name resolution and earlier-version Microsoft clients that require NetBIOS naming. In these environments, WINS lookup provides a method for permitting UNIX DNS clients to locate your WINS clients by extending DNS host name resolution into the WINS-managed NetBIOS namespace.

The WINS lookup integration feature is supported only by Windows DNS servers. If you use a mixture of Windows and other DNS servers to host a zone, you should select the **Do not replicate this record** check box option for any primary zones when you use the WINS lookup record. This prevents the WINS lookup record from being included in zone transfers to other DNS servers that do not support or recognize this record. If you do not enable the WINS lookup record to be used only on the local server, it can cause data errors or failed zone transfers at servers running other DNS server implementations that replicate the zone:

- How the caching Time to Live (TTL) and lookup time-out values are configured for use with the WINS and WINS-R records
- The format of the WINS and WINS-R resource records as they are used in zone files that are created by the DNS Server service

**WINS Lookup Interoperability**

Typically, WINS lookup provides the best and most predictable results if only Windows DNS servers are used, and it is only available directly for use at Windows DNS servers. There are ways, however, that you can use and benefit from WINS lookup as an interoperable solution when other DNS servers are deployed.

For example, consider adding a Windows DNS server that hosts a new WINS lookup-enabled zone. When you create and name the zone, use a subdomain that is added to your existing DNS namespace that is used just for WINS-specific referrals that are added to your DNS domain namespace.

For instance, in sales.wingtiptoys.com, call the zone wins.sales.wingtiptoys.com when you create it. You can then use this new WINS referral zone as the root zone for any of your WINS-aware computers that have names that are not found in your other traditional DNS zones.

To use the WINS referral zone, you must specify its domain name (wins.sales.wingtiptoys.com) in a DNS suffix search list for your clients. The suffix list is configurable as part of the TCP/IP properties for a client connection, and it can be updated either manually, by using Dynamic Host Configuration Protocol (DHCP) or by using Group Policy. As long as the name of the WINS referral zone is included in the domain suffix list, any DNS names that are not resolved in traditional zones can be resolved by using the WINS referral subdomain.

Under normal conditions, this should result in recursion from your other DNS servers to the Windows DNS servers that host the WINS-enabled zone. If the queried host names match NetBIOS computer names that are found in the WINS database, the names are resolved to the Internet Protocol (IP) addresses that are mapped in WINS data there.

In our example, the WINS-enabled zone is used only for WINS lookup; therefore, no additional resource records need to be added to it. In general, WINS records can be added to any forward lookup zone.

By using a specific subdomain just for WINS lookup and specifying a static DNS suffix list to be used in resolving and searching for names, you can prevent unusual situations in which DNS queries for different fully qualified domain names (FQDNs) resolve to the same WINS client name and IP address. This might easily occur if you add and configure many zones at each level of your namespace and enable each of them to use WINS lookup integration.

For example, suppose you have two zones, both configured to use WINS lookup. The zones are rooted and originate at the following DNS domain names:

sales1.wingtiptoys.com.

sales2.wingtiptoys.com.

With this configuration, a WINS client named HOST-A can be unintentionally resolved by using either of the following FQDNs:

host-a.sales1.wingtiptoys.com.

host-a.sales2.wingtiptoys.com.

**Advanced Parameters for WINS Lookups**
The two following advanced timing parameters are used with the WINS and WINS-R records:

- The Cache timeout value, which indicates to a DNS server how long it should cache any of the information that is returned in a WINS lookup. By default, this value is set to 15 minutes.

- The Lookup timeout value, which specifies how long to wait before timing out and expiring a WINS lookup that is performed by the DNS Server service. By default, this value is set to two seconds.

You can configure these parameters by using the **Advanced** button in the zone properties dialog box when you configure the zone. This button appears on either the WINS or WINS-R tab, depending on whether the zone that you are configuring is being used for forward lookup or reverse lookup.

If you are using either the WINS or WINS-R resource record, be aware that the minimum TTL that is set in the start-of-authority (SOA) record for the zone is not the default TTL that is used with these records. Instead, when either an IP address or a host name is resolved with WINS lookup, the information is cached on the DNS server for the amount of time that is configured for the WINS cache time-out value. If this address is then ever forwarded to another DNS server, the WINS cache time-out value TTL is what is sent. If your WINS data rarely changes, you can increase the default TTL of 15 minutes.

### Notes

- If you have a zone that is configured for WINS lookup, all DNS servers that are authoritative for that zone need to be capable of WINS lookup or you will have intermittent behavior.

- Because you can specify that the WINS and WINS-R resource records not be replicated to other DNS servers, you can selectively enable and configure WINS lookup at each of your secondary servers for zones where this feature is used. This is not a standard practice for other types of resource records, which are only to be configured at the primary server for the zone.

For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

### Task requirements

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform the following procedures:

1. Allow DNS to use WINS resolution

2. Verify that WINS is answering a DNS query

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Allow DNS to use WINS resolution

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to enable Domain Name System (DNS) to use Windows Internet Name Service (WINS) name resolution. The specified WINS servers that are configured in this procedure are used for final referral of names that are not found in the applicable zone.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To allow DNS to use WINS resolution**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. Do one of the following:
   - If the applicable zone is a forward lookup zone, on the **WINS** tab, select the **Use WINS forward lookup** check box. In **IP address**, type the Internet Protocol (IP) address of a WINS server to be used for resolution of names not found in DNS, and then click **Add**.
   - If the applicable zone is a reverse lookup zone, on the **WINS-R** tab, select the **Use WINS-R lookup** check box. In **Domain to append to returned name**, type a name.
4. Select the **Do not replicate this record** check box for this WINS record, if applicable.

   If you are replicating this zone between DNS servers that do not recognize the WINS or WINS-R resource records, select this check box. This prevents these records from being replicated to these other servers during zone transfers. If this zone will be used in performing zone transfers to BIND servers, this is a critical option because Berkeley Internet Name Domain (BIND) does not recognize WINS records.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Verify that WINS is answering a DNS query

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to verify that Windows Internet Name Service (WINS) is resolving a Domain Name System (DNS) query.

Normally, when a DNS server answers a query from its authoritative zone data, it uses the set minimum or default Time to Live (TTL) for the zone or the record-specific TTL value (if one is configured). In so doing, TTLs are decreased in answers that the server returns if they are based on nonauthoritative data, such as a cached record at the server.

WINS lookups present an exceptional case, in which an answer that is received back from a WINS server is cached by the DNS server but is also considered to be authoritative data. In this case, the WINS sourced data is returned to clients as authoritative, but it ages while it is in the DNS server names cache, which causes the TTL that is used by the server to decrease over time.

**Administrative credentials**

You do not need administrative credentials to perform this procedure. Therefore, as a security best practice, consider performing this procedure as a user without administrative credentials.

**To verify that WINS is answering a DNS query**

1. At a command prompt, type the following command, and then press ENTER:

   **nslookup**

2. At the **nslookup ("")** prompt, type the following command, and then press ENTER:

   **set debug**

3. Next, either type:

   **set querytype=a**

   if you are testing for a WINS forward lookup, or:

   **set querytype=ptr**

   if you are testing for a WINS-R reverse lookup, and then press ENTER.

   Respectively, these two commands can be used to set the query type to filter either by host address (A) or pointer (PTR) resource records as appropriate for researching either a forward lookup or a reverse lookup.

4. Based on whether you are verifying possible WINS sourcing for either a forward lookup or a reverse lookup, type the appropriate fully qualified domain name (FQDN).

   For example, if the forward lookup that you are tracing is for a domain name host-a.sales.wingtiptoys.com, type:

   **host-a.sales.wingtiptoys.com.**

   If the reverse lookup that you are tracing is for an Internet Protocol (IP) address 10.0.0.1, type:

   **1.0.0.10.in-addr.arpa.**

5. In the response, note whether the server answered authoritatively or nonauthoritatively, and note the TTL value.

6. If the server answered authoritatively, repeat the same query that you performed in step 4.

7. In the response, note whether the TTL value decreased with the second query answer or if it remained consistent with the TTL value that was specified in the first query answer.

   If the TTL value decreased for an authoritatively answered query, the source of the query answer is a WINS server.

8. To leave debug mode and return to the command prompt, type **exit**, and then press ENTER.

| Value | Description |
|---|---|

| | |
|---|---|
| **set debug** | Enables the **nslookup** command to operate in debug mode, providing extended information in the command output.<br>This mode is required to view query response information about whether the source for a query answer is:<br>● Authoritative (from a DNS zone or a WINS server database)<br>● Nonauthoritative (cached data from previous queries made by the DNS server or loaded from root hints) |
| **set querytype** | Changes the type of information query. More information about types can be found in Request for Comments (RFC) 1035. |

# Managing DNS Resource Records

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following tasks for managing Domain Name System (DNS) resource records are described in this objective:

Adding, Changing, and Deleting Resource Records

Disable NS resource record registration

Allow NS resource record creation for domain controllers

Restrict the DNS resource records that are updated by Netlogon

# Adding, Changing, and Deleting Resource Records

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you create a zone, additional resource records must be added to it. The most common resource records include the following:

- **Host address (A).** Maps a Domain Name System (DNS) domain name to an Internet Protocol (IP) address that is used by a computer.
- **Alias canonical (CNAME).** Maps an alias DNS domain name to another primary name or canonical name.
- **Mail Exchanger (MX).** Maps a DNS domain name to the name of a computer that exchanges or forwards mail.
- **Pointer (PTR).** Maps a reverse DNS domain name based on the IP address of a computer that points to the forward DNS domain name of that computer.
- **Service (SRV).** Maps a DNS domain name to a specified list of DNS host computers that offer a specific type of service, such as Active Directory domain controllers.
- Other resource records, as needed.

**Host A Resource Records**

Host A resource records are used in a zone to associate DNS domain names of computers (or "hosts") to their IP addresses. These resource records can be added to a zone in several ways:

- You can create an A resource record for a static TCP/IP client computer manually by using the DNS snap-in.
- Windows clients and servers use the DHCP Client service to dynamically register and update their own A resource records in DNS when an IP configuration change occurs.
- Dynamic Host Configuration Protocol (DHCP)–enabled client computers running earlier versions of Microsoft operating systems can have their A resource records registered and updated by proxy if they obtain their IP lease from a qualified DHCP server. (Only the Windows 2000 and Windows Server 2003 DHCP Server service currently supports this feature.)

The host A resource record is not required for all computers, but it is required by computers that share resources on a network. Any computer that shares resources and needs to be identified by its DNS domain name must use A resource records to provide DNS name resolution to the IP address for the computer.

Most A resource records that are required in a zone can include other workstations or servers that share resources, other DNS servers, mail servers, and Web servers. These resource records make up the majority of resource records in a zone database.

**Alias CNAME Resource Records**

Alias CNAME resource records are also sometimes called canonical name resource records. With these records, you can use more than one name to point to a single host, making it easy to do such things as host both a File Transfer Protocol (FTP) server and a Web server on the same computer. For example, the well-known server names (ftp, www) are registered by using CNAME resource records that map to the DNS host name — for example, server1 — for the server computer that hosts these services.

CNAME resource records are recommended for use in the following scenarios:

- When a host that is specified in an A resource record in the same zone needs to be renamed
- When a generic name for a well-known server, such as www, must resolve to a group of individual computers (each with individual A resource records) that provide the same service, for example, a group of redundant Web servers

When you rename a computer with an existing A resource record in the zone, you can use a CNAME resource record

temporarily to allow a grace period for users and programs to switch from specifying the old computer name to using the new one. To do this, you need the following:

- For the new DNS domain name of the computer, a new A resource record is added to the zone.
- For the old DNS domain name, a CNAME resource record is added that points to the new A resource record.
- The original A resource record for the old DNS domain name (and its associated PTR resource record, if applicable) is removed from the zone.

When you use a CNAME resource record for aliasing or renaming a computer, set a temporary limit on how long the record is used in the zone before it is removed from DNS. If you forget to delete the CNAME resource record and later its associated A resource record is deleted, the CNAME resource record can waste server resources by trying to resolve queries for a name that is no longer used on the network.

The most common or popular use of a CNAME resource record is to provide a permanent, DNS-aliased domain name for generic name resolution of a service-based name, such as www.sales.wingtiptoys.com, to more than one computer or one IP address that is used in a Web server. For example, the following shows the basic syntax of how a CNAME resource record is used:

*alias_name* **IN CNAME** *primary_canonical_name*

In this example, a computer named host-a.sales.wingtiptoys.com must function as both a Web server named www.sales.wingtiptoys.com. and an FTP server named ftp.sales.wingtiptoys.com. To achieve the intended use for naming this computer, you can add and use the following CNAME entries in the sales.wingtiptoys.com zone:

```
host-a     IN  A      10.0.0.20
ftp        IN  CNAME  host-a
www        IN  CNAME  host-a
```

If you later decide to move the FTP server to another computer, separate from the Web server on host-a, simply change the CNAME resource record in the zone for ftp.sales.wingtiptoys.com and add an additional A resource record to the zone for the new computer hosting the FTP server.

Based on the earlier example, if the new computer is named hostb.sales.wingtiptoys.com, the new and revised A and CNAME resource records are as follows:

```
host-a     IN  A      10.0.0.20
host-b     IN  A      10.0.0.21
ftp        IN  CNAME  host-b
www        IN  CNAME  host-a
```

**MX Resource Records**

The MX resource record is used by e-mail applications to locate a mail server based on a DNS domain name that is used in the destination address for the e-mail recipient of a message. For example, a DNS query for the name sales.wingtiptoys.com can be used to find an MX resource record, which enables an e-mail application to forward or exchange mail to a user with the e-mail address user@wingtiptoys.com.

The MX resource record shows the DNS domain name for the computer or computers that process e-mail for a domain. If multiple MX resource records exist, the DNS Client service attempts to contact e-mail servers in the order of preference from lowest value (highest priority) to highest value (lowest priority). The following shows the basic syntax for use of an MX resource record:

*mail_domain_name* **IN MX** *preference mailserver_host*

By using the MX resource records shown below in the sales.wingtiptoys.com zone, e-mail that is addressed to user@sales.wingtiptoys.com is delivered to user@mailserver0.sales.wingtiptoys.com first, if possible. If this server is unavailable, the resolver client can then use user@mailserver1.sales.wingtiptoys.com instead.

```
@          IN  MX   1    mailserver0
@          IN  MX   2    mailserver1
```

Note that the use of the "at" symbol (@) in the records indicates that the mailer DNS domain name is the same as the name of origin (sales.wingtiptoys.com) for the zone.

**PTR Resource Records**

PTR resource records are used to support the reverse lookup process, based on zones that are created and rooted in the in-addr.arpa domain. These records are used to locate a computer by its IP address and to resolve this information to the DNS domain name for that computer.

PTR resource records can be added to a zone in several ways:

- You can create a PTR resource record for a static TCP/IP client computer manually by using DNS, either as a separate procedure or as part of the procedure for creating an A resource record.

- Computers use the DHCP Client service to dynamically register and update their PTR resource record in DNS when an IP configuration change occurs.

- All other DHCP-enabled client computers can have their PTR resource records registered and updated by the DHCP server if they obtain their IP lease from a qualified server. The Windows 2000 and Windows Server 2003 DHCP Server service provides this capability.

The PTR resource record is used only in reverse lookup zones to support reverse lookup.

**SRV Resource Records**
To locate Active Directory domain controllers, SRV resource records are required. Typically, you can avoid manual administration of the SRV resource record when you install Active Directory.

By default, the Active Directory Installation Wizard attempts to locate a DNS server based on the list of preferred or alternate DNS servers, which are configured in any of its TCP/IP client properties, for any of its active network connections. If a DNS server that can accept dynamic update of the SRV resource record (and other resource records that are related to registering Active Directory as a service in DNS) is contacted, the configuration process is complete.

If, during the installation, a DNS server that can accept updates for the DNS domain name that is used to name your Active Directory domain is not found, the wizard can install a DNS server locally and automatically configure it with a zone to support the Active Directory domain.

For example, if the Active Directory domain that you choose for your first domain in the forest is sales.wingtiptoys.com, a zone that is rooted at the DNS domain name of sales.wingtiptoys.com is added and configured to use with the DNS server that is running on the new domain controller.

Whether or not you install the DNS Server service locally, a file (Netlogon.dns) is written and created during the Active Directory installation process that contains the SRV resource records and other resource records that are necessary to support the use of Active Directory. This file is created in the systemroot\System32\Config folder.

If you are using a DNS server that fits one of the following scenarios, use the records in Netlogon.dns to manually configure the primary zone on that server to support Active Directory:

1. The computer that operates your DNS server is running on another platform, such as UNIX, and it cannot accept or recognize dynamic updates.

2. A DNS server at this computer that does not use the DNS Server service that is provided with Windows Server 2003 is authoritative for the primary zone that corresponds to the DNS domain name for your Active Directory domain.

3. The DNS server supports the SRV resource record, as defined in the Internet draft "A DNS RR specifying the location of services (DNS SRV)," but the DNS server does not support dynamic updates.

   For example, the DNS Server service that is provided with Windows NT Server 4.0, when it is updated to Service Pack 4 or later, fits this description.

In the future, the SRV resource record might also be used to register and look up other well-known TCP/IP services on your network if applications implement and support DNS name queries that specify this record type.

**Other Resource Records**
Other additional resource records are supported by Windows Server 2003 DNS, and they are used less frequently in most zones. You can add these additional types of resource records as needed by using the DNS snap-in.

### Task requirements

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform one of the following procedures:

- Add an A resource record to a zone
- Add an MX resource record to a zone
- Add a CNAME resource record to a zone
- Add a PTR resource record to a reverse zone
- Add a resource record to a DNS zone
- Add a domain to a zone
- Modify an existing resource record
- Delete a resource record
- View unsupported resource records

# Add an A resource record to a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to add a host address (A) resource record to a zone. Pointer (PTR) resource records that are created automatically when you add an A resource record to a zone are deleted automatically if the corresponding A resource record is deleted.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Adding an A resource record to a zone**

- Using the Windows interface
- Using the command line

### To add an A resource record to a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable forward lookup zone, and then click **New Host (A)**.
3. In **Name**, type the Domain Name System (DNS) computer name for the new host.
4. In **IP address**, type the Internet Protocol (IP) address for the new host.
5. As an option, select the **Create associated pointer (PTR) record** check box to create an additional PTR resource record in a reverse zone for this host, based on the information that you enter in **Name** and **IP address**.
6. Click **Add Host** to add the new host (A) resource record to the zone.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To add an A resource record to a zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName***/RecordAdd** *ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] **A** *IPAddress*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordAdd** | Required. Adds a new resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| **/Aging** | Specifies that this resource record is able to be aged and scavenged. If this command is not used, the resource record remains in the DNS database unless it is manually updated or removed. |

| | |
|---|---|
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. The default TTL is defined in the start-of-authority (SOA) resource record. |
| **A** | Required. Specifies the resource record type of the record that you are adding. |
| *IPAddress* | Required. The IP address for the host. |

# Add an MX resource record to a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to add a mail exchanger (MX) resource record to a zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Adding an MX resource record to a zone**

- Using the Windows interface
- Using the command line

### To add an MX resource record to a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable forward lookup zone, and then click **NewMail Exchanger (MX)**.
3. In **Host or child domain**, type the domain name for which this record is to be used to deliver mail.
4. In **Mail server**, type the Domain Name System (DNS) host computer name of the mail exchanger or mail server host that delivers mail for the specified domain name.

   As an option, you can click **Browse** to view the DNS namespace for mail exchanger hosts in this domain that have host (A) records already defined.
5. Adjust the value in **Mail server priority** as needed for this zone.
6. Click **OK** to add the new record to the zone.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To add an MX resource record to a zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName***/RecordAdd** *ZoneNameNodeName* [**/Aging**] [*Ttl*] **MX** *PreferenceMXServerName*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordAdd** | Adds a new resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone in which you will add the new MX resource record. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |

| | |
|---|---|
| **/Aging** | Specifies that this resource record is able to be aged and scavenged. If this command is used, this resource record is able to be aged and scavenged. If this command is not used, the resource record remains in the DNS database unless it is manually updated or removed. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. |
| **MX** | Required. Specifies the MX resource record type for the record that you are adding. |
| *Preference* | Required. Specifies a numeric value (between 0 and 65535) that indicates the mail exchange server's priority with respect to the other mail exchange servers. Lower numbers are given greater preference. |
| *MXServerName* | Required. Specifies the FQDN for a mail exchanger. The value entered here must resolve to a corresponding host A resource record in this zone. |

# Add a CNAME resource record to a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to add an alias canonical (CNAME) resource record to a zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Adding a CNAME resource record to a zone**

- Using the Windows interface
- Using the command line

### To add a CNAME resource record to a zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable forward lookup zone, and then click **New Alias (CNAME)**.
3. In **Alias name**, type the alias name.
4. In **Fully qualified domain name (FQDN) for target host**, type the FQDN of the Domain Name System (DNS) host computer for which this alias is to be used.

   As an option, you can click **Browse** to search the DNS namespace for hosts in this domain that have host address (A) records already defined.
5. Click **OK** to add the new record to the zone.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To add a CNAME resource record to a zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordAdd** *ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] **CNAME** *HostName*|*DomainName*

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/RecordAdd** | Adds a new resource record. |
| *ZoneName* | Required. Specifies the name of the zone where this CNAME resource record will be added. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| **/Aging** | Specifies that this resource record is aged and scavenged. If this parameter is not used, the resource record remains in the DNS database unless it is manually updated or removed. |
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |

| | |
|---|---|
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. The default TTL is defined in the start-of-authority (SOA) resource record. |
| **CNAME** | Required. Specifies the resource record type of the record that you are adding. |
| *HostName*\|*DomainName* | Required. Specifies the FQDN of any valid DNS host or domain name in the namespace. For FQDNs, a trailing period (.) is used to fully qualify the name. |

# Add a PTR resource record to a reverse zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to add a pointer (PTR) resource record to a reverse zone. When you create a new address (A) resource record, there is an option to create an associated PTR resource record automatically. PTR resource records that are created automatically during the addition of an A resource record to a zone are deleted automatically if the corresponding A resource record is deleted.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Adding a PTR resource record to a reverse zone**

- Using the Windows interface
- Using the command line

### To add a PTR resource record to a reverse zone using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable reverse lookup zone.
3. On the **Action** menu, click **New Pointer (PTR)**.
4. In the **Host IP number** text box, type the host Internet Protocol (IP) address octet number.
5. In **Host name**, type the fully qualified domain name (FQDN) for the DNS host computer for which this pointer record is to be used to provide reverse lookup (address-to-name resolution).

   As an option, you can click **Browse** to search the Domain Name System (DNS) namespace for hosts in this domain that have host address (A) records already defined.
6. Click **OK** to add the new record to the zone.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To add a PTR resource record to a reverse zone using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName***/RecordAdd** *ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [**Ttl**] **PTR** *HostName*|*DomainName*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordAdd** | Adds a new resource record. |
| *ZoneName* | Required. Specifies the FQDN of the zone where this new PTR resource record will be added. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |

| | |
|---|---|
| **/Aging** | Specifies that this resource record is able to be aged and scavenged. If this command is used, this resource record is able to be aged and scavenged. If this command is not used, the resource record remains in the DNS database unless it is updated or removed manually. |
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| **Ttl** | Specifies the Time to Live (TTL) setting for the resource record. |
| **PTR** | Required. Specifies the resource record type for the record that you are adding. |
| *HostName*\|*DomainName* | Required. Specifies the FQDN of a resource record that is located in the DNS namespace. The host that you specify is used as the data for answering reverse lookups based on the address information that is specified by this PTR resource record. |

# Add a resource record to a DNS zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to add a resource record to a zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Adding a resource record to a zone**

- Using the Windows interface
- Using the command line

**To add a resource record to a zone using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Other New Records**.
3. In **Select a resource record type**, select the type of resource record that you want to add.
4. Click **Create Record**.
5. In **New Resource Record**, enter the information necessary to complete the resource record.
6. After you specify all the necessary information for the resource record, click **OK** to add the new record to the zone.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To add a resource record to a zone using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordAdd***ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [**Ttl**] *RRType RRData*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordAdd** | Required. Adds a new resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| **/Aging** | Specifies that this resource record is able to be aged and scavenged. If this command is used, this resource record is able to be aged and scavenged. If this command is not used, the resource record remains in the DNS database unless it is updated or removed manually. |
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |

| | |
|---|---|
| **Ttl** | Specifies the Time to Live (TTL) setting for the resource record. |
| *RRTypeRRData* | Required. Specifies the type of resource record to add, followed by the data to be contained in the resource record. |

| **Resource record type** | **Resource record data** |
|---|---|
| A | *IPAddress* |
| NS,CNAME,MB,MD,PTR,MF,MG,MR | *HostName*\|*DomainName* |
| MX,RT,AFSDB | *PreferenceServerName* |
| SRV | *PriorityWeightPortHostName* |
| SOA | *PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL* |
| AAAA | *Ipv6Address* |
| TXT,X25,HINFO,ISDN | *String* [*String*] |
| MINFO,RP | *MailboxName ErrMailboxName* |
| WKS | *Protocol IPAddress Service...* |
| WINS | *MapFlag LookupTimeout CacheTimeout IPAddress...* |
| WINSR | *MapFlag LookupTimeout CacheTimeout RstDomainName* |

| **Value** | **Description** |
|---|---|
| *IPAddress* | Specifies a standard IP address, for example, 255.255.255.255. |
| *ipv6Address* | Specifies a standard IPv6 address, for example, 1:2:3:4:5:6:7:8. |
| *Protocol* | Specifies the transmission protocol: UDP or TCP. |
| *Service* | Specifies a standard service, for example, domain, smtp. |
| *HostName*\|*DomainName* | Specifies the FQDN of a resource record that is located in the DNS namespace. |

# Add a domain to a zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to add a new domain to a zone.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To add a domain to a zone**

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.

   Where?

   - DNS/*applicable DNS server*/Forward Lookup Zones (or Reverse Lookup Zones)/*applicable zone*

3. On the **Action** menu, click **New Domain**, and then type the name of the new domain without using periods.
4. Click **OK** to add the new domain to the zone.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Modify an existing resource record

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to modify an existing resource record in a zone. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Modifying an existing resource record**

- Using the Windows interface
- Using the command line

**To modify an existing resource record using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.
3. In the details pane, right-click the resource record that you want to modify, and then click **Properties**.
4. In **Properties**, edit the properties that can be modified.

   If necessary, you can view and modify advanced resource record properties with the DNS snap-in. To display advanced properties, on the **View** menu, click **Advanced**.
5. When you have finished modifying the record, click **OK**.

| **Note** |
| --- |
| When advanced view options are enabled, you can modify additional settings for an existing resource record, such as its record-specific Time to Live (TTL). |

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To modify an existing resource record using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName***/RecordAdd***ZoneNameNodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] *RRTypeRRData*

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordAdd** | Required. Adds a new resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |

| | |
|---|---|
| *RRType RRData* | Required. Specifies the type of resource record to add, followed by the data to be contained in the resource record. |

| **Resource record type** | **Resource record data** |
|---|---|
| A | *IPAddress* |
| NS,CNAME,MB,MD,PTR,MF,MG,MR | *HostName*\|*DomainName* |
| MX,RT,AFSDB | *Preference ServerName* |
| SRV | *Priority Weight Port HostName* |
| SOA | *PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL* |
| AAAA | *Ipv6Address* |
| TXT,X25,HINFO,ISDN | *String* [*String*] |
| MINFO,RP | *MailboxName ErrMailboxName* |
| WKS | *Protocol IPAddress Service...* |
| WINS | *MapFlag LookupTimeout CacheTimeout IPAddress...* |
| WINSR | *MapFlag LookupTimeout CacheTimeout RstDomainName* |

| **Value** | **Description** |
|---|---|
| *IPAddress* | Specifies a standard IP address, for example, 255.255.255.255. |
| *ipv6Address* | Specifies a standard IPv6 address, for example, 1:2:3:4:5:6:7:8. |
| *Protocol* | Specifies the transmission protocol: UDP or TCP. |
| *Service* | Specifies a standard service, for example, domain, smtp. |
| *HostName*\|*DomainName* | Specifies the FQDN of a resource record that is located in the DNS namespace. |

# Delete a resource record

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to delete a resource record from a zone. Pointer (PTR) resource records are deleted automatically if the corresponding address (A) resource record is deleted.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Deleting a resource record**

- Using the Windows interface
- Using the command line

### To delete a resource record using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.
3. In the details pane, right-click the resource record that you want to delete, and then click **Delete**.
4. When you are asked to confirm that you want to delete the selected resource record, click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To delete a resource record using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordDelete** *ZoneName NodeName RRType RRData* [**/f**]

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RecordDelete** | Required. Deletes a resource record. |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| *RRType RRData* | Required. Specifies the type of resource record to add, followed by the data to be contained in the resource record. |

| Resource record type | Resource record data |
|---|---|
| A | *IPAddress* |
| NS,CNAME,MB,MD,PTR,MF,MG,MR | *HostName*\|*DomainName* |
| MX,RT,AFSDB | *PreferenceServerName* |
| SRV | *Priority Weight Port HostName* |
| SOA | *PrimSvr Admin Serial#\ Refresh Retry Expire MinTTL* |
| AAAA | *Ipv6Address* |
| TXT,X25,HINFO,ISDN | *String* [*String*] |
| MINFO,RP | *MailboxName ErrMailboxName* |
| WKS | *Protocol IPAddress Service...* |
| WINS | *MapFlag LookupTimeout CacheTimeout IPAddress...* |
| WINSR | *MapFlag LookupTimeout CacheTimeout RstDomainName* |

| Value | Description |
|---|---|
| *IPAddress* | Specifies a standard IP address, for example, 255.255.255.255. |
| *ipv6Address* | Specifies a standard IPv6 address, for example, 1:2:3:4:5:6:7:8. |
| *Protocol* | Specifies the transmission protocol: UDP or TCP. |
| *Service* | Specifies a standard service, for example, domain, smtp. |
| *HostName*\|*DomainName* | Specifies the FQDN of a resource record that is located in the DNS namespace. |
| **/f** | Specifies that the command is executed without asking for confirmation. If you omit this parameter, you are prompted to confirm the deletion of the resource record. |

# View unsupported resource records

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to view unsupported resource records in a zone.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To view unsupported resource records**

1. Open the DNS snap-in.
2. In the console tree, click the applicable zone.
3. In the details pane, right-click the record that you want to view, and then click **Properties**.
4. In **Properties**, view properties that are specific to this record.
5. When you have finished viewing the record, click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Disable NS resource record registration

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following procedure restricts name server (NS) resource records that are registered for Active Directory domain controllers only. You can perform this procedure by using the Registry Editor or by using the Dnscmd command-line tool.

To configure the Domain Name System (DNS) server to automatically add NS resource records corresponding to itself when loading a zone, you can assign a value of **0x0** to the registry key or enter no value (the default setting). This setting has the same effect as not creating the **DisableNSRecordsAutoCreation** registry entry.

If you configure the registry to restrict the DNS server from registering NS resource records for authoritative zones, any existing NS resource records for the authoritative zones that are located on the DNS server are deleted automatically.

Regardless of the settings of these registry entries, query responses that are sent to DNS clients from the authoritative DNS server will indicate that the responses are from an authoritative DNS server.

The registry key entry that is described in this procedure does not exist by default. It must be created and configured according to this procedure.

| **Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

#### Disabling NS resource record registration

- Using the Windows interface
- Using the command line

### To disable NS resource record registration using the Windows interface

1. Open Registry Editor.
2. In Registry Editor, navigate to the following registry key:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\DNS\Parameters**

3. Add the following **REG_DWORD** value:

   **DisableNSRecordsAutoCreation**

4. Assign a value of **0x1**.

   The **REG_DWORD** value is a local DNS server setting, and it applies to DNS zones for which this DNS server is authoritative.

| **Note** |
| --- |
| To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**. |

### To disable NS resource record registration using the command line

- At a command prompt, type the following command, and then press ENTER:

**dnscmd** *ServerName* **/Config /DisableNSRecordsAutoCreation0x1**

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/DisableNSRecordsAutoCreation** | Determines the local DNS server configuration for registering NS resource records for authoritative zones. |
| **0x1** | Specifies that the DNS server that is specified in *ServerName* should not add NS resource records for authoritative zones.<br><br>To specify that the DNS server should add NS resource records for all its authoritative zones, type a value of **0x0**. |

# Allow NS resource record creation for domain controllers

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to allow name server (NS) resource record creation for specific domain controllers. This procedure applies to domain controller NS resource records in Active Directory–integrated Domain Name System (DNS) zones that are hosted on DNS servers that are configured to not add these resource records for their authoritative zones.

**Administrative credentials**

To perform this procedure, you must be a member of the DnsAdmins or the Domain Admins group in Active Directory. As a security best practice, consider using the **Run as** command to perform this procedure.

**To allow NS resource record creation for specific domain controllers**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** *ZoneName* **/AllowNSRecordsAutoCreation** *IpAddresses...*

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| **/AllowNSRecordsAutoCreation** | Required. Specifies that domain controllers that are entered for *Value* add their names to NS resource records for the zone that is specified in *ZoneName*. NS resource records that were previously registered for this zone are not affected. Therefore, you must remove them manually if you do not want them. |
| *IpAddresses...* | Required. Specifies the IP addresses of the domain controllers that add their names in NS resource records for the zone that is specified in *ZoneName*. Type a space-separated list of the IP addresses of the DNS servers, for example, 10.0.0.0 172.16.0.0 192.168.0.0. |

If any domain controllers in the specified zone are not listed for *IpAddresses...*, their names are deleted from the NS resource records for the zone that is specified in *ZoneName*.

To specify that all domain controllers are allowed to add their names to NS resource records for the zone or to clear the list of allowed DNS server IP addresses, type the command and omit *IpAddresses...*:

**dnscmd** *ServerName* **/Config** *ZoneName* **/AllowNSRecordsAutoCreation**

Regardless of the settings that are specified in this command, query responses that are sent to DNS clients from authoritative DNS servers and selected domain controllers will indicate that the responses are from authoritative DNS servers.

# Restrict the DNS resource records that are updated by Netlogon

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following procedure restricts Domain Name System (DNS) resource records that are registered by the Net Logon service for Active Directory domain controllers only.

| ⚠Caution |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To restrict the DNS resource records that are updated by NetlLogon**

1. Open Registry Editor.
2. In Registry Editor, navigate to the following registry key:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**
3. Add the following multistring value **(REG_MULTI_SZ)** value:

   **DnsAvoidRegisterRecords**
4. In this value, specify the list of data corresponding to the DNS resource records that *should not* be registered for this domain controller by the Net Logon service. The following table contains the list of data.

| Data Value | Resource Record Type | DNS Resource Record |
| --- | --- | --- |
| LdapIpAddress | A | *DnsDomainName* |
| Ldap | SRV | _ldap._tcp.*DnsDomainName* |
| LdapAtSite | SRV | _ldap._tcp.*SiteNam*._sites.*DnsDomainName* |
| Pdc | SRV | _ldap._tcp.pdc._msdcs.*DnsDomainName* |
| Gc | SRV | _ldap._tcp.gc._msdcs.*DnsForestName* |
| GcAtSite | SRV | _ldap._tcp.*SiteName*._sites.gc._msdcs.*DnsForestName* |
| DcByGuid | SRV | _ldap._tcp.*DomainGuid*.domains._msdcs.*DnsForestName* |
| GcIpAddress | A | _gc._msdcs.*DnsForestName* |
| DsaCname | CNAME | *DsaGuid*._msdcs.*DnsForestName* |
| Kdc | SRV | _kerberos._tcp.dc._msdcs.*DnsDomainName* |

| | | |
|---|---|---|
| KdcAtSite | SRV | _kerberos._tcp.dc._msdcs.*SiteName*._sites.*DnsDomainName* |
| Dc | SRV | _ldap._tcp.dc._msdcs.*DnsDomainName* |
| DcAtSite | SRV | _ldap._tcp.*SiteName*._sites.dc._msdcs.*DnsDomainName* |
| Rfc1510Kdc | SRV | _kerberos._tcp.*DnsDomainName* |
| Rfc1510KdcAtSite | SRV | _kerberos._tcp.*SiteName*._sites.*DnsDomainName* |
| GenericGc | SRV | _gc._tcp.*DnsForestName* |
| GenericGcAtSite | SRV | _gc._tcp.*SiteName*._sites.*DnsForestName* |
| Rfc1510UdpKdc | SRV | _kerberos._udp.*DnsDomainName* |
| Rfc1510Kpwd | SRV | _kpasswd._tcp.*DnsDomainName* |
| Rfc1510UdpKpwd | SRV | _kpasswd._udp.*DnsDomainName* |

**Notes**

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.

- Restart of the Net Logon service is *not* required to make the changes to this value effective. If the **DnsAvoidRegisterRecords** registry key is created or modified while the Net Logon service is stopped or within the first 15 minutes after it is started, appropriate DNS updates may take place with a short delay. However, the delay is no later than 15 minutes after the Net Logon service starts.

# Monitoring DNS

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Monitoring your Domain Name System (DNS) infrastructure on a regular basis and resolving any issues that you find will help to keep your network accessible to your users.

The following tasks for monitoring DNS are described in this objective:

- Check DNS event log
- Verify DNS server responsiveness with Nslookup
- Verify dynamic DNS record updates
- Verify zone transfers
- Check the DNS server debug log file
- Test a query on the DNS server

# Check DNS event log

Published: September 19, 2007

Updated: November 4, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to check for errors in the Domain Name System (DNS) event long for troubleshooting or monitoring purposes.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Checking the DNS event log**
**To check the DNS event log**

1. Open the DNS console.
2. In the console tree, open **Event Viewer** and then click **DNS Events**.
3. Review the list of events that is displayed. The following table provides examples some critical DNS events and procedures you can use to resolve them.

| Event ID | Description |
|---|---|
| 140 | The DNS server could not initialize the Remote Procedure Call (RPC) service. If it is not running, start the RPC service or reboot the computer. For specific error code, see the Record Data page on the Event Viewer.<br><br>In order for DNS to run, the Remote Procedure Call (RPC) service must be running on the DNS server.<br><br>a. Verify that the Remote Procedure Call (RPC) service has been started.<br><br>b. Open Administrative Tools, and double-click Services.<br><br>c. If the service has been started, try restarting the server.<br><br>d. If the error continues, remove and reinstall the **Client for Microsoft Networks** service on the network connection. This will reinstall the Netlogon and RPC locator services. |
| 403 | The DNS server could not create a Transmission Control Protocol (TCP) socket. Restart the DNS server or reboot the computer. For the specific error code, see the Record Data page.<br><br>The Wsock32.dll might be incompatible with a third-party TCP/IP stack. This problem can also occur if the TCP/IP protocol is not bound to the network adapter.<br><br>If you are using a third-party TCP/IP protocol, verify that the protocol is compatible with the Wsock32.dll.<br><br>Check the bindings of the protocol stack. It is a good idea to have TCP/IP bound at the top of the stack. If the error continues, remove and reinstall the TCP/IP protocol, and then try again.<br><br>a. Open Control Panel, and then double-click Network and Dial-up Connections.<br><br>b. Right-click the connection, and then click Properties.<br><br>c. Verify that the bindings for all protocols to network adapters are enabled and that no broken connections exist in the stack. |

| | |
|---|---|
| 407 | DNS server could not bind the main datagram socket. The data is the error.<br><br>This error can occur if there is a mismatch between the configured IP address in the Advanced IP Addressing dialog box and the addresses listed in the Server Properties dialog box for the DNS server. This problem can also occur if the TCP/IP protocol is not bound to the network adapter.<br><br>Verify that the TCP/IP addresses configured in the Advanced IP Addressing dialog box match those configured in the Server Properties dialog box in DNS Manager:<br><br>a. Open Control Panel, and double-click Network.<br><br>b. Click the Protocols tab, and click TCP/IP Protocol in the Network Protocols list.<br><br>c. Click Properties, and then click Advanced.<br><br>Match the IP addresses to those displayed in the DNS server Properties dialog box:<br><br>a. In DNS Manager, right-click the DNS server name, and then click Properties.<br><br>b. Compare the IP addresses with those from the Advanced IP Addressing dialog box. If there are no IP addresses configured in the Advanced IP Addressing dialog box or on the Interfaces tab of the Server Properties dialog box, enter the IP address of your network adapter. Use the ipconfig -all command to obtain your IP address.<br><br>Check the binding of the TCP/IP protocol to the network adapter:<br><br>a. Open Control Panel, and double-click Network.<br><br>b. Click the Bindings tab.<br><br>c. Verify that the bindings for all protocols to network adapters are enabled and that no broken connections exist in the stack. |
| 408 | DNS server could not open socket for address [IP address of server].<br><br>The DNS server could not open a socket with the current TCP/IP and DNS service configurations.<br><br>Verify that this is a valid IP address on this computer.<br><br>If the IP is not valid:<br><br>a. Use the Interfaces dialog under Server Properties in the DNS Manager to remove it from the list of IP interfaces.<br><br>b. Stop and restart the DNS server. (If this was the only IP interface on this computer, the DNS server may not have started as a result of this error. In that case, remove the DNS\Parameters\ListenAddress value in the services section of the registry and restart.)<br><br>If the IP is valid:<br><br>Verify that no other application (for example, another DNS server) is running that would attempt to use the DNS port. |

| | |
|---|---|
| 4000, 4004, 4007, 4014, 4015 | The DNS Server service relies on Active Directory to store and retrieve information for Active Directory–integrated zones. This error indicates that Active Directory is not responding to requests from the DNS Server service. Ensure that Active Directory is functioning properly, troubleshoot any problems, and then restart the DNS Server service.<br><br>For information about troubleshooting Active Directory, see Active Directory Troubleshooting Topics (http://go.microsoft.com/fwlink/?LinkId=95789).<br><br>To restart the DNS Server service:<br><br>a. Open the Services console. To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then click **Services**.<br><br>b. Right-click **DNS Server**, and then click **Restart**.<br><br>If the problem continues, restart the computer, and then use the Services console to verify that the DNS Server service has started. |
| 4001 | The DNS Server service relies on Active Directory to store and retrieve information for Active Directory–integrated zones. This error indicates that Active Directory is not responding to requests from the DNS Server service. Ensure that Active Directory is functioning properly, troubleshoot any problems, and then reload the zone.<br><br>For information about troubleshooting Active Directory, see Active Directory Troubleshooting Topics (http://go.microsoft.com/fwlink/?LinkId=95789).<br><br>To reload a zone:<br><br>a. Open the DNS console.<br><br>b. In the console tree, right-click the applicable zone, and then click **Reload**. |

| | |
|---|---|
| 4016 | The DNS Server service relies on Active Directory to store and retrieve information for Active Directory–integrated zones. This error indicates that Active Directory is not responding to requests from the DNS Server service. Ensure that Active Directory is functioning properly, troubleshoot any problems, and then retry the operation that failed.<br><br>For information about troubleshooting Active Directory, see Active Directory Troubleshooting Topics (http://go.microsoft.com/fwlink/?LinkId=95789).<br><br>Add a zone<br><br>If the event message indicates that an attempt to add a zone failed, you must create the zone after resolving any problems with Active Directory.<br><br>To add a zone:<br><br>a. Open the DNS console.<br><br>b. In the console tree, expand the DNS server, right-click the zone folder for the type of zone that you want to add, and then click **New Zone** to open the New Zone Wizard.<br><br>c. Follow the instructions in the wizard to create the zone.<br><br>Delete a zone<br><br>If the event message indicates that an attempt to remove a zone failed, you must delete the zone after resolving any problems with Active Directory.<br><br>To delete a zone:<br><br>a. Open the DNS console.<br><br>b. In the console tree, expand the DNS server, right-click the zone folder for the type of zone that you want to delete.<br><br>c. Right-click the zone, and then click **Delete**. |

| **Note** |
|---|
| To open the DNS console, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

| **Note** |
|---|
| If the DNS server for which you want to view the log is located on another computer, in the console tree, click **DNS**, and then on the **Action** menu, click **Connect to DNS Server**. Click **The following computer**, and then specify the name or Internet Protocol (IP) address of the remote computer. |

# Verify DNS server responsiveness with Nslookup

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to verify name resolution on a Domain Name System (DNS) server for monitoring or troubleshooting purposes.

**Verifying DNS server responsiveness**
**To verify DNS server responsiveness**

1. Open a command prompt, type the following command, and then press ENTER:

   **nslookup 127.0.0.1** *server_ip_address*

2. If the server is responding, the name "localhost" is returned.

| Value | Description |
|---|---|
| *server_ip_address* | The Internet Protocol (IP) address of the DNS server. For example, if the IP address of your DNS server is 10.0.0.1, type:<br><br>**nslookup 127.0.0.1 10.0.0.1** |

**Note**

In the previous procedure, the syntax for the nslookup command is: **nslookup***[-option] host server* . This command can be entered from any computer that is running a Microsoft Windows operating system and has network connectivity to the DNS server you wish to query. Only the host entry is required for the command. However, if an IP address or hostname for the server is not supplied, then the default DNS server specified in TCP/IP properties will be queried.

When you enter 127.0.0.1 as the host, this IP address will automatically resolve to the name **localhost** if the DNS Server service is running at the IP address that you specify as the *server*.

# Verify dynamic DNS record updates

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

It is possible to view dynamic update activity of clients by using the DNS server log (dns.log). This log includes server-side information; client-side information is intuitive only.

**Verifying dynamic DNS record updates**

**To verify dynamic DNS record updates**

1. Click **Start**, click **Run**, type **dnsmgmt.msc**, and then click **OK**.
2. In the console tree, click the DNS server for which you want to view dynamic record updates.
3. On the **Action** menu, click **Properties**.
4. Click the **Debug Logging** tab.
5. Select the **Log packets for debugging** check box.
6. Under **Packet direction**, select the **Outgoing** and **Incoming** check boxes.
7. Under **Transport protocol**, select the **UDP** and **TCP** check boxes.
8. Under **Packet contents**, select the **Updates** check box.
9. Under **Packet type**, select the **Request** and **Response** check boxes.
10. Under **Other options**, select the **Details** check box.
11. Click **OK** to begin debug logging.
12. Review the dns.log file.

# Verify zone transfers

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

With Active Directory–integrated Domain Name System (DNS), all DNS servers in the domain can modify the zone and then replicate the changes to other domain controllers. Therefore, the procedures for verifying zone transfers of an Active Directory–integrated DNS server are equivalent to Active Directory replication verification procedures.

Although Active Directory-integrated zones are transferred by using Active Directory replication, you can also perform standard zone transfers to secondary servers in a manner similar to standard DNS zone transfers. You can use the following procedure to verify zone transfers.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Verifying zone transfers**

**To verify zone transfers**

1. Open the DNS snap-in.
2. In the console tree, double-click **Event Viewer**, and then click **DNS Events**.
3. Check for the following critical events:

| Event ID | Description |
|---|---|
| 6527 | Zone expired before it could obtain a successful zone transfer or update from a master server acting as its source for the zone. The zone has been shut down.<br><br>This event ID might appear when the DNS server is configured to host a secondary copy of the zone from another DNS server acting as its source or master server. Verify that this server has network connectivity to its configured master server.<br><br>If the problem continues, consider one or more of the following options:<br><br>a. Delete the zone and recreate it, specifying either a different master server, or an updated and corrected IP address for the same master server.<br><br>b. If zone expiration continues, consider adjusting the expire interval. |
| 6004 | The DNS server received a zone transfer request from %1 for a non-existent or non-authoritative %2. |

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Check the DNS server debug log file

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Checking the DNS server debug log file**

### To check the DNS server debug log file

1. Stop the DNS Server service.
2. Open WordPad.
3. On the **File** menu, click **Open**.
4. In **Open**, for **File name**, specify the path to the Domain Name System (DNS) server debug log file.

   By default, if the applicable DNS server is running locally, the file and path are as follows:

   systemroot\System32\Dns\Dns.log
5. After you specify the correct path and file, click **Open** to view the log file.

# Test a query on the DNS server

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To insure that Domain Name System (DNS) name resolution is functioning according to specifications, you can perform periodic testing with the following procedure.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Testing a query on the DNS server**

**To test a query on the DNS server**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.
3. On the **Action** menu, click **Properties**.
4. Click the **Monitoring** tab.
5. To test a simple query, under **Select a test type**, select the **A simple query against this DNS server** check box.

   Or

   To test a recursive query, under **Select a test type**, select the **A recursive query to other DNS servers** check box.
6. Click **Test Now**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Optimizing DNS

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When Domain Name System (DNS) servers are initialized for service, they use server configuration settings that are taken from the parameters that are stated in a boot information file, the registry, and (possibly) zone information that is provided through Active Directory integration.

In most situations, the installation defaults are acceptable and should not require modification. However, when necessary, you can tune various parameters to accommodate special deployment needs and situations.

The following table describes advanced parameters that you can change to optimize the performance of DNS servers.

| Parameter | Description |
|---|---|
| *Disable recursion* | Determines whether or not the DNS server uses recursion. By default, the DNS Server service is enabled to use recursion. |
| *BIND secondaries* | Determines whether to use fast transfer format for transfer of a zone to DNS servers running legacy Berkeley Internet Name Domain (BIND) implementations.<br><br>By default, all Windows-based DNS servers use a fast zone transfer format. This format uses compression, and it can include multiple records per TCP message during a connected transfer. This format is also compatible with more recent BIND-based DNS servers that run versions 4.9.4 and later. |
| *Fail on load if bad zone data* | Sets the DNS server to parse files strictly.<br><br>By default, the DNS Server service logs data errors, ignores any erred data in zone files, and continues to load a zone. You can reconfigure this option by using the DNS snap-in so that the DNS Server service logs errors and fails to load a zone file containing records data that is found to contain errors. |
| *Enable round robin* | Determines whether the DNS server uses the round robin mechanism to rotate and reorder a list of resource records if multiple resource records exist of the same type that exist for a query answer.<br><br>By default, the DNS Server service uses round robin. |
| *Enable netmask ordering* | Determines whether the DNS server reorders address (A) resource records within the same resource record that is set in the server's response to a query based on the Internet Protocol (IP) address of the source of the query.<br><br>By default, the DNS Server service uses local subnet priority to reorder A resource records. |
| *Secure cache against pollution* | Determines whether the DNS server attempts to clean up responses to avoid cache pollution. This setting is enabled by default.<br><br>By default, DNS servers use a secure response option that eliminates adding unrelated resource records that are included in a referral answer to their cache. In most cases, any names that are added in referral answers are typically cached, and they help expedite the resolution of subsequent DNS queries.<br><br>With this feature, however, the server can determine that referred names are potentially polluting or insecure and then discard them. The server determines whether to cache the name that is offered in a referral on the basis of whether or not it is part of the exact, related, DNS domain name tree for which the original queried name was made.<br><br>For example, if a query is made originally for sales.wingtiptoys.com and a referral answer provides a record for a name outside the wingtiptoys.com domain name tree, such as tailspintoys.com, that name is not cached where this feature is enabled for use. |

For more information about planning DNS, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

To optimize DNS, complete the following procedures:

- Enable or disable fast DNS zone transfers

- Prevent loading of a zone with bad data
- Disable DNS round robin
- Restore Domain Name System server default preferences
- Disable recursion
- Disable local subnet prioritization
- Update root hints
- Secure the server cache against names pollution
- Clear server names cache
- Configure DNSSEC
- Configure EDNS0
- Change UDP message size

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Enable or disable fast DNS zone transfers

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure for optimizing zone transfers only between Windows-based Domain Name System (DNS) servers and other DNS server implementations. Zone transfers between Windows-based DNS servers always use the fast transfer format.

DNS servers running versions of the Berkeley Internet Name Domain (BIND) server implementation earlier than version 4.9.4 do not support the fast transfer format. Enable this option only if you are transferring zones to BIND servers running version 4.9.4 or later.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Enabling or disabling fast DNS zone transfers**

- Using the Windows interface
- Using the command line

### To enable or disable fast DNS zone transfers using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab.
5. In **Server options**, select the **BIND secondaries** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To enable or disable fast DNS zone transfers using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config /BindSecondaries** {**1**|**0**}

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| **/BindSecondaries** | Specifies use of the fast transfer format that is used by legacy BIND servers. |
| {**1**\|**0**} | To enable fast transfer format when transferring a zone to legacy BIND DNS servers, type **1** (on). To disable fast transfer format, type **0** (off). |

# Prevent loading of a zone with bad data

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to prevent loading of a zone when bad data is found.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To prevent loading of a zone with bad data**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab.
5. In **Server options**, select the **Fail on load if bad zone data** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Disable DNS round robin

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to disable round-robin rotation for multihomed names. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Disabling DNS round robin**

- Using the Windows interface
- Using the command line

### To disable DNS round robin using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab.
5. In **Server options**, clear the **Enable round robin** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To disable DNS round robin using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config /RoundRobin** {**1**|**0**}

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/RoundRobin** | Configures round-robin rotation. |
| {**1**\|**0**} | To enable round robin, type **1** (on). To disable round robin, type **0** (off). |

# Restore Domain Name System server default preferences

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to restore Domain Name System (DNS) server default preferences. The DNS server default preferences are listed in the following table.

| **Property** | **Setting** |
|---|---|
| Disable recursion | Off |
| BIND secondaries | On |
| Fail on load if bad zone data | Off |
| Enable round robin | On |
| Enable netmask ordering | On |
| Secure cache against pollution | On |
| Name checking | Multibyte (UTF8) |
| Load zone data on startup | From Active Directory and registry |
| Enable automatic scavenging of stale records | Off |

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To restore DNS server default preferences**

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable DNS server, and then click **Properties**.
3. Click the **Advanced** tab.
4. Click **Reset to Default**, and then click **OK**.

| **Note** |
|---|
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Disable recursion

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to disable recursion on the Domain Name System (DNS) server.

| **Note** |
| --- |
| If you disable recursion on the DNS server, you will not be able to use forwarders on the same server. |

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

#### Disabling recursion

- Using the Windows interface
- Using the command line

### To disable recursion using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable DNS server, then click **Properties**.
3. Click the **Advanced** tab.
4. In **Server options**, select the **Disable recursion (also disables forwarders)** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, , point to **Administrative Tools**, and then click **DNS**. |

### To disable recursion using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config /NoRecursion** {**1**|**0**}

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/NoRecursion** | Required. Disables recursion. |
| {**1**\|**0**} | Required. To disable recursion, type **1** (off). To enable recursion, type **0** (on). By default, recursion is enabled. |

# Disable local subnet prioritization

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to disable local subnet prioritization for multihomed names. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Disabling local subnet prioritization**

- Using the Windows interface
- Using the command line

### To disable local subnet prioritization using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable Domain Name System (DNS) server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab.
5. In **Server options**, clear the **Enable netmask ordering** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To disable local subnet prioritization using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config /LocalNetPriority** {**1**|**0**}

| Value | Description |
| --- | --- |
| *ServerName* | Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/LocalNetPriority** | Configures netmask ordering. |
| {**1**\|**0**} | To enable netmask ordering, type **1** (on). To disable netmask ordering, type **0** (off). |

# Update root hints

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to update root hints on the Domain Name System (DNS) server.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Updating root hints**

**To update root hints**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Root Hints** tab.
5. Modify server root hints as follows:
   - To add a root server to the list, click **Add**, and then specify the name and Internet Protocol (IP) address of the server to be added to the list.
   - To modify a root server in the list, click **Edit**, and then specify the name and IP address of the server to be modified in the list.
   - To remove a root server from the list, select it in the list, and then click **Remove**.
   - To copy root hints from a DNS server, click **Copy from Server**, and then specify the IP address of the DNS server from which you want to copy a list of root servers to use in resolving queries. These root hints will not overwrite any existing root hints.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Secure the server cache against names pollution

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to secure the server cache against names pollution. This setting is enabled by default.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Secure the server cache against names pollution**

**To secure the server cache against names pollution**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab.
5. In **Server options**, select the **Secure cache against pollution** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Clear server names cache

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to clear the server names cache. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Clearing the server names cache**

- Using the Windows interface
- Using the command line

### To clear the server names cache using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Clear Cache**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To clear the server names cache using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/clearcache**

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/clearcache** | Clears the DNS server cache. |

# Configure DNSSEC

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to modify the configuration of Domain Name System (DNS) Security Extensions (DNSSEC). The value of the registry entry **EnableDnsSec** determines whether the DNS server includes or excludes DNSSEC resource records when it receives queries.

| **Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**To configure DNSSEC**

1. Open Registry Editor.
2. In Registry Editor, navigate to the following registry subkey:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\DNS\Parameters**
3. Add the following **DWORD** entry:

   **EnableDnsSec**
4. Do one of the following:
   - To exclude DNSSEC resource records in query responses other than responses to requests for SIG, KEY or NXT resource records, assign a value of **0x0**. Appropriate resource records will be included in responses to requests for SIG, KEY, or NXT resource records only.
   - To include the DNSSEC resource records in all query responses (according to RFC 2535), assign a value of **0x2**.
   - To include DNSSEC resource records only in cases where the original client query contained the OPT resource record (according to RFC 2671), assign a value of **0x1**, or do not create the value at all. The DNS server behaves the same if the value is **0x1** or if the entry does not appear in the registry.

| **Note** |
| --- |
| To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**. |

# Configure EDNS0

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to modify EDNS0 configuration. The value of the registry key **EDNSCacheTimeout** determines how long the Domain Name System (DNS) server keeps information about the extension mechanisms for DNS (EDNS) versions that are supported by other DNS servers that have responded to a query with an OPT resource record.

You can perform this procedure by using Registry Editor or by using the Dnscmd command-line tool.

| **Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

#### Configuring EDNS0

- Using the Windows interface
- Using the command line

### To configure EDNS0 using the Windows interface

1. Open Registry Editor.
2. In Registry Editor, navigate to the following registry subkey:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\DNS\Parameters**
3. Add the following **DWORD** entry:

   **EDNSCacheTimeout**
4. To change the cache timeout, type a value in seconds between 3600 (1 hour) and 15724800 (182 days).
5. In the same registry subkey (**Parameters**), add the following **DWORD** entry:

   **EnableEDNSProbes**
6. To configure the DNS server to include an OPT resource record only in response to EDNS0 requests containing OPT resource records, type **0x1** (**DWORD**).
7. Restart the DNS server.

| **Note** |
| --- |
| To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**. |

### To modify EDNS0 configuration using the command line

- At a command prompt, type one of the following commands, and then press ENTER:
  - **dnscmd** *ServerName* **/Config /EDNSCacheTimeout** *Value*

- **dnscmd** *ServerName* **/Config /EnableEDNSProbes** *Value*

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/Config** | Required. Specifies the command to configure the DNS server. |
| **/EDNSCacheTimeout** | Required. Specifies the length of time that the DNS server remembers the EDNS parameters remote servers report. |
| **/EnableEdnsProbes** | Required. Specifies whether or not the DNS server probes other DNS servers to determine if they support EDNS. |
| *Value* | Required. For **/EDNSCacheTimeout**, type a value in seconds between 3600 (1 hour) and 15724800 (182 days). For **/EnableEDNSProbes**, type **1** to configure the DNS server to probe other DNS servers and determine if they support EDNS. Type **0** to configure the DNS server to not probe remote servers for EDNS support. If you type **0**, the DNS server will continue to use EDNS if other servers request it. |

# Change UDP message size

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to modify User Datagram Protocol (UDP) message size.

| **Caution** |
| --- |
| When you configure the UDP packet size to be larger than 512 bytes, remember that UDP packets must travel through devices other than UDP hosts, such as routers, and these devices may not support UDP packets larger than 512 bytes. It is recommended that you establish the maximum UDP packet length support for all devices — and the path's maximum transmission unit (MTU), if possible — and configure your UDP hosts according to this maximum. |

| **Caution** |
| --- |
| It is recommended that you do not directly edit the registry unless there is no other alternative. Modifications to the registry are not validated by the registry editor or by Windows before they are applied, and as a result, incorrect values can be stored. This can result in unrecoverable errors in the system. When possible, use Group Policy or other Windows tools, such as Microsoft Management Console (MMC), to accomplish tasks rather than editing the registry directly. If you must edit the registry, use extreme caution. |

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

### To change UDP message size

1. Open Registry Editor.
2. In Registry Editor, navigate to the following registry key:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\DNS\Parameters**
3. Add the following **DWORD** entry:

   **MaximumUdpPacketSize**
4. Type a maximum UDP packet size value in bytes.

   The default value is 1280 bytes. The value must be between 512 and 16384 in decimal format (200 and 4000 in hexadecimal format).
5. Restart the DNS server.

| **Note** |
| --- |
| To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**. |

# Securing DNS

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain Name System (DNS) was originally designed as an open protocol. Therefore, it is vulnerable to attackers. Security features in Windows Server 2003 DNS can help you prevent an attack on your DNS infrastructure. Before considering which of the Windows Server 2003 security features to use, you should be aware of the following:

- Common threats to DNS security
- The level of DNS security in your organization

**DNS Security Threats**

The following are the typical ways in which your DNS infrastructure can be threatened by attackers:

- **Footprinting.** The process by which DNS zone data, including DNS domain names, computer names, and Internet Protocol (IP) addresses for sensitive network resources, is obtained by an attacker. An attacker commonly begins an attack by using this DNS data to diagram, or "footprint," a network. DNS domain names and computer names usually indicate the function or location of a domain or computer to help users remember and identify domains and computers more easily. An attacker takes advantage of this same DNS naming principle to learn the function or location of domains and computers in the network.
- **Denial-of-service attack.** A scenario in which an attacker attempts to deny the availability of network services by flooding one or more DNS servers in the network with recursive queries. As a DNS server is flooded with queries, its CPU usage eventually reaches its maximum, and the DNS Server service becomes unavailable. Without a fully operating DNS server on the network, network services that use DNS are unavailable to network users.
- **Data modification.** An attempt by an attacker that has footprinted a network by using DNS to use valid IP addresses in IP packets that the attacker has created. This gives these packets the appearance of coming from a valid IP address in the network. This process is commonly called IP "spoofing." With a valid IP address — that is, an IP address within the IP address range of a subnet — the attacker can gain access to the network and destroy data or conduct other attacks.
- **Redirection.** A scenario in which an attacker is able to redirect queries for DNS names to servers that are under the control of the attacker. One method of redirection involves an attempt to pollute the DNS cache of a DNS server with erroneous DNS data that may direct future queries to servers that are under the control of the attacker. For example, if a query is made originally for sales.wingtiptoys.com and a referral answer provides a record for a domain name that the attacker has outside the wingtiptoys.com domain, the DNS server uses the cached data for the attacker's domain to resolve a query for that name. Redirection can occur whenever an attacker has writable access to DNS data, for example, in a scenario that includes dynamic updates that are not secure.

**Mitigating DNS Security Threats**

The following sections explain three levels of DNS security that you can apply to your current DNS configuration. You can use these three levels of security to increase the DNS security of your organization.

**Low-Level Security**

Low-level security is a standard DNS deployment without any security precautions configured. You should deploy this level of DNS security only in network environments where there is no concern for the integrity of your DNS data or in a private network where there is no threat of external connectivity:

- The DNS infrastructure of your organization is fully exposed to the Internet.
- Standard DNS resolution is performed by all DNS servers in your network.
- All DNS servers are configured with root hints pointing to the root servers for the Internet.
- All DNS servers permit zone transfers to any server.

- All DNS servers are configured to listen on all of their IP addresses.
- Cache pollution prevention is disabled on all DNS servers.
- Dynamic update is allowed for all DNS zones.
- User Datagram Protocol (UDP) and TCP/IP port 53 is open on the firewall for your network for both source and destination addresses.

**Medium-Level Security**
Medium-level security uses the DNS security features that are available without running DNS servers on domain controllers and storing DNS zones in Active Directory:

- The DNS infrastructure of your organization has limited exposure to the Internet.
- All DNS servers are configured to use forwarders to point to a specific list of internal DNS servers when they cannot resolve names locally.
- All DNS servers limit zone transfers to servers that are listed in the name server (NS) resource records in their zones.
- DNS servers are configured to listen on specified IP addresses.
- Cache pollution prevention is enabled on all DNS servers.
- Dynamic update that is not secure is not allowed for any DNS zones.
- Internal DNS servers communicate with external DNS servers through a firewall with a limited list of allowed source addresses and destination addresses.
- External DNS servers in front of the firewall are configured with root hints that point to the root servers for the Internet.
- All Internet name resolution is performed by using proxy servers and gateways.

**High-Level Security**
High-level security uses the same configuration as medium-level security. It also uses the security features that are available when the DNS Server service is running on a domain controller and DNS zones are stored in Active Directory. In addition, high-level security completely eliminates DNS communication with the Internet. This is not a typical configuration, but it is recommended whenever Internet connectivity is not required:

- The DNS infrastructure of your organization has no Internet communication by means of internal DNS servers.
- Your network uses an internal DNS root and namespace, where all authority for DNS zones is internal.
- DNS servers that are configured with forwarders use internal DNS server IP addresses only.
- All DNS servers limit zone transfers to specified IP addresses.
- DNS servers are configured to listen on specified IP addresses.
- Cache pollution prevention is enabled on all DNS servers.
- Internal DNS servers are configured with root hints that point to the internal DNS servers that host the root zone for your internal namespace.
- All DNS servers are running on domain controllers. A discretionary access control list (DACL) is configured on the DNS Server service to allow only specific individuals to perform administrative tasks on the DNS server.

- All DNS zones are stored in Active Directory. A DACL is configured to allow only specific individuals to create, delete, or modify DNS zones.

- DACLs are configured on DNS resource records to allow only specific individuals to create, delete, or modify DNS data.

- Secure dynamic update is configured for DNS zones except the top-level zones and root zones, which do not allow dynamic updates at all.

**Securing DNS**

The following tasks for securing DNS are described in this objective:

- Securing Domain Name System Zones

- Securing the Domain Name System Server Service

- Securing Domain Name System Clients

# Securing Domain Name System Zones

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To secure the Domain Name System (DNS) zones in your environment, use the following guidelines:

- **Configure secure dynamic updates.** By default, the **Dynamic updates** option is not set to allow dynamic updates. This is the most secure setting because it prevents an attacker from updating DNS zones. However, this setting prevents you from taking advantage of the benefits to administration that dynamic updates provide. To make it possible for computers to update DNS data securely, store DNS zones in Active Directory, and use the secure dynamic update feature. Secure dynamic update restricts DNS zone updates to only the following:

    - Computers that are authenticated and joined to the Active Directory domain where the DNS server is located

    - The specific security settings that are defined in the access control lists (ACLs) for the DNS zone

- Restrict zone transfers. By default, the DNS Server service allows zone information to be transferred only to servers that are listed in the name server (NS) resource records of a zone. This is a secure configuration. However, for increased security this configuration should be changed to enable the option to allow zone transfers to specified Internet Protocol (IP) addresses. Changing this configuration to allow zone transfers to any server at all may expose your DNS data to an attacker who is attempting to footprint your network.

- Understand the compromise involved in zone delegation. When you decide whether to delegate DNS domain names to zones that are hosted on DNS servers that are administered separately, it is important to consider the security implications of giving the ability to administer the DNS data for your network to multiple individuals. DNS zone delegation involves a compromise between the security benefits of having a single authoritative DNS server for all DNS data and the administrative benefits of distributing responsibility for your DNS namespace to separate administrators. This issue is very important when you delegate the top-level domains of a private DNS namespace, because those domains contain very sensitive DNS data.

For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform the following procedures:

1. Enable secure dynamic updates

2. Modify DNS zone transfer settings

3. Managing DNS Resource Records

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Enable secure dynamic updates

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to allow only secure dynamic updates for a zone. Secure dynamic update is supported only for Active Directory–integrated zones. If the zone type is configured differently, you must change the zone type and directory-integrate the zone before securing it for Domain Name System (DNS) dynamic updates.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Enabling secure dynamic updates**

- Using the Windows interface
- Using the command line

### To enable secure dynamic updates using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable zone, and then click **Properties**.
3. On the **General** tab, verify that the zone type is **Active Directory-Integrated**.
4. In **Dynamic updates**, click **Secure only**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To enable secure dynamic updates using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config** {*ZoneName*|**..AllZones**} **/AllowUpdate 2**

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName*\|**..AllZones** | Required. Specifies the fully qualified domain name (FQDN) of the zone. To configure all zones that are hosted on the specified DNS server to allow dynamic updates, type **..AllZones**. |
| **2** | Required. Configures the server to allow secure dynamic updates. If you exclude the **2**, the zone is set to perform standard dynamic updates only. |

# Modify DNS zone transfer settings

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to change Domain Name System (DNS) zone transfer settings. To improve the security of your DNS infrastructure, zone transfers should be allowed only for either the DNS servers in the name server (NS) resource records for a zone or for specified DNS servers. If you allow any DNS server to perform a zone transfer, you are allowing internal network information to be transferred to any host that can contact your DNS server.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Modifying DNS zone transfer settings**

- Using the Windows interface
- Using the command line

### To modify DNS zone transfer settings using the Windows interface

1. Open the DNS snap-in.
2. Right-click a DNS zone, and then click **Properties**.
3. On the **Zone Transfers** tab, do one of the following:
   - To disable zone transfers, clear the **Allow zone transfers** check box.
   - To allow zone transfers, select the **Allow zone transfers** check box.
4. If you allowed zone transfers, do one of the following:
   - To allow zone transfers to any server, click **To any server**.
   - To allow zone transfers only to the DNS servers that are listed on the **Name Servers** tab, click **Only to servers listed on the Name Servers tab**.
   - To allow zone transfers only to specific DNS servers, click **Only to the following servers**, and then add the Internet Protocol (IP) address of one or more DNS servers.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To modify DNS zone transfer settings using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ZoneResetSecondaries** *ZoneName* {**/NoXfr**|**/NonSecure**|**/SecureNs**|**/SecureList**[*SecondaryIPAddress*...]}

| Value | Description |
| --- | --- |

| | |
|---|---|
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of zone. |
| **/NoXfr** | Disables zone transfers for the zone. |
| **/NonSecure** | Permits zone transfers to any DNS server. |
| **/SecureNs** | Permits zone transfers only to DNS servers that are listed in the zone using NS resource records. |
| **/SecureList** | Permits zone transfers only to DNS servers that are specified by *SecondaryIPAddress*. |
| *SecondaryIPAddress* | Required if **/SecureList** is specified. A list of one or more IP addresses for DNS servers that are permitted to obtain zone transfers. |

# Delegating a Zone

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain Name System (DNS) provides the option of dividing up the namespace into one or more zones, which can then be stored, distributed, and replicated to other DNS servers. When deciding whether to divide your DNS namespace to make additional zones, consider the following reasons to use additional zones:

- You want to delegate management of part of your DNS namespace to another location or department in your organization.
- You want to divide one large zone into smaller zones for distributing traffic loads among multiple servers, improving DNS name resolution performance, or creating a more fault-tolerant DNS environment.
- You want to extend the namespace by adding numerous subdomains at once, for example, to accommodate the opening of a new branch or site.

If, for any of these reasons, your network can benefit from delegating zones, it may make sense to restructure your namespace by adding additional zones. When choosing how to structure zones, use a plan that reflects the structure of your organization.

When you delegate zones within your namespace, be aware that for each new zone you create, you will need delegation records in other zones that point to the authoritative DNS servers for the new zone. This is necessary both to transfer authority and to provide correct referral to other DNS servers and clients of the new servers that are being made authoritative for the new zone.

When a standard primary zone is first created, it is stored as a text file that contains all resource record information on a single DNS server. This server acts as the primary master for the zone. Zone information can be replicated to other DNS servers to improve fault tolerance and server performance.

When you structure your zones, there are several good reasons to use additional DNS servers for zone replication:

- Added DNS servers provide zone redundancy, enabling DNS names in the zone to be resolved for clients if a primary server for the zone stops responding.
- Added DNS servers can be placed so as to reduce DNS network traffic. For example, adding a DNS server to the opposing side of a low-speed, wide area network (WAN) link can be useful in managing and reducing network traffic.
- Additional secondary servers can be used to reduce loads on a primary server for a zone.

For more information about planning DNS zones, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.
- Install Nslookup.

To complete this task, perform one of the following procedures:

- Create a new zone delegation
- Verify a zone delegation

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Create a new zone delegation

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to create a new zone delegation. All domains (or subdomains) that appear as part of the applicable zone delegation must be created in the current zone before you perform delegation as described in this procedure. As necessary, use the DNS snap-in to first add domains to the zone before you perform this procedure. You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Creating a new zone delegation**

- Using the Windows interface
- Using the command line

### To create a new zone delegation using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable subdomain, and then click **New Delegation**.
3. Follow the instructions in the New Delegation Wizard to finish creating the new delegated domain.

| **Note** |
|---|
| To open DNS, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

### To create a new zone delegation using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/RecordAdd** *ZoneName NodeName* [**/Aging**] [**/OpenAcl**] [*Ttl*] **NS** {*HostName*|*FQDN*}

| Value | Description |
|---|---|
| *ServerName* | Required. Specifies the Domain Name System (DNS) host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.) |
| *ZoneName* | Required. Specifies the fully qualified domain name (FQDN) of the zone. |
| *NodeName* | Required. Specifies the FQDN of the node in the DNS namespace for which the start-of-authority (SOA) record is added. You can also type the node name relative to the *ZoneName* or @, which specifies the zone's root node. |
| **/Aging** | If this command is used, this resource record is able to be aged and scavenged. If this command is not used, the resource record remains in the DNS database unless it is updated or removed manually. |
| **/OpenAcl** | Specifies that new records are open to modification by any user. Without this parameter, only administrators may modify the new record. |
| *Ttl* | Specifies the Time to Live (TTL) setting for the resource record. (The default TTL is defined in the SOA resource record). |
| **NS** | Required. Specifies that you are adding a name server (NS) resource record to the zone that is specified in *ZoneName*. |

| | |
|---|---|
| *HostName\|FQDN* | Required. Specifies the host name or FQDN of the new authoritative server. |

# Verify a zone delegation

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative credentials**

You do not need administrative credentials to perform this task. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

**To verify a zone delegation**

1. At a command prompt, type the following command, and then press ENTER:

   **nslookup** *RootServerIpAddress*

2. Type the following command, and then press ENTER:

   **nslookup**

3. At the next prompt, type the following command, and then press ENTER:

   **set norecurse**

4. At the next prompt, type the following command, and then press ENTER:

   **set q=NS**

5. Type the fully qualified domain name (FQDN) for the failed name.

   Use the trailing period (**.**) when you type the name. If zone delegations are set correctly, a list of name server (NS) resource records for delegated servers is returned in the response.

6. If the NS query response contains no names or Internet Protocol (IP) addresses for delegated servers, type **q=ns**, and then query again using the FQDN for the parent zone of the failed name.

   For example, if the failed name that you used in the previous step was sales.wingtiptoys.com, query for wingtiptoys.com.

7. If the response contains NS resource records, but no host address (A) resource records, type **set recurse**, and then query individually for any of the A resource records of the servers that are listed in the NS resource records.

   If, for each NS resource record that you encounter in a zone, you do not find at least one valid IP address in an A resource record, you have a broken delegation.

8. Either fix the broken delegation or retry the delegation test that is described in the previous step and use a different IP address.

   If more than one A resource record or IP address is found, use it to repeat the delegation test described in the previous step. To fix a delegation, add or update an A resource record in the parent zone with a valid IP address for a correct DNS server for the delegated zone.

| Value | Description |
|---|---|
| *RootServerIpAddress* | The IP address of a valid root server for your network. |
| **set norecursion** | Instructs the root server to not perform recursion on your query. |
| **set q=NS** | Sends the query for NS resource records to the root server. |

# Securing the Domain Name System Server Service

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To secure the Domain Name System (DNS) servers in your network, use the following guidelines:

- Limit the Internet Protocol (IP) addresses that the DNS Server service listens on to the IP address that is used by its DNS clients as their preferred DNS server. By default, a DNS Server service that is running on a multihomed computer is configured to listen for DNS queries on all its IP addresses.

- Leave the **Secure cache against pollution** option enabled. By default, the DNS Server service is secured from cache pollution, which occurs when DNS query responses contain nonauthoritative or malicious data. The **Secure cache against pollution** option prevents an attacker from polluting the cache of a DNS server with resource records that were not requested by the DNS server. Changing this default setting reduces the integrity of the responses that are provided by DNS Server service.

- Disable recursion. By default, recursion is not disabled for the DNS Server service. This enables the DNS server to perform recursive queries on behalf of its DNS clients and the DNS servers that have forwarded DNS client queries to it. Recursion can be used by attackers to deny the DNS Server service. Therefore, if a DNS server in your network is not intended to receive recursive queries, it should be disabled.

- If you have an internal DNS root in your DNS infrastructure, configure the root hints of internal DNS servers to point only to the DNS servers that host your root domain, not to the DNS servers that host the Internet root domain. This prevents your internal DNS servers from sending private information over the Internet when they resolve names.

For more information about planning DNS, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform the following procedures:

1. Restrict the DNS server to listen on selected IP addresses

2. Secure the server cache against names pollution.

3. Disable recursion

4. Update root hints

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Restrict the DNS server to listen on selected IP addresses

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to restrict the DNS Server service to listen only on selected Internet Protocol (IP) addresses. By default, the DNS Server service listens for Domain Name System (DNS) message communications on all configured IP addresses for the server computer. Restricting the DNS Server service to listen only on specific IP addresses is an effective security measure because only hosts on the same network subnet — or hosts with a router that connects them to that same segment — have access to the server.

| **Note** |
| --- |
| Server IP addresses that you add with this procedure must be managed statically. If you later change or remove addresses specified here from TCP/IP configurations that are maintained at this server, update this list accordingly. |

After you update or revise the list of restricted interfaces, stop and restart the DNS server to apply the new list.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Restricting the DNS server to listen on selected IP addresses**

- Using the Windows interface
- Using the command line

**To restrict the DNS server to listen on selected IP addresses using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. On the **Interfaces** tab, click **Only the following IP addresses**.
5. In **IP address**, type an IP address for the DNS server to be enabled for use, and then click **Add**.
6. Repeat the previous step as needed to specify other server IP addresses to be enabled for use by this DNS server.

   If you want to remove an IP address from the list, click the IP address, and then click **Remove**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To restrict the DNS server to listen on selected IP addresses using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ResetListenAddresses** [*ListenAddress...*]

| Value | Description |
| --- | --- |

| | |
|---|---|
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/ResetListenAddresses** | Required. Resets the IP addresses of the interfaces on which the DNS server listens. |
| *ListenAddress...* | Specifies one or more IP addresses for the interfaces on which you want the DNS server to listen. By default, the DNS Server service listens for DNS message communications on all configured IP addresses for the server computer. |

# Secure the server cache against names pollution

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to secure the server cache against names pollution. This setting is enabled by default.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Secure the server cache against names pollution**

**To secure the server cache against names pollution**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab.
5. In **Server options**, select the **Secure cache against pollution** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Disable recursion

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to disable recursion on the Domain Name System (DNS) server.

| **Note** |
| --- |
| If you disable recursion on the DNS server, you will not be able to use forwarders on the same server. |

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

#### Disabling recursion

- Using the Windows interface
- Using the command line

### To disable recursion using the Windows interface

1. Open the DNS snap-in.
2. In the console tree, right-click the applicable DNS server, then click **Properties**.
3. Click the **Advanced** tab.
4. In **Server options**, select the **Disable recursion (also disables forwarders)** check box, and then click **OK**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, , point to **Administrative Tools**, and then click **DNS**. |

### To disable recursion using the command line

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/Config /NoRecursion** {**1**|**0**}

| Value | Description |
| --- | --- |
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the Internet Protocol (IP) address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/NoRecursion** | Required. Disables recursion. |
| {**1**\|**0**} | Required. To disable recursion, type **1** (off). To enable recursion, type **0** (on). By default, recursion is enabled. |

# Update root hints

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to update root hints on the Domain Name System (DNS) server.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Updating root hints**

**To update root hints**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. Click the **Root Hints** tab.
5. Modify server root hints as follows:
   - To add a root server to the list, click **Add**, and then specify the name and Internet Protocol (IP) address of the server to be added to the list.
   - To modify a root server in the list, click **Edit**, and then specify the name and IP address of the server to be modified in the list.
   - To remove a root server from the list, select it in the list, and then click **Remove**.
   - To copy root hints from a DNS server, click **Copy from Server**, and then specify the IP address of the DNS server from which you want to copy a list of root servers to use in resolving queries. These root hints will not overwrite any existing root hints.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

# Securing Domain Name System Clients

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following Domain Name System (DNS) client considerations have security implications for DNS clients in a DNS infrastructure:

- Whenever possible, specify static Internet Protocol (IP) addresses for the preferred and alternate DNS servers that are to be used by a DNS client. If a DNS client is configured to obtain its DNS server addresses automatically, it will obtain them from a Dynamic Host Configuration Protocol (DHCP) server. While this method of obtaining DNS server addresses is secure, it is only as secure as the DHCP server. By configuring DNS clients with static IP addresses for the preferred and alternate DNS servers, you eliminate one possible avenue of attack.

- Control which DNS clients have access to the DNS server. If a DNS server is configured to listen only on specific IP addresses, only DNS clients that are configured to use these IP addresses as preferred and alternate DNS servers will contact the DNS server.

For more information about planning DNS, see Deploying Domain Name System (DNS) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45677).

**Task requirements**

To begin this task, perform the following requirements:

- Install Dnscmd.

To complete this task, perform the following procedures:

1. Configure DNS settings in Network Connections.

2. Restrict the DNS server to listen on selected IP addresses.

**See Also**
**Other Resources**
Deploying Domain Name System (DNS)

# Configure DNS settings in Network Connections

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use this procedure to configure TCP/IP to use Domain Name System (DNS).

**Administrative credentials**

To complete this procedure, you must be a member of the Administrators group or the Network Configuration Operators group on the local computer.

**To configure DNS settings in Network Connections**

1. Open Network Connections.
2. Right-click the network connection that you want to configure, and then click **Properties**.
3. On the **General** tab (for a local area connection) or the **Networking** tab (for all other connections), click **Internet Protocol (TCP/IP)**, and then click **Properties**.
4. If you want to obtain DNS server addresses from a DHCP server, click **Obtain DNS server address automatically**.
5. If you want to configure DNS server addresses manually, click **Use the following DNS server addresses**, and in **Preferred DNS server** and **Alternate DNS server**, type the Internet Protocol (IP) addresses of the preferred DNS server and alternate DNS server.
6. To configure advanced DNS properties, click **Advanced**, click the **DNS** tab, and then do one or more of the following:
   - To configure an additional DNS server IP address:

     a. Under **DNS server addresses**, in order of use, click **Add**.

     b. In **DNS server**, type the IP address of the DNS server, and then click **Add**.

   - To resolve an unqualified name by appending the primary DNS suffix and the DNS suffix of each connection (if configured), click **Append primary and connection specific DNS suffixes**. If you also want to search the parent suffixes of the primary DNS suffix up to the second-level domain, select the **Append parent suffixes of the primary DNS suffix** check box.
   - To resolve an unqualified name by appending the suffixes from a list of configured suffixes, click **Append these DNS suffixes (in order)**, and then click **Add** to add suffixes to the list.
   - To use a DNS dynamic update to register the IP addresses of this connection and the primary domain name of the computer, select the **Register this connection's addresses in DNS** check box. This option is enabled by default. The primary domain name of the computer is the primary DNS suffix appended to the computer name, and it can be viewed as the full computer name on the **Computer Name** tab (which is available in **System** in **Control Panel**).
   - To use a DNS dynamic update to register the IP addresses and the connection-specific domain name of this connection, select the **Use this connection's DNS suffix in DNS registration** check box. This option is disabled by default. The connection-specific domain name of this connection is the DNS suffix for this connection appended to the computer name.
   - To completely disable DNS dynamic update for all names on the computer, clear the **Register this connection's addresses in DNS** and **Use this connection's DNS suffix in DNS registration** check boxes for all connections in Network Connections.

**Note**

To open Network Connections, click **Start**, point to **Control Panel**, and then click **Network Connections**.

# Restrict the DNS server to listen on selected IP addresses

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the following procedure to restrict the DNS Server service to listen only on selected Internet Protocol (IP) addresses. By default, the DNS Server service listens for Domain Name System (DNS) message communications on all configured IP addresses for the server computer. Restricting the DNS Server service to listen only on specific IP addresses is an effective security measure because only hosts on the same network subnet — or hosts with a router that connects them to that same segment — have access to the server.

| **Note** |
| --- |
| Server IP addresses that you add with this procedure must be managed statically. If you later change or remove addresses specified here from TCP/IP configurations that are maintained at this server, update this list accordingly. |

After you update or revise the list of restricted interfaces, stop and restart the DNS server to apply the new list.

You can perform this procedure by using the DNS snap-in or by using the Dnscmd command-line tool.

**Administrative credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

**Restricting the DNS server to listen on selected IP addresses**

- Using the Windows interface
- Using the command line

**To restrict the DNS server to listen on selected IP addresses using the Windows interface**

1. Open the DNS snap-in.
2. In the console tree, click the applicable DNS server.

   Where?

   - DNS/*applicable DNS server*

3. On the **Action** menu, click **Properties**.
4. On the **Interfaces** tab, click **Only the following IP addresses**.
5. In **IP address**, type an IP address for the DNS server to be enabled for use, and then click **Add**.
6. Repeat the previous step as needed to specify other server IP addresses to be enabled for use by this DNS server.

   If you want to remove an IP address from the list, click the IP address, and then click **Remove**.

| **Note** |
| --- |
| To open the DNS snap-in, click **Start**, point to **Administrative Tools**, and then click **DNS**. |

**To restrict the DNS server to listen on selected IP addresses using the command line**

- At a command prompt, type the following command, and then press ENTER:

  **dnscmd** *ServerName* **/ResetListenAddresses** [*ListenAddress...*]

| Value | Description |
| --- | --- |

| | |
|---|---|
| *ServerName* | Required. Specifies the DNS host name of the DNS server. You can also type the IP address of the DNS server. To specify the DNS server on the local computer, you can also type a period (.). |
| **/ResetListenAddresses** | Required. Resets the IP addresses of the interfaces on which the DNS server listens. |
| *ListenAddress...* | Specifies one or more IP addresses for the interfaces on which you want the DNS server to listen. By default, the DNS Server service listens for DNS message communications on all configured IP addresses for the server computer. |

# Troubleshooting Domain Name System

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides troubleshooting information for Domain Name System (DNS) in Windows Server 2003 SP 1. It is designed to help you identify and resolve problems that may be related to DNS.

**In this guide**

- Introduction to Troubleshooting Domain Name System
- Verifying Computer Settings for Domain Name System
- Configuring a Computer for Troubleshooting Domain Name System
- Troubleshooting Domain Name System Problems
- Additional Resources for Domain Name System

Project Editor: Jim Becker

# Introduction to Troubleshooting Domain Name System

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide explains how to troubleshoot Domain Name System (DNS). If you are not familiar with this guide, review the following sections of this introduction.

**When to Use This Guide**
You should use this guide when:

- You have a problem that you believe is related to DNS, but you do not know how to resolve it.
- You configure DNS settings, but DNS does not behave the way that you anticipate.
- A program is not working properly, and you believe that DNS is causing the problem.

Do not use this guide to find out how to perform a task, such as configuring a stub zone or installing DNS. Information about how to perform tasks and configure settings can be found in Administering DNS Operations.

This guide assumes that you have a basic understanding of what DNS is, how it works, and why your organization uses it for name resolution. You should also have a thorough understanding of how DNS is deployed and managed in your organization. This includes an understanding of the mechanism that your organization uses to configure and manage DNS settings.

**How This Guide Is Organized**
This guide is divided into four sections. Each section addresses a type of problem, ranging from less complex to more complex.

Verifying Computer Settings for Domain Name System

This section provides a list of prerequisites and settings that must be verified before you troubleshoot. Read this section first.

Configuring a Computer for Troubleshooting Domain Name System

This section describes how to configure your computer for troubleshooting.

Troubleshooting Domain Name System Problems

This section provides step-by-step diagnostic procedures and possible solutions that help you identify and fix DNS problems.

Additional Resources for Domain Name System

This section provides additional resources that are related to DNS.

# Verifying Computer Settings for Domain Name System

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you begin troubleshooting, verify that your computer is configured properly and that Domain Name System (DNS) is set up and running properly.

**Settings to Verify Before You Troubleshoot**
Verify all of the following items:

Make sure you have administrative rights on the computer that you are troubleshooting

Install all critical updates and security updates for Windows Server 2003

Verify DNS client settings

**Make sure you have administrative rights on the computer that you are troubleshooting.**
You cannot modify DNS settings unless you are a member of the Administrators group on the computer that you are troubleshooting.

### To verify that you are a member of the Administrators group that you are troubleshooting

1. Open the Computer Management snap-in.
2. In the console tree, double-click **Local Users and Groups**, and then click **Groups**.
3. In the details pane, double-click **Administrators** and verify that your account name or a group to which your account is a member appears in the **Members** list.

**Install all critical updates and security updates for Windows Server 2003.**
Some updates might be required for DNS to function properly.

### To verify that you have all critical updates and security updates for Windows Server 2003

- Click **Start**, click **Windows Update**, and then follow the instructions that appear on your screen.

**Verify DNS client settings.**
Verify that the DNS client does not have an external DNS server, such as a DNS server from an Internet service provider (ISP), in its TCP/IP configuration. In most cases, the client should not use a DNS server from an ISP as either the preferred or alternate DNS server because the DNS server from the ISP is unable to resolve internal names. Using a DNS server from an ISP in the TCP/IP configuration of a client can also cause problems with conflicting internal and external namespaces.

### To verify DNS client settings

1. Log on to the computer with your Administrator account.
2. Click **Start**, click **Control Panel**, and then double-click **Network Connections.**
3. In **Network Connections**, right-click the local area connection that you want, and then click **Properties**.
4. In **Local Area Connection Properties**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
5. If **Obtain an IP address automatically** is selected, type the following at a command prompt:

   **ipconfig /all**

6. Review the DNS server settings and verify that they are correct.

# Configuring a Computer for Troubleshooting Domain Name System

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you can use advanced troubleshooting techniques to identify and fix Domain Name System (DNS) problems, you need to configure your computer for troubleshooting. In addition, you need a basic understanding of troubleshooting concepts, procedures, and tools.

**Configuration Tasks for Troubleshooting**
To configure your computer for troubleshooting, perform the following tasks:

Install Windows Server 2003 SP1

Install Windows Support Tools

Install Network Monitor

Enable DNS Debug Logging

**Install Windows Server 2003 SP1**
If possible, upgrade your DNS servers with Windows Server 2003 Service Pack 1 (SP1). To install this service pack, go to the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=9999) and follow the instructions for downloading the service pack.

**Install Windows Support Tools**
