If you determine that you have more print servers than you can manage efficiently, consolidate some of them onto one of your more powerful print servers. Central print server management offers an easier way to administer print servers, and consolidation reduces the cost incurred by maintaining more print servers than you need. At the same time, consolidating servers increases the value of recovery planning and procedures.

As you consider whether or not to consolidate print servers, weigh the following advantages and disadvantages.

**Advantages of consolidating printers**

- You have fewer print servers to maintain.
- You can reassign the servers that no longer serve as print servers.

**Disadvantages of consolidating printers**

- If a server stops responding, your users have fewer servers to depend on.
- If the print server is no longer near users on the network, your users might experience delays in processing print jobs.

Using Print Migrator version 3.0 helps you automate the process of consolidating your print servers. You merely back up your existing servers and restore them to the new Windows Server 2003 print server. For more information about Print Migrator 3.0, see "Choosing a Print Server Migration Method" later in this chapter.

**Creating a Standard Print Server Configuration**

Creating a standard print server configuration is highly recommended. This involves defining a specific hardware and software combination that works well for your organization and operates with minimal maintenance. The specific configuration varies from business to business. The needs of your organization might necessitate more than one standard print server configuration.

Designing a standard configuration for print servers provides two important benefits:

- It reduces the complexity of managing and maintaining hardware. You need to learn hardware management and maintenance tasks for only one type of print server instead of for multiple types.
- It reduces the amount of testing that you must perform when updating drivers on the print server. Instead of testing the updates on multiple hardware and software configurations, you can test the updates on one print server and then deploy the updates to the other print servers.

If your organization has selected Cluster service to provide the highest level of availability, create a standard configuration for clustered print servers as well. For more information about clustering, see "Designing and Deploying Server Clusters" in this book.

As you design your configuration, consider creating a logical and standard naming convention for your printers, which can make it easier for users to locate printers across a network if you decide to publish your printers in Active Directory.

# Designing for Printer Driver Compatibility

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Designing for Printer Driver Compatibility**

When designing your new printing environment, you must understand how different types of drivers work on different versions of the Windows operating system. Print servers running Windows Server 2003 use two types of drivers:

- Version 2 printer drivers operate in *kernel mode* (inside the operating system kernel memory space) and are designed for Windows NT 4.0.
- Version 3 printer drivers operate in *user mode* (outside the operating system kernel memory space) and are designed for Windows 2000, Windows XP, and Windows Server 2003.

Windows Server 2003 supports both Version 2 and Version 3 printer drivers. To ensure the stability of your print servers, use Version 3 drivers whenever possible. If some computers in your organization run Windows NT 4.0 and other computers run Windows 2000, Windows XP Professional, or Windows Server 2003, you must ensure that you have the proper mix of drivers to support all of these clients, and you might have to modify the Windows Server 2003 print server to include additional Version 2 drivers that work with Windows NT 4.0 clients.

**Note**

- Poorly written device drivers have been identified as a major cause of system instability. To ensure that your drivers are reliable, use drivers approved under the Windows Hardware Logo Program on your print servers.

Having the correct drivers installed on your server is important if you plan to use the Point and Print feature. By using Point and Print, a user running Windows NT 4.0, Windows 2000, Windows XP Professional, or Windows Server 2003 can create a connection to a remote printer without using disks or other installation media. All necessary files and configuration information automatically download from the print server to the client. Point and Print eases your administrative overhead by eliminating the need to visit each workstation to install the appropriate device drivers.

Windows Server 2003 also provides Point and Print support for Windows 95, Windows 98, and Windows Millennium Edition clients on your network. However, Point and Print does not support automatic driver upgrades for these clients.

Your new print servers must include printer drivers that support all the clients on your network. Maintain a list of printers that are using Version 2 drivers, so that you can replace these drivers with Version 3 drivers if you upgrade the client base to Windows 2000 or Windows XP Professional. Additionally, if you have PostScript printers, you can use PostScript drivers to increase interoperability in a mixed Windows NT 4.0, Windows 2000, and Windows XP Professional client environment.

Table 3.2 notes the compatibility of Version 2, Version 3, and PostScript drivers with different versions of the Windows operating systems.

**Table 3.2 Printer Driver Compatibility with Windows Operating Systems**

| Driver type | Version 2 | Version 3 | PostScript |
|---|---|---|---|
| Windows NT 4.0 | ● | Supported as additional drivers* | ● |
| Windows 2000 | ● | ● | ● |
| Windows XP Professional | ● | ● | ● |
| Windows Server 2003 | Supported as additional drivers | ● | ● |

* Must be installed remotely from Windows 2000 and Windows XP Professional clients to allow those clients to print to a Windows NT 4.0 print server.

**Version 2 and Version 3 Drivers**

Version 3 drivers are recommended over Version 2 drivers because they support advanced printing features and improved performance. If a server stops responding as a result of a Version 3 driver problem, you only need to stop and restart the print

spooler instead of restarting the server. Additionally, Version 3 drivers can reduce printer downtime, because Windows Server 2003 provides automatic recovery of the spooler service by default. If a Version 2 driver stops responding, you must reboot the server, taking all other services offline while the server restarts.

Often the existing Version 2 drivers on your print server function properly with Windows Server 2003. Although a default local Group Policy setting in Windows Server 2003 prohibits the installation of new Version 2 drivers, this policy setting does not affect existing Version 2 drivers when you perform an upgrade unless a driver is known to be problematic. To identify drivers that will not carry through the upgrade, use the command-line tool Fixprnsv.exe prior to upgrading.

For more information about Fixprnsv.exe, see "Identifying Interoperability Issues with Print Server Upgrades" later in this chapter. For more information about disallowing installation of printers using kernel-mode drivers, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**PostScript Drivers**

Microsoft recommends that you consider using PostScript minidrivers (.ppd files) to increase compatibility in mixed environments with Windows NT 4.0, Windows 2000, and Windows Server 2003 systems. Computers running Windows NT 4.0, Windows 2000, Windows XP, and Windows Server 2003 can all run the same PSCRIPT5 core code, regardless of whether these computers are running Version 2 or Version 3 drivers. This offers a higher level of interoperability among clients running different versions of Windows.

**Choosing Drivers for Point and Print Connectivity**

If you are using Point and Print to connect clients to printers, driver compatibility is particularly important. Clients that use the same driver architecture as the print server can simply download the primary driver used on the server and therefore do not require the installation of any additional drivers on the print server for full support. For example, a Windows Server 2003 print server using a Version 3 driver for a shared printer does not require the installation of any additional drivers to provide full Point and Print support for Windows 2000 and Windows XP Professional clients, because those clients also support Version 3 drivers.

If Windows 95, Windows 98, Windows Millennium Edition, and Windows NT 4.0 clients connect to the print server, you must install the appropriate driver as an additional driver on the Windows Server 2003 print server.

For additional information about network printing, including Point and Print driver installation, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Point and Print for clients running Windows NT 4.0 and earlier versions of Windows**

Setting up printer drivers on a print server running Windows Server 2003 to support Point and Print is generally the same for clients running Windows NT 4.0 and earlier versions of Windows as it is for clients running Windows 2000 or Windows XP. However, you may encounter some specific differences.

You can select the printer driver versions to install on the print server on the **Drivers** tab of the **Server Properties** property sheet, or, when you install additional drivers using the Add Printer Driver Wizard, in the **Additional Drivers** dialog box shown in Figure 3.4.

**Figure 3.4 Additional Drivers Dialog Box**

Before you load any additional drivers on x86-based systems, one of three printer driver versions is selected by default,

represented by the three following options:

- **Windows 2000, Windows XP, or Windows Server 2003.** If this option is selected before you load any additional drivers, it indicates that the server is running a Version 3 driver written specifically for the Windows 2000, Windows XP, or Windows Server 2003 platform. You cannot send that driver to a Windows NT 4.0 client for Point and Print functionality. You need to add a Version 2 driver to support Point and Print on Windows NT 4.0 client computers.

- **Windows NT 4.0.** This option indicates that a Windows NT 4.0 Version 2 driver is running on a server that is running Windows 2000 or Windows Server 2003. No additional drivers are required to support Point and Print on Windows NT 4.0–based client computers.

- **Windows 95, 98, or Windows Millennium Edition.** If this option is selected, users can connect to and download the existing driver from the server. However, those clients will not receive automatic updates when the driver on the server is updated.

**Point and Print for servers running Unidrv Version 3 drivers**

When a Version 3 driver written specifically for the Windows Server 2003 or Windows 2000 platforms is installed on the server, you must install a Version 2 driver with the same model name on Windows NT 4.0 clients in order to support Point and Print. Changes in the internal data structures between the Version 2 and Version 3 Unidrv.dll can cause problems in sharing or preserving settings between the clients and the server. These problems primarily manifest themselves in two ways:

- New or advanced settings on the Print Server might not be visible from the property sheet of a client printer.

- The print server might not correctly interpret the client printer properties, causing the properties to be lost. As a result, the Point and Print connection allows the client to print, but might not allow modification of certain device settings or preferences if they do not match those on the server.

### Note

- Incompatible data structures can cause certain printer settings — such as **Print Text as Graphics** or **Print Optimization** — to be lost between computers running Windows NT 4.0 and computers running Windows 2000. Additionally, settings such as paper tray assignments and media types might not be preserved between driver models.

# Choosing the Print Server Installation Method

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Print server installation includes installing or upgrading to the Windows Server 2003 operating system and creating or migrating printers. The type of installation that you choose depends on your existing printing environment. If you have new servers with no operating system installed, you must perform a clean installation of the Windows Server 2003 operating system. If you have existing servers, you can perform a clean installation or, if the server is running Windows 2000 or Windows NT 4.0, you can upgrade.

Other considerations might also play a part in your decision. For example, some organizations have software standards that prohibit upgrading the operating system on servers. These organizations choose to perform only clean installations. With a clean installation, you can install the latest printer drivers from the independent hardware vendor (IHV), thus eliminating older, potentially problematic drivers.

Consider the following points when choosing between a clean installation and an upgrade.

**Choosing a clean installation**

- In a clean installation, you must create all new printers or migrate existing printers.
- If you want to practice good print queue management (for example, by complying with the company's print queue naming conventions), you might want to perform a clean installation instead of upgrading a server.

**Choosing to upgrade**

- Configuration is simpler when you upgrade. You retain your existing print queues, drivers, and ports, minimizing the impact on users.
- You might encounter interoperability issues with your existing printer drivers.

# Choosing a Print Server Migration Method

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you decide that a clean installation of Windows Server 2003 is best for your organization, you must also decide if moving some of your existing printers from other print servers makes sense. Migrating a print server is a method of moving existing printers onto your new server. If you intend to add new print servers to your existing environment, consider migrating some of your existing print servers to these new, typically more powerful servers to take full advantage of your improved hardware resources.

Three approaches are available for migrating existing print server configurations:

- Manual migration
- Automated migration
- Partially automated migration

**Manual Print Server Migration**
A manual print server migration requires that you document the current printing environment on your existing Windows print servers (including ports, printer names, share names, and driver models and versions). Then, using the Add Printer Wizard, recreate each printer on your new Windows Server 2003 print servers. The advantage of this method is that you can create all of the queues by using the most recent corporate standard and the newest available driver versions. The disadvantage is that this method can be very time consuming for large print environments — and it is more error-prone than the automated method.

**Automated Print Server Migration with Print Migrator**
Microsoft has developed a printer migration utility called Print Migrator, which can back up and restore print server configurations with minimal user intervention. Print Migrator handles the migration of print queues, drivers, and printer ports. You can also use Print Migrator to consolidate print servers.

Print Migrator does not change the driver versions when moving printers to the Windows Server 2003. For example, Print Migrator copies any Version 2 drivers used on a Windows NT 4.0 print server and recreates them on the new Windows Server 2003 print server. This process provides a much higher level of interoperability with any Windows NT 4.0 clients that might still be using print services from that server. To download Print Migrator, see the Print Services link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Note**

- Print Migrator ships with documentation about its operation and use. Review the material carefully for more details about this tool's capabilities and limitations.

The newest version of Print Migrator, Print Migrator 3.0, provides the following functionalities:

- Version support across operating systems
- Cluster support
- Port conversion from Line Printer Remote (LPR)-to-standard port monitor (standard TCP/IP port monitor)

**Version support across operating systems**
Differences in the way that Version 3 and Version 2 drivers work present interoperability issues when you migrate printers across versions of the Windows operating system. Cross-version support in Print Migrator 3.0 ensures successful migration from Windows NT 4.0 to Windows 2000 or Windows Server 2003.

**Cluster support**
Print Migrator 3.0 also supports migrating your print cluster from a server running Windows NT 4.0 or Windows 2000 to a print server running Windows Server 2003.

**LPR to standard TCP/IP port conversion**

If your print servers currently have LPR ports, consider converting the ports to standard TCP/IP ports. The standard TCP/IP port is the preferred printer port in Windows Server 2003. You can use other printer ports with Windows Server 2003, but they offer limited functionality.

**Partially Automated Print Server Migration**

Administrators can migrate printers by using a combination of manual and automated methods. Scripts supported by Windows 2000, Windows XP, and Windows Server 2003 can perform most of the necessary tasks. For more information about using scripts to partially automate your migration, see "Managing printing from the command line" in Help and Support Center for Windows Server 2003.

# Identifying Interoperability Issues with Print Server Upgrades

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Upgrading print servers from previous versions of Windows can present interoperability issues because of changes in the printer driver model beginning with Windows 2000 and continuing with Windows Server 2003. For more information about driver compatibility, see "Designing for Printer Driver Compatibility" earlier in this chapter.

To handle driver-related issues more easily, use the command-line utility Fixprnsv.exe, a powerful tool for working with printer driver issues on printer servers that are running Windows NT 4.0, Windows 2000, or Windows Server 2003. The Fixprnsv.exe identifies incompatible drivers before you upgrade, finds all known bad drivers on your system, and identifies Version 2 drivers that work properly with Windows Server 2003.

The Windows Server 2003 installation CD-ROM includes Fixprnsv.exe. The executable file is located in Windows\Printers directory. To view a list of commands used with this utility, use the command **fixprnsv.exe /?** from that directory.

For more information about specific compatibility issues involved in upgrading from Windows NT or Windows 2000, see "Deploying Print Servers with Upgrade Installations" later in this chapter.

# Choosing an Installation Method for Clustered Print Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Several options are available for upgrading a clustered print server. You can use any of the following methods:

- Upgrade a cluster that is running Windows NT Server 4.0, Enterprise Edition with Service Pack 4 or later.
- Upgrade a cluster that is running Microsoft Windows 2000 Advanced Server or Microsoft Windows 2000 Datacenter Server.
- Perform a clean installation of Windows Server 2003, Enterprise Edition and at the same time upgrade an existing stand-alone server to a server cluster.

**Upgrading a Windows NT 4.0 Server Cluster**

You cannot perform a rolling upgrade (upgrading the nodes sequentially) directly from Windows NT Server 4.0, Enterprise Edition to Windows Server 2003, Enterprise Edition. Instead, you have two options:

- Perform a nonrolling upgrade directly from Windows NT 4.0, Enterprise Edition with Service Pack 4 or later to Windows Server 2003, Enterprise Edition by taking the cluster resources offline and upgrading each node. With a nonrolling upgrade, you cannot maintain cluster availability during the upgrade.
- To maintain cluster availability, perform a rolling upgrade to Windows 2000 and then perform a second rolling upgrade to Windows Server 2003.

  To perform the rolling upgrade to Windows 2000, first move all of the cluster resources from the target node to other nodes. Install Windows 2000 Advanced Server or Windows 2000 Datacenter Server on the target node, and move the cluster resources back to the newly upgraded cluster node. Then install Windows 2000 Advanced Server or Windows 2000 Datacenter Server on the remaining nodes in the cluster.

  Complete the rolling upgrade by following the same process to install Windows Server 2003 on your cluster.

**Upgrading a Windows 2000 Server Cluster**

The easiest method for upgrading a Windows 2000 Server cluster is to perform a rolling upgrade. A rolling upgrade has two major advantages:

- Clients experience minimal interruption of service. (However, server response time might increase during the phases in which fewer nodes handle the work of the entire cluster.)
- You do not have to recreate your cluster configuration, because the configuration remains intact during the upgrade process.

**Upgrading an Existing Stand-Alone Server to a Cluster**

To upgrade an existing stand-alone print server to a print server cluster, use Print Migrator 3.0 to back up and restore the print server configurations to the newly created server cluster. You must create the cluster first, before adding the print spooler resource.

Additional hardware requirements exist for using the Windows Cluster service. For a list of supported cluster hardware, see the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources and search for "cluster."

**Note**

- Only Standard TCP/IP ports and LPR ports are supported on a server cluster.

For more information about clustering, see "Designing and Deploying Server Clusters" in this book.

# Determining the Print Server Network Connection Method

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After installing Windows Server 2003, choose one of the following three methods to connect your print servers to the network:

- Whenever possible, use the standard TCP/IP port, also know as the *standard port*. The standard port is the preferred printer port in Windows Server 2003.
- For older devices that do not function correctly with the standard port, use the Line Printer Remote (LPR) port.
- To connect to printers over the Internet or an intranet, use the Internet Printing Protocol (IPP).

When creating printer ports, Windows Server 2003 installs the associated port monitor for that port type.

**Connecting Through the Standard TCP/IP Port**
The standard port is designed for Windows Server 2003–based print servers that use TCP/IP to communicate with printing devices, including network-ready printers, network adapters such as Hewlett-Packard JetDirect, and external print servers such as Intel NetPort. The standard port uses the standard TCP/IP port monitor (TCPMon.dll), also known as the *standard port monitor*. The standard port monitor can support many printers on one server. It is faster and easier to configure than the LPR Port Monitor (Lprmon), and it provides rich status information and error condition reporting that eases administration of your print servers.

The standard port monitor uses Simple Network Management Protocol (SNMP) and the standard printer message information base as defined in RFC 1759, "Printer MIB." As a result, the standard port monitor provides much more detailed status information than does LPR when, for example, the printer generates an error indicating a paper jam or low toner, or a print job is not responding and must be purged.

Although Windows Server 2003 requires TCP/IP on the print server in order to communicate with the printer, clients do not need TCP/IP. Because clients communicate with the print server rather than with the printer, they can do so using any common network protocol.

For example, a Novell NetWare client might use the Internetwork Packet Exchange (IPX) protocol to send documents to a Windows Server 2003 print server. The server then passes the document to the printer using the TCP/IP protocol. Status and error information is relayed from the printer to the print server using TCP/IP, and from the print server to the client using IPX.

**Connecting Through the LPR Port**
The LPR port uses the LPR monitor **Lprmon**, which is provided with Print Services for UNIX. The LPR port acts as the client for printing according to guidelines defined in RFC 1179, "Line Printer Daemon Protocol." The LPR port spools to a target host enabled for Line Printer Daemon (LPD). The target is usually a computer running one of the following:

- UNIX
- Multiple Virtual Storage (MVS)
- Virtual Address Extension (VAX)/Virtual Memory System (VMS)

However, the target alternatively can be one of the following:

- A printer with a network adapter that supports LPD
- An external print server
- A computer running Windows XP Professional, Windows Server 2003, Windows 2000, or Windows NT
- A print server running Print Services for UNIX or another version of LPD.

Before you can create an LPR port, the client must have TCP/IP and Print Services for UNIX installed. The target server must be running a Berkeley Software Distribution (BSD)–compatible LPD utility that is installed according to RFC 1179. If the server is running Windows Server 2003, Windows 2000, or Windows NT 4.0, make sure that Print Services for UNIX is started.

**Using the Internet Printing Protocol (IPP)**

You can make Windows Server 2003 printing features accessible over the Internet. To install a printer over the Internet, use the printer's URL as the name of the printer. Within an intranet, you can alternatively use the printer's share name (for example, http://*servername/sharename*).

If you are connecting to a print server on the same intranet, it is recommended that users' intranet security settings for Microsoft® Internet Explorer be set to medium-low or lower. Having this setting throughout an intranet creates a true Point and Print connection, which offers many advantages over an IPP connection. You can view, connect to, and manage printers from any browser. On clients running Windows 95, Windows 98, or Windows Millennium Edition, you must install the Web Client in order to manage printers by using a browser. For clients running Windows NT 4.0, you can manage printers from a browser, but cannot connect to them for printing.

To configure a computer to print to a printer by using a URL address, perform the following procedure.

**To configure a computer to print to a printer by using a URL address**

1. Install Microsoft Internet Information Services (IIS) on a computer that is running Windows XP Professional

   or

   Install Microsoft Peer Web Services (PWS) on a computer running Windows 2000 Professional.

2. Install IIS on a print server that is running Windows Server 2003.

   The low-level protocol used for job submission is Internet Printing Protocol (IPP) version 1.0, which uses the Hypertext Transfer Protocol (HTTP) protocol as a carrier.

3. Ensure that all clients use Internet Explorer version 4.0 or later to connect to a printer.

For information about Internet Printing, see "Internet Printing" in Help and Support Center for Windows Server 2003.

# Planning for Print Server Security

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Planning for print server security is vital in order to protect your organization's resources. As with any production server, you need to protect the physical print server and safeguard access to data stored on the server. Consequently, your security plan must address three areas:

- Physical location
- Group Policy settings
- Printer permissions

**Ensuring the Physical Security of Each Print Server**

Locate your print servers in a physically secure location that only designated individuals can access. Allowing unauthorized access to your print servers risks harm to the system. In addition, consider to what extent you also need to restrict physical access to network hardware. The details of implementing these security measures depend on your physical facilities as well as your organization's structure and policies.

**Securing the Print Environment**

Windows Server 2003 adds new Group Policy settings that affect how clients connect to print servers on the network. Two of these policy settings are particularly useful for security.

**Allow print spooler to accept client connections** This Group Policy setting, which is configured on the server, determines how clients access the print server over the network. If an individual with administrative credentials creates shared printers for use by managed clients, the spooler automatically allows connections upon creation of the first shared printer. If a virtual spooler resource is created on a clustered server, the spooler likewise automatically allows connections. If no shared printers or virtual spooler resources already exist, you might need to enable this policy setting by using the Computer Management snap-in from a remote computer. To administer print services on a server running Windows Server 2003, log on to the server locally, or log on remotely through a Remote Desktop session.

**Point and Print restrictions** This Group Policy setting, which is configured on client computers, determines the print servers to which the client can connect. To provide a higher level of security for managed workstations, this policy setting controls a client computer's ability to connect to and install a printer driver from specified print servers. By default, managed clients can use Point and Print only with servers that are within their forest. An administrator can use this policy to add additional servers to the list of trusted print servers. Alternatively, administrators can disable this policy to enable managed clients to connect to any accessible print server and install a printer driver from it.

**Using Printer Permissions to Control Access to Shared Printers**

Even if the physical server is in a secure room, the print server might still be accessible through remote administration tools. Therefore, you need to implement methods for restricting access to remote administration of print servers. You can restrict access to a print server by setting printer permissions.

You might also want to restrict access to a particular network printer. For example, the graphics department in your organization might use a high-speed color printer regularly. The cost of supplies for a color printer is substantially higher than for a black-and-white printer, so you decide to deny access to anyone outside the graphics department. The best way to restrict access is to establish a new security group. You establish a group named Graphics Department, and grant access only to members of this group.

For a procedure describing how to restrict access to printers by using printer permissions, see "Restricting Access to Printers" later in this chapter.

# Testing the Print Server Design

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Testing is a key part of designing your print environment. Before you deploy your print servers in a production environment, make sure that your users can print successfully in a test environment. In most cases, thorough testing of your print servers during the design phase minimizes any impact on your users' ability to print.

It is recommended that you conduct testing in two stages. During the first stage, test your Windows Server 2003 deployment in a laboratory or controlled environment. After verifying that your design is successful in the lab, conduct a pilot deployment in a controlled real-world environment in which users perform their normal business tasks using the new printing features. This two-stage approach reduces your risk of encountering problems during full-scale deployment.

Before conducting the tests, make sure that the computers used in your pilot test run the same operating systems that you have in your production environment, and that the appropriate drivers are installed.

The following are some typical scenarios that you might want to test:

- If you list your printers in Active Directory, make sure that all the printers appear as choices when users try to add a network printer.

- Make sure that all users participating in the pilot test can print after connecting to each of the printers on the new servers.

- Have several users send various print jobs to the print server to measure how well the server holds up under a typical load.

- If you implement default printer location strings by using Group Policy objects, verify that these Group Policy settings are working as expected for the various groups to which they are assigned.

  For more information about Printer Location Strings, see the *Server Management Guide* of the *Windows Server 2003 Resource Kit* (or see the Server Management Guide on the Web at http://www.microsoft.com/reskit).

- If you use the standard port monitor with SNMP enabled, let the printer run out of paper to ensure that you receive an "out of paper" message when you send the next print job. For more information about standard port monitor, see "Determining the Print Server Network Connection Method" earlier in this chapter.

- If you set up a print server cluster, turn off one of the servers and see if the resources fail over to the other nodes. For more information about initiating a resource failure, see "Initiate a resource failure in Help and Support Center for Windows Server 2003.

# Deploying Print Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After your design team completes its work, the print server deployment team can implement the design for your new printing environment. Deploying print servers involves installing Windows Server 2003 on the servers, adding the servers to the network, and then adding the printers. Organizations that plan to deploy clustered print servers must take the additional step of configuring the clusters before creating the print spooler resource.

Figure 3.5 shows the tasks involved in deploying print servers.

**Figure 3.5 Deploying Print Servers**

# Installing Windows Server 2003 on Print Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The details of the print server deployment process vary depending on whether your design specifies a clean installation or an upgrade installation. If you are upgrading existing stand-alone or clustered servers, the upgrade process also differs depending on the version of the Windows operating system installed on your existing print servers.

# Deploying Print Servers with Clean Installations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you deploy print servers with clean installations of Windows Server 2003, you can decide whether to create new printers or migrate existing printers to the new servers. If you create new printers, you can enforce the standard printer naming convention that the design team developed during the design phase. If you have existing printers, it is a good idea to migrate them by using Print Migrator 3.0.

**Setting Up a New Print Server**

The first step in setting up a new print server is to install and configure Windows Server 2003. Identify each operating system that the printer server must support to determine any special selections that you must make while setting up your server. For example, if you support computers running Windows NT 4.0, you must install additional drivers during the upgrade process. After installing Windows Server 2003, you can begin adding printers.

**Migrating Printers by Using Print Migrator 3.0**

By using Print Migrator 3.0, you can back up your current print server configuration and restore the settings on a new print server, eliminating the need to manually recreate print queues and printer ports, install drivers, and assign IP addresses. Having to manually perform these tasks is a significant obstacle for most organizations. Using Print Migrator greatly reduces the manual intervention required when migrating your print servers from previous versions of Windows.

For example, an administrator obtains three new high-end servers to use as print servers. Rather than manually configure each server, the administrator uses Print Migrator 3.0 to back up three of the existing print servers and then restores the settings on the new servers. For more information about Print Migrator 3.0, see "Choosing a Print Server Migration Method" earlier in this chapter.

To ensure that your printer migration goes smoothly, read the documentation provided with Print Migrator 3.0.

# Deploying Print Servers with Upgrade Installations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Deploying an upgraded installation of Windows Server 2003 can be a simple process depending on the printer drivers installed on your servers. One of the biggest challenges of upgrading is resolving any printer driver problems. Before upgrading your servers, use the command-line utility Fixprnsv.exe, provided with Windows Server 2003, to help you identify any printer driver problems. If you are upgrading from Windows NT 4.0 or Windows 2000, consider the issues presented in the following sections.

**Important**

- As with any major software installation, it is recommended that you back up the hard disk before beginning an upgrade.

**Using Fixprnsv.exe to Resolve Driver Issues**

To manage driver-related issues, use the command-line utility Fixprnsv.exe. Fixprnsv.exe automatically replaces incompatible printer drivers or those with known problems. It locates existing printer drivers that can replace unsuitable drivers. In many cases, IHVs provide new printer drivers for this purpose. If replacement drivers are available, Fixprnsv.exe replaces problem drivers with Microsoft-provided drivers. If Fixprnsv.exe does not find a suitable replacement driver, it displays a message advising you to check the printer manufacturer's Web site for a newer version of the driver. Fixprnsv.exe installs drivers only for printers that are already configured on the print server.

The Fixprnsv.exe utility is located on the Windows Server 2003 installation CD-ROM in the \Windows\Printers\ directory. For a list of commands for use with Fixprnsv.exe, use the following procedure.

**To list the commands for Fixprnsv.exe**

1. Insert the Windows Server 2003 installation CD-ROM in the CD-ROM drive.

2. At the command prompt, change to the drive that contains the CD-ROM and type:

   **fixprnsv.exe /?**

**Upgrading from Windows 2000**

If you are upgrading a Windows 2000 print server that does not have Version 2 device drivers installed, your upgrade can be seamless. If your Windows 2000 print server has Version 2 drivers, you might encounter some of the issues involved in upgrading from Windows NT 4.0, which are discussed in the following section.

**Upgrading from Windows NT 4.0**

When upgrading from Windows NT 4.0 to Windows Server 2003, one or more of the following situations might occur:

- Windows NT 4.0 drivers that shipped with the operating system are upgraded to the new version of these drivers in Windows 2000, Windows XP, or Windows Server 2003. The Windows NT 4.0 driver remains as an additional driver.

- If the name of an IHV driver matches the name of a driver that ships with Windows 2000, Windows XP, or Windows Server 2003, the installation might upgrade the driver to the a Version 3 inbox driver (a driver that ships with Windows Server 2003). This upgrade occurs with no user intervention.

- Unstable drivers are blocked and are not carried through the upgrade. Printers that use these drivers are removed during the upgrade process. If the printer is connected directly to the computer and has a recognized Plug and Play ID, Windows searches for a suitable driver. If a suitable driver is found, the printer is installed during the upgrade as a new printer.

- Drivers that are not blocked and do not have name matches are carried through the upgrade unchanged.

**Windows NT 4.0 inbox drivers**

All Windows NT 4.0 Printer Control Language (PCL) drivers and Raster Device Drivers (RASDD) are upgraded to the latest Unidrv drivers as part of the upgrade process. The latest Unidrv drivers include UNIDRV5 for Windows 2000, and UNIDRV5.1

for Windows XP or Windows Server 2003. PostScript drivers that were shipped with Windows NT 4.0 are automatically upgraded to PostScript 5.0 in Windows 2000 or PostScript 5.2 in Windows XP or Windows Server 2003.

**Note**

- Drivers that you have installed as additional drivers for Point and Print on clients running Windows 95, Windows 98, or Windows Millennium Edition are not preserved during an upgrade from Windows NT 4.0 to Windows 2000 or Windows Server 2003. After you configure the print server, you must reinstall these additional drivers.

**IHV drivers with matching names**

IHV Windows NT 4.0 drivers are upgraded to Windows 2000, Windows XP, or Windows Server 2003 drivers with no user intervention if the driver name matches the existing Windows NT 4.0 driver name or if a newer version of the driver is available. In this situation, the IHV driver is treated exactly the same as the Microsoft driver.

Because of interaction problems between Windows 2000 drivers and Windows NT 4.0 drivers in Point and Print environments, many IHVs recommend that you reinstall their Windows NT 4.0 driver following the upgrade. This applies to users who plan to use Point and Print between Windows NT and Windows 2000, Windows XP, or Windows Server 2003.

**Blocked IHV drivers**

Microsoft designed the upgrade path from Windows NT 4.0 so that the new operating system replaces an old driver if a newer driver is available. Windows preserves a driver during an upgrade if the installation utility does not find a newer version and does not identify a driver as causing problems in Windows 2000, Windows XP, or Windows Server 2003. A driver is blocked for one of two reasons:

- Microsoft determines, through testing, that the driver causes substantial instability of the operating system.
- The IHV requests that the driver be blocked based on the IHV's own testing and available updates.

The system file Printupg.inf contains a list of known bad drivers. Drivers in this list might have an alternative inbox driver. If an alternative driver does not exist, the driver is not upgraded during the operating system installation. Instead, you need to install a newer version of the driver from the IHV. The information found in Printupg.inf can be helpful in identifying whether or not a new version from an IHV is blocked. The upgrade report also contains information about all drivers slated for removal during the upgrade.

In addition, the Fixprnsv.exe tool automatically replaces known bad drivers if inbox substitutes are available. If a compatible driver cannot be located, Fixprnsv.exe reports that fact and refers the user to the IHV's Web site. By running Fixprnsv.exe prior to upgrading, you can identify printers that are slated for deletion during the upgrade ahead of time. Otherwise, you might discover after the upgrade that some printers are unexpectedly missing.

**Non-blocked IHV drivers**

Certain Windows NT 4.0 drivers are not blocked and do not match the driver name of an inbox driver. These drivers proceed through the upgrade process without being altered or replaced. Use Fixprnsv.exe to identify drivers that must be replaced. For drivers that are not blocked (either because they are not in the Printupg.inf file or because they have a later date than the date of similar drivers listed in Printupg.inf), Fixprnsv.exe takes no action.

# Adding Printers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After installing Windows Server 2003 on the print server, you must add the printers to the server. Depending on the decisions that the design team made, adding printers can involve the following steps:

- Adding spooler resources to server clusters
- Installing printer ports
- Adding additional printer drivers
- Publishing printers in Active Directory
- Connecting clients to printers
- Restricting access to printers
- Setting up Internet printing

# Adding Spooler Resources to Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In order to add printers to server clusters, you first need to create and configure print spooler resources. After creating the spooler resource, you can add printers, publish them in Active Directory, and add any additional drivers that your users require. You must also create and specify the spooler resource in order to use Print Migrator 3.0 to restore printers from another print server.

**Creating a Spooler Resource**
To create a spooler resource for a cluster, you must be the administrator of the cluster as well as of each node within the cluster. You must also have the administration software installed on your computer. Cluster Administrator is the graphical application that is supplied with the Cluster service to manage clusters. Alternatively, you can use Cluster.exe, a command-line tool, or develop custom administration tools by using the Cluster service command interfaces. Cluster Administrator is included in the Administrative Tools Pack (Adminpak.msi). The Cluster.exe tool and Adminpak.msi files are located in the Windows\System32 directory of a Windows 2003 Server.

The procedure for creating a print spooler resource is like the procedure for creating any resource in a cluster service. For more information about creating a cluster-managed printer, see "Create a cluster-managed printer in Help and Support Center for Windows Server 2003.

After you create the print spooler resource, migrate existing printers from existing print servers, if necessary, by using Print Migrator 3.0. For more information about Print Migrator, see "Choosing a Print Server Migration Method" earlier in this chapter.

**Configuring the Resource**
Configure the spooler resource by selecting the print spooler resource type in the Cluster Administrator window or by using Cluster.exe. Each cluster group can have only one print spooler resource, because resources are organized into interdependent groups that must fail over together.

After you create and configure the print spooler resource, you might need to install any third-party port monitors and print processors that are cluster-compatible on each node of the cluster. To do this, take each spooler resource offline, and then bring it online again so that the new resource is visible to the cluster. Then add printers to the clustered spooler. For more information about printing and the Cluster service, see "Print Spooler resource type" in Help and Support Center.

**Adding a Printer to a Cluster**
After creating a group and resources, you can add printers to the cluster. Each node must have connectivity to the remote print device. A printer that is locally connected to a node cannot be part of a cluster configuration, because the printer connects directly to the node and does not fail over if that node goes down.

Adding a printer to a cluster is very similar to adding the printer to any other computer, with the following exceptions:

- You never start from the local **Printers and Faxes** folder. The cluster always appears remote, even if you are working on the active cluster node. Instead type the virtual server name (for example, \\Virtual_Server_Prn) in the **Run** dialog box, and then click the remote **Printers and Faxes** folder that is displayed.

- If the Add Printer Wizard does not appear when you open the remote **Printers and Faxes** folder, you cannot continue. One of three things might be wrong:

    - The associated print spooler resource is not online or is not configured

    - You are not logged on as the administrator.

    - The spooler service is not started on the local computer. (This is unlikely.)

When a cluster group containing a print spooler resource fails over to another node, the document that is currently being sent to the printer is restarted on the other node after the failure. When you move a print spooler resource or take it offline, Cluster service waits until all documents are spooled or the configured wait time elapses. The cluster discards any documents that are submitted while the spooler resource is unavailable or the cluster is offline, and users must resubmit those print jobs.

For more information about clustering, see "Designing and Deploying Server Clusters" in this book.

# Installing Printer Ports

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If your users print over a network, you must create printer ports to enable connections between print servers and printers. You can install printer ports for stand-alone servers and clusters from the Printers and Faxes folder on the print server. The printer port can be one of two port types:

- Standard TCP/IP port
- LPR port

If you are using clustered print servers, you need to install the printers on each node and ensure that each node has the appropriate protocols, port monitors (not ports), and print processors installed. You can do this remotely, but you must address each node by its node name, not the cluster name. Ensure that the settings on all nodes are identical, because a specification made on one node does not carry over to the other nodes.

**Standard TCP/IP Port**

The standard port is the preferred printer port in Windows Server 2003. The standard port uses the standard TCP/IP port monitor (standard port monitor) and is designed for Windows Server 2003–based print servers that communicate with printers by using TCP/IP. For more information about the advantages of using the standard port and the prerequisites for installing a standard port, see "Determining the Print Server Network Connection Method" earlier in this chapter.

**To install a standard port**

1. In Control Panel, open the **Printers and Faxes** folder, right-click the printer that you want to configure, and click **Properties**.
2. On the **Ports** tab, click **Add Port**.
3. In the **Printer Ports** dialog box, select **Standard TCP/IP port**, and click **New Port** to launch the **Add Standard TCP/IP Printer Port Wizard**.
4. Complete the **Add Standard TCP/IP Printer Port Wizard by** using the information provided in Table 3.3.

   **Table 3.3 Using the Add Standard TCP/IP Printer Port Wizard**

   | Wizard Page | Action |
   |---|---|
   | Printer Name or IP Address | To identify the printer that will be connected to the port, type its name in the **Printer Name** or its IP address in the **IP Address** box. |
   | Port Name | In the **Port Name** box, type a port name, which can be any character string, or use the default name that the wizard supplies. |
   | Additional Port Information Required | To configure a standard port, click **Standard**, and then select one of the listed devices. If you do not know the details of the port, try using the **Generic Network Card**.<br><br>To create a custom configuration, click **Custom**, and then configure the port by using the **Configure Standard TCP/IP Port Monitor** screen that appears. |

   If the wizard cannot determine the appropriate protocol for the port, it prompts you for the information. Follow the vendor's instructions for selecting either the RAW or LPR option.

   If you are not prompted for more information, continue to step 5.

5. Review the port information, and click **Finish**.

The new port is listed on the **Ports** tab of the **Properties** property sheet.

**Note**

- With Windows Server 2003, administrators can remotely configure and manage ports from any server running Windows Server 2003. This feature applies to local ports, the standard TCP/IP port, and LPR ports. You must configure AppleTalk ports locally on the server.

You can reconfigure the standard port monitor by adjust the settings in the property sheet for the print server.

**Caution**

- The Configure Port dialog box does not validate the settings created in the following procedure. If they are incorrect, the port no longer works.

**To reconfigure the standard TCP/IP port**

1. In Control Panel, open the **Printers and Faxes** folder, right-click the appropriate printer, and click **Properties**.
2. On the **Ports** tab, click the **Configure Port** button.
3. In the **Configure Standard TCP/IP Port Monitor** dialog box, click either the RAW or LPR protocol.
4. To configure the protocol, take one of the following actions:
   - For **RAW Settings**, type the port number that the printer vendor specified (usually 9100).
   - For **LPR Settings**, type the LPR queue name that the printer vendor specified.
5. If the printer supports SNMP and RFC 1759, select the **SNMP Status Enabled** check box.
6. If **SNMP Status Enabled** is selected, you can change both the SNMP community name and the host device index:
   - The community name is usually "Public," but you can enter another community name if you want to limit access to the printer.
   - The device index is used mainly for multiport devices that support several printers; each port on a multiport device has a different device index, specified by the device vendor.

**LPR Port**

If your network includes clients that are running UNIX, install LPD, which acts as the client for printing according to RFC 1179 guidelines. For more information about the LPR port, see "Determining the Print Server Network Connection Method" earlier in this chapter.

**To install an LPR port**

1. In Control Panel, open the **Printers and Faxes** folder.
2. Under Printer Tasks, click **Add a printer** to open the **Add Printer Wizard**. Then click **Next**.
3. Complete the **Add Printer Wizard** byusing the information provided in Table 3.4.

**Table 3.4 Steps for Completing the Add Printer Wizard**

| Wizard Page | Action |
|---|---|
| Local or Network Printer | Click **Local printer attached to this computer**, clear the **Automatically detect and install my Plug and Play printer** check box, and then click **Next**. |
| Select a Printer Port | Click **Create a new port**, and then select **LPR Port**. |
| Add LPR compatible printer | If **LPR Port** is not available, click **Cancel** to stop the Wizard. To add the LPR Port, install the optional networking component, **Print Services for UNIX.** |
| Name or address of server providing LPD | Type the Domain Name System (DNS) name or Internet Protocol (IP) address of the host for the printer that you are adding. The host might be the direct-connect TCP/IP printing device or the UNIX computer to which the printing device is connected. The DNS name can be the name specified for the host in the Hosts file. |
| Name of printer or print queue on that server | Type the name of the printer as it is identified by the host, which is either the direct-connect printer itself or the UNIX computer. |

**Configuring LPR to print text files to a PostScript printer in UNIX**

In some cases, sending an ASCII text file to a PostScript printer on a UNIX-based computer can cause PostScript code to be output on the printer. This can occur because the PostScript printer is processing the text as RAW data without interpreting the PostScript code.

LPR sends a processing instruction in each print job in the form of a control command indicating the data format. Table 3.5 shows the LPR commands for specific data types. Under **Lprmon**, the default is **l** (RAW data); under Lpr.exe, the default is **f** (text).

**Table 3.5 Control Commands for LPR Printing**

| LPR Control Command | Data Format Transmitted |
|---|---|
| f, p | Text data type |
| L | RAW data type |
| O | RAW data type formatted for a PostScript printer |

Using the default value of **l** can cause the PostScript code to be printed on a UNIX-based system. The **l** value sets the RAW data type, which causes the text file to be printed ignoring the PostScript instructions. To correct this, set **0** (RAW data type formatted for a PostScript printer) as the default value. This might not be necessary on some UNIX systems, which include software that scans arriving documents for PostScript code with the **l** value. If the software detects the **l** value, the document goes directly to the printer; otherwise, the software adds PostScript code. You can change the default control command that LPR sends by editing the **PrintSwitch** entry in the registry.

**Caution**

- Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Windows Server 2003 Resource Kit Registry Reference on the *Windows Server 2003 Deployment Kit* companion CD, or at http://www.microsoft.com/reskit.

**To change the default control command for a printer**

1. In the registry editor, navigate to:

   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Print \Monitors\LPRPort\Ports\Port-name\IP Address or Host name: Printer-name

2. Double-click **PrintSwitch**.

3. In the **Data type** box, type REG_SZ, and then in the **Value Data** box, type the control command you want to specify. (See Table 3.5 for a list of control commands and the value data types that they represent.)

**Respooling**

*Respooling* is a method of spooling a document twice to enable the print monitor to locate the appropriate LPD print server. LPR must include an accurate byte count in the control file, but it cannot get the byte count from the local print provider. After Lprmon receives a document from the local print provider, it spools the document a second time to a temporary file in the default spool directory, finds the size of that file, and then sends the size to the LPD print server.

**Status reporting**

LPR is a one-way protocol and does not return a detailed error status report. If a problem occurs, the message is always ERROR. For more information about LPR or LPR errors, see the Microsoft Knowledge Base link on the Web Resources page at www.Microsoft.com/windows/reskits/webresources. Search the Knowledge Base using the keywords "LPR" or "LPR Errors".

**Pooling printers**

Printer pooling is especially useful in high-volume printing environments. Pooled printers appear to clients as a single printer, but printing throughput is increased because the load is distributed among the printers in the pool.

Before you set up a printer pool, consider the following issues:

- Two or more printers are required; Windows Server 2003 does not limit the number of printers in a pool.
- The printers in the pool must be of the same model, and they must use the same printer driver.
- Printer ports can be of the same type or mixed (such as parallel, serial, and network).
- If you want to ensure that documents are first sent to the faster printers, add the faster printers to the pool first and the slower printers last. Print jobs are routed in the order in which you create the ports.
- Because users do not know which printer prints their documents, it is a good idea to locate all of the pooled printers in the same physical location. Otherwise, users might not be able to find their printed documents.

**To create a printer pool**

1. In Control Panel, open the **Printers and Faxes** folder, right-click the appropriate printer, and click **Properties**.
2. On the **Ports** tab, select the **Enable printer pooling** check box.
3. In the list of ports, select the check boxes for the ports connected to the printers that you want to pool.
4. Repeat steps 2 and 3 for each additional printer to be included in the printer pool.

# Adding Additional Printer Drivers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By adding additional drivers to your print server, you can support clients that are running various versions of the Windows operating systems. It is preferable to use Version 3 drivers rather than Version 2 drivers as your primary drivers, because Version 2 drivers can cause the system to become unstable or stop responding. However, you might need to use Version 2 drivers as additional drivers if you support clients running Windows NT 4.0. If your server has known bad drivers when it is upgraded, those drivers are deleted during the upgrade process. Any additional drivers that are added must have the same name as the primary driver unless they are Windows 95, Windows 98, or Windows Millennium Edition drivers.

**Note**

- With Windows Server 2003, you no longer need to install printer drivers on each node of a cluster. The drivers automatically propagate to the other nodes of the cluster after they are installed on the virtual server.

# Publishing Printers in Active Directory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Publishing your shared printers in Active Directory can make locating printers across a network more efficient for your users. In Windows Server 2003, the print subsystem is tightly integrated with Active Directory, making it possible to search across a domain for printers at different locations. By using the standard printer object that Windows Server 2003 provides, you enable users to search for printer-based attributes such as printing capabilities (including PostScript, color, and paper size) and printer locations (allowing users to find printers located near them).

If you plan to publish printers to Active Directory, follow the naming standard that the print services design team created when you fill out the location fields on the printer properties pages across your network. This enables users to enter a standard string to search for printers by location. If you use subnets to define the sites within your organization, Active Directory can find nearby printers – a process that has formerly been difficult for both administrators and users.

For example, if you are in Los Angeles and want to find all the Los Angeles printers in your deployment, search for a network printer by using the Add Printer Wizard and type **US/LAX** in the **Location** dialog box. If **US/LAX** matches the printer location syntax in Active Directory, your search might return the following results:

- US/LAX/1/101
- US/LAX/2/103

These results indicate that two printers are available in Los Angeles, located in buildings 1 and 2, in rooms 101 and 103.

Printer publishing is controlled by the **List in the Directory** check box on the **Sharing** tab of the **Properties** sheet for each printer. Printers that are added by using the Add Printer Wizard are published by default, and the wizard does not let you change this setting. If you do not want to publish a printer in Active Directory, after adding the printer, open the printer property sheet, and clear the **List in the directory** check box on the **Sharing** tab.

The printer is placed in the **Computer** object in Active Directory on the print server. After publishing the printer in Active Directory, you can move or rename the object by using the Users and Computers snap-in in Active Directory.

**To publish a printer in Active Directory**

1. In Control Panel, open the **Printers and Faxes** folder.
2. Right-click the icon for the printer that you want to publish in Active Directory, and click **Properties**.
3. On the **Sharing** tab, select the **List in the directory** check box.

# Connecting Clients to Printers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Generally, clients can establish a connection to a shared network printer hosted on a Windows Server 2003 print server in one of three ways:

- **Entering the Universal Naming Convention (UNC) path.** In the **Run** dialog box, type the UNC path for the printer (for example, \\PrintServer\Printer), and then click **OK**.

- **Using the Add Printer Wizard.** From the **Printer and Faxes** folder, select **Add a Printer**. When the Add Printer Wizard opens, click **Next**, select the network printer option, and either type or browse to the path for the shared printer.

- **Using drag-and-drop.** In the **Run** dialog box, open the shared printers folder on the remote print server. Then drag the desired printer icon into the **Printers and Faxes** folder on the local workstation.

# Restricting Access to Printers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If your design calls for restricting access to certain printers, you can do so by using printer permissions. To do this, it is recommended that you create a user group and then limit access to a printer to members of the group.

**To create a local group**

1. Right-click **My Computer**, and click **Manage**.
2. In the console tree, double-click **Local Users and Groups**.
3. To add the group, right-click **Groups**, and click **New Group**.
4. In the **Group name** box, type the name of the new local group.
5. To add users to the group, click **Add**, and enter the user names in the **Enter the object names to select** box.

**To restrict access to a specific printer**

1. In Control Panel**,** open the **Printers and Faxes** folder.
2. Right-click the icon for the printer to which you want to restrict access, and click **Properties**.
3. To remove extraneous group members, on the **Security** tab, remove all entries in the **Groups or user names** list box except Administrator and Creator Owner.
4. To grant access to the printer, click **Add**, and then enter the names of the groups and users that you want to grant access to this printer.

# Enabling Internet Printing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By using Internet printing, you can manage print resources from your Web browser. To be able to print over the Internet, clients within the same Local Area Network (LAN) must use a remote procedure call (RPC) to connect to the print server. For more information about prerequisites for Internet printing, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Installing a Printer from a Web Page**

To install a printer for Internet printing, you can either view a Web page to find a printer that is identified by a URL, or — if the client is running Windows Server 2003, Windows XP Professional, Windows 2000, Windows 95, Windows 98, or Windows Millennium Edition — connect to a printer share through a Web page.

Open a web browser, and type: http*://servername*/printers. Under **Printer Actions,** click **Connect**. The installation page displays available options based on your permissions. Windows Server 2003 downloads the printer software to the client, and the printer is displayed in the **Printers and Faxes** folder on the client.

The installation route depends on whether the client and the print server are on the same intranet and are both running Windows XP Professional, Windows Server 2003, Windows 2000, or Windows NT 4.0. If they are, the client and print server communicate by means of an RPC, and the installed printer continues to use an RPC to link the client and the server even if HTTP is not specified in the address.

The installation uses HTTP instead of RPC in the following instances:

- The client and server are not on the same intranet.
- The client is not running Windows Server 2003, Windows XP Professional, Windows 2000, or Windows NT 4.0.
- The printer contains an internal network adapter, supports Internet Printing Protocol 1.0, and is not connected to a server.

With HTTP, the print server generates a .cab file containing the required .inf and installation files and sends the .cab file to the client. On the client computer, the .cab file starts the Add Printer Wizard to complete the installation. A progress report is displayed in HTML while the wizard is working.

**Important**

- Installation is not automatic for Web-based printers with internal network adapters. You must start the Add Printer Wizard, enter the printer's URL instead of a UNC path, and manually enter information that the wizard requires. You can use this method to install any URL-identified printer by means of HTTP.

**Security for Internet Printing**

Print server security is provided by IIS, which runs on the print server. IIS allows basic authentication, which all browsers support. The administrator must select basic authentication to enable the print server to support all browsers and all Internet clients. IIS and PWS allow the use of Integrated Windows authentication and Kerberos authentication, both of which are supported by Internet Explorer.

The authentication method for Internet printing in IIS or PWS is set in the print server's property sheet on the **Directory Security** tab.

By default, print jobs are sent over HTTP as RAW data. If it is important to keep this data secure, use either a Virtual Private Network (VPN) or Secure Socket Layer (SSL) connection.

**To select an authentication method**

1. In the console tree of the IIS console, expand the node for the server, expand the Web Sites node, expand the Default Web Site node, and then expand the Printers node.
2. Click the icon at the Printers node.

This node represents a virtual directory that is used to set all security for Internet printing. A list of Application Server Pages (ASP) appears in the details pane.

3. In the console tree, right-click the printer, click **Properties**, and then click the **Directory Security** tab.

4. Choose one of the following Directory Security options by clicking the respective **Edit** button:

   - **Authentication and access control**
   - **IP address and domain name restrictions**
   - **Secure communications**

Typically, administrators select **Enable anonymous access**,which allows a client to access each server resource by impersonating the Anonymous account IUSR_*computername*. No user action is required. If a user attempts to connect to another domain or proxy server that does not allow anonymous access, a dialog box prompts for the user name and password.

**To choose anonymous access authentication**

1. On the **Directory Security** tab of the **Printers Properties** page, click the **Edit** button for **Authentication and access control**.

2. Select the **Enable Anonymous access** check box.

3. Clear the **Windows Integrated authentication** check box.

**Note**

- **Integrated Windows authentication** is checked by default and takes precedence over other types of authentication. To ensure that users are authenticated anonymously, clear all check boxes except **Enable anonymous access**.

Integrated Windows authentication is more secure, because it does not send the password. During Integrated Windows authentication, IIS applies either challenge and response encryption technology, or Kerberos encryption technology, depending on the capability of the client. For more information about IIS security, see the *Internet Information Services (IIS) 6.0 Resource Guide* of the *Windows Server 2003 Resource Kit* (or see the Internet Information Services (IIS) 6.0 Resource Guide on the Web at http://www.microsoft.com/reskit).

# Additional Resources for Designing and Deploying Print Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Related Information**

- The *Server Management Guide* of the *Windows Server 2003 Resource Kit* (or see the Server Management Guide on the Web at http://www.microsoft.com/reskit).
- The at http://www.microsoft.com/reskit, or see the MSDN Scripting Clinic link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources, for more information about scripting.
- RFC 1759: *Printer MIB* for more information about Printer Message Information Base.
- RFC 1179: *Line Printer Daemon Protocol* for more information about using an LPR port that uses the Line Printer Daemon Protocol.

**Related Help topics**

For best results in identifying Help topics by title, in Help and Support Center, under the **Search** box, click **Set search options**. Under **Help Topics**, select the **Search in title only** checkbox.

- "Initiate a resource failure in Help and Support Center for Windows Server 2003 for more information about initiating a resource failure.
- "Create a cluster-managed printer in Help and Support Center for Windows Server 2003 for more information about creating a cluster-managed printer.
- "Print Spooler resource type" in Help and Support Center or more information about printing and the Cluster service.
- "Windows Server 2003 Administration Tools Pack Overview in Help and Support Center for Windows Server 2003 for more information about the Administration Tools Pack.
- "Managing printing from the command line" in Help and Support Center for Windows Server 2003 for more information about managing printers from the command line.
- "Internet Printing" in Help and Support Center for Windows Server 2003 for more information about the Internet Printing.

**Related Job Aids**

- "Print Server Inventory Worksheet" (Sdcpsv_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "Print Server Inventory Worksheet" on the Web at http://www.microsoft.com/reskit).
- "Print Server Design Worksheet" (Sdcpsv_2.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "Print Server Design Worksheet" on the Web at http://www.microsoft.com/reskit).

**Related Tools**

- Print Migrator 3.0 (Printmig.exe)

  Use Printmig.exe to help automate printer consolidation on Windows Server 2003. Instead of recreating all of the printer objects manually, you can back up existing printers and restore them to your new print servers. To download Print Migrator, see the Print Services link on the Web Resources page at

http://www.microsoft.com/windows/reskits/webresources.

- Fixprnsv.exe

  Use Fixprnsv.exe to help resolve printer driver compatibility issues between Windows NT 4.0, Windows 2000 and Windows Server 2003. Fixprnsv.exe is located on the Windows Server 2003 installation CD-ROM. The executable file is located in Windows\Printers directory. To view a list of commands used with this utility, use the command **fixprnsv.exe /?** from that directory.

- PrnAdmin

  Use PrnAdmin to help migrate from Windows NT 4.0 to Windows Server 2003. You can use Prnadmin.dll to inventory your current environment. PrnAdmin enumerates ports, drivers, printers, or forms on local or remote printers. The Visual Basic script for the PrnAdmin utility is named Prnmgr.vbs. PrnAdmin is located on the *Windows Server 2003 Deployment Kit* companion CD. To install PrnAdmin, type the following command:

  **regsvr32 "C:\Program Files\Resource Kit\PrnAdmin.dll"**

# Hosting Applications with Terminal Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

With Terminal Server you can host applications in a central location, which saves management and deployment time and increases security because you install the applications once on a server, rather than on every desktop.

**In This Chapter**

Overview of the Terminal Server Deployment Process

Planning for Application Hosting

Planning Network and Hardware Resources

Designing Domain and User Configuration

Designing Terminal Server Installation and Configuration

Designing the Remote Desktop Connection Installation and Configuration

Additional Resources for Hosting Applications with Terminal Server

**Related Information**

- For information about using Terminal Services and other remote management tools for remote administration, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

- For more information about Remote Desktop, see "Configuring Remote Desktop" in *Microsoft® Windows® XP Professional Resource Kit Documentation* (or see "Configuring Remote Desktop" on the Web at http://www.microsoft.com/reskit).

# Overview of the Terminal Server Deployment Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Hosting applications from a central location with Terminal Server enables centralized management of those applications. You also gain added security because data is stored on the server, rather than on local computers. The following examples illustrate the kinds of business solutions that Terminal Server can provide.

**Bandwidth-constrained locations** In areas where high bandwidth is not available or cost-effective, deploying applications on a terminal server can improve performance for remote users because large amounts of data are not being transmitted over the connection.

**Applications in development or transition** You can simplify administration of crucial line-of-business applications that are in development or require frequent updating by deploying these applications on a terminal server. You can ensure that all users have access to the latest version by updating the application on the server rather than on individual client computers, reducing the total number of updates required.

**Use of third-party platforms** You can reduce desktop hardware costs for users who have a primary line-of-business application that is available only on a desktop running an operating system other than a Microsoft® Windows® operating system, but who still require access to Windows-based applications. Users can connect to a terminal server to run the Windows-based applications.

**Use of thin clients** Data-entry workers can access their primary application from a Windows-based terminal (or thin client) rather than a personal computer, reducing total cost of ownership. Using thin clients also minimizes work disruption for task workers. If a terminal stops running, you can replace it quickly, with minimal setup.

For more details about the solutions that Terminal Server provides, see "Identifying the Role of Terminal Server in Your Organization" later in this chapter.

Before you plan your deployment of Terminal Server, you need to design your domain infrastructure. After you complete the tasks outlined in this chapter, you can conduct a pilot test of your Terminal Server solution, adjust your design if necessary, and deploy the completed solution to the production environment. For more information about pilot testing, see Planning for Deployment in *Planning. Testing, and Piloting Deployment Projects* of this kit. For more information about implementing your Terminal Server solution, see "Terminal server role: Configuring a terminal server" in the Configure Your Server Wizard and "Checklists: Setting up Terminal Server" in Help and Support Center for the Microsoft® Windows® Server 2003 operating system.

Terminal Server is available with the Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; and Windows® Server 2003, Datacenter Edition operating systems.

# Process for Planning and Deploying Terminal Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Figure 4.1 illustrates the high-level process for planning and deploying Terminal Server for hosting applications. Although the primary tasks remain the same for anyone planning to deploy Terminal Server, the steps differ depending on the solution you want to provide. Those differences are described in context throughout the chapter.

**Figure 4.1 Planning and Deploying Terminal Server**

For a job aid to assist you in recording your design decisions, see "Terminal Server Planning and Design Worksheet" (SDCTS_1.xls) on the *Microsoft® Windows® Server 2003 Deployment Kit* companion CD (or see "Terminal Server Planning and Design Worksheet" on the Web at http://www.microsoft.com/reskit). For a job aid to assist you in recording your Terminal Server Group Policy configuration decisions, see "Group Policy Configuration Worksheet" (SDCTS_2.xls) on the *Windows Server 2003 Deployment Kit* companion CD (or see "Group Policy Configuration Worksheet" on the Web at http://www.microsoft.com/reskit).

# Basic Terminal Server Concepts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Terminal Server component of Windows Server 2003, which was called Terminal Services in Application Server Mode in the Microsoft® Windows® 2000 operating system, can deliver the Windows desktop, in addition to Windows-based applications, from a centralized server to virtually any desktop computing device, including those that cannot run Windows.

Terminal Server uses the Remote Desktop Protocol (RDP) to communicate between client and server. After you deploy an application on a terminal server, clients can connect over a remote access connection, local area network (LAN), wide area network (WAN), or the Internet. The client computers can run Windows (including the Microsoft® Windows® CE operating system) or run on other operating systems such as the Apple Macintosh or even UNIX (using a third-party add-on). When a user accesses an application on a terminal server that is running Windows Server 2003, all of the work of the application takes place on the server and only the keyboard, mouse, and display information are transmitted over the network to the user desktop. Each user sees only their individual session, which is managed transparently by the server operating system and is independent of any other client session.

Windows Server 2003 Terminal Server offers the following new features and improvements:

- For improved load-balancing performance, the new Session Directory feature automatically reconnects users to an existing session within a load-balanced server farm, rather than just being directed to the least loaded server when they reconnect.

- For improved logon security, you can use a smart card to log on to a terminal server running Windows Server 2003 and run applications from client computers with a smart card subsystem (including computers running the Microsoft® Windows® XP operating system, Windows 2000, and the Windows CE operating system). This provides an additional level of physical security to your network environment.

- For a better user experience, Terminal Services supports a wider variety of data redirection types (including file system, serial port, printer, audio, and time zone) and supports connections in up to 24-bit color.

- For improved management, there is an expanded set of Group Policy settings for Terminal Server and a full Windows Management Instrumentation (WMI) provider allowing for scripted configuration of Terminal Server settings.

- For improved license management, you can install Terminal Services Enterprise Licensing on either a domain controller or a member server. Terminal Services Licensing wizards have been improved to reduce the complexity of activating a terminal server and assigning it licenses. There is also a new security group that allows only specific terminal servers to request licenses from a license server in a domain.

For more information about improvements in Windows Server 2003 Terminal Server, see the "What's New in Terminal Server" white paper at the Terminal Services: Community Center link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources and Using Terminal Server to host applications centrally in Help and Support Center for Windows Server 2003.

# Planning for Application Hosting

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As shown in Figure 4.2, the first step in planning your deployment of Windows Server 2003 Terminal Server is to clearly identify the scope of your deployment. This step provides you with a high-level specification on which to base the design of your network and domain infrastructure.

**Figure 4.2 Planning for Application Hosting with Terminal Server**

# Identifying the Role of Terminal Server in Your Organization

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The way in which you plan to use Terminal Server has an effect on how you deploy it. The following sections outline the various ways in which you might use Terminal Server in your organization. Use the information in these sections to clarify how you are going to use Terminal Server in your organization.

**Hosting Line-of-Business Applications**

If your organization or certain groups within your organization use specialized applications to do their work, it might be beneficial to host the applications with Terminal Server. For example, you might decide to use Terminal Server in the following situations:

- **Custom applications.** If your line-of-business application is developed in-house or especially for your organization, and it tends to require frequent updating or repair, deploying the application once on a terminal server can simplify administration of the application. This is especially useful if your environment is geographically dispersed or if you are deploying Terminal Server to centrally serve your organization's branch offices.

- **Large central data pool.** Applications that rely on access to a single data source often run better on a terminal server because large amounts of data do not have to travel across the network to users. Instead, the data processing takes place on the server. Only the keystrokes and display information travel across the network, so you can use lower bandwidth connections. This is especially useful if the users of the data pool are located remotely, for example in a branch office with a slow connection to the database server.

- **Task workers.** In environments where you want workers to access only the application that they need to perform their jobs, you can centralize the administration of these users by using Terminal Server.

- **IT Admin tools.** System administrators can perform tasks that require Enterprise Admin or Domain Admin permissions on a terminal server that has the necessary tools installed on it. They can also run their desktop applications on their local computer without these permissions.

- **Upgrading operating systems.** If your organization uses a line-of-business application that is not optimized for your desktop operating system, you can host the application with Terminal Server rather than change operating systems.

**Hosting the Desktop**

You can use Terminal Server to host users' entire desktop environments, so that when users log on, they see their usual desktop environments or desktop environments especially designed for their remote use. In this situation, users can open and close the applications they choose in the same way that they access applications from the Windows desktop on the local computer. You can host the desktop in the situations discussed in the following sections.

**Remote users**

Hosting the desktop with Terminal Server can provide higher levels of consistency and performance for users in remote locations because large amounts of application data are not being transmitted over the connection. For example, you might use Terminal Server in the following situations:

- **Bandwidth-constrained locations.** In areas where high bandwidth is not available or cost-effective, deploying applications on a terminal server can improve performance for users who are connecting to the network from a remote location over slow dial-up connections.

- **Mobile users .** For users who are traveling and tend to access the corporate network over connections of varying bandwidth, Terminal Server can provide a more consistent experience.

**Client heterogeneity**

If your organization is in the process of converting all users to the same platform or upgrading desktop hardware, you can use Terminal Server to quickly deliver the most up-to-date version of the operating system and applications to the user while enabling you to spread the desktop platform or hardware conversion over a longer period of time. You can also deliver a highly controlled standard desktop to users by using Terminal Server, as illustrated in more detail in the following list:

- **Mixed-platform environment.** If you have users who require applications based on operating systems other than Windows to perform their jobs, but your organization is transitioning to or requires a Windows-based desktop, you can host the desktop with Terminal Server. This requires the use of third-party software in conjunction with Terminal Server.

- **Upgrading hardware.** If your organization is planning to upgrade to Windows XP on the desktop, but not all of the desktop hardware is compatible, you can use Terminal Server to host the desktops of users who have older hardware while you are in the process of upgrading the hardware. All users can have the same desktop environment and run the latest versions of the applications designed for Windows XP regardless of their desktop hardware.

- **Highly controlled environments.** In situations where you want to deliver a standardized and controlled environment to users, you can host the desktop with Terminal Server to centralize management.

**Hardware Considerations**

You can reduce hardware costs by hosting applications with Terminal Server and using thin client devices or older hardware on your users' desktops.

- **Use of thin clients.** Windows Powered thin clients (sometimes called Windows-based terminals) offer an alternative to personal computers and traditional "green screen" terminals by enabling easy remote access to productivity and line-of-business applications that are hosted on Windows-based terminal servers.

- **Extending the life of older hardware.** Rather than replacing older hardware that is no longer capable of running new Windows-based applications, you can use that older hardware much like a thin client to access the desktop and applications on the server rather than on the local computer.

**Using the Remote Desktop Web Connection**

The Remote Desktop Web Connection is an ActiveX control that provides virtually the same functionality as the executable version of Remote Desktop Connection, but it delivers this functionality over the Web even if the executable version is not installed on the client computer. When hosted in a Web page, the ActiveX Client Control allows a user to log on to a terminal server through a TCP/IP Internet or intranet connection and view a Windows desktop inside Internet Explorer.

The Remote Desktop Web Connection provides an easy way to offer Terminal Server through a URL. Consider using the Remote Desktop Web Connection in the following situations:

- **Roaming users.** Users who are away from their computers can use Remote Desktop Web Connection to gain secure access to their primary workstations from any computer running Windows and Internet Explorer, provided they can reach the target computers.

- **Delivery of extranet applications**. You can use Remote Desktop Web Connection to allow business partners or customers access to internal applications over the Internet. Users who gain access in this manner do not need to reconfigure their computers, and they do not gain access to your internal network.

- **Deployment transition.** You can deploy the Remote Desktop Web Connection quickly and use it while you are deploying your full Remote Desktop Connection infrastructure.

For more information about the Remote Desktop Web Connection, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit)..

# Choosing Applications to Host

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before deploying applications with Terminal Server, you must determine which applications are ideal candidates for hosting in your organization, and determine if those applications will work well in a Terminal Server environment. You might also want to host the entire desktop through Terminal Server.

# Identifying Ideal Candidates for Hosting

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When choosing applications to host with Terminal Server, consider the compatibility of those applications with Terminal Server. Many desktop applications load and run correctly with Terminal Server. Applications that have been certified for Windows are generally compatible with Terminal Server. For more information about the Certified for Windows program, see the Certified for Windows link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

With any Windows-based application the definitive source of compatibility information should always be the application's vendor or developer. For more information about application compatibility with Terminal Services, see "Program Compatibility" in Help and Support Center for Windows Server 2003. There are also application compatibility notes for some applications available on the VeriTest Catalog of Certified Windows Server Applications link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Application Characteristics That Affect Performance with Terminal Server**
Because Terminal Server is available for multisession (multiuser) use, and because the display and keystroke information travels over the network, applications that have certain characteristics might perform poorly with Terminal Server. When planning for your organization, establish a set of acceptable performance guidelines and determine through testing whether such applications run better on the user's local computer. For example:

- Multimedia applications or applications that have very large graphical output do not run well with Terminal Server. Because large amounts of display information travel over the network, the performance of these types of applications is often unacceptable, especially over low-bandwidth connections. Many computer-aided design (CAD) and streaming media applications fall into this category.

- Running 16-bit programs with Terminal Server can reduce the number of users a processor supports and increases the memory required for each user. Windows Server 2003 translates 16-bit programs in enhanced mode through a process called Windows on Windows (WOW). This causes 16-bit programs to consume additional system resources. A similar situation exists with running 32-bit applications on the 64-bit versions of Windows Server 2003.

  **Note**

  - You can prevent 16-bit applications from running on Windows Server 2003 by enabling the **Prevent access to 16-bit applications** Group Policy setting. This setting is located in Administrative Templates/Windows Components/Application Compatibility. You can set this setting for both the computer and the user.

  There are third-party add-ons that you can use to help with the performance of 16-bit applications and other application compatibility issues. For more information about these add-ons, see the AppSense and Tame Software links on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

- Applications that are based on the Microsoft® MS-DOS® operating system use keyboard polling that can consume all the available resources on a CPU.

- Applications with features that run continuously in the background (for example automatic spelling and grammar checking in Microsoft® Word) can affect performance with Terminal Server. In some cases, you can restrict user or group access to certain application types, disable unnecessary features that require the most resources, or install applications on separate servers to minimize the performance effects.

- Complex automation or macros can be CPU-intensive and are not recommended. If you use or plan to use macros with the applications you plan to host, test your plans thoroughly to ensure adequate performance.

- If you plan to use Terminal Server to host custom applications or applications developed in-house, you need to consider the specification for applications for the Certified for Windows program. For more information about the Certified for Windows program, see the Certified for Windows link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. For information about guidelines for developing applications for use with Terminal Server, see the Optimizing Applications for Windows 2000 Terminal Services link on the Web

Resources page at http://www.microsoft.com/windows/reskits/webresources.

- If you plan to host older applications with Windows Server 2003 Terminal Server, for example applications that you have hosted with the Microsoft® Windows® NT 4.0 Terminal Server Edition operating system, be aware that you might need to run Terminal Server in Relaxed Security mode, which allows access to system files and the registry on the server, in order for these applications to function properly. For more information about security modes, see "Designing the Terminal Server Configuration" later in this chapter.

After you choose the applications you want to host, analyze these applications for potential problems in a multiuser environment and thoroughly test them, including end-user testing and pilot testing, to ensure that they work in your environment. For more information about piloting and testing, see "Planning for Deployment" in *Planning, Testing, and Piloting Deployment Projects* of this kit.

**Compatibility Scripts**

You might have to modify or provide support for custom applications or applications that are not written to accommodate multiuser access. Such applications might not use per user data storage, the user-specific portions of the registry, or appropriate permissions. You can run compatibility scripts for these applications after you install the application. These scripts are available:

- **With the Windows Server 2003 operating system**. These scripts are located in the *systemroot*\Application Compatibility Scripts\Install folder.

- **From your application vendor**. These scripts might be available on the application CD, on the Web, or by special order from the company.

- **By developing them yourself**. Use the scripts in the *systemroot*\Application Compatibility Scripts\Install\Template folder as a template.

Information about running these scripts is available in the "Designing Application Installation" section later in the chapter. For more information about the Windows Application Compatibility Toolkit, see "Testing Application Compatibility" in *Automating and Customizing Installations* of this kit.

# Hosting Full Desktops with Terminal Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you determine that hosting with Terminal Server is an ideal way to manage an application, consider running just the application (not the entire desktop) on the terminal server. This can save significant resources on the terminal server and can allow many more users to log on to the server simultaneously.

If, however, you want your users to access their full desktop from the terminal server as outlined in "Identifying the Role of Terminal Server in Your Organization" earlier in this chapter, be sure to fully test for performance and server capacity using the full load of applications to which your users will have access. For more information about server capacity, see "Terminal Server Capacity Planning" later in this chapter.

**Choosing the Desktop Theme**

If you host the full desktop with Terminal Server, the desktop environment is like the Windows desktop. The default desktop theme for Windows Server 2003, however, is Windows Classic. You can use the Windows XP default theme, however this theme affects performance for the user because it is more graphic intensive than Windows Classic. Test the responsiveness for the end user and perform real-user testing to ensure that the performance is satisfactory when using this theme. For more information about testing, see "Terminal Server Capacity Planning" later in this chapter.

You can also choose a specific theme for your end users or enforce the use of the Windows Classic theme through Group Policy. For more information, see "Configuring User Group Policy Settings" later in this chapter.

# Choosing the Licensing Model

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To use Terminal Server in your organization, you are required to have a Windows Server 2003 license for every terminal server that you deploy in your organization as well as Terminal Server Client Access Licenses (CALs) for devices that access the terminal servers. For terminal servers that are running Windows Server 2003, there are two types of Terminal Server CALs:

- Per Device
- Per User

Which CAL you choose depends on how you plan to use Terminal Server. By default, Terminal Server is configured in Per Device mode, but it can be switched to Per User mode using the Terminal Services Connection Configuration (TSCC) tool or by using Windows Management Instrumentation (WMI). You can serve both license types from the same license server. For more information about how to set your licensing mode, see "Designing the Terminal Server Configuration" later in this chapter.

**Note**

- Windows 2000 Internet Connector Licensing has been replaced by Terminal Server External Connector Licensing in Windows Server 2003. Improvements include licensing qualification extended to business partners in addition to customers, authenticated access, and unlimited concurrent users per server. For information about External Connector Licensing, see "External Connector License Overview" at http://go.microsoft.com/fwlink/?LinkID=100438. Windows Server 2003 retains support for Windows 2000 Internet Connector Licensing.

A Terminal Server license server on your network manages the Terminal Services CALs. A license server stores all Terminal Server CAL tokens that have been installed for a terminal server and tracks the license tokens that have been issued to clients. For more information about setting up a license server, see "Planning the License Server" later in this chapter.

For more information about Terminal Server licensing, see Terminal Server Licensing overview in Help and Support Center for Windows Server 2003 and "Microsoft Windows Server 2003 Terminal Server Licensing" at http://go.microsoft.com/fwlink/?LinkID=26220. For general information about licensing, see "Microsoft Volume Licensing" at http://go.microsoft.com/fwlink/?LinkId=100481.

**Note**

- Each service or application that users access from the terminal server must be licensed appropriately. Typically each device requires application licenses and CALs associated with it, even if the application or service is accessed indirectly through the terminal server. For more information, check the product documentation, End User License Agreement (EULA), or any other document that specifies product usage rights.

**Per Device Licensing Mode**

A Per Device CAL provides each client computer the right to access a terminal server that is running Windows Server 2003. The Per Device CAL is stored locally and presented to the terminal server each time the client computer connects to the server.

Per Device licensing is a good choice for:

- Hosting a user's primary desktop for devices the customer owns or controls.
- Thin clients or computers that connect to a terminal server for a large percentage of the working day.
- Hosting line-of-business applications that are used for the bulk of your users' work.

This type of licensing is a poor choice if you do not control the device accessing the server, for example computers in an Internet café, or if you have a business partner who connects to your terminal server from outside your network.

**Per User Licensing Mode**

In Per User licensing mode you must have one license for every user. With Per User licensing, one user can access a terminal

server from an unlimited number of devices and only needs one CAL rather than a CAL for each device.

**Note**

- At the release of Windows Server 2003, Per User licensing is not enforced. However the terminal server must be able to discover a license server after the 120-day grace period expires. Otherwise, clients are denied access to the terminal server. For more information about the 120-day grace period, see "Planning the License Server" later in this chapter. For more information about Per User licensing, see "Microsoft Windows Server 2003 Terminal Server Licensing" at http://www.go.microsoft.com/fwlink/?LinkID=26220. For information about plans for enforcing per user licensing, see "Microsoft Volume Licensing" at http://go.microsoft.com/fwlink/?LinkId=100481.

Per User licensing is a good choice in the following situations:

- Providing access for roaming users.
- Providing access for users who use more than one computer, for example, a portable and a desktop computer.
- Providing ease of management for organizations that track access to the network by user, rather than by computer.

In general, if your organization has more computers than users, Per User licensing might be a cost-effective way to deploy Terminal Server because you only pay for the user to access Terminal Server, rather than paying for every device from which the user accesses Terminal Server. Check the end-user license agreement for the applications that you plan to host to determine if they support per user licensing.

# Planning Network and Hardware Resources

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you select the applications to host with Terminal Server, assess your network infrastructure, hardware, and security components to be sure your network is ready to deploy and run Terminal Server. Figure 4.3 shows the steps in this process.

**Figure 4.3 Planning Network and Hardware Resources**

# Planning Server Resources

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Careful planning of the servers and server infrastructure on which you deploy Terminal Server determines the number of users who can access a terminal server at one time and the quality of their experience. You can also load balance your terminal servers for fault tolerance.

# Terminal Server Capacity Planning

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server Capacity Planning**
Size your terminal servers with sufficient CPU, memory, and disk resources to handle the client demand. For adequate performance, a terminal server requires a minimum of 128 megabytes (MB) RAM, plus additional RAM for each user running applications on the server, depending on the type of user. For more information about server capacity requirements for Terminal Server, see the Terminal Services link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Important**

- Guidelines outlined on this Web site are for specific server configurations, and provide a baseline for estimating server capacity. Terminal Server capacity can vary depending on factors such as type of user, server and network configuration, and the applications you are hosting. Test your design thoroughly and monitor the server load after deployment to be sure your servers have adequate capacity to provide users with an acceptable experience.

A multiprocessor configuration can maximize CPU availability. In general, processor and memory requirements scale linearly. You can support nearly double the number of users on a multiprocessor-capable Pentium system by doubling the number of processors and doubling the amount of memory. For this reason, purchasing a system that supports multiple processors, even if you initially purchase only one processor, allows you to add capacity easily as your requirements grow.

**Estimating User Demand**
The amount of RAM and CPU that Terminal Server users consume depends on the application features that they use, how often they use the application, and how much work they accomplish in any unit of time. If you understand the work patterns of your users, you can use the Terminal Server capacity planning tools on the *Windows Server 2003 Deployment Kit* companion CD — Roboserver (Robosrv.exe) and Roboclient (Robocli.exe) — to more accurately emulate the activity level of your users. For more information about Roboserver and Roboclient, click **Tools** in Help and Support Center, and then click Windows Resource Kit Tools Help. How to use the capacity planning tools to emulate the activity of your users is discussed later in this section.

**Application Considerations**
When determining server sizing, examine the types of applications your server runs. Check system requirements for each application carefully and consider that RAM and CPU requirements increase according to the number of sessions expected to run simultaneously. Also, a terminal server shares executable resources among individual users, just as Windows shares executable resources among individual programs. As a result, the memory requirements for additional users running the same program are typically less than the requirements for the first user who loads the application. Although you cannot make precise estimates based on these factors, they give you a basis for projecting program performance.

**Testing Server Capacity**
Test the servers on which you plan to host applications in order to ensure adequate server capacity. Using a server that you estimate to be of the correct capacity, construct a test environment with the appropriate number of sessions running the application for a specified period of time and at a level of activity that simulates actual use. Because adequate performance can be subjective, you need to also perform real-user testing. Ask users to identify perceived performance issues, and make sure that you establish baseline task completion times based on user feedback, and use a stopwatch to accurately measure the effect of server capacity on performance throughout testing. A good indicator of unacceptable performance is when the time to complete the tasks in the simulation takes 10 percent longer than the baseline.

**Using the Capacity Planning Tools**
To test the capacity of your terminal server to handle the estimated user demand, the *Windows Server 2003 Deployment Kit* provides Terminal Server capacity planning tools — Roboserver (Robosrv.exe) and Roboclient (Robocli.exe) — which include application scripting support. You can use these tools, which are available on the *Windows Server 2003 Deployment Kit* companion CD, to easily place and manage simulated loads on a server. This information can help you determine whether your environment can handle the load that users place on it. Used together, these tools make capacity planning easier and more automated. For more information about Roboserver and Roboclient, click **Tools** in Help and Support Center, and then click Windows Resource Kit Tools Help.

To use these tools, you will need to equip your test lab with the following hardware and software:

- A domain controller

- A server running Terminal Server
- Any additional servers needed to emulate the intended use of Terminal Server in the production environment, such as:
    - A server running Microsoft® SQL Server™ (if you are going to host an application with a SQL Server back end)
    - A server running Microsoft® Exchange (if you intend to host e-mail)
- Client computers

**Note**

- The scripts included with the tools are designed for use with an Exchange server, and emulate typical usage patterns for knowledge workers and data entry workers. You can use these scripts as a template to create custom scripts for your needs. You should alter these scripts to emulate the users and infrastructure in your own environment.

The following sections summarize the hardware requirements for capacity planning tests.

For more information about using the capacity planning tools, click **Tools** in Help and Support Center for Windows Server 2003, and then click Windows Resource Kit Tools Help.

**Note**

- Using these tools can also help you identify compatibility issues with the applications you plan to host with Terminal Server.

**Domain controller** Roboserver runs on the domain controller. The domain controller should run Windows Server 2003, Enterprise Edition, or Microsoft® Windows® 2000 Advanced Server and be configured as the domain controller of a private domain. It should also be configured as a DNS server with both a Forward Lookup Zone and a Reverse Lookup Zone.

**Terminal server** The server that runs Terminal Server should have the same hardware and be configured the same as the server planned for the production environment.

**Client computers** Roboclient runs on the client computers. You need enough client computers to represent the number of users you plan to access the terminal server. You can emulate several users by using a single client computer. It is recommended that you limit the number to five, but if resources are limited, a low-end client computer can emulate as many as 20 users. In general, limit the number of users emulated on each client computer so as to keep the CPU usage of the computer below 20 percent.

**Note**

- Emulating several users by using a single computer in the test lab alters network traffic differently than in the production environment. Network usage is higher in the production environment.

You can also use System Monitor, a Windows Server 2003 support tool, to monitor the performance on the terminal servers in your test lab. To start System Monitor, at the command line type **perfmon**. For more information about System Monitor, see Perfmon in Help and Support Center for Windows Server 2003.

**Note**

- Measure disk performance from a remote computer because having the perfmon log on the disk that is being measured can affect the performance results.

Microsoft Operations Manager (MOM) is also a very useful tool for performance monitoring and scalability planning. For more information, see the Microsoft Operations Manager link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Real-User Capacity Testing**

Because a terminal server running at or above capacity affects performance, it is important that you also test server capacity with a sampling of real users. Also, the Terminal Server capacity planning tools simulate user activity but do not reflect actual human behavior, such as breaks and peaks and lulls in activity, and adequate performance for users is subjective. You can use your pilot test to further determine whether the capacity of your terminal servers is adequate. For more information about pilot testing, see "Planning for Deployment" in *Planning. Testing, and Piloting Deployment Projects* of this kit.

**Note**

- It is highly recommended that you conduct a pilot test for your design before implementing it in the production environment. For Terminal Server, pilot testing is crucial for determining correct server size and satisfactory application performance levels in the production environment.

**Data Storage Considerations**

With Terminal Server, there are some storage access regions that you should consider distributing across several hard drives or redundant array of independent disks (RAID) array, especially for implementations serving large number of users:

- System binaries
- Application binaries
- User profiles and data
- Page files

For Terminal Server, it is best to put your page files on a dedicated hard drive. In addition, because of the multiuser nature of Terminal Server, be sure that your page file is twice the size of your RAM. For example, if your Terminal Server has 2 gigabytes (GB) of RAM, you should have a 4 GB paging file. You should also have two paging files if necessary. For information about how to change the default paging file size, see "Change the size of the virtual memory paging file" in Help and Support Center for Windows Server 2003.

For improved performance of storage devices with a backup power supply, you can use the following procedure.

**To enable advanced disk performance for storage devices**

1. From the **Start** menu, click **All Programs**, click **Administrative Tools**, and then click **Computer Management**.
2. In **Computer Management**, under **Storage**, click **Disk Management**.
3. Right-click the disk for which you want to enable advanced performance and click **Properties**.
4. On the **Policies** tab, check the **Enable advanced performance** checkbox.

# Load Balancing Terminal Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Using a load-balancing solution with Terminal Server distributes sessions across multiple servers for improved performance. Terminal Services Session Directory, which is available with Windows Server 2003, Enterprise Edition, works with your load-balancing solution. Session Directory is a database that tracks user sessions that are running on load-balanced terminal servers. It provides information when a user reconnects (after disconnecting intentionally or because of a network failure) to ensure that the user reconnects to the same session rather than starting a new session. Session Directory, which can support several thousand sessions, is also cluster-aware, so that you can support users who have concurrent sessions on different terminal server farms without confusion

**Note**

- Load-balancing solutions that do not allow direct client network access to servers in the load-balanced farm need to support redirection tokens to work with Session Directory.

To implement load balancing and Session Directory with Terminal Server, you need to have the following in place:

- A load-balancing solution.
- Two or more terminal servers logically grouped into a Terminal Server farm.
- A Session Directory server.

**Setting Up a Terminal Server Load-Balanced Farm**

In general, set up your terminal server load-balanced farm and your load-balancing solution as you would in any other situation. Consult the documentation for your load-balancing solution.

There are a few things to consider for Terminal Server:

- Split network traffic between two network adapters — one used for Terminal Server, and the other for access to other network resources and infrastructure — placed on different subnets. By allowing RDP traffic only over the Terminal Services adapter, you can have more consistent traffic analysis and better security. More information about this is available later in this section.
- For easier administration, place load-balanced terminal servers into an organizational unit (OU) and apply Group Policy settings to that OU. If you have more than one Terminal Server load-balanced farm in your organization, place each in its own OU inside your Terminal Server OU so that you can apply Terminal Server–specific settings to the overall OU, but manage the separate farms individually.
- Configure your home directories and other user data storage in such a way that your users can easily access their data in the event of their being on a different server the next time they log on. For more information about how to do this, see "Planning Per-User Requirements" later in this chapter.
- Consider placing your terminal server farm and your clients on the same network backbone with your user profile servers and at least one domain controller. This allows for faster logon times.

**Network Separation**

Network separation is the separation of RDP traffic from other network traffic protocols. By dedicating one network adapter to Terminal Server traffic and the RDP, and one network adapter to application traffic, you can realize better overall performance on the Terminal Server load-balanced farms. This arrangement reduces the risk of having a network adapter bottleneck on the servers. Also, you can provide additional security by assigning different IP addresses and subnets to application traffic and to the RDP traffic. You can then constrain these separate routes as necessary by using routers, or switches and firewalls. This also tends to provide better auditing of users and traffic occurring on the network.

You can use IP packet filtering to achieve network separation. For more information about IP packet filtering, see "Designing a

TCP/IP Network" in *Deploying Network Services* of this kit. You can specify the network adapter on which you want to place the RDP traffic on the **Network Adapter** tab of the TSCC. For more information about Terminal Server configuration tools, see "Designing the Terminal Server Configuration" later in this chapter.

#### Selecting a Host Server for Session Directory

The Session Directory server can be any server on the network that is running the Terminal Server Session Directory service. It is best if the Session Directory server is a highly available network server that is not running Terminal Server. However, you can place the Session Directory on a member of the cluster, if necessary. The Session Directory requires very little CPU, memory, and hard drive resources, so you can use a low-end member server to host the Session Directory service.

**Important**

- Running the Session Directory service on a domain controller is not recommended. On a member server, the Session Directory Computers group is a local group, but on a domain controller this group is a domain local group and is available on all domain controllers. The Session Directory Computers group is discussed in the following section.

One Session Directory host server can service multiple load-balanced clusters, and it is cluster-aware so it can handle users who have sessions running on different clusters seamlessly. You can also cluster the Session Directory itself for improved reliability.

#### Configuring Session Directory

After you choose a server on which to host Session Directory, you must start and configure the Session Directory service and configure the servers it will serve. You must configure the Session Directory host server to accept connections from authorized computers and you must configure the load-balanced servers to use Session Directory.

#### Host server configuration

When the Session Directory service starts, by default it creates the Session Directory Computers group (if one does not already exist). The group is empty and you need to add to this group the load-balanced terminal servers that will use this Session Directory server.

#### Session directory settings

If you are load balancing several terminal servers and using Session Directory, you can configure the servers to use Session Directory through TSCC (under Server Settings), Group Policy, or WMI.

Set the following settings to configure your load-balanced Terminal Server farm to use the session directory server:

- **Terminal Server IP Address Redirection.** When the client computer cannot connect directly to the terminal server, you can use the **Terminal Server IP Address Redirection** Group Policy setting to mask the IP address of the destination server in a load-balanced farm.

  **Notes**

  - You can only configure this setting through Group Policy or WMI.
  - This policy setting is enabled by default. Disable this setting only if both of the following are true:

Your load-balancing solution does not allow direct connectivity from the client computer to the terminal server (for example, if your load-balancing solution is also a router).

Your load-balancing solution supports the use of Session Directory routing tokens.

- **Join Session Directory.** Enable this setting and apply it to your load-balanced Terminal Server OU to allow your server farm to use Session Directory. When you enable this setting, you must set the Session Directory Server and Session Directory Cluster Name settings.
- **Session Directory Server.** Enable this setting and enter the Domain Name System (DNS) name, IP address, or fully qualified domain name of the Session Directory server.
- **Session Directory Cluster Name.** Enable this setting and enter the DNS name for the load-balanced farm.
- **Network adapter and IP address session directory should redirect users to.** If your load-balanced farm is

configured so that network traffic is separated between two or more network adapters, use the drop-down list in TSCC to choose the network adapter on the load-balanced server to which client computers should be directed.

**Note**

- You can only configure this setting through TSCC or WMI.

**Implementing a Load-Balancing Solution with Session Directory**

After you install and configure the terminal servers, you can set up your load-balancing solution and the Session Directory service if you are planning to use this service. To set up load balancing, consult the documentation for your solution. To use Group Policy to configure and manage your load-balanced Terminal Server farm centrally, create an OU and add each computer in the farm to the OU.

To set up Session Directory, you need to set up both the Session Directory host server and the servers that will be using Session Directory.

**To set up the Session Directory host computer**

1. Right-click **My Computer** and click **Manage.**

2. Navigate to Services and Applications/Services, double-click **Terminal Services Session Directory**, and set the Startup type to Automatic.

   This service is off by default, and it is set to Manual. Starting this service and setting it to Automatic ensures that the service starts when the host server is turned on.

3. Add the computer group containing the load-balanced Terminal Server farm to the Session Directory Computers group that is created when the Session Directory service starts.

   **Note**

   - By default, the Session Directory Computers group is empty. You can also create this group prior to starting the Session Directory service.

4. Configure the servers that will use the Session Directory service according to your plans from the previous section.

# Running Terminal Server with Other Applications and Services

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Choosing the servers on which you deploy your applications depends on the applications you plan to host with Terminal Server and the applications and services you plan to run on the server with it. For example, you might want to conserve resources by hosting Terminal Server on a computer that also serves other purposes, or an application you plan to host might require another back-end service to run.

**Sharing Terminal Servers with Other Applications and Services**

To conserve resources, you can deploy Terminal Server on a server with other applications and services on the network. However, because Terminal Server is optimized for the desktop experience, this can affect the performance and scalability of both Terminal Server and the other application or service. You should, for example, avoid deploying server-based services, such as SQL Server and Exchange Server, with Terminal Server. Likewise, deploying Terminal Server on a server along with file, print, or other services can affect the performance of these services. This can cause problems especially if non-Terminal Server users access these services. Also, some services can cause conflicts with certain applications that you are hosting with Terminal Server if the client and server applications use different versions of DLLs. Test your setup if you plan to deploy Terminal Server on a server with other applications and services.

**Hosting Data on a Separate Server or Drive**

If you are planning to use Terminal Server to host a server-side, data-intensive application (for example a custom line-of-business application that has a SQL Server back end), you can improve performance by hosting the database and Terminal Server on separate servers. Placing the terminal server and the database on the same high-speed link or even on the same subnet increases the responsiveness of the application. You can optimize disk access performance by configuring multiple SCSI channels and distributing your operating system and application traffic across different physical drives. You can also dedicate a network adapter to operating system and application traffic, while the other network adapter handles RDP traffic.

# Planning the License Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A license server is required when Terminal Server is deployed for hosting applications and desktops. A license server stores all Terminal Server client license tokens that have been installed for a terminal server or group of terminal servers. It tracks the license tokens that have been issued by the Microsoft License Clearinghouse (the service that Microsoft maintains to activate license servers and to issue licenses to the license servers that request them). The license server manages client licenses through the terminal server. There is no direct communication between the client and the license server. For more information about Terminal Services licensing and how it works, see Terminal Server Licensing overview in Help and Support Center for Windows Server 2003 and the "Microsoft Windows Server 2003 Terminal Server Licensing" white paper at the Terminal Services link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

If you have a terminal server that is running Windows Server 2003, you must also have a license server that is running Windows Server 2003. You can use a license server that is running Windows Server 2003 to serve license tokens onto the terminal server that is running Windows Server 2003, or you can upgrade an existing license server that is running Windows 2000 to Windows Server 2003. You can set the **Prevent License Upgrade** Group Policy setting to prevent the license server from handing out Windows Server 2003 CALs to terminal servers that are running Windows 2000.

**Note**

- For Windows Server 2003 you are no longer required to host Terminal Server licensing on a domain controller, but if you do not, you must configure the Terminal Server to discover the license server. For more information, see "Configuring the Preferred License Server" later in this section.

For information about how to transfer licenses from one license server to another, see Repeat the installation of a client access license in Help and Support Center for Windows Server 2003.

A terminal server must be able to connect to an activated license server before license tokens can be issued. To help you with your deployment planning and to give you time to install a license server and add license tokens, there is a 120-day grace period after the first client connects to a terminal server that is running Windows before you must have a license server activated. After this period, if the terminal server does not find an activated license server, clients are denied access. This grace period also ends when the first license token is issued to a client.

You can manage your license servers and Terminal Services license tokens using the Terminal Server Licensing administrative tool. For more information, see Terminal Services administrative tools in Help and Support Center for Windows Server 2003.

When planning your license server requirements, consider your organization's domain structure in order to choose a license server type and to select a server that is a good candidate for hosting Terminal Server Licensing. If, for example, you are deploying terminal servers for different business units or cost centers within your organization, consider deploying a license server for each Terminal Server deployment rather than a license server to service an entire domain or site. This enables each business unit to manage its own licenses and related costs. You must, however, configure your terminal servers to discover the correct license server in this situation. There is information about configuring a preferred license server later in this section.

**Choosing the License Server Type**

There are two types of license servers for Windows Server 2003, a domain license server and an enterprise license server. Decide which of the two types of license servers you require.

**Domain license server**

A domain license server is appropriate for managing Terminal Server users within a domain. Use a domain license server if you have only one domain, or if you want to manage licenses in each of your domains separately. If you have workgroups or Windows NT 4.0 domains, a domain license server is the only type that you can install, and any terminal server within the Windows NT 4.0 domain or workgroup can discover the license server. Terminal servers in a Windows 2000 or Windows Server 2003 domain can discover domain license servers only if they are in the same domain as the license server.

**Enterprise license server**

An enterprise license server can serve terminal servers in any domain within a site, but the domain must be a Windows Server 2003 or Windows 2000 Active Directory domain. Both the license server and Terminal Server must be within the same site.

This type of license server is appropriate if you manage users across multiple domains within a site, or if you are planning to restructure your domains. Enterprise license servers can be installed only by using Add or Remove Programs, not during

Windows Server 2003 Setup. For more information about installing the license server, see "Designing Server Setting Configurations" later in this chapter.

#### Choosing a License Server Host Server

Servers running Windows Terminal Services can work only with license servers that are running Windows. In Windows Server 2003 domains, you can deploy the enterprise license server on either a domain controller or a member server. You are no longer required to install the license server on a domain controller, as was required in Windows 2000. For information about upgrading your license servers, see "Upgrading to Windows Server 2003 Terminal Server" later in this chapter.

### Important

- If you plan to deploy a domain license server, and you choose not to deploy your license server on a domain controller, you must directly edit the registry to configure Terminal Server to locate the license server. You must do this even if the license server and the terminal server are the same computer. For more information about this process, see "Configuring the Preferred License Server" later in this section.

Take the following situations into consideration when choosing where to host Terminal Server Licensing:

- If you are deploying a license server to serve only one terminal server, consider installing the license server on the same server as Terminal Server. Terminal Server licensing causes negligible network traffic, but placement on the same server as Terminal Server eliminates the need for the server to go over the network to obtain licenses, and Terminal Server users experience no downtime if problems occur on the network.

- If you are deploying a license server for a terminal server that is hosting applications for remote clients or for users who access applications over the Internet, place the license server so that it can be accessed easily by the terminal server because there is no direct communication between the client and the license server.

Terminal Services Licensing takes about a megabyte (MB) of disk space to install, and about 10 MB of additional disk space per 1,000 licenses. If you plan to activate the license server and install subsequent license key packs automatically through the Terminal Services Licensing tool, the license server must communicate with the Microsoft License Clearinghouse using Secure Sockets Layer (SSL). SSL is a secure connection; however, as an added security precaution, avoid placing your license server on a server that hosts sensitive data that you would not otherwise want exposed to the Internet. For more information about methods to activate the license server, see Activating a Terminal Server license server in Help and Support Center for Windows Server 2003. For more information about methods for installing subsequent Client Access Licenses, see Install Client Access Licenses in Help and Support Center for Windows Server 2003.

#### Setting Up Fault Tolerant License Servers

One activated license server can serve many terminal servers and Terminal Server users simultaneously. In large implementations of Terminal Services, you might want to deploy at least two licensing servers for fault tolerance. Terminal Server Licensing is not cluster-aware. However, you can improve fault tolerance for the license server by deploying two license servers per domain.

### Note

- You can host Per Device and Per User licensing on the same server.

Choose two host servers for licensing and install all licenses on one license server; do not install any licenses on the backup server. The full server functions as the primary license server and can service all license requests. If the primary license server becomes unavailable, the backup license server can issue 90-day temporary license tokens to clients that need them. When the primary license server is back online, it replaces the temporary license tokens the next time the clients connect.

#### Configuring the Preferred License Server

If you choose not to deploy your license server on a domain controller, you must configure Terminal Services to locate the license server by directly editing the registry. For more information about the Terminal Services license server discovery process for Windows Server 2003, see article 279561, "How to Override the License Server Discovery Process in Windows Server 2003 Terminal Services." To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

### Caution

- Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing

settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Windows Server 2003 Resource Kit Registry Reference on the *Windows Server 2003 Deployment Kit* companion CD, or at http://www.microsoft.com/reskit.

**To select a specific license server**

1. On each terminal server, in the **Run** dialog box, type **regedit**, and then click **OK**.

2. Locate the following path in the registry and select it:

   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\TermService\Parameters

3. On the **Edit** menu, point to **New**, and then click **Key** to add a subkey named LicenseServers, if one does not already exist.

4. Select the LicenseServers subkey, and on the **Edit** menu, point to **New**, and then click **Key** and type in the NetBIOS name, fully qualified domain name, or IP address of the appropriate license server to add the new subkey under LicenseServers.

5. Repeat step 4 for each license server you want the terminal server to discover.

The order of the license servers listed in the registry subkey does not guarantee the order in which the license servers are discovered. If you have more than one implementation of Terminal Server in your organization, you should also configure the license servers themselves to discover only the servers intended to service that implementation by using this procedure.

When Terminal Server discovers a license server, it continues to use that license server until it becomes unavailable. If the licence server is out of licenses, it will forward the request to a license server that has the requested type of license.

**Note**

- If your license servers are not on domain controllers, they will only discover other license servers if their registries are configured for them to do so.

If you are deploying more than one license server to serve separate Terminal Server implementations and if you do not need to keep the licenses allocated to each implementation separate, consider adding the names of all of the license servers in your site or domain to the registry subkey LicenseServers for fault tolerance. However, if you need to keep the licenses allocated to each implementation separate, for example if they are managed by a different administrator or are in different cost centers, you should add to the registry subkey only the name of the license server or servers specific to each terminal server. In this situation, consider deploying two license servers if fault tolerance is a concern.

# Planning Network Connectivity and Bandwidth

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Terminal Server uses RDP to communicate between client and server. RDP works only across a TCP/IP connection, such as a local area network (LAN), wide area network (WAN), dial-up, Integrated Services Digital Network (ISDN), digital subscriber line (DSL), or virtual private network (VPN) connection. You can still use other protocols, such as Internetwork Packet Exchange (IPX) or NetBIOS Extended User Interface (NetBEUI), as the transport protocol for non–Terminal Server traffic, such as network file or printer sharing, or between the client portion of a client-server application and its server.

**Note**

- The Remote Desktop client requires TCP/IP to connect to the server, but after Terminal Server users connect to a terminal server, they can use IPX to gain access to Novell servers if necessary.

**Bandwidth Considerations**

Terminal Server works very well over low-bandwidth connections and uses whatever IP connection you provide. However, you can optimize both application and overall network performance by making sure the type of connection is appropriate to the work that is done. For example, a single user can connect over a low-bandwidth modem line and realize good performance, but it is not appropriate to share a 28.8-kilobit line among an active office of 100 people. Also, consider whether the security that an IP connection provides is appropriate to the data that you plan to transmit. For more information about bandwidth requirements, see the Terminal Services link and the Remote Desktop Protocol (RDP) Features and Performance link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Note**

- Printing, sound, drive redirection, and user file transfer requirements can increase the bandwidth requirement and might cause performance to drop below a level that is considered acceptable performance for users.

**Access to Terminal Server over a VPN**

Users can gain access to Terminal Server over a VPN by using Layer Two Tunneling Protocol (L2TP) or Point-to-Point Tunneling Protocol (PPTP). By using encryption, either one of these tunneling options provides secure access to a private network for users operating over a public medium.

**Access to Terminal Server Over a Wide Area Network**

Terminal Services can provide remote users with access to applications that would otherwise be unusable because of poor performance across dial-up or slow WAN connections.

Give additional consideration to applications with offline capabilities and synchronization if users will be accessing Terminal Server over a WAN. No offline synchronization of the local application is performed over the terminal server connection.

# Planning Network Security Components

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use firewalls and smart cards with Terminal Server to increase security. Use the information in the following sections to help you plan for the use of these security components in your environment. You also need to carefully choose the file system you plan to use with Terminal Server.

**Using Firewalls with Terminal Server**

If your organization uses a firewall for security and if you need clients to connect from the other side of the firewall, keep port 3389 open for RDP connections between the client and server and implement filter rules to ensure this traffic can reach only the terminal servers. This is not necessary if you use PPTP, L2TP, or other VPN technologies to tunnel through the firewall, because the port will be available through the tunnel, without being explicitly closed by the firewall. If you are using the Remote Desktop Web Connection, you must also check to be sure that port 80 is open.

You can change the RDP port if necessary, but you must apply the modification to both the server and clients. However changing the RDP port, for example to a well known and already open port such as 80, makes separation, identification, and audit of RDP traffic much more difficult. For more information about changing the RDP port, see article 187623, "How to Change Terminal Server's Listening Port" in the Microsoft Knowledge Base. To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

For best results, use a firewall that uses user-based authentication. This is especially important for secure access over a WAN, because a firewall that grants access based on an IP address (rather than based on user credentials) allows users through if the IP address of the server running Terminal Services has been granted access. For more information, see "Planning Network Connectivity and Bandwidth" earlier in this chapter.

Determine if the firewall used in your organization is a packet-level or application-level firewall. Packet-level firewalls are easier to configure for new protocols. If your organization uses an application-level firewall, check to see if the vendor has defined a filter for the RDP.

**Using NTFS with Terminal Server**

Because of the multiuser nature of Terminal Services, it is strongly recommended that you use the Windows Server 2003 version of NTFS as the only file system on the server, rather than file allocation table (FAT). FAT does not offer any user and directory security, whereas with NTFS you can limit subdirectories to certain users or groups of users. This is important in a multiuser system such as Terminal Services. Without the security that NTFS provides, any user has access to every directory and file on the terminal server. For more information about file systems, see "Designing and Deploying File Servers" in this book.

**Using Smart Cards with Terminal Server**

With Windows Server 2003, you can now enable users to log on to a remote session in an Active Directory domain using a smart card. Smart cards allow you to require strong credentials from users in a manageable way, providing a more secure environment.

To use smart cards with Windows Server 2003 Terminal Server, you must have Active Directory® directory service deployed in your organization and your client computers must be running a Microsoft client operating system with built-in smart card support, such as Windows XP or Windows 2000, or most devices running Microsoft® Windows® CE .NET. You must also install smart card readers on the client computers.

Otherwise, deploying smart cards for use with Windows Server 2003 Terminal Server is the same as deploying smart cards that will not be used with Terminal Server. For more information see "Planning a Smart Card Deployment" in the *Designing and Deploying Directory and Security Services* book of this kit.

# Choosing Client Computers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Client computers, or terminals, connect to a terminal server that is running Windows Server 2003 using the Remote Desktop Connection tool, which you can install on a disk or in firmware. The Remote Desktop Connection tool is installed by default when you install Windows Server 2003, Windows XP (you need to install Windows XP Service Pack 1 to benefit from features such as Auto-Reconnect), and most versions of Windows CE. On earlier versions of Windows and on the Pocket PC, you have to manually install Remote Desktop.

You can also install this tool manually from the Windows Server 2003 operating system CD or download it from the Web for use on a computer running the Microsoft® Windows® 95, Microsoft® Windows® 98, Microsoft® Windows® Millennium Edition, Windows NT 4.0, or Microsoft® Windows® 2000 Professional operating systems. Remote Desktop Connection has very low physical RAM requirements and generally works on any device that meets the minimum requirements for the operating system on which it runs. For information, see the Terminal Server link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

A Remote Desktop Connection Client for Mac OS X is also available from Microsoft. For more information, see the Mactopia Downloads: Remote Desktop Connection Client link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

For other platforms such as UNIX, you need to obtain a third-party tool to connect to a terminal server. There are a number of third-party RDP clients available. Many of these are reverse engineered and are not supported or endorsed by Microsoft. These clients might cause performance and compatibility problems, and lack of functionality. Check with the software vendor to ensure that your RDP software is a licensed client. For more information about third-party Terminal Server solutions, see the Citrix and New Moon Systems links on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

Your choice of client platform depends on the current installed base and individual user need. Consider the following issues when choosing a client computer or platform from which to connect to your terminal server:

- You can use Windows-based terminals in the following situations:
    - Task workers can access their primary application from a Windows-based terminal (or thin client) rather than a personal computer, reducing hardware costs and work disruption. If a terminal stops responding, you can replace it quickly, with minimal setup.
    - In locations where a personal computer does not fare well — such as in exceptionally dirty, hot, or cold environments — consider deploying Windows-based thin clients, which typically have no moving parts and have a sealed-case design.
    - Windows-based thin clients can be used to replace green-screen terminals.
- You can use client computers running earlier versions of Windows to provide access to applications that require a more recent version of Windows by upgrading your terminal server and hosting the application.
- To save on hardware costs, you can use older computers that are not capable of running newer versions of Windows to access the latest application versions through Terminal Server.
- The Remote Desktop Web Connection requires a browser that supports ActiveX (available with Internet Explorer).
- Non-Windows-based computers such as Macintosh or UNIX computers need additional client software to connect to Terminal Server.

# Planning Use of Peripheral Hardware

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use desktop peripherals such as bar code readers, scanners, or card swipes with Windows Server 2003 Terminal Server if your line-of-business application requires them. You can use peripheral hardware attached to serial and parallel ports of the client computer. You can also use printers attached to the client, as well as network printers, with Terminal Server. Peripherals that connect to the local computer through a specialized third-party hardware card are not recognized by the RDP-based Remote Desktop client, but they might be available using third-party software. For more information, see Peripherals that affect performance in Help and Support Center for Windows Server 2003.

**Port Redirection**

Terminal Server supports port redirection in Windows Server 2003. Using port redirection, applications running within the Terminal Server session have access to ports on the client, enabling you to use devices like bar code readers or scanners with Terminal Server. Test your devices for use with Terminal Server before deploying your solution in the production environment.

By default Windows Server 2003 Terminal Server enables LPT and COM port redirection. If you are not planning to enable these types of peripherals, you might want to disable them so that the client computer is not vulnerable to security threats that could access your computer through those ports. You can disable LPT and COM port redirection by using Terminal Server Group Policy or TSCC. For more information, see "Designing the Terminal Server Configuration" later in this chapter.

By default, Terminal Server does not allow redirection of FireWire (IEEE 1394) ports with Windows XP and Windows 2000 clients. However, you can enable FireWire port redirection on these clients by enabling all ports to be redirected by using the following procedure to modify the registry on the client computer.

**Caution**

- Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Windows Server 2003 Resource Kit Registry Reference on the *Windows Server 2003 Deployment Kit* companion CD or at http://www.microsoft.com/reskit.

**To filter ports for redirection**

1. On the client computer, in the **Run** dialog box, type **regedit**, and then click **OK**.
2. Locate the following subkey in the registry and select it:

   HKEY_CURRENT_USER\Software\Microsoft\Terminal Server Client\Default\AddIns\RDPDR
3. On the **Edit** menu, point to **New**, and then click **DWORD Value**.
4. Type **FilterQueueType**, and then press **ENTER**.
5. With **FilterQueueType** selected, on the **Edit** menu, click **Modify**.
6. Type **FFFFFFFF**, and then click **OK**.

For more information about port redirection, see article 302361, "Multifunction Printers That Use DOT4 Ports Are Not Redirected By Using Remote Desktop." in the Microsoft Knowledge Base. To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Printer Redirection**

When the user logs on to the terminal server, the server detects the client's local printer and installs the appropriate printer driver on the remote computer. If multiple printers are connected to the client computer, Terminal Services defaults to routing all print jobs to the client computer's default printer. Only printers whose drivers are available on the Windows client computer appear as available in a Remote Desktop session for local redirected printers (server-side printers are always available). If the driver for your printer is not included with the client operating system, you must manually install it on the server.

# Designing Domain and User Configuration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Developing your design also involves planning the location of Terminal Server within your proposed Windows Server 2003 domain infrastructure, as shown in Figure 4.4. After you have determined how Terminal Server integrates into your domain model, you can plan the user and security settings that can be managed through Active Directory and Group Policy.

**Figure 4.4 Planning Domain and Security Configuration**

# Integrating Terminal Server into Your Domain Model

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Terminal Server need not be in an Active Directory domain to function, but without a domain architecture, users must have separate accounts on every computer running Terminal Server. This limits manageability and makes it more difficult to administer groups of users.

**Integrating with Existing Windows NT 4.0 Domain Structure**
If your organization does not currently use Active Directory, you can use an existing Windows NT 4.0 domain, which allows you to take advantage of the new features available in Windows Server 2003 Terminal Server without affecting the production environment. However, limitations apply, such as the existing Security Accounts Manager (SAM) 40,000-objects-per-domain limitation of the Windows NT 4.0 domain model. Administrators have the option of adding Terminal Server–specific attributes to users' accounts. This adds a small amount of information, typically 1 kilobyte (KB) or less, to a user's entry in the domain SAM database.

**Integrating with the Windows Server 2003 and Windows 2000 Active Directory Infrastructure**
This option takes full advantage of Active Directory, giving you the option of applying Group Policy settings to control the Terminal Server environment. Just as you are likely to manage your portable computers or domain controllers in a manner different from your desktop computers, you also manage your terminal servers and Terminal Server users differently. When you define your Active Directory structure, it is recommended that you place your terminal servers in a separate Terminal Services OU. Reserve this OU for Terminal Services computers. Do not include other users or non-Terminal Services computer objects. In addition, if you are deploying load-balanced server farms for Terminal Services, place each farm in a separate OU within the Terminal Services OU. It is also recommended that you place your Terminal Server users in a separate Terminal Server users OU.

In an Active Directory environment, avoid configuring Terminal Server as a domain controller for the following reasons:

- Any user rights policies you apply to such a server apply to all domain controllers in the domain. For example, to use Terminal Services, users must be authorized to log on locally to the server. If the server running Terminal Services is a domain controller, users can log on locally to all domain controllers in the Terminal Services domain, presenting a serious security risk.

- Domain controller functions place a heavy load on system resources and would thus have an effect on the user's Terminal Server experience.

- By default, enabling Terminal Services sets the server process-scheduling priority to favor interactive applications. The system does not assign top priority to critical domain-level processes such as user count replication, logon requests, logon script replication, and authentication requests.

# Planning Per-User Requirements

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Because of the multiuser nature of Terminal Server, it is important to plan per-user settings and data storage carefully for ease of management and an optimal user experience. How you plan to use Terminal Server in your organization affects your choice of user profile types, and your plan for using these profiles.

# Using User Profiles in Windows Server 2003

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A profile describes the Windows Server 2003 configuration for a specific user, including the user's environment and preference settings. Profiles typically contain such user-specific information as installed applications, desktop icons, and color options. To plan for user profiles in a Terminal Server environment, choose the solution that is best for your environment, and then plan for the storage of the profiles. For more information about user profiles, see User profiles overview in Help and Support Center for Windows Server 2003. For information about general planning for user profiles, see "Implementing User State Management" in *Designing a Managed Environment* of this kit.

Unless you plan carefully for the use of user profiles, they tend to grow in size. This is a problem in a Terminal Server environment because user profiles are stored on the terminal server by default. If you have many users accessing the terminal server, the user profile files soon consume a large amount of space on the server hard drive. You should store user data and profiles on a separate drive from the system installation hard drive.

There are three different types of profiles you can use with Terminal Server:

- Terminal Server–specific profile
- Windows Server 2003 mandatory roaming profile
- Windows Server 2003 local profile

When a user logs on to a server running Terminal Server, the server first searches for the Terminal Server–specific profile. If Terminal Server cannot locate this profile, it attempts to load the user Windows Server 2003 roaming profile or Windows Server 2003 local profile.

It is recommended that you plan to use either Terminal Server–specific or roaming user profiles for your Terminal Server users, rather than local profiles, in order to better manage the size of the profiles and optimize the user experience. Terminal Server–specific profiles are recommended in most cases. Consider the following situations when choosing which type of user profile to use with Terminal Server:

- If you are planning to keep the environment for your Terminal Server users standardized and under tight control, you can use mandatory roaming user profiles to restrict access to certain applications. You can also use mandatory roaming user profiles to assign users profiles that cannot be changed.
- If you assign roaming user profiles to users who tend to access the terminal server from different computers (for example IT administrators, users who access the application from a kiosk, or users who work in certain task-worker environments), those users can retain their settings regardless of where they log on.
- If you are using Terminal Server to deliver a consistent desktop to client computers of varying platforms or configurations, you cannot use roaming user profiles unless you can group the different configurations and platforms into different OUs.
- If you are using Terminal Server in a load-balanced farm, you should plan to use roaming user profiles.

**Using Terminal Server–Specific Profiles**

Use Terminal Server–specific profiles to present a session to the user that is different from the user's desktop or to create user profiles optimized to the Terminal Services environment. The following are some of the situations where using Terminal Server–specific profiles might be advantageous:

- To provide users who are accessing Terminal Server with an environment that is different from the environment on their local computers.
- To provide a different look and feel for different users on the same terminal server, for example, if you have task workers and a manager on the same server.

- To better manage the size of user profiles for Terminal Services users who do not have controlled user environments that have been set through assigned or mandatory user profiles. You can use Group Policy to manage the profiles on the server that stores your Terminal Server profiles.

You can configure Terminal Services–specific profile settings for each user by using the following procedure.

**To configure Terminal Services–specific profile settings**

1. Open Active Directory Users and Computers.
2. Right-click the user for which you want to set profile settings, and then click Properties.
3. Click the Terminal Services profile tab.

You can configure the following Terminal Services–specific profile settings:

- **Terminal Services User Profile path**. You can choose a place to store users' Terminal Services profiles other than the default location.

  **Note**

  - You can also set this through Group Policy under Computer Configuration\Administrative Templates\Windows Components\Terminal Services. For more information, see "Designing the Terminal Server Configuration" later in this chapter.

- **Terminal Services home folder**. You can specify a path to a home folder for use with Terminal Server sessions. This directory can be either a local folder or a network share.

For information about setting Terminal Server profiles, see Terminal Services Profile in Help and Support Center for Windows Server 2003.

**Using Roaming Mandatory User Profiles**

Roaming user profiles allow users to move between different computers and maintain the same environment and preference settings. A roaming mandatory user profile is a preconfigured user profile that you assign to users. Because users cannot change a roaming mandatory profile, using this type of profile ensures that these user profiles remain at a manageable size. Additionally, you can assign one mandatory profile to all users who require identical desktop configurations. This allows you to change the desktop environments for all those users by changing only one profile.

Take the following issues into consideration when planning to use roaming mandatory user profiles with Terminal Server:

- When planning for the use of profiles for a large number of Terminal Server users, consider using Terminal Server profiles rather than roaming user profiles.
- If you are combining Folder Redirection and roaming user profiles, it is recommended you not use quotas on the profile.
- If your users roam between computers that are running Windows XP Professional, Windows XP 64-Bit Edition, Windows Server 2003, and Windows 2000, you can use the **Prevent Roaming Profile changes from being propagated to the server** Group Policy setting to be sure that each client computer receives only the profile that applies to the particular platform that the user is logged on to. For more information, see "Group Policy in multiplatform networks" in Help and Support Center for Windows Server 2003. To find this topic, click **Index** in Help and Support Center, type the keywords "Group Policy," and then select the topic "multiplatform networks."

The roaming profile information is stored on the local hard drive of the terminal server. It is recommended that this information be deleted after the user logs off. You can do this by enabling the **Delete cached copies of roaming profiles** Group Policy setting (in System/User Profiles under User Configuration in the Group Policy Object Editor) and applying the setting to your Terminal Server OU.

**Important**

- In order to use roaming profiles on a group of Terminal Services computers, the Terminal Services computers must be identical in application and operating system configuration, such as the location of the systemroot folder and the installation location of all applications. Otherwise, group different configurations into different OUs and administer the roaming profiles separately.

For information about how to set or change a user's roaming profile path, see Change a user's Terminal Services profile path in Help and Support Center for Windows Server 2003.

**Planning for User Profile Storage and Management**

Unless you manage user profiles correctly, they can become very large and can cause problems for your Terminal Server users. In order to keep the size of your user profiles for Terminal Server under control, use the **Limit profile size** Group Policy setting or use mandatory profiles. You can find the **Limit profile size** Group Policy setting under User Configuration\Administrative Templates\System\User Profiles.

The profile path copies all user profiles to drive C of the terminal server by default. Depending on the number of users accessing your terminal server, this could greatly deplete the free space on this disk. Choose a location on a file or print server that has enough space to store the profiles and that is readily available to Terminal Server users, and then create a Windows Server 2003 share that users can access with read/write permissions. Do not store Terminal Server profiles and users' primary desktop profiles in the same location. You should store profiles in a different location from user home directories. For information, see "Change a user's Terminal Services profile path" in Help and Support Center for Windows Server 2003.

**Increasing Time-out Values for Profiles with Terminal Server**

**Caution**

- Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Windows Server 2003 Resource Kit Registry Reference on the *Windows Server 2003 Deployment Kit* companion CD, or at http://www.microsoft.com/reskit.

In a Terminal Server environment, because many users tend to access the terminal server and the profile server at the same time, the server can develop bottlenecks or the network itself can become saturated. This can cause problems with user profiles primarily because a time-out can occur during profile unloading or write back. As a result, changes to the profile are not saved. By increasing the time-out values when you set up Terminal Server, you can reduce the incidence of profile-related issues. You can increase profile time-out values by using the following procedure.

**To increase profile time-out values**

1. In the Group Policy Object Editor, navigate to the **Maximum retries to unload and update user profile** policy, which is located in Computer Configuration/Administrative Templates/System/User Profiles.

2. Enable this setting and set it to 120.

3. In the **Run** dialog box, type **regedit**, and then click **OK**.

4. Locate the following subkey in the registry and select it:

   HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Terminal Server

5. On the **Edit** menu, click **Add,** and then click **DWORD Value.**

6. Add a registry entry named LogoffTimeout with the following settings:

   - Base: Decimal

   - Value: 120 (4 minutes, time-out expressed in 2-second units)

     **Note**

Do not set this value lower than 3 minutes or higher than 15 minutes.

For more information, see article 299386, "Logoff Process May Not Be Completed Because Time-Out Is Too Slow" in the Microsoft Knowledge Base. To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Using Home Directories with Terminal Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

It is important that you plan for use of home directories in a Terminal Server environment because most applications must install user-specific information or copy configuration files for each user. By default, Windows Server 2003 defines a home directory for each user. For Terminal Server users, the default user's home directory is his or her user profile directory on the terminal server, for example \Wtsrv\Profiles*Username*. This directory contains user settings. Terminal Services writes user-specific application files, such as .ini files, and by default refers any application seeking the Windows system directory to the user's home directory.

Users typically save their personal files to their home directory, in the My Documents folder. This can be a problem if roaming profiles are used and the home directory is located within the user's profile directory. Windows Server 2003 copies everything in the user's profile directory to the profile cache on the local computer each time the user logs on. This can take considerable time and resources, particularly if the roaming profile is stored across the network or over a slow link. You can use Group Policy to redirect the My Documents folder to a central non–Terminal Server computer. For more information, see "Change a user's Terminal Services profile path" in Help and Support Center for Windows Server 2003.

It is recommended that you use Terminal Services–specific home directories. Choose a location on a file or print server for the home directories. Share the file and give Change permissions to Everyone, then change the home directory path for Terminal Server users. By default, users have full access to their individual home directory. Administrators can copy files into the directory, but not read or delete files there.

You can specify a location for redirecting the home directory for Terminal Services users with the **TS User Home Directory** Group Policy setting. With this setting you can specify the location of the home directory on the network or on the local computer, the root path, and the network drive letter if the root path is located on the network.

**Note**

- To facilitate the use of application compatibility scripts, use the same virtual drive letter for all user home directory redirection points. The first time you run an application compatibility script on a server, the server prompts you to set the drive letter that references the root of the user home directory. This drive letter is used for all subsequent application compatibility scripts. For terminal server farms, it is essential that the same drive letter be used on all the servers within the farm.

# Using Folder Redirection with Terminal Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Folder Redirection allows users and administrators to redirect the path of a folder to a new location. The new location can be a folder on the local computer or a directory on a network share. It is recommended that you redirect users' My Documents folder to a private server share by using Folder Redirection. Users can then access their My Documents folders from either a Windows XP Professional client computer or Terminal Server session as if they were accessing their local drives. This is especially useful for roaming users who access the terminal server from different computers at different times.

For general information about Folder Redirection, see "Folder Redirection" in Help and Support Center for Windows Server 2003. To find this topic, click **Index** in Help and Support Center, type the keywords "Folder Redirection," and then select the topic "overview."

When setting Folder Redirection, make sure that the user has write access to the folder in which you create the new folder for that user. If the user does not have sufficient access to the shared folder, the folder redirection fails and defaults to a dedicated folder created on the server or desktop to which the user logs on.

# Configuring User Group Policy Settings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Under User Configuration in the Group Policy Object Editor, you can set several Group Policy settings that are particularly useful for Terminal Server. Use these settings to control the user experience and prevent access to areas of the terminal server. For more information about each of the settings listed here, see the Group Policy Explain text associated with each setting. For a job aid to assist you in recording your Terminal Server Group Policy configuration decisions, see "Group Policy Configuration Worksheet" (SDCTS_2.xls) on the *Windows Server 2003 Deployment Kit* companion CD (or see "Group Policy Configuration Worksheet" on the Web at http://www.microsoft.com/reskit).

See the following resources for more specific information about using Group Policy:

- For general information about Group Policy, see the Management Services link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.
- For more information about designing a Group Policy infrastructure, see "Designing a Group Policy Infrastructure" in *Designing a Managed Environment* of this kit.
- For information about using Group Policy to lock down a Terminal Server session, see article 278295, "How to Lock Down a Windows 2000 Terminal Server Session" in the Microsoft Knowledge Base. To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.
- For more information about applying Group Policy to Terminal Server, see article 260370, "How to Apply Group Policy Objects to Terminal Services Servers." To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Note**

- Because these settings apply to the user, and not the computer, they affect the user environment regardless of which computer the user accesses. When applying settings that you want to apply only when users have a session on the terminal server (as opposed to their own desktop computer), use computer settings that apply to the terminal server. For more information, see "Designing Terminal Server Installation and Configuration" later in this chapter.

**Configuring the User Display**

A graphic-intensive display can affect performance for users of Terminal Server. To ensure the best possible performance, you can control what users can put on their desktops by configuring the Group Policy settings located under User Configuration/Administrative Templates/Control Panel/Display.

**Configuring desktop items**

Many organizations permit users to choose their own desktop wallpaper or screen savers. However, in a Terminal Server environment, these graphics can have an effect on performance. Use the following Group Policy settings to control users' ability to change wallpaper and screen savers.

**Screen savers** You can use several Group Policy settings to affect the user's screen saver. You can disable screen savers altogether by disabling the **Screen Saver** policy. You can also specify the screen saver by enabling this policy and also by enabling and specifying the screen saver executable name in the **Screen Saver executable name** policy. For more information about these Group Policy settings, see the **Explain** tab located on the property sheet for each policy.

**Wallpaper** By enabling the **Prevent changing wallpaper** setting you can disable all the options in the **Desktop** tab of Display in Control Panel. This includes changing the wallpaper and changing the appearance of the desktop icons. By not allowing these changes, you can ensure that users do not choose desktop display items that might affect the performance of the server.

**Configuring the desktop theme**

If you are hosting the full desktop with Terminal Server, by default the desktop environment resembles a Windows Classic desktop. By default Windows Server 2003 does not have themes enabled. You can enable themes by starting the Themes service and configuring it to start automatically. For more information about starting the Themes service, see "Configure how a service is started" in Help and Support Center for Windows Server 2003.

After you have configured the Themes service to start automatically, you can enforce a specific desktop theme or the Windows XP theme for your Terminal Server users by using the following procedure. For more information about choosing to use desktop themes with Terminal Server, see "Hosting Full Desktops with Terminal Server" earlier in this chapter.

**To load a specific theme for the desktop**

1. In the Group Policy Object Editor, navigate to User Configuration/Administrative Templates/Control Panel/Display/Desktop Themes.

2. Open the **Load a specific visual style file or force Windows Classic** setting.

3. Take one of the following actions, depending on what you are trying to achieve:

    - To force Windows Classic, enable this setting.

    - To load the Windows XP theme, enable the setting and type **%windir%\resources\Themes\Luna\Luna.msstyles** in the **Path to Visual Style** dialog box. For information about using the Windows XP theme with Terminal Server, see "Choosing Applications to Host" earlier in this chapter.

    - To load another theme or a custom theme, type the path to that theme in the dialog box.

**Restricting Access to Drives on a Terminal Server**

You can use Group Policy settings to hide and restrict access to drives on the terminal server. By enabling these settings you can ensure that users do not inadvertently access data stored on other drives, or delete or damage program or other critical system files on the C drive. The following settings are located in the Group Policy Object Editor under User Configuration/Administrative Templates/Windows Components/Windows Explorer:

- **Hide these specified drives in My Computer.** You can remove the icons for specified drives from a user's My Computer folder by enabling this setting and using the drop-down list to select the drives you would like to hide. However, this setting does not restrict access to these drives.

- **Prevent access to drives from My Computer.** Enable this setting to prevent users from accessing the chosen combination of drives. Use this setting to lock down the terminal server for users accessing it for their primary desktop.

**Configuring Start Menu and Taskbar Items**

You can use Group Policy settings to remove and to restrict access to items from the **Start** menu for Terminal Server users. The following settings are located in User Configuration/Administrative Templates/Start Menu and Taskbar:

- Enabling the **Remove Run menu from Start Menu** setting removes this menu from the **Start** menu. It also removes the **New Task** command from Task Manager and blocks the user from accessing Universal Naming Convention (UNC) paths, local drives, and local folders from the Internet Explorer address bar. While these are not the only methods for running applications, enabling this setting makes it difficult for users to access resources on the server or network.

- Enabling the **Remove Logoff on the Start Menu** setting prevents users from logging off the server from the Start menu. Enabling this setting does not prevent users from logging off using CTRL+ALT+DEL.

- Enabling the **Remove and Prevent access to the Shut Down command** prevents administrators from accidently shutting down the terminal server.

- Enabling the **Remove links and access to Windows Update** setting prevents users from attempting to download updates to Windows on to the server.

- Enabling the **Remove Favorites menu from Start Menu** setting reduces confusion for users who do not have access to the Internet.

# Planning Terminal Server User Rights and Logon

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the Remote Desktop Users group to manage user rights on a terminal server. There are also special logon configurations and Internet Explorer security configurations you can set for Terminal Server.

**The Remote Desktop Users Group**

Before users can create a remote connection with Remote Desktop, they must have the appropriate permissions. By default, members of the Administrator group can connect remotely to the server. Members of the Remote Desktop Users built-in local group also have remote logon permissions. This built-in group gives administrators control over the resources that Terminal Server users can access. Access to Terminal Server is distributed with a default set of user rights that you can change for extra security. To provide users or groups with the appropriate rights, use the Terminal Services Configuration snap-in Permissions tab to add these groups or users and to modify permissions. For more information about managing permissions, see Managing Permissions on Connections in Help and Support Center for Windows Server 2003.

**Important**

- By default, the Remote Desktop Users local group for Windows Server 2003 Terminal Server is empty.

Populate the Remote Desktop Users group with your Terminal Services users group by using the Computer Management tool. For more information about populating the Remote Desktop Users group, see "Add users to the Remote Desktop Users group" in Help and Support Center for Windows Server 2003.

To control who can add members to the Remote Desktop Users group, add this group to **Restricted Groups** by using the following procedure:

**To add the Remote Desktop Users group to Restricted Groups**

1. In the Security Templates Microsoft Management Console (MMC) snap-in, create a new template, or use an existing one.
2. In the navigation pane, right-click **Restricted Groups** in the template, click **Add Group**, and then type **Remote Desktop Users**.
3. In the details pane, double-click **Remote Desktop Users**, click **Add Members**, and select the users who you want to add to this group.

**Planning for Automatic Logon**

With Terminal Server, you can allow users to connect without entering a user name and password. You can do this on a per-user basis through the Remote Desktop Connection tool or on a per-server basis through TSCC or through Group Policy.

When you enable this, anyone with a Remote Desktop client can log on to the server. Use this connection method only in conjunction with starting users directly into a line-of-business application, especially if the application itself requires a password for access. You can enable this setting on a per-user basis through the Remote Desktop Connection tool or Group Policy or on a per-server basis through TSCC or through Group Policy. A per-server automatic logon policy is appropriate when a server is dedicated to a particular task-based application. If a server hosts more than one application, assign automatic logon on a per-user basis.

**Editing User-Specific Logon Information**

When users log on to the system, Terminal Services executes a batch file called UsrLogon.cmd in the system32 directory to make any modifications to the end-user environment and to ensure that users can run their applications correctly. If Terminal Server modifications are necessary to the user environment, you can make them by editing this file. Be aware that editing this file can affect the logon compatibility scripts that were written for applications. For more information about compatibility scripts, see "Identifying Ideal Candidates for Hosting" earlier in this chapter.

In your logon scripts, consider checking for the presence of the environment variables *clientname* or *sessionname*. These environment variables are Terminal Server–specific, and they only appear in a user environment when the user is logged on to a terminal server. You might choose to make changes to the user environment, for example omitting the execution of antivirus software, if the script determines that the environment is running on Terminal Server.

**Internet Explorer Enhanced Security Configuration**

Windows Server 2003 is installed with the Internet Explorer Enhanced Security Configuration enabled. This configuration decreases the exposure of your server to attacks that can occur through Web content and application scripts. As a result, some Web sites might not display or perform as expected. For a better user experience with Terminal Server, remove the enhanced security configuration from members of the Users group. Because these users have fewer privileges on the server, they present a lower level of risk if they are victims of an attack. This configuration allows users to browse Internet and intranet sites much as if they were using a stand-alone desktop computer.

For more information about Internet Explorer Enhanced Security Configuration settings, see "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

You can also configure Internet Explorer Enhanced Security Configuration through Unattended Setup. For more information, see "Enabling Terminal Server Using an Automated Installation Method" later in this chapter.

# Designing Terminal Server Installation and Configuration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By carefully planning how you install and configure the various components of your Terminal Server solution, you can save considerable time in the installation and make management of your servers easier. Figure 4.5 describes the steps in this process. The components needed for a complete Terminal Server solution include the terminal servers themselves, the license server, and the applications that you plan to host, as well as a load-balancing solution and a Session Directory server if you plan to use them.

**Figure 4.5 Designing Terminal Server Installation and Configuration**

# Designing the Installation Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Selecting the best way to deploy your terminal servers depends on the scope of your use of Terminal Server. You can enable Terminal Server on a server that has Windows Server 2003 already installed by using Add or Remove Programs in Control Panel or the Configure Your Server Wizard. You can also deploy Windows Server 2003 with Terminal Server enabled by using an automated installation method. These options are discussed in further detail in the following sections.

# Enabling Terminal Server Manually

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are deploying just one terminal server, or if you are upgrading to Windows Server 2003, it might be easiest to enable Terminal Server on a server that already has the operating system installed and configure the server individually. You can accomplish this through the Configure Your Server Wizard or through Add or Remove Programs in Control Panel. For information about how to use the Configure Your Server Wizard, see "Install Terminal Server" in Help and Support Center for Windows Server 2003. To enable Terminal Server through Add or Remove Programs, open Add or Remove Programs from Control Panel, or in the **Run** dialog box, type **control appwiz.cpl**, and click Add/Remove Windows Components.

**Note**

- You can also install Terminal Server Licensing through Add or Remove Programs.

**Internet Explorer Enhanced Security Configuration Considerations**

If you choose to install Terminal Server by using Add or Remove Windows Components in Add or Remove Programs, a warning appears if the installation will proceed with Internet Explorer Enhanced Security Configuration enabled, and allows you to choose whether you want to proceed with this configuration. It is recommended that you choose No and return to Add or Remove Windows Components and disable this configuration to allow users to browse the Internet.

If you install Terminal Server through the Configure Your Server Wizard, no warning appears. When the Manage Your Server window appears after you have added the Terminal Server role, a message appears that indicates the status of the Internet Explorer Enhanced Security Configuration, and gives instructions about how to change it.

For more information about Internet Explorer Enhanced Security Configuration settings, see "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

# Enabling Terminal Server Using an Automated Installation Method

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

One way to ensure that your servers have a consistent configuration is by using an automated installation method to install Windows Server 2003 with Terminal Server enabled. The following automated installation methods are available in Windows Server 2003:

- Unattended Setup
- Sysprep
- Remote Installation Services (RIS)

If you are deploying Terminal Server with several configurations, you can enable Terminal Server on all of the servers by using an automated installation method, and then configure the servers individually after the installation.

You cannot configure settings such as Group Policy settings within the automated installation itself. However you can set up the installation to run scripts that can configure these settings and perform a wide variety of other configurations after the setup is complete. For more information about the options for automated installations, see the design chapters for the various automated installation methods in *Automating and Customizing Installations* of this kit and the "Microsoft Windows Corporate Deployment Tools User's Guide" in the \Support\Tools folder of the Windows Server 2003 operating system CD.

**Tip**

- If you deploy Terminal Server for use in a load-balanced farm, an automated installation method is an easy way to ensure an identical configuration on all the servers in the farm.

**Unattended Setup**

Unattended Setup uses an answer file to automate the setup of Windows Server 2003. It is the only way to automate an upgrade to Windows Server 2003. Unattended Setup is a good choice for installing Terminal Server if, for example, you are planning to deploy terminal servers with a few applications for different purposes. For more information about designing an Unattended Setup, see "Designing Unattended Installations" in *Automating and Customizing Installations* of this kit.

For Terminal Server, you need to make entries in a few of sections of the answer file (Unattend.txt) in order to complete the automated installation:

**[Components]**

The [Components] section contains entries for installing the components of Windows XP or Windows Server 2003 operating systems. These components use the values **On** or **Off** to install or not install the component.

**Note**

- The entries in this section can also be set in the Sysprep Factory mode, **sysprep -factory**, which is used for the preinstallation of Windows in an OEM manufacturing environment.

For Terminal Server, you can install the following components:

- **LicenseServer**. Set this to **On** if you are setting up the server as a license server for Terminal Server.
- **TerminalServer**.Set this to **On** if you are setting up the server as a terminal server.

  **Important**

  - When you install Terminal Server through Unattended Setup, it is installed by default with Internet Explorer Enhanced Security Configuration enabled for administrators, and disabled for users. To change Internet Explorer

Enhanced Security Configuration during Unattended Setup, you can configure IEHArdenUser and IEHArdenAdmin, also found in the [Components] section of the answer file. For more information about Internet Explorer Enhanced Security Configuration settings, see "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

- **TSWebClient**. Set this to **On** to install the ActiveX control and sample pages for hosting Remote Desktop client connections over the Web.

- **IEHardenUser.** This is set to **Off** by default, which removes the Internet Explorer Enhanced Security Configuration from members of the Restricted Users and Guests groups. For more information about Internet Explorer Enhanced Security Configuration settings, see "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

- **IEHardenAdmin**. This is set to **On** by default, which applies the Internet Explorer Enhanced Security Configuration to members of the Administrators and Power Users groups. For more information about Internet Explorer Enhanced Security Configuration settings, see "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

**[TerminalServices]**
If you set the TerminalServer entry to **On** in the answer file, you also need to set the following entries in the [TerminalServices] section:

**Note**

- You can also set these settings through the TSCC. If these settings are changed in TSCC after the installation, the new settings take precedence.

- **AllowConnections**. When set to **1** this entry enables Terminal Server by allowing connections. The default for this setting is **0**. You can also set this through Group Policy.

- **LicensingMode**. This setting configures how Terminal Services manages CALs — **PerDevice** or **PerUser**. The default for this setting is **PerDevice**. For more information about choosing a licensing mode, see "Choosing the Licensing Model" earlier in this chapter.

- **PermissionsSetting**. This setting allows you to choose the security mode for Terminal Server users during terminal server sessions. This entry maps to the Permission Compatibility setting in TSCC. The default setting for this entry is **0**, which maps to Full Security in TSCC.

  **Important**

  - Only set PermissionSetting to **1**, which maps to Relaxed Security in TSCC, if you are running older applications and your testing has determined that your applications will not run properly with the setting at **0**. For more information, see "Designing the Terminal Server Configuration" later in this chapter.

**Sysprep**
Sysprep is an image-based method that you can use for clean installations of Windows Server 2003 with Terminal Server enabled. Using Sysprep is the quickest way to install Terminal Server along with many applications. Sysprep is a good choice for installing Terminal Server if, for example, you are deploying a terminal server farm.

If you plan to use a single image for many server configurations, you can use Sysprep in factory mode. For Terminal Server, you can configure the entries in the [Components] section of the Winbom.ini file for use with Sysprep in factory mode. These settings are the same as for the [Components] section of the Unattend.txt file for Unattended Setup discussed earlier in this section. For more information about using Sysprep for automated installations, see "Designing Image-based Installations with Sysprep" in *Automating and Customizing Installations* of this kit.

**RIS**
RIS requires the deployment of a network infrastructure specifically for its use and requires that you install Active Directory in your organization. Plan to use RIS for the automated installation of Terminal Server only if you are planning to use it throughout your organization for installing Windows Server 2003. If you do plan to use RIS for installing Terminal Server, you

need to be sure to image a terminal server that does not already have licenses. You need to install licenses on the servers after the installation. For more information about using RIS for automated installations, see "Designing RIS Installations" in *Automating and Customizing Installations* of this kit.

# Upgrading to Windows Server 2003 Terminal Server

Updated: March 10, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The best way to install Terminal Server is by performing a clean installation. However, if you already have a Windows 2000 Terminal Services in Application Mode or Windows NT 4.0 Terminal Server Edition infrastructure in place, you might want to perform an upgrade. There are a number of other reasons why you might perform an upgrade, for example, if you are transitioning gradually to Windows Server 2003 or if you want to retain the ability to use your older software and device drivers. If you are upgrading your terminal servers from Windows 2000 to Windows Server 2003, you must take into consideration a number of changes and new requirements with Windows Server 2003.

**Note**

- When performing an operating system upgrade on a terminal server, the security template that is applied does not reset the access control lists (ACLs). This is in contrast to a non-Terminal Server upgrade, which resets the ACLs. If you are moving from Windows NT 4.0 Terminal Server Edition or Windows 2000 in Relaxed Security mode to Windows Server 2003 Terminal Server, consider performing a clean installation.

**Upgrading Terminal Server Licensing**

With Windows Server 2003, you must use a license server that is running Windows Server 2003. You can still issue licenses to Windows 2000 Terminal Server with a license server that is running Windows Server 2003, if you plan to gradually upgrade your terminal servers. Also, with Windows Server 2003 you no longer need to host your license server on a domain controller. For more information about choosing a host server for Terminal Server Licensing, see "Planning the License Server" earlier in this chapter.

Table 4.1 summarizes the licensing issues to be aware of when upgrading from Windows 2000 Terminal Services to Windows Server 2003 Terminal Server.

**Table 4.1 Licensing Issues for Upgrading Terminal Server**

| If you are... | You need to... |
|---|---|
| Gradually upgrading your terminal servers to Windows Server 2003 from Windows 2000. | Upgrade your license server to Windows Server 2003 at the same time that you upgrade the first terminal server. You can also ensure that the license server issues the appropriate CAL for Windows 2000 or Windows Server 2003 through Group Policy. For more information, see "Designing the Terminal Server Configuration" later in this chapter. |
| Performing an in-place upgrade of the domain controller that hosts Terminal Server Licensing. | Consider keeping your licenses on the same server whether or not you plan to host your license server on a domain controller. You can demote the domain controller either before or after you upgrade the server to Windows Server 2003 by using the Active Directory Installation Wizard (dcpromo.exe).<br><br>If you upgrade your license server, you must reactivate the license server.<br><br>For information about upgrading a domain controller, see "Upgrading from Windows 2000 Domains to Windows Server 2003 Domains" in *Designing and Deploying Directory and Security Services* of this kit. |

| | |
|---|---|
| Performing a clean installation of the server that hosts Terminal Server Licensing. | Deploy Terminal Server Licensing on a server that runs Windows Server 2003, migrate the client access licenses (TS CALs) to the new license server, and then deactivate the previous license server by doing the following:<br><br>1. Determine the server on which you want to install Terminal Server Licensing and whether you want it to serve as an Enterprise license server or as a Domain license server. For more information, see Terminal Server license server roles (http://go.microsoft.com/fwlink/?LinkId=62981).<br><br>2. Install and then activate Terminal Server Licensing on the new Windows Server 2003 license server. For step-by-step instructions, see Install Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkId=62988) and Activate a Terminal Server License Server (http://go.microsoft.com/fwlink/?LinkId=62991).<br><br>3. Install the same number and type of TS CALs on the new license server that you had on the Windows 2000 license server. To do this, call the Microsoft Clearinghouse. When you call the Clearinghouse, make sure that you have your License Purchase Agreement information (documentation of your purchased TS CALs) readily available to facilitate the re-issuance of the CALs. For step-by-step instructions on how to locate the correct telephone number for the Clearinghouse, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=62994).<br><br>4. Make sure that your terminal server can discover the new license server. For step-by-step instructions, see "verify whether the terminal server can discover the license server" in The terminal server cannot locate the license server (http://go.microsoft.com/fwlink/?LinkId=62995). Clients that received CALs from the previous license server will continue to operate as normal until their CALs expire. When the previously issued CALs expire, new licenses will be requested for these clients from the new license server. For information about license issuance and expiration, see Recovering client access licenses on a Terminal Server license server (http://go.microsoft.com/fwlink/?LinkId=62996).<br><br>**Important**<br>To be discoverable in a domain, a license server must be a domain controller. If you did not install Terminal Server Licensing on a domain controller, then, on the terminal servers, configure the new license server as a preferred license server, so that it can be discovered in the domain. For step-by-step instructions, see "Set a preferred license server" in The terminal server cannot locate the license server (http://go.microsoft.com/fwlink/?LinkId=62995). For detailed information about the license server discovery process, see "Licensing Service Discovery" in Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkId=26220).<br><br>5. Deactivate the previous license server. For step-by-step instructions, see Deactivate a Terminal Server license server (http://go.microsoft.com/fwlink/?LinkId=62998). |

| | |
|---|---|
| Redeploying Terminal Server Licensing to a new server. | Deploy Terminal Server Licensing on a server that runs Windows Server 2003, migrate the client access licenses (TS CALs) to the new license server, and then deactivate the previous license server by doing the following:<br><br>1. Determine the server on which you want to install Terminal Server Licensing and whether you want it to serve as an Enterprise license server or as a Domain license server. For more information, see Terminal Server license server roles (http://go.microsoft.com/fwlink/?LinkId=62981).<br><br>2. Install and then activate Terminal Server Licensing on the new Windows Server 2003 license server. For step-by-step instructions, see Install Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkId=62988) and Activate a Terminal Server License Server (http://go.microsoft.com/fwlink/?LinkId=62991).<br><br>3. Install the same number and type of TS CALs on the new license server that you had on the Windows 2000 license server. To do this, call the Microsoft Clearinghouse. When you call the Clearinghouse, make sure that you have your License Purchase Agreement information (documentation of your purchased TS CALs) readily available to facilitate the re-issuance of the CALs. For step-by-step instructions on how to locate the correct telephone number for the Clearinghouse, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=62994).<br><br>4. Make sure that your terminal server can discover the new license server. For step-by-step instructions, see "verify whether the terminal server can discover the license server" in The terminal server cannot locate the license server (http://go.microsoft.com/fwlink/?LinkId=62995). Clients that received CALs from the previous license server will continue to operate as normal until their CALs expire. When the previously issued CALs expire, new licenses will be requested for these clients from the new license server. For information about license issuance and expiration, see Recovering client access licenses on a Terminal Server license server (http://go.microsoft.com/fwlink/?LinkId=62996).<br><br>**Important**<br>To be discoverable in a domain, a license server must be a domain controller. If you did not install Terminal Server Licensing on a domain controller, then, on the terminal servers, configure the new license server as a preferred license server, so that it can be discovered in the domain. For step-by-step instructions, see "Set a preferred license server" in The terminal server cannot locate the license server (http://go.microsoft.com/fwlink/?LinkId=62995). For detailed information about the license server discovery process, see "Licensing Service Discovery" in Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkId=26220).<br><br>5. Deactivate the previous license server. For step-by-step instructions, see Deactivate a Terminal Server license server (http://go.microsoft.com/fwlink/?LinkId=62998). |

**Group Policy Upgrade Issues**

Windows Server 2003 offers more Terminal Server–specific Group Policy settings than did earlier versions of the Windows operating system. Your initial Group Policy settings vary depending on whether you perform an upgrade or clean installation. When you upgrade your terminal servers to Windows Server 2003, the new Group Policy settings are left Not Configured rather than set to their default. When you perform a clean installation, the default settings are used. Carefully review the Group Policy settings for Terminal Server to choose the best settings for your environment. For more information, see "Designing the Terminal Server Configuration" later in this chapter.

Also new with Windows Server 2003 is the Remote Desktop Users group. Users are required to be members of this built-in local group in order to gain access to the terminal server. This group is empty by default. For more information, see "Planning Terminal Server User Rights and Logon" earlier in this chapter.

**Permission Compatibility**

If you are upgrading from Windows 2000 Terminal Services or Windows NT 4.0 Terminal Server Edition, and are planning to host the same applications with Windows Server 2003, be aware that, in order for them to work, some older applications require access to system resources, such as the registry, for members of the Users group on a terminal server. If your older applications require this type of access, you can control the Permission Compatibility setting in TSCC on the **Server**

**Configuration** tab for application compatibility. This setting is set to Full Security by default, which restricts access to system resources.

**Important**

- Do not set this setting to Relaxed Security unless you have performed thorough testing and have determined that your applications will not work properly otherwise. Relaxed Security mode gives users access to system components on the server, such as the ability to modify the system32 directory where operating system files are stored, access to the Program Files directories, and read/write access to registry settings in HKEY_LOCAL_MACHINE.

For more information about configuring this setting, see "Designing the Terminal Server Configuration" later in this chapter.

**Automated Installation**

If you are planning to use an automated installation method to upgrade your terminal servers, you can do this only by using Unattended Setup. For more information about using Unattended Setup with Terminal Server, see "Designing Application Installation" later in this chapter. For more information about installing Windows Server 2003 by using an automated installation method, see *Automating and Customizing Installations* of this kit.

**Internet Explorer Enhanced Security Configuration**

When you upgrade from Windows 2000 Terminal Services, Internet Explorer Enhanced Security Configuration is enabled for administrators and disabled for users by default. With this configuration, users are able to browse and download files from the Internet without restriction, but administrators cannot do so. For more information about Internet Explorer Enhanced Security Configuration settings, see "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

# Designing Application Installation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

There are several ways in which to install the applications you plan to host on the terminal server. The size of your deployment and whether you have Active Directory installed are factors in deciding which method to use.

**Installing Applications Manually**
With manual installations, in order for Terminal Services to replicate the necessary registry entries or .ini files for each user, the user must install the application by using **Add or Remove Programs** in Control Panel. You can also install applications from the command line by using the **change user /install** command, but using **Add or Remove Programs** is preferable.

**Installing Applications Using Group Policy and Windows Installer**
A recommended way to distribute applications to a server in a Terminal Services farm is to use Group Policy. Active Directory is required for this. By separating the terminal servers into their own OU, you can create a Group Policy object that is linked to only that OU, and you can then assign Windows Installer (.msi) packages to it. Assigned applications are installed on the server when the server is turned on. For more information, see "Assigned and published programs" in Help and Support Center for Windows Server 2003. For more information about deploying software using Group Policy, see "Deploying and upgrading software" in Help and Support Center for Windows Server 2003 and "Deploying a Managed Software Environment" in *Designing a Managed Environment* of this kit.

**Note**

- Terminal Server cannot accept published programs because publishing occurs on a per-user basis. Additionally, you must assign programs on a per-computer basis, rather than on a per-user basis.

Some applications require a transform file (.mst) when when you install them by using Windows Installer. *Transform files* are modifications to .msi packages that you create to instruct Windows Installer to install the application and all the needed components locally on the terminal server. Test your application installation to determine if a transform file is needed. For more information about .mst files, see "Deploying a Managed Software Environment" in *Designing a Managed Environment* of this kit.

To create and install applications using an .mst file, see the Office 2000 Resource Kit at the MSDN Library link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. Search for the topics under "Installing Office in a Windows Terminal Server Environment" in the Office 2000 Resource Kit on this Web site.

**Note**

- Microsoft® Office XP installs and runs on a terminal server correctly without requiring a transform file.

**Running Compatibility Scripts**
If it is necessary to run application compatibility scripts for any of the applications that you are hosting with Terminal Server, you must run them after you install the application, but before you restart the server. For more information about compatibility scripts, see "Identifying Ideal Candidates for Hosting" earlier in this chapter and the Optimizing Applications for Windows 2000 Terminal Services link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

When you run the first compatibility script, you are asked to select a drive letter to be used by this script and all future compatibility scripts. This drive letter must be the same as the users' home directory. For more information about using home directories with Terminal Server, see "Using Home Directories with Terminal Server" earlier in this chapter.

# Supporting Multilingual and International Users

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Server 2003 with Terminal Server enabled offers multilingual support. Using this capability, Terminal Services can simultaneously serve users in any language that is installed on the server. Terminal servers that are running Windows Server 2003 can take advantage of the multilingual user interface (MUI). This interface allows you to install multiple languages on the system and configure them on a per user basis. You must load MUI to take advantage of this functionality, which simplifies the deployment of Terminal Services within a multinational organization. It is also recommended that you install the keyboard drivers for any language-specific keyboards that you use in your organization as part of the Terminal Services installation. You can support your users around the world who can understand and work in English by hosting all users on the International English version of Windows Server 2003. This ensures that the organization is not in violation of United States export laws regulating strong encryption. However, using the International English Version might be inadequate if the organization must provide support for different languages. By default, Terminal Server installs all the available keyboard layouts, including support for Asian non-Input Method Editor keyboards.

While loading the MUI, install all of the languages that you expect users to need. The installation copies the appropriate language DLLs and Help files. By using Regional and Language Options in Control Panel, users can select their default language and keyboard settings. Regional and Language Options also includes such settings as date and currency formatting. Because this setting is stored in the user profile, individual users can adjust the settings to match their locality. If a user has a roaming profile that specifies a different language than the language that is loaded in the user profile, then the system uses the default user language from the profile.

**Important**

- Roaming users should not use Folder Redirection with MUI. If they do, they might create multiple language versions of My Documents and other per-user folders on the computer. If the user interface (UI) language files that are needed to support the roaming user's default UI language have not been installed on the computer, the localized names of the new folders might not display correctly.

For more information about MUI, see the MultiLanguage Version link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Designing the Terminal Server Configuration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can configure Terminal Services by using TSCC Microsoft Management Console (MMC) snap-in, Group Policy, or WMI. Some server configurations settings for Terminal Services, for example the Sessions settings, are also configurable for the user. Because the server settings can override the user settings, it is recommended that you set these settings on the server whenever possible.

# Choosing a Terminal Server Configuration Tool

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Choose a configuration tool based on your level of permission, the tasks you want to accomplish, and the level at which you want to apply settings. If you are a domain administrator configuring global settings on a number of terminal servers, it is recommended that you use Group Policy. WMI is a good choice for automating the configuring of global settings on a number of terminal servers if you are not a domain administrator and if you are familiar with scripting. However, you must be a local administrator on every computer you want to configure using WMI. You can also invoke WMI to configure settings automatically after you install Windows Server 2003 with an automated installation method. For more information about configuring automated installation to invoke scripts, see the design chapter in *Automating and Customizing Installations* that corresponds to the automated installation method you have chosen to use. The TSCC snap-in is an easy-to-use tool for configuring a single terminal server, and is useful for configuring unique settings for a particular server. Table 4.2 summarizes these tools, and the following sections describe each tool in further detail.

**Table 4.2 Benefit and Restriction Comparison for Terminal Server Configuration Tools**

| Tool | Benefits | Restrictions |
|---|---|---|
| Group Policy | Can centrally configure terminal servers and Terminal Server users by applying policies to OUs.<br>Always overrides configurations set by using other tools. | Administrator must be a domain administrator to apply Group Policy settings to OUs.<br>Must have Active Directory in place. |
| WMI Terminal Server provider | Can configure many terminal servers or Terminal Server users using scripts. | Administrator must know how to write scripts. |
| Terminal Server Connection Configuration snap-in | Can configure unique per-server settings.<br>Some configurations only available in TSCC snap-in. | Can be overwritten by Group Policy settings.<br>Can be applied only to a single terminal server and its users.<br>Cannot be used to configure a remote server. |

Your choice of tools might also depend on your server environment or number of connections. Take the following information into consideration when making your choice:

- In an operating system environment where only Windows Server 2003 is run, you can use Terminal Server Group Policy settings to configure all settings that apply across an OU. You can also configure individual Windows Server 2003 operating systems using Group Policy on the local Group Policy object.

- In server environments where several different versions of the Windows operating system are run, you might need to use a combination of tools. For example, you might configure the Windows Server 2003 operating systems with Group Policy, while using TSCC to configure servers that are running earlier versions of Windows.

- If you have two or more connections on the same computer, and you want to configure each connection differently, you cannot use Group Policy. Instead, use the TSCC tool, which allows you to configure Terminal Services settings on a per-connection basis.

**Using Group Policy**

You can use Group Policy to configure Terminal Server connection settings, set user policies, configure terminal server clusters, and manage Terminal Server sessions. You can apply Group Policy settings for users of a computer through the Remote Desktop Users group, for individual computers through local Group Policy, or for groups of computers through a Terminal Server OU. To set local policies for users of a particular computer, you must be an administrator for that computer. To set policies for an OU in a domain, you must be an administrator for that domain. Settings that are specific to Terminal Server are located under Computer Configuration/Administrative Templates/Windows Components/Terminal Services. For more information, see "Configuring Terminal Services with Group PolicyConfiguring Terminal Services with Group Policy" in Help

and Support Center for Windows Server 2003.

**Note**

- There are many new Group Policy settings with Windows Server 2003. If you are upgrading your terminal servers from Windows 2000, the new Group Policy settings will be set to Disabled by default. For new Windows Server 2003 deployments, the defaults are stated in the "Designing Terminal Server Connection Configurations" section later in this chapter.

**Using the Terminal Services WMI provider**

The Terminal Services WMI provider allows administrators to create custom scripts for configuring, managing, and querying terminal servers. It contains properties and methods that can perform the same tasks as Terminal Services configuration tools and command-line tools, but remotely and through scripted applications. A *provider* is an architectural element of WMI that extends the WMI schema of classes to allow WMI to work with new types of objects. The Terminal Services provider defines classes for querying and configuring Terminal Services. The Terminal Services WMI provider is defined in *systemroot*\System32\Wbem\tscfgwmi.mof. For more information about WMI, see "Configuring Terminal Services with WMIConfiguring Terminal Services with WMI" in Help and Support Center for Windows Server 2003.

**Note**

- Configuration settings applied with the Terminal Services WMI provider operate in the same order of precedence as they do if applied with the corresponding configuration tool. In general, Group Policy settings always override settings applied with WMI. For more information about using WMI, see the TechNet Script Center link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Using the TSCC snap-in**

With the TSCC snap-in you can configure the RDP connection parameters and connection permissions for the terminal server. You can apply settings only to a single terminal server and its users, however, and you cannot use TSCC to configure a remote server. In addition, there are several settings that you can set only by using TSCC. For more information, see "Configuring Terminal Services with TSCC" in Help and Support Center for Windows Server 2003.

# Designing Terminal Server Connection Configurations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the following guidelines to design the configuration of the connections to your terminal servers. If you are using TSCC to configure a single server, you can use the Terminal Services Connection Wizard to configure these settings when you create a new connection. For more information about configuring Terminal Server with TSCC when you create a new connection, see "Make a new connectionMake a new connection" in Help and Support Center for Windows Server 2003. You can also use Group Policy or WMI to configure the connections to many terminal servers. For a job aid to assist you in recording your Terminal Server Group Policy configuration decisions, see "Group Policy Configuration Worksheet" (SDCTS_2.xls) on the *Windows Server 2003 Deployment Kit* companion CD (or see "Group Policy Configuration Worksheet" on the Web at http://www.microsoft.com/reskit).

**Data Encryption**

You can assign data transfer encryption levels between the Remote Desktop client and Terminal Server by using either Group Policy or TSCC. The default RDP encryption level is **Client Compatible**. You can choose one of the following possible choices for encryption:

- **FIPS Compliant.** Encrypts traffic between client and server to meet the Federal Information Processing Standard 140-1 (FIPS 140-1). Use this level when Terminal Services connections require the highest degree of encryption, such as those required by the U.S. federal government.

- **Client Compatible.** With Client Compatible encryption, traffic between the client and the server is encrypted using the RC4 algorithm and the strongest key the client supports (40-bit, 56-bit, or 128 bit). The server negotiates with the client to determine the key strength on connection, however the server does not accept non-encrypted client connections.

- **High.** Traffic in both directions is encrypted using the RC4 algorithm and a 128-bit key only. If a client does not support 128-bit encryption, it is not permitted to connect.

- **Low.** Traffic from the client to the server only is encrypted, at the strongest key that the client supports. This can improve performance on the client because the client does not have to decrypt the screen update data coming from the server. The client still encrypts the keystroke and mouse data that it sends to the server. This also allows you to use products to improve performance over a WAN, for example to use between a branch and a home office. Use this setting only if you are planning to use these products. A malicious user can monitor documents and data coming from the server over the link if this setting is used.

On the **General** tab of TSCC or on the Data Encryption property page of the Terminal Services Connection Wizard, the **Use standard Windows authentication** check box is cleared by default. If you select this check box, lower security authentication mechanisms are permitted.

**Logon Settings**

By default, users are allowed access to the terminal server using the information that they provided to log on to their remote desktop client. For a more secure system, you can require users to provide logon credentials to access the terminal server.

You can allow access to the server based on the credentials provided here by clicking the **Always use the following logon information** radio button on the **Logon Settings** tab of TSCC or by enabling the **Always prompt client for password upon connection** Group Policy setting located in the Encryption and Security folder under Terminal Services in Computer Configuration. Use one of these options only if you are hosting an application that requires a password for access. For more information, see "Planning Terminal Server User Rights and Logon" earlier in this chapter.

**Remote Procedure Call (RPC) Security Policy**

You can enable this Group Policy setting to allow Terminal Server to accept only authenticated and encrypted requests. It is recommended that you enable this setting for increased security.

**Sessions**

You can set Terminal Server time-out and reconnection settings on the server to help manage the number of sessions held by a terminal server at any one time, to help manage unreliable connections for remote users, or to reduce the impact on the CPU of many users logging on to the server at the same time. You can set most of these settings by using TSCC or Group Policy. Exceptions are noted.

### Note

- You can also set these settings per user through Group Policy User Configuration and through Active Directory Users and Computers user properties. However, the Group Policy computer settings listed here take precedence over user settings.

**End a disconnected session**
You can set a limit on the time that a disconnected session continues to exist on the server. There can be many reasons why a session becomes disconnected, for example if a user's computer fails or if the user places the session into a disconnected state in order to access the same session from another location. The programs and processes that the user had running before the disconnection continue to run during a disconnected session. Because a user can have a disconnected session running on the server without realizing it, it is best to set a limit on how long disconnected sessions continue to run on the server. However, by setting this as high as possible you can achieve better server performance by reducing the additional CPU usage needed when a user reconnects to the server.

**Active session limit**
You can set a limit on how long a user can maintain an active session with the server. If you choose **Never**, the server allows an active session to continue forever.

**Idle session limit**
You can set a limit on how long an idle session remains open. An idle session occurs if there has been no mouse or keyboard activity for a certain period of time. This can indicate that the user has stepped away from the computer, presenting someone else with the opportunity to use his or her session. When a session has been idle for more time than you have specified, the user is notified and given two minutes to place the session back into an active state. If the two minutes elapse, the server disconnects or ends the session, depending on the settings you choose. Just as with choosing a timeframe for ending a disconnected session, it is important to understand users' work patterns and needs when choosing a limit for idle sessions.

### Note

- In a load-balanced farm, an idle session cannot be moved to a different server within the farm.

**Session reconnection**
By default, users can reconnect to a disconnected session from a computer other that the one from which they originally connected to the session. However, if a user connects from a Citrix ICA client, you can restrict the user to reconnecting only from the computer that originally connected to the session. This setting does not apply to Windows clients.

**Session limit behavior**
If you choose to enforce session limits for your users, you can ensure that users do not choose to have their sessions end when the connection to the server is broken for whatever reason. This way, you can be sure that all users can pick up where they left off in the event of a server failure, thereby reducing the loss of work and helpdesk incidents. If you choose to have sessions disconnect, you can use TSCC or Group Policy to specify the amount of time the session remains in a disconnected state.

**Shut down options**
You can use the following two Group Policy settings, found in the Terminal Services folder under Computer Configuration/Administrative Templates/Windows Components, to remove items from the **Start** menu and **Shut Down** dialog box so that users cannot use certain methods to disconnect or log off from their session:

- Enable the **Remove Windows Security item from the Start menu** policy to prevent users from unintentionally logging off of Terminal Server.

- Enable the **Remove Disconnect option from Shut Down dialog** policy to prevent users from using this method to disconnect from Terminal Server.

**Automatic reconnection**
You can allow a session to automatically reconnect to Terminal Server if the network connection is lost.

**User Environment**
Use the following settings to control the users' desktop environment.

**Launch application on connection**
If you are hosting a single application with Terminal Server, for example a line-of-business application or an application for

task workers who use the server for only one thing, you can have that application start automatically when the user logs on. This eliminates the possibility of the user running unauthorized applications on the server or accessing other parts of the server or the network through the server. For information about how to start an application on connection, see "Specify a program to start on session connectionSpecify a program to start on session connection" in Help and Support Center for Windows Server 2003. For more information about automatic logon, see "Planning Terminal Server User Rights and Logon" earlier in this chapter. You can configure this setting by using Group Policy (which you can apply to both computers and users), TSCC, and for users through the Remote Desktop Connection tool.

**Desktop wallpaper**

By default, sessions connecting to Windows Server 2003 Terminal Server do not display desktop wallpaper. For sessions connecting to servers running previous versions of Windows server operating systems and clients running Windows XP Professional or earlier, you can accomplish this by using Group Policy. For more information, see "Enforce removal of Remote Desktop wallpaperEnforce removal of Remote Desktop wallpaper" in Help and Support Center for Windows Server 2003.

### Note

- In Windows 2000 you can disable desktop wallpaper on the client from the **Environment** tab of the Terminal Services Connection Configuration tool.

**Remote Control**

You can use Remote Control to control or troubleshoot a user's session from a remote location. You can configure this setting by using Group Policy settings (which you can apply to both computers and users) or TSCC. If you choose to enable this in your organization, you can configure this setting in the following ways:

- Full Control with user's permission
- Full Control without user's permission
- View Session with user's permission
- View Session without user's permission

It is recommended that you configure this setting so that the user's permission is required to allow another person to access their computer through Remote Control. Keep in mind that even if you require a user to give permission, the user can choose to allow anyone who has acquired the correct permissions to access his or her computer. Also, some countries and regions have laws that do not allow the **View Session with user's permission** setting. If your organization has offices in several countries and regions, check the local laws before configuring Remote Control in this way. For more information about configuring sessions for Remote Control, see "Configure remote control settingsConfigure remote control settings" in Help and Support Center for Windows Server 2003.

**Client Settings**

You can use the settings discussed in this section to control certain aspects of the user experience and allow users to perform certain operations through their desktop computer rather than through the server.

**Client/Server data redirection**

You can use data redirection with Terminal Server to enable users to access and use resources from their desktop computers rather than from the terminal server. The most notable of these resources is printing, but you can also enable drive, audio, smart card, and clipboard redirection to the client computer. In general, restricting user's options to only those required to do their jobs can minimize the likelihood of introducing a security issue. You can configure most of these settings through Group Policy (which you can apply to computers only) or TSCC. Exceptions are noted.

### Note

- You can also configure redirection for disk drives, printer, and serial ports by using the Remote Desktop Connection tool on the client. For more information, see "Configuring Remote Desktop Connection" later in this chapter.

Table 4.3 summarizes the data redirection settings.

**Table 4.3 Data Redirection Settings**

| Data redirection type | Characteristics |
|---|---|
| Time zone | Only configurable by using Group Policy.<br><br>By default the session time zone is the same as the time zone of the terminal server. This can be an issue if you are using Terminal Server for remote or mobile users, especially when your line-of-business applications (for example, financial applications) have time dependencies. |
| Clipboard | By default, you can copy and paste between the terminal server and the Remote Desktop client. Disable this ability if you have sensitive data on the terminal server that should not be shared outside of the application in which it is used. |
| Smart card | Only configurable by using Group Policy.<br><br>By default the ability to log on to the Remote Desktop client is allowed. For more information about using smart card with Terminal Server, see the "Planning Network Security Components" earlier in this chapter. |
| Audio | By default, users cannot play audio on the Remote Desktop client. The sound plays on the server rather than the client computer. If you enable this setting, users can specify on the Remote Desktop Connection tool whether to play audio at their computer or the server, or to not have the sound play at all. |
| Serial port | By default, Terminal Server allows users to redirect data to peripherals attached to the serial (COM) port. Disable this capability unless there is a requirement for it. This prevents users from printing or copying sensitive data stored on the terminal server, and reduces vulnerabilities to security threats that could access your computer through these ports. |
| Client printer | By default, users can redirect print jobs to a printer attached to their client computer. Unless users need to print to a local printer, disable this capability so that users cannot print or copy sensitive data stored on the terminal server. |
| Parallel port | By default, Terminal Server allows users to redirect data to peripherals attached to the parallel (LPT) port. Disable this capability unless there is a requirement for it. This prevents users from printing or copying sensitive data stored on the terminal server, and reduces vulnerabilities to security threats that could access your computer through these ports. |
| Drive | By default, Terminal Server allows users to redirect data to the drives on the client computer. Unless there is a requirement for this, you should disable this capability so that users cannot copy sensitive data stored on the terminal server onto their local computer. |
| Default printer | By default, Terminal Server designates the client default printer as the default printer in a session. Unless users need to be able to print to a local printer, disable this capability so that users cannot print or copy sensitive data stored on the terminal server. |

**Color depth**
You can reduce or increase the maximum color depth depending on your bandwidth and fidelity requirements (greater color depth requires more bandwidth and resources on the terminal server).

**Number of connections**
By default, an unlimited number of sessions are permitted on the terminal server. Restricting the number of sessions improves the performance of Terminal Server because fewer sessions are demanding system resources.

You can configure this setting in the Terminal Services folder of the Group Policy Object Editor. In TSCC, you can configure the number of settings on the **Network Adapter** tab. You can also select the network adapter you want to use for the RDP connection traffic.

**Permissions**
You can use TSCC to change your permissions lists by adding and removing users and groups. You can also customize the permissions for users or groups on a per-connection basis. It is recommended that you give permissions to as few users and groups as is necessary, and to give those users and groups the lowest level permissions necessary for them to do their jobs. For more information about how to set permissions, see the topics under "Managing Permissions on ConnectionsManaging Permissions on Connections" in Help and Support Center for Windows Server 2003.

# Designing Server Setting Configurations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the following guidelines to design the configuration of your terminal servers.

**Keep-Alive Connections**
Configure this Group Policy setting to Enabled to ensure that the session state remains consistent with the client state. Use this setting only if you are having problems with users who cannot reconnect.

**Temporary Folders**
These settings can be set in the Server Settings folder of TSCC or in the Temporary Folders node of the Terminal Services administrative template in the Group Policy Object Editor. In TSCC, both of these settings are configured Yes by default, which means that temporary folders are used per session and deleted upon logging off. It is recommended that you keep the default settings unless there is a compelling business reason to change them.

**Delete or retain temporary folders when exiting** It is recommended that you configure your servers so that the data stored in the temporary folder for user sessions is deleted when users log off. This provides added security by eliminating a point of access for user data. It also provides a way to manage the load on the server, because temporary folders tend to grow quickly in size in a multiuser environment. If you are using Group Policy to set this setting (set to Disable to delete temporary folders), you must also configure the server to use per-session temporary folders.

**Use separate temporary folders for each session** This setting keeps each session's temporary folders in a separate folder, which enables you to configure the server to delete temporary folders when a single user logs off without affecting other users' sessions.

**Active Desktop**
You can restrict users from using Active Desktop by using TSCC or Group Policy under User Configuration/Administrative Templates/Desktop/Active Desktop. Active Desktop allows users to choose JPEG and HTML wallpaper, both of which can affect performance for the user because of the amount of data that needs to transfer from the server to the desktop. The default setting is Enable. It is recommended that you disable Active Desktop.

**Session Directory Settings**
If you are load balancing several terminal servers and using Session Directory, you can use TSCC or Group Policy to configure the servers to use Session Directory. Session Directory is a database that tracks user sessions that are running on load-balanced terminal servers. For more information about using Session Directory (including configuring Session Directory), see "Load Balancing Terminal Servers" earlier in this chapter. For more information about Session Directory, see the "Session Directory and Load Balancing Using Windows Server 2003 Terminal Server" white paper at the Terminal Services link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Licensing**
Use the following settings to configure the license server for Terminal Server. Most of these settings can be configured only through Group Policy. Exceptions are noted.

**Licensing Mode** You can set the licensing mode to Per Device or Per User through the TSCC Server Settings folder. For more information about licensing modes for Terminal Server, see "Choosing the Licensing Model" earlier in this chapter.

**License Server Security Group** Enabling this Group Policy setting and applying it to your license server creates a local group called Terminal Services Computers. The license server issues licenses only to the terminal servers in this group. You must add both the terminal servers for which you need to provide licenses and any license servers that might need to acquire licenses to this group for each license server. For ease of management in a large Terminal Server deployment, create an Active Directory global group named Terminal Server Licensing and add all of your terminal servers and all of your license servers to this group. Then add this group to the Terminal Services Computers group of each license server. Whenever you deploy a new terminal server or license server, if you add it to the Terminal Server Licensing group, it automatically appears in the Terminal Services Computers group for each license server.

**Prevent License Upgrade** In an environment with both Windows Server 2003 and Windows 2000 Terminal Server, enable this Group Policy setting to prevent the license server from handing out Windows Server 2003 CALs to terminal servers that are running Windows 2000.

**Limit users to one remote session**
By default, the TSCC setting that restricts users to one session is set to Yes. This ensures that a user who disconnects can

reconnect to the same session. This also conserves server resources by keeping the number of sessions on your server to a known number. You can enforce this setting domain-wide by using Group Policy. Limit users to one session unless you have a valid business reason for allowing more than one.

**Permission Compatibility**
This TSCC setting is set to Full Security by default. It restricts access to system resources, such as the registry, to members of the Users group on a terminal server.

### Important

- Although some older applications require such access, do not set this setting to Relaxed Security unless you have determined through testing that your applications do not work properly in Full Security mode.

**Home Directory**
Use this Group Policy setting to set the path for storing your user home directories. For more information about planning for storage of home directories, see "Using Home Directories with Terminal Server" earlier in this chapter.

**Roaming Profiles**
Use this Group Policy setting to set the path for storing your roaming user profiles. For more information about planning for storage of roaming user profiles, see "Using User Profiles in Windows Server 2003" earlier in this chapter.

# Using Software Restriction Policies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Software restriction policies, which are new with Windows XP and Windows Server 2003, enable you to identify software running on computers in your domain and to control whether a user can run them. Restricting certain types of applications can, for example, protect your organization against viruses. As a way to lock down the user environment on a terminal server, you can set up software restriction policies that allow users to run only specific applications on the server.

Software restriction policies are located in the Group Policy Object Editor under Windows Settings/Security Settings. Windows Installer operates with applications permitted by these Software Restriction Policies. For more information, see "Software Restriction Policies" in Help and Support Center for Windows Server 2003.

You can use software restriction policies with Terminal Server by using path rules, as shown in Table 4.4. These rules allow groups of users, when separated into different OUs, to access only the applications or application components that you want the groups of users to access on the server. For example, a company has a terminal server with a line-of-business application and a few productivity applications for the use of the accounts payable department. The company has decided that account managers need access to all of the available applications for that department, but the data-entry workers in that department need access only to the line-of-business application. The company sets the default rule to Disallowed and configures the software restriction policies as outlined in the following table.

**Table 4.4 Example Software Restriction Policy Configuration**

| Path Rule | Security Level |
|---|---|
| **Terminal Server OU** | |
| %windir% | Unrestricted |
| %windir%\regedit.exe | Disallowed |
| %windir%\system32\cmd.exe | Disallowed |
| %windir%\system32\command.com | Disallowed |
| %windir%\system32\dllcache | Disallowed |
| %windir%\system32\gpresult.exe | Disallowed |
| %windir%\system32\gpupdate.exe | Disallowed |
| %ProgramFiles%\Windows NT\Accessories | Unrestricted |
| **Data Entry OU** | |
| %ProgramFiles%\Accounts Payable Software | Unrestricted |
| **Account Managers OU** | |
| %ProgramFiles%\Microsoft Office\Office | Unrestricted |
| %ProgramFiles%\Internet Explorer | Unrestricted |

# Configuring Terminal Server for Differing Time Zones

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By default Terminal Server keeps track of time according to the time zone in which it has been configured, rather than on a per-user basis. This can be a problem when a user connects to a terminal server outside of the time zone in which the user is located because the local computer uses the time configured on the terminal server rather than the local time. If you are hosting time-sensitive applications on your terminal server or if you have processes in place that depend on the user's current local time, such as financial systems and calendaring, you might want to enable the Allow Time Zone Redirection Group Policy setting. This policy is located in Windows Components/Terminal Services. With this setting enabled, Terminal Services uses the server base time on the terminal server and the client time zone information to calculate the time on the session.

# Designing the Remote Desktop Connection Installation and Configuration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Remote Desktop Connection is the client-side tool that enables the connection to the terminal server. You need to install the Remote Desktop Connection on clients running Windows 2000 or earlier versions of the Windows operating system. On Windows XP clients, the Remote Desktop Connection is already installed. However you can preconfigure and distribute a connection to ensure the optimal settings for your users. For more information about the Remote Desktop Connection, see "Configuring Remote Desktop" in the *Windows XP Professional Resource Kit Documentation* (or see "Configuring Remote Desktop" on the Web at http://www.microsoft.com/reskit). Figure 4.6 shows the process for designing the Remote Desktop Connection installation and configuration.

**Figure 4.6 Designing the Remote Desktop Connection Installation and Configuration**

# Designing the Remote Desktop Connection Installation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you currently have Windows XP deployed to the clients, the Remote Desktop Connection is already built in. No further deployment is required unless you want to configure the connection.

The Remote Desktop Connection Windows Installer Setup package is a tool for deploying the Remote Desktop Connection and associated files for specially configured connections and on computers running Windows NT 4.0, Windows 2000 Server, Windows 2000 Professional, Windows 98, and Windows 95. You can also place the Client Windows Installer Setup package on a share for distribution through Group Policy to workstations running Windows Server 2003.

# Configuring Remote Desktop Connection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By using the Remote Desktop Connection tool, you can set from the client many of the same settings that you can set on the server using TSCC, Group Policy, or WMI. Because server settings override client settings, it is recommended that you set these settings on the server for ease of management. However, there are some situations where you might need to set these settings using the Remote Desktop Connection tool. An example is if you are providing access to the same terminal server for users with slightly different user roles or purposes. These settings are summarized in Table 4.5. For detailed explanations and recommendations for these settings, see "Designing the Terminal Server Configuration" earlier in this chapter.

**Table 4.5 Remote Desktop Connection Tool Settings**

| Tab | Description |
|---|---|
| General | Enter or change logon and connection settings. |
| Display | Change remote Desktop size (resolution) and color depth, and choose whether to display the connection bar in full-screen mode. |
| Local Resources | Control sound, the behavior of keyboard combinations, and connections to local devices (drives, printers, and serial ports). |
| Programs | Start a program upon connection to the terminal server. |
| Experience | Configure the connection speed and adjust the desktop environment for optimal performance |

With the Remote Desktop Connection tool you can also create and save a preconfigured Remote Desktop Connection for distribution.

**Preconfiguring a Remote Desktop Connection**

Remote Desktop Connection is installed by default on all versions of Windows Server 2003, most versions of Windows CE, and all versions of Windows XP operating systems. On earlier versions of Windows and on the Pocket PC you must manually install Remote Desktop Connection in order to connect to Terminal Server.

**Note**

- Windows 2000 includes the 32-bit Terminal Services Client for connecting to Terminal Services. It is recommended that you install the latest version of the Remote Desktop Connection to get the latest performance improvements.

You can preconfigure a Remote Desktop Connection for distribution to your client computers through Group Policy as an .msi package along with associated files.

**To create a preconfigured Remote Desktop Connection for distribution**

1. Open Remote Desktop Connection.

2. Expand the dialog box by clicking the **Options** button and configure the connection.

3. On the **General** tab of the Remote Desktop Connection tool, click the **Save As** button, navigate to the folder in which you want to save the configured connection, rename the file, and click **Save**.

4. Create an .msi package and distribute it to your Terminal Server users OU. For information about how to create an .msi package, see the Windows Installer documentation link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Note**

- Users need to enter their own user name and password into the connection.

**Configuring the Desktop Experience**

You can configure the connection speed and fine-tune the desktop environment for optimal performance by using the settings located on the **Experience** tab of the Remote Desktop Connection tool. The settings available on this tab are summarized in Table 4.6. Most of these settings relate to the graphical nature of the desktop. Because the processing for graphics happens on the server and must be transmitted to the desktop over the network connection, you can increase performance by allowing only the minimal settings that are necessary for your users. When you choose a connection speed, the check boxes are automatically selected to indicate the recommended settings for the richest visual experience possible at that speed.

**Table 4.6 Desktop Experience Settings**

| Setting | Description |
|---|---|
| Desktop background | Allows user to choose a custom background or wallpaper for their desktop. Because these can be very graphic-intensive, disable this setting unless it is necessary for your users. |
| Show contents of window while dragging | Redraws the contents of a window rather than showing just the frame of the window when you move the window across the screen. Because this redrawing takes place on the server and needs to be transmitted over the network connection to display on the user's desktop, disable this setting unless it is necessary. |
| Menu and window animation | Enables cascading menus and scroll transitions for menus and tool tips. Because this rendering takes place on the server and needs to be transmitted over the network connection to display on the user's desktop, disable this setting unless it is necessary. |
| Themes | Allows user to choose a background plus a set of sounds, icons, and other elements for their desktop. Because many themes are graphic-intensive, disable this setting unless it is necessary for your users. |
| Bitmap caching | Stores frequently used images on the local computer to speed up the connection. By enabling this setting, these images do not have to be transmitted across the network connection each time they appear on the desktop. This setting is enabled by default. |

**Locking Down the User Session**

You can configure Group Policy settings and apply them to your Terminal Server Users group to control your users sessions and user access to certain features on the server. For more information about controlling user sessions, see article 278295, "How to Lock Down a Windows 2000 Terminal Server Session." To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. You can also lock down your users' sessions by using the Security Templates MMC snap-in or the settings under Computer Configuration/Windows Settings/Security Settings in the Group Policy Object Editor.

# Additional Resources for Hosting Applications with Terminal Server

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

These resources contain additional information and tools related to this chapter.

**Related Information**

- The *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit) for information about using Terminal Services for remote administration.
- "Configuring Remote Desktop" in the *Windows XP Professional Resource Kit Documentation* (or see "Configuring Remote Desktop" on the Web at http://www.microsoft.com/reskit).
- The Terminal Services link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.
- The Terminal Services Community Center link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.
- The Terminal Services Scaling link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Related Tools**

- Roboserver and Roboclient

  Using these tools you can easily place and manage simulated loads on a terminal server. This information can help you determine whether your environment can handle the load that users place on it. Used together, these tools make capacity planning easier and more automated. For more information about Roboserver and Roboclient, click **Tools** in Help and Support Center, and then click Windows Resource Kit Tools Help.

**Related Help Topics**

For best results in identifying Help topics by title, in Help and Support Center, under the **Search** box, click **Set search options**. Under **Help Topics**, select the **Search in title only** checkbox.

# Planning for Remote Server Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you deploy servers running the Microsoft® Windows® Server 2003 operating system, determine the extent to which system administrators need to manage them remotely. If you need to perform only typical administrative tasks over the network, conventional tools suffice. For remotely administered servers — those having no keyboard, video display, or mouse — or for any servers having high availability requirements, you might need to use Emergency Management Services, possibly in conjunction with other hardware and software components, to remotely bring servers back into service even when they are not accessible by means of the standard network connection.

**In This Chapter**

Overview of Remote Management Planning

Evaluating Remote Management Needs

Choosing Software and Hardware Tools

Designing the Hardware Configuration

Configuring Your Infrastructure for Remote Management

Planning for Remote Management Deployment

Additional Resources for Remote Server Management

**Related Information**

- For more information about Emergency Management Services for either remotely administered or standard servers, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

- For an overview of remote administration and information about associated remote management tools, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Overview of Remote Management Planning

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Although local administration is the most secure way to manage the computers in a networked environment, cost, staffing, and system availability requirements typically preclude this approach in medium to large organizations. Remote management can solve many of these problems by increasing productivity, decreasing time to resolution, decreasing staffing requirements, and allowing more flexibility in server placement. Remote management can also resolve physical accessibility issues for servers that are remotely located or rack mounted — whether they are remotely administered or use keyboard-video-mouse (KVM) switches.

Windows Server 2003 provides a variety of tools and technologies to help you remotely administer the servers in your network. Conventional tools help you perform common tasks on computers that are functioning and available over the network. These tools are sometimes referred to as *in-band* tools because they function through the standard network connection. Other tools allow you to connect to a computer that is not responding to the standard network connection for some reason, such as when a Stop error occurs or the network adapter fails. These tools are sometimes referred to as *out-of-band* tools because they use a connection that does not depend on network drivers.

Emergency Management Services is a new feature in Windows Server 2003 that supports out-of-band connections. Emergency Management Services is included with Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Datacenter Edition; and Windows® Server 2003, Web Edition.

Before you begin managing servers remotely using in-band or out-of-band tools, you need to develop a remote management plan. A remote management plan ensures that you choose the appropriate remote management tools and management configurations for your organization and that you address all the impacts they might have on your infrastructure.

To develop your plan, you first need to know the server configuration in your organization: where the servers are located and what roles they perform. You also need to know the availability requirements for the servers you plan to manage remotely and who the administrators are.

Follow the planning process presented here to develop a plan for remotely managing the servers in your environment. This planning process addresses tools for Windows Server 2003 remote installation, in-band management tasks — such as configuring, monitoring, and troubleshooting — and out-of-band management tasks — such as restarting the computer and viewing Stop error messages. It does not address workstation management or software distribution tools for applications and updates.

# Remote Management Planning Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To produce an effective remote management plan, you need to determine which servers to manage and when to manage them remotely or locally, the tools to use, the required supporting hardware components and configurations, network and security considerations and remediation, and whether and how to deploy Windows Server 2003 remotely. These factors are included in the process presented here. Figure 5.1 illustrates the steps in the remote management planning process.

**Figure 5.1 Planning Remote Management**

# Remote Management Concepts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Conventional remote management involves establishing an in-band connection to a server to manage it across the network. As a class, in-band management tools are robust, versatile, and secure. Whenever a server is functioning and available across the network, in-band management tools are the tools of choice. In the past, this type of management was the only type of remote management available for servers running Windows operating systems.

By using Windows Server 2003, you can also manage servers by using out-of-band connections that make it possible to perform management tasks when the server is not responding to the standard network connection. When you lose the capability to manage the server with the in-band connection — such as when the firmware is initializing, a Stop error occurs, or the server stops responding — you need to use an out-of-band connection to manage it remotely.

A primary purpose of the out-of-band connection is to provide a means for you to return the server to a functioning state so that you can continue to manage it with your conventional in-band tools. Out-of-band management also makes it possible for you to configure your servers for remote administration, which means the local keyboard and monitor are optional. When combined with appropriate out-of-band hardware components, Windows Server 2003–based servers need to be managed locally only for hardware installation or replacement.

**Note**

- For a document to assist you in setting up servers for remote administration, see "Headless Server Quick Start" (SDCEMS_1.doc) on the *Microsoft® Windows® Server 2003 Deployment Kit* companion CD (or see "Headless Server Quick Start" on the Web at http://www.microsoft.com/reskit).

**In-Band Management**

Conventional remote management tools, such as Telnet, use in-band connections for communicating with the managed server. In-band connections rely on operating system network drivers for establishing connections between computers, so a server must be initialized and operational to be managed with these tools.

The most common in-band connection hardware device is a network adapter, such as an Ethernet adapter, analog modem, or Integrated Services Digital Network (ISDN) modem. The most typical method of in-band remote management is connecting through the network directly to the server, but you can also use Windows Server 2003 remote access and virtual private network (VPN) connections to manage servers through an in-band connection.

Typical tasks performed by using in-band management tools include routine configuration, monitoring, troubleshooting, and maintenance.

**Out-of-Band Management**

When a server is not in a functional state and cannot be accessed by using the standard network connection, you need to use an out-of-band connection to manage it remotely. Out-of-band connections do not rely on operating system network drivers for establishing connections between computers. The following are typical situations when you might need to manage a computer by using an out-of-band connection:

- The server is powered down.
- The BIOS is conducting the POST.
- A Stop error occurs.
- The server is too low on resources to respond adequately.
- The network adapter malfunctions or fails.
- The Windows loader or Recovery Console is running.
- The server is not fully initialized.

Common out-of-band connection hardware devices include serial ports, analog modems, and ISDN modems. In addition, out-of-band hardware components known as service processors can in some cases provide out-of-band connections over the network. A *service processor* is a microprocessor that functions independently of the CPU(s) in a computer and provides additional server management functionality for any operating state, whether or not the operating system is functioning.

Emergency Management Services, as well as features built into some hardware components and firmware, support out-of-band connections. Hardware components that support out-of-band connections include service processors, terminal concentrators, intelligent uninterruptible power supplies (UPSs), and intelligent power switches. A *terminal concentrator* is a hardware device that allows you to monitor multiple servers simultaneously by connecting to their out-of-band serial ports through a single network connection. An *intelligent UPS* or *intelligent power switch* is one that provides some remote functionality, such as powering up or down or resetting a computer. These components are described in detail in "Choosing Software and Hardware Tools" later in this chapter.

*Console redirection* is a key out-of-band feature that sends keyboard input and character-based output destined for the local display device to the out-of-band port so that you can view the information on a remote computer. Console redirection does not preclude locally attached monitors and keyboards: a computer with console redirection can still process input from a local keyboard and display output to a local monitor.

Emergency Management Services, service processors, and some system firmware provide console redirection. The extensible firmware interface (EFI) on Itanium-based computers typically provides console redirection. The BIOS on x86-based computers might or might not provide console redirection; contact your computer manufacturer to find out.

The specific component that controls console redirection changes as the operating state changes. For example, a service processor or firmware provides console redirection during power up and during the Power On Self Test (POST), and Emergency Management Services provides console redirection as soon as the Windows loader (Ntldr) starts. You can transfer control of console redirection to another component, such as a service processor, by entering specific escape sequences from the management computer.

Additional components that support out-of-band connections are described later in this chapter.

**Emergency Management Services**

Emergency Management Services is a new feature in Windows Server 2003 that provides out-of-band connections through a serial port or, in the case of some service processors, an alternate network connection. With Emergency Management Services, you can perform administrative tasks remotely using an out-of-band connection. When you combine Emergency Management Services with the appropriate out-of-band hardware, you can perform all administrative tasks remotely, except for installing or replacing hardware.

Emergency Management Services features are fully or partially available when the Windows Server 2003 operating system is loading, is running, or is in distress — such as when it is slow or not responding or when a Stop error occurs.

The three Emergency Management Services features that support out-of-band management are console redirection, Special Administration Console (SAC), and !Special Administration Console (!SAC). The Windows Server 2003 loader or kernel must be at least partially functioning for these features to be available.

**Console redirection**

Emergency Management Services can redirect keyboard input and character-based output when any of the following Windows Server 2003 components are running:

- The operating system loader on x86-based multiple-boot computers
- Recovery Console
- The Windows Server 2003 kernel
- The command prompt (cmd.exe)
- Text-mode Setup, during Windows Server 2003 installation
- Remote Installation Services (RIS) Setup

For more information about how Emergency Management Services console redirection works with these components and when it is not available, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Special Administration Console**
Special Administration Console (SAC) is the primary Emergency Management Services command-line environment. It provides a variety of commands for monitoring server status and troubleshooting problems during emergencies. SAC is available whenever the Windows Server 2003 kernel is running in normal mode, safe mode, and during the graphical user interface (GUI)–mode phase of Setup.

### Caution

- Using SAC during an operating system upgrade or installation might cause the upgrade or installation to fail or become unstable.

Using SAC, you can establish multiple user sessions, called *channels*, and switch between them. Although SAC is separate from the Windows Server 2003 command prompt (cmd.exe), you can establish a command prompt channel from SAC and then switch between SAC and the command prompt channels by using SAC commands or escape sequences. During the GUI-mode phase of Setup, you can also establish a channel for viewing setup logs so that you can troubleshoot unresponsive or failed operating system installations. You can access only one channel at a time, which means that multiuser access to SAC is not available. To create a SAC channel, you must use a local Administrator account; therefore, all the commands that you run in a channel run as local administrator.

For more information about SAC capabilities and how to use them, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit). For more information about SAC commands, see "Special Administration Console (SAC) and SAC commands" in Help and Support Center for Windows Server 2003.

**!Special Administration Console**
!Special Administration Console (!SAC) is a scaled-down version of SAC that is designed to recover an unresponsive system — for example, due to a Stop error. You cannot directly invoke !SAC; it becomes available automatically when a server experiences a system failure or fault. !SAC is a last-resort tool that lets you view Stop messages, obtain computer identification information, and restart the server.

**Remotely Administered Servers**
Remotely administered servers (also known as "headless servers") are computers that can operate without a keyboard, mouse, and local monitor. If the system firmware supports it, the video adapter and keyboard controller are also optional. Emergency Management Services, in combination with the appropriate hardware and system firmware console redirection, makes it possible for you to configure servers running Windows Server 2003 for remote administration. Redirecting firmware allows the system to pass the POST without a video adapter. When a server runs Emergency Management Services, you can manage it with both in-band and out-of-band tools, making locally attached input and output devices unnecessary.

Using remotely administered servers does not preclude having locally attached input devices. Depending on your hardware configuration, you might be able to attach and remove local devices, such as Universal Serial Bus (USB) keyboards and mouse devices, as needed.

Computer manufacturers offer systems preconfigured for remote administration that have no keyboard controller, video adapter, or mouse. For more information about purchasing a computer that you can administer remotely or configuring your existing computers for remote administration, contact your computer manufacturer.

# Evaluating Remote Management Needs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To implement an efficient, cost effective, secure remote management plan, you need to determine which servers to manage remotely by considering the tradeoffs — including cost, convenience, and system availability — for various ways of managing the servers in your environment. Before you decide whether or what to manage remotely, you need to evaluate remote and local management, and in-band and out-of-band management.

With Windows Server 2003, you can choose to remotely perform server management tasks that previously could be done only locally. By using Emergency Management Services with the appropriate hardware and software tools, you can remotely perform almost everything except hardware installation. When considering this type of solution, you need to weigh the level of support provided by the solution against the possible need to use legacy hardware. You might need to make a compromise between the level of support you want and the cost of additional hardware. You might also want to evaluate the savings you can obtain by configuring some of your servers for remote administration.

The first step in developing a remote management plan is to determine which servers in your environment need to be managed remotely. Figure 5.2 illustrates the place of this step in the planning process.

**Figure 5.2 Evaluating Your Remote Management Needs**

# Assessing Your Server Environment

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Assessing your server environment includes determining how many and what kind of servers you have, where they are located, and who administers them. The goal is to decide which servers should be managed remotely and which should be managed locally. For servers you want to manage remotely, you need to decide whether you want to perform only in-band tasks — those performed when the operating system is up and running — or both in-band and out-of-band tasks — those performed when the operating system is not running or is not responding appropriately. For example, you might want to configure some servers so that you can remotely install the operating system and perform all management tasks remotely, regardless of the state of the system, while for other servers you might only want to perform routine maintenance tasks remotely.

**Identifying Computers for Remote Management**

When determining which servers to manage remotely and which locally, consider the following issues:

- **Number of servers.** Does your organization have many servers or just a few? How manageable are they in relation to the number of technicians available for local support? If your organization has few servers and technicians are readily available, you might not need to manage remotely. On the other hand, if you have many servers and limited support resources, you probably want to manage at least some of them remotely.

- **Location of servers.** Are the servers in your organization consolidated in a single or a few locations where they are easily accessed by technicians, or are they widely dispersed? If the computers are distributed throughout your organization, what distances are involved? For example, are they located internationally, in different buildings in the same city, or down the hall? The more servers you have and the farther apart their locations, the greater the savings you are likely to achieve by remote management.

- **Server roles supported.** Do you have different management requirements for different types of servers, such as domain controllers, print servers, file servers, Web servers, application servers, and database servers? You might decide to manage different types of servers differently for reasons such as security or criticality to your business. For example, you might want to manage application servers remotely for mission-critical applications, but domain controllers locally for security reasons.

- **Availability requirements.** What percentage of the time must a server be up and running? For example, if you have servers with an availability rating of 99.99 percent, you can't afford a downtime of anything more than minutes. How many users typically access a server? For example, if a domain controller has a problem, many users might be affected, while if a print server in a small department fails, only a few users are affected. What is the impact to your business if a server is not available for a period of time? Remotely managing servers that have high availability requirements can significantly save downtime while waiting for someone to perform local management.

- **Reliability history.** How reliable is the server? How frequently does it typically encounter problems? The lower the reliability, the more benefit you can derive from managing it remotely.

- **Number and expertise of on-site technicians.** How many technicians do you have for local management and where are they based? For example, are there administrators on-site in branch offices? How experienced are they? If you have few technicians in certain areas, or they are inexperienced, you can probably benefit from remote management.

- **Security issues.** Do you have servers you prefer to manage locally for security reasons? For example, do you have public servers that you prefer to manage locally rather than by establishing a VPN connection? Or do have specific tasks that you prefer to perform locally and others you prefer to perform remotely?

**Identifying Tasks for Remote Management**

After you know which servers you want to manage remotely, the next step is to assess which kinds of management tasks to perform remotely and which to perform locally. For example, do you want to perform tasks remotely only when a server can be accessed across the network, or also when it cannot be accessed across the network?

If you have enough experienced technicians available or have highly reliable servers, in-band remote management support

might be sufficient. On the other hand, if some of your servers have high availability requirements or a history of poor reliability, or if you have insufficient on-site technical support, you might need out-of-band remote management support.

If you have many servers mounted in racks and tethered to KVM switches, you might decide to configure them for remote administration. You can then perform all administrative tasks remotely. Because remotely administered servers do not have monitors, keyboards, or mouse devices and might not require video adapters, they can present significant savings in space, energy consumption, and hardware costs.

Another consideration is whether your current servers are designed for out-of-band management. If you plan to use the hardware you already own and it is not designed for out-of-band support, your options might be more limited. For more information about deciding whether to use existing or new hardware, see "Planning for Remote Management Deployment" later in this chapter.

If you decide you need out-of-band remote management support, the next step is to determine how much support you need. As you determine the degree of out-of-band support you want, you need to weigh the costs of any additional hardware components — and possibly the cost of upgrading existing computers — against the savings in system uptime and reduced on-site support.

By using Emergency Management Services with nothing but a serial port, you can access nearly all Windows Server 2003 operating system states. By combining Emergency Management Services with appropriate out-of-band hardware, however, you can perform nearly every administrative task remotely — even before the operating system is fully initialized or after it stops responding — and you can effectively manage many servers from a single management computer.

To help determine the degree of out-of-band remote support you need, decide which of the following tasks you need to perform remotely:

- Start up a server
- Change BIOS settings
- View POST results
- Select which operating system to start
- View Stop error messages
- Reset a server
- Access the server when it is inaccessible through the network
- Install the Windows Server 2003 operating system

Different out-of-band tasks might require different types of hardware components. For more information about which components are needed for which tasks, see "Choosing Out-of-Band Management Tools" later in this chapter.

**Identifying Responsibilities for Remote Management**

As you plan for remote server management, you also need to decide whether you want different administrators to be responsible for different groups of tasks or whether you want all administrators to be authorized to perform the entire range of tasks. Depending on the size of your organization, the number and skill level of available administrators, and security requirements, you might decide to make some administrators responsible for only certain administrative tasks. To decide how to assign remote management tasks, consider the following issues:

- **Security issues.** Do you want to divide up tasks for security reasons? For example, you might decide that certain tools — based on the power of the tool or its level of built-in security — are to be used only by some administrators or that specific servers are to be accessible only to some administrators.
- **Skill level of administrators.** Do you have highly skilled administrators in all locations or only in some locations? For locations with less skilled administrators, you might decide to use remote management rather than telephone support.

# Examples: Determining Remote Management Requirements

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As you evaluate your needs for remote management, you develop a list of requirements. These requirements determine which tools and out-of-band configurations are most appropriate for your environment. The following descriptions illustrate three different types of remote management requirements and the level of remote management support appropriate to each. The tools and configurations appropriate to these levels of remote management are described later in this chapter.

**Minimal Remote Management**
You need minimal support for remote management if you have requirements such as the following:

- The site has few servers and those servers are located close together.
- The servers have low availability requirements.
- Experienced on-site technicians are typically available.
- Some routine management tasks are performed centrally.

An example business situation with minimal requirements for remote management might be a branch office that has a single, or just a few, servers running Windows Server 2003. The servers are primarily file and print servers and have low availability requirements. The branch has some on-site support available.

In this situation, on-site technicians perform most administrative tasks locally, but centrally located administrators perform some routine in-band tasks remotely over the network, such as changing a static IP address or other configuration settings,

**Moderate Remote Management**
You need moderate support for remote management if you have requirements such as the following:

- The site has many servers.
- The servers have availability requirements that range from low to high.
- Experienced on-site technicians are typically available to perform out-of-band tasks for servers with low to medium availability requirements.
- Many routine management tasks can be performed efficiently by using in-band remote management tools.

A situation with moderate requirements for remote management might be a data center that has many computers, some of which are legacy systems that do not support Emergency Management Services.

In this situation, the organization plans to supplement existing systems with out-of-band hardware components in order to perform some out-of-band management tasks remotely, even though the computers are not built for Emergency Management Services.

Administrators use in-band remote management tools for the systems in the data center. They use out-of-band management for some systems that have high availability requirements, but not for others that do not have such requirements. For example, the print servers are very reliable, so the organization decided it was not cost effective to support out-of-band management for these servers.

**Maximum Remote Management**
You need maximum support for remote management if you have requirements such as the following:

- The servers have high availability requirements.
- You need to perform a number of out-of-band tasks remotely.

- The servers are remotely administered.

A situation with maximum requirements for remote management might exist when a group of computers has very high availability requirements. These computers support remote administration and have built-in service processors. They are mounted in racks in a highly secured room.

Administrators go into the highly secured room only when they add or replace hardware. All other administrative tasks are performed remotely, by using an in-band connection when possible and by using an out-of-band connection when a server cannot be accessed through the standard network. The Windows Server 2003 operating system is installed on these computers remotely by using RIS.

# Choosing Software and Hardware Tools

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you determine how much you want to manage remotely, the next step is to select the tools and supporting components you need to accomplish your remote management tasks. Figure 5.3 illustrates the place of this step in the process.

**Figure 5.3 Choosing Software Tools and Hardware Components**

As you select your tools, think about the tasks you want to perform remotely when you have network access — by using in-band connections — and those you want to perform remotely when you do not have network access — by using out-of-band connections. As you select tools, evaluate their potential impact on your environment and build any needed environmental adjustments into your remote management plan.

**Selecting In-Band or Out-of-Band Tools**

In-band management is always the method of choice for managing servers when you can access them through their standard connections. If a server is functional enough to respond through the standard connection, conventional in-band management tools can provide a much broader range of functionality — and possibly greater security — than you might achieve with out-of-band management.

**Note**

- While the security of in-band management is highly dependent on the individual management tool, the security of out-of-band management is highly dependent on your out-of-band component configuration. For example, in a configuration that uses a remote serial connection, the security of the out-of-band management is dependent on the security built into the modem. For information about the security implications for different out-of-band configurations, see "Designing the Hardware Configuration" later in this chapter.

Keep in mind that out-of-band management is a last resort when you cannot access the server in any other way. The goal of out-of-band management is always to bring a server back into service so that you can manage it with in-band tools.

Table 5.1 shows whether to use in-band or out-of-band tools for various types of tasks during various operating states. After you know whether to use an in-band tool or an out-of-band tool, you can select the most appropriate specific tool or component, as described later in this chapter, for the tasks you want to perform remotely.

**Table 5.1 Choosing In-Band or Out-of-Band Tools**

| During This Operating State | For This Type of Task | Use This Type of Tool |
|---|---|---|

| | | |
|---|---|---|
| System powering on or off, or resetting | Power up, power down, reset | Out-of-band and in-band with Remote Desktop for Administration |
| Firmware initializing | Configure firmware, troubleshoot, restart | Out-of-band with supporting firmware |
| Operating system loading | Choose operating system to start, troubleshoot | Out-of-band, including Emergency Management Services |
| Text mode setup | Monitor, troubleshoot | Out-of-band, including Emergency Management Services |
| GUI mode setup | Monitor, troubleshoot | Out-of-band, including Emergency Management Services |
| Operating system fully functional | Monitor, troubleshoot, modify configuration settings | In-band |
| Operating system not responding on network | Troubleshoot, restart | Out-of-band, including Emergency Management Services |
| Stop message occurred | Troubleshoot, restart | Out-of-band, including Emergency Management Services |
| System extremely slow responding on network | Troubleshoot, restart | In-band and out-of-band, including Emergency Management Services |

**Evaluating Tools for Environmental Impact**

As you evaluate the software and hardware tools to use, consider the impact they might have on your network environment. For example, some tools present more security risks than others, and some increase network traffic more than others. Considerations such as these might influence your selection of one tool over another, or they might identify additional changes you need to make to your environment to mitigate the impact. The documentation provided with a remote management tool might contain information indicating its potential impact on your environment and any configuration changes needed for its use. For more information about configuring your environment for remote management, see "Configuring Your Infrastructure for Remote Management" later in this chapter.

As you develop your remote management plan, include the following lists:

**Tasks you plan to perform remotely** The more comprehensive you make this list, the easier it will be to identify all the tools you need. A task can be broad in scope (for example, manage DHCP servers), or it can be narrow in scope (for example, change the static IP address on a server). This list should include not only in-band tasks but also any required out-of-band tasks, such as remotely installing the operating system or powering up the computer.

**Tools for performing the tasks** Typically, you can use several different remote management tools to perform the same task. Include in your list all the tools that apply to each remote task you want to perform. In some cases, you do not need to use a specific tool to perform a remote administration task; rather, you simply need to change a configuration setting. If a task does not require a specific tool, note this in your remote administration plan. If your environment includes a mix of operating systems, you might need to look for tools that provide interoperability for some tasks. Make sure this list also includes any out-of-band tools or components you plan to obtain or install.

**Network impacts to be addressed** Remote administration can have any of several impacts on your network: it can increase network traffic, decrease server performance, or create security vulnerabilities. You might need to reconfigure network, system, or security settings to mitigate or eliminate these impacts. Include in this list each potential impact and the specific steps you plan to take to address it.

# Choosing In-Band Management Tools

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Server 2003 supports a wide variety of in-band remote management tools that you can use to manage servers. Use in-band tools when your Windows Server 2003–based server is functioning and accessible through your standard network connection.

Tools for remotely managing servers are available from many sources. Some of the tools are specific to a task, while others support a range of tasks. Some provide a command-line environment, while others provide a graphical user interface (GUI) environment. Some tools work best for managing a single computer at a time, while others support sessions with multiple computers.

In addition to the many tools built in to Windows Server 2003, management tools are available from the following sources:

- Windows Support Tools, located in the Support\Tools folder on the Windows Server 2003 operating system CD, provide command-line tools for specific management tasks in a variety of areas such as performance, security, and deployment. For more information about Windows Support Tools, in Help and Support Center for Windows Server 2003, click **Tools**, and then click "Windows Support Tools."

- Resource Kit Tools provide a variety of command-line tools for specific tasks. For more information about Resource Kit Tools, click **Tools** on Help and Support Center for Windows Server 2003, and then click Windows Resource Kit Tools Help.

- Third-party tools available from independent software vendors (ISVs) provide a wide variety of specific or general remote management capabilities.

This section describes major characteristics of some common remote management tools for servers. Some of these tools can also be used for performing management tasks through out-of-band connections. For in-depth information about the technical considerations and potential impacts of specific remote management tools, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit). For information about software distribution tools, see "Deploying a Managed Software Environment" in *Designing a Managed Environment* of this kit.

Table 5.2 summarizes the characteristics of common remote management tools.

**Table 5.2 Common Remote Management Tools**

| Tool | Key Characteristics |
|---|---|
| Telnet | Command line; efficient and versatile; provides interoperability in mixed environments; in general, not secure |
| Windows Management Instrumentation Command-line (WMIC) | Customized applications and command-line scripts for remote management |
| Windows Script Host (WSH) | Customized scripts for remote management |
| Microsoft Management Console (MMC) | Multiple sessions; variety of snap-ins for various administrative tasks |
| Remote Desktop for Administration | GUI; multiple sessions; high resource usage |
| Group Policy | Efficient way to manage a variety of settings for groups of servers |

**Telnet**

Telnet is a global, versatile tool that has minimal system resource and network bandwidth requirements and that provides interoperability with other operating systems. With Windows Server 2003 Telnet Server, any client that supports the Telnet

protocol can connect to Windows–based systems. For example, a UNIX Telnet client can connect to a Windows–based server.

By using Telnet, you can establish a command console session on a remote computer and use it to run command-line programs and shell commands, interacting with the remote server as though you were logged on locally. Telnet can establish any number of connections and supports interactive scripts.

The Windows Server 2003 32-bit version of Telnet does not support secure logon, while the 64-bit version provides secure logon by using NTLM authentication. Some versions of Telnet provided with terminal concentrators also support secure logon. Telnet does not support encryption.

By using Telnet, you can perform out-of-band management tasks by establishing a network connection to a terminal concentrator that is connected to servers through their serial ports. For more information about terminal concentrators, see "Using Terminal Concentrators for Remote Management" later in this chapter.

**Windows Management Instrumentation**
Windows Management Instrumentation (WMI) is an infrastructure that enables you to access and modify standards-based information about objects — such as computers, applications, and network components — in your enterprise environment. Using WMI, you can create powerful administration applications to monitor and respond to specific events in your environment. For example, you can create applications to check CPU usage on your Windows Server 2003–based servers and notify you when it exceeds a specified level. Although WMI is a powerful tool for building customized applications, it does require a certain amount of developer time and expertise.

Windows Management Instrumentation Command-line (WMIC) provides a simplified interface to WMI. By using WMIC, you can access WMI-based information using the command line or scripts. You can use WMIC from any computer where WMIC is enabled to manage any remote computer. WMIC does not have to be available on the remote computer.

For technical information about developing applications using WMI and using WMIC, see the WMI SDK link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Windows Script Host**
Windows Script Host (WSH) is a language-independent scripting infrastructure that allows you to write scripts for local or remote management tasks. You can use WSH to write scripts that include WMI, Active Directory® directory service, and other application programming interface (API) calls. WSH typically is used for noninteractive scripts, such as logon and computer automation scripts.

**Microsoft Management Console**
Microsoft Management Console (MMC) is a framework for hosting tools, also known as snap-ins, that you can use to manage servers locally or remotely. With MMC, you can create consoles that include the tools you use most often.

Each MMC snap-in has unique advantages and disadvantages that make it suitable in some cases and unsuitable in others. For example, some are suitable for slow network connections and some transmit encrypted data. Before you use a snap-in to perform a remote management task, make sure that it is the best remote management tool for the task. For more information about using MMC snap-ins for remote management, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Remote Desktop for Administration**
Remote Desktop for Administration is an MMC snap-in that you can use to establish a remote console session on one or more servers and switch between sessions. By using Remote Desktop for Administration, you can log on to a remote server and use the server's desktop to perform administrative tasks, just as if you were logged on locally. Remote Desktop for Administration supports Kerberos authentication and built-in encryption.

Remote Desktop for Administration is a versatile remote management tool because it supports both GUI and command-line interfaces. Because Remote Desktop for Administration uses Remote Desktop Protocol (RDP), it efficiently transmits the user interface from the server to the client and keyboard sequences and mouse clicks from the client to the server. Nevertheless, this tool requires more memory and network bandwidth resources than many other tools.

### Important

- Remote Desktop for Administration is affected by the Internet Explorer Enhanced Security Configuration, which places your server and Microsoft Internet Explorer in a configuration that decreases the exposure of your server to attacks that can occur through Web content and application scripts. As a result, some Web sites might not display or perform as expected. For more information, see "Setting up Remote Desktop Web Connection" and "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

**Windows Server 2003 Administration Tools Pack**

The Windows Server 2003 Administration Tools Pack includes several of the most common tools for remotely managing servers from a Microsoft® Windows® XP Professional–based computer with Service Pack 1. Many of the tools are MMC snap-ins. The tools pack is included on the 32-bit version of the Windows Server 2003 operating system CD, and the Windows Installer package — Adminpak.msi — is placed in C:\windows\system32\adminpak during the operating system installation. For 64-bit versions, use Remote Desktop for Administration instead.

For more detailed information about the tools pack, see "Windows Server 2003 Administration Tools Pack Overview" in Help and Support Center for Windows Server 2003. Help topics for the Administration Tools Pack are installed when you install the tools.

### Note

- You cannot install the Windows Server 2003 Administration Tools Pack on a server that is running a member of the Microsoft® Windows® 2000 Server or Windows Server 2003 family operating systems. The administrative tools already exist on all servers running these systems. You can install the tools pack only on a computer that is running Windows XP Professional with Service Pack 1.

**Group Policy**

In an Active Directory environment, you can use Group Policy to control such things as permissions, application availability, and security for member servers, domain controllers, and any other server running Windows Server 2003 within the scope of management. You can use Group Policy to manage registry-based policy by using Administrative Templates and to assign scripts, such as for startup and shutdown. For more information about Group Policy, see the following:

- "Designing a Group Policy Infrastructure" in *Designing a Managed Environment* of this kit.

- The *Windows Security Collection* of the *Windows Server 2003 Technical Reference* (or see the Windows Security Collection on the Web at http://www.microsoft.com/reskit).

# Choosing Out-of-Band Management Tools

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you cannot manage a server by using conventional in-band tools for some reason, an out-of-band connection is the only way to remotely manage it. If you configure your servers for remote administration, and you cannot access them by using your in-band tools, an out-of-band connection is the only way to manage them.

To configure a server for out-of-band management, you need to consider software, firmware, and hardware. Emergency Management Services, which is included with Windows Server 2003, is the principal out-of-band component. With only Emergency Management Services and a serial port, you can manage most Windows Server 2003 operating states. When you combine Emergency Management Services with supporting firmware and hardware components, you can also perform tasks ranging from powering up computers to recovering unresponsive systems — everything, in fact, except for replacing and installing hardware.

The additional components you choose depend on which tasks you want to perform remotely, how much you are willing to spend for extra features, and how many servers you have to manage. The following tools and components work with Emergency Management Services to support out-of-band remote management:

- Firmware — BIOS for x86-based computers or EFI for Itanium-based computers — that provides console redirection
- Serial ports and modems
- Terminal concentrators
- Service processors
- Intelligent UPSs or intelligent power switches

By selecting the optional components that best meet your remote management requirements, you can capitalize on the full range of out-of-band management capabilities supported by Emergency Management Services.

For more information about selecting hardware components, see "Best practices for selecting and configuring hardware" in Help and Support Center for Windows Server 2003.

Table 5.3 shows which out-of-band tools support various operating states and remote management tasks.

**Table 5.3 Components Required for Out-of-Band Situations**

| Operating State or Task | Type of Tool |
|---|---|
| Windows Server 2003 is starting | Emergency Management Services |
| Server fails to fully initialize | Emergency Management Services |
| Administrator needs to run Recovery Console | Emergency Management Services |
| Server is not functioning due to stop message | Emergency Management Services |
| System is low on resources, resulting in slow or no response to requests | Emergency Management Services |
| Network stack has malfunctioned or failed | Emergency Management Services |
| System is not responding on the network | Emergency Management Services |

| | |
|---|---|
| System is not responding on the network or to Emergency Management Services | Service processor |
| System is powered down | Wake-on-LAN network adapter*, intelligent UPS, intelligent power switch, or service processor |
| BIOS is conducting POST | Redirecting firmware or service processor |
| Change firmware configuration settings | Redirecting firmware or service processor |
| Operating system installation by using RIS | Emergency Management Services (see "Selecting the Installation Method" later in this chapter |

* Wake-on-LAN is a combined hardware and software technology that allows you to remotely turn on Advanced Configuration and Power Interface (ACPI)–compliant computers. Several vendors provide Wake-on-LAN remote management solutions. Some vendors support this functionality across a local area network (LAN) or wide area network (WAN), while some support it over the Internet. For more information about Wake-on-LAN technology, use a Web search engine and search using the keyword "Wake-on-LAN."

Some trade-offs you might experience with out-of-band components include:

- Limited maximum throughput.
- No GUI support.
- Optionally, additional hardware requirements.

# Emergency Management Services in Windows Server 2003

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To manage a server from a remote computer when the server is not available on the network, you must enable Emergency Management Services. Emergency Management Services is a Windows Server 2003 service that runs on the managed server. This service is not enabled by default when you install the Windows Server 2003 operating system, but you can enable it during installation or at any later time.

Emergency Management Services features are available when the Windows Server 2003 loader or kernel is at least partially running. You can access all Emergency Management Services output by using terminal emulator software that supports VT100, VT100+, or VT-UTF8 protocols on the management computer, although VT-UTF8 is the preferred protocol. For more information about terminal emulator software and the supported protocols, see "Management Software for Out-of-Band Connections" later in this chapter. For more information about enabling, configuring, and using Emergency Management Services, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

When Emergency Management Services is enabled:

- Console redirection automatically sends output to the out-of-band port for any supported operating state, as indicated in Table 5.4.
- You can use SAC to issue supported commands or switch to the command shell (cmd.exe) whenever the kernel is running.
- You can view logs during the GUI-mode phase of Setup.
- !SAC automatically becomes available whenever a system failure occurs.

Table 5.4 shows when you can use Emergency Management Services features for remote management, with or without special out-of-band hardware.

**Table 5.4 Using Emergency Management Services Features**

| Task | Feature |
|---|---|
| Selecting operating system during system load | Console redirection |
| Running Recovery Console | Console redirection |
| Viewing text mode setup messages | Console redirection |
| Viewing GUI mode setup messages | SAC, including setup logs |
| Viewing RIS loading messages | Console redirection |
| Viewing Stop error messages | Console redirection |
| Monitoring and managing with out-of-band connections | SAC |
| Performing last-resort system recovery | !SAC |

**Emergency Management Services Console Redirection**

Emergency Management Services console redirection redirects the output from supported Windows Server 2003 functions to the out-of-band port. When Emergency Management Services is enabled, you can perform remote management through the out-of-band port, as shown in Table 5.5.

**Table 5.5 Emergency Management Services Console Redirection**

| Managed Operating State | Example Tasks |
|---|---|
| Windows Server 2003 Loader | • Select the operating system to load on x86-based multiple-boot systems.<br>• Verify the load of Windows Server 2003 components before in-band tools become available. |
| Kernel at least partially functioning | • Perform SAC commands, such as changing the priority of a process.<br>• Perform !SAC commands, such as viewing Stop messages when a system problem occurs. |
| Recovery Console running | • Troubleshoot startup problems. |
| Text-mode Setup | • View Windows Server 2003 Setup progress.<br>• Respond to text-mode Setup prompts. |
| GUI-mode Setup | • Perform SAC commands and monitor setup logs. |
| RIS-based Setup | • Respond to the **F12** prompt to initiate RIS-based Setup. |

**Note**

- You must have firmware redirection to view server information before the Windows Server 2003 operating system starts.

**Special Administration Console**

When Emergency Management Services is enabled, SAC is always available through the specified out-of-band port, as long as the Windows Server 2003 kernel is running. You can use SAC at any time to carry out out-of-band management commands during the following system operating states:

- Normal system operation
- Windows Server 2003 components initialization
- Safe mode
- GUI-mode during Windows Server 2003 Setup

The SAC prompt appears when you connect to a server that is running Emergency Management Services. The SAC command-line environment supports a specific set of commands. For information about SAC commands, see "Special Administration Console (SAC) and SAC commands" in Help and Support Center for Windows Server 2003.

Using SAC, you can perform management tasks such as the following:

- Gathering server information, such as computer name and IP address.
- Changing a server's TCP/IP networking information to resolve issues caused by incorrect parameters or a duplicate IP address.
- Obtaining a list of processes and threads running on the computer to determine if they are causing a system

performance problem, if you cannot perform this task by using in-band tools.

- Raising or lowering the priority of a process, or ending a process that is consuming excessive server processor resources or other system resources to eliminate performance issues.
- Restarting or shutting down a server as part of unplanned maintenance task, when the in-band mechanism fails.
- Setting the system time and date, for example, for Kerberos authentication.
- Starting a command shell and running text-based tools, and switching between the command prompt and SAC.
- Viewing setup logs during GUI mode setup and switching between the setup logs and SAC.

**!Special Administration Console**

When Emergency Management Services is enabled and a system failure occurs, !SAC — an abbreviated form of SAC — automatically replaces SAC as the command-line environment. For information about !SAC commands, see " !Special Administration Console (!SAC) and !SAC commands" in Help and Support Center for Windows Server 2003.

**Important**

- !SAC is not available if the debugger is running or the system is set to restart automatically when Stop errors occur.

Using !SAC, you can perform tasks such as the following:

- View redirected Stop messages.
- Display computer identification information.
- View an abbreviated log of loaded drivers and some kernel events.
- Restart the computer.

# Using serial ports for out-of-band management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To perform out-of-band management, you need to establish a secure connection through a serial port, phone line, or an additional network connection. The serial port, also known as a COM port, is the most common out-of-band interface. It is the default out-of-band device for Emergency Management Services. You can provide remote access to an out-of-band serial port by using modems or terminal concentrators, as described later in this section.

To use the serial port as an out-of-band device with Emergency Management Services, it must meet the following requirements:

- The serial port must be a standard 16450 or 16550 Universal Asynchronous/Receive Transmit (UART) device. Windows Server 2003 tests the device for compliance before using it with Emergency Management Services.
- The serial port interface must be provided by hardware, not by a Windows driver.
- If the system firmware is compatible with Emergency Management Services, the firmware and the serial port must be configured to use the same serial port settings.
- A kernel debugger cannot share the same COM port. To avoid this problem, disable kernel debugging on servers with Emergency Management Services enabled. For more information about using kernel debuggers with Emergency Management Services, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).
- The serial port must be the only out-of-band management port. Emergency Management Services does not support one out-of-band port for outbound communication and a second port for inbound communication.

Direct serial connections provide no logical security and therefore must be secured physically. For more information about security considerations, see "Providing Security for Remote Management" later in this chapter.

**Note**

- When you use Emergency Management Services with a serial port, use null modem cables that support the carrier detect signal.

For Emergency Management Services technical details and information about configuring serial port settings, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Using Modems for Remote Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A modem can provide remote access to a single server through its out-of-band serial port. Modems can be useful when you have just a few servers to manage remotely, such as a branch office with one or two servers. For an example of this type of implementation, see "Designing the Hardware Configuration" later in this chapter.

Take the following considerations into account when selecting a modem to use for out-of-band remote management:

- Security for modem connections is determined by the modem. The preferred security mechanism for modems is dial-back.

- The modem must be configurable and must not rely on initialization. Emergency Management Services does not initialize the modem, so you must configure the modem to answer or dial back automatically and pass all serial data through unchanged. For information about configuring modems for callback, see "Configure client callback options" in Help and Support Center for Windows Server 2003.

# Using Terminal Concentrators for Remote Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Terminal concentrators provide remote access to multiple servers through their out-of-band serial ports. The servers connect to the serial ports on the terminal concentrator with null modem cables. The remote management computer establishes a network connection to the terminal concentrator by using its network port. Typically, you use Telnet or a Web interface to remotely perform management tasks on the servers connected to the terminal concentrator.

Terminal concentrators facilitate remote management of servers in the following ways:

- You can manage servers using a serial connection without being within the distance of a serial cable length.
- You can monitor and manage multiple servers simultaneously from a single management computer.
- Several administrators can simultaneously view information for different servers.

Setup, configuration, and features for terminal concentrators vary by manufacturer. When choosing a terminal concentrator, assess the following features:

- Number of available serial ports.
- Built-in security features, such as use of passwords and encryption.
- Power switch capabilities.
- Number of available Ethernet ports, if important in your environment.

Some terminal concentrators support Secure Shell (SSH), which is a secure command-line alternative to Telnet. SSH is a protocol for establishing secure connections over networks. It provides logical security for the in-band connection from the management computer by supporting strong authentication and encryption and protecting against a variety of network-level attacks. Because SSH is independent of the operating system, it provides interoperability in environments with mixed operating systems. Several vendors provide Windows implementations of SSH clients and servers. Use a Web search engine and search using the keyword "SSH" to find a variety of SSH vendors, as well as frequently asked questions (FAQs) and other documentation.

You need to provide physical security for the serial connections from the servers to the terminal concentrator. Because the security features for terminal concentrators are not standardized, you might need to provide your own logical security for the in-band connection. If your terminal concentrator does not support authentication and encryption, consider using one of the following techniques to secure the connection:

- Use a secondary private management network that you can access with direct-dial remote access or with a VPN connection.
- Use a router to secure the network traffic.
- Use SSH, if the terminal concentrator supports it, instead of Telnet to provide authentication and encryption.

# Console Redirection by Firmware

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Console redirection provided by system firmware (either BIOS for x86-based computers or EFI for Itanium-based computers) provides out-of-band access to server information before the Windows Server 2003 operating system starts. Firmware console redirection works together with Emergency Management Services console redirection to provide out-of-band support for any operating state.

If your firmware does not provide console redirection — and you do not have a service processor that provides console redirection, as described later in this chapter — you cannot remotely manage servers during the time between system restart and the initial loading of the Windows Server 2003 operating system.

If you configure your servers for remote administration, you need to have either firmware console redirection or a service processor with console redirection so that you can access the servers when the Windows Server 2003 operating system is not functioning.

**Note**

- Firmware console redirection typically redirects only during text mode, not during GUI mode.

By using firmware console redirection, you can perform the following out-of-band tasks from a remote computer:

- View server status before the operating system starts up. For example, you can view POST status or disk-related error messages. Firmware console redirection typically allows the POST to complete without a local keyboard, mouse, or monitor.
- View and make modifications to firmware settings, such as disabling a peripheral device or changing boot sequence, with the built-in firmware configuration program.
- View master boot record (MBR) errors.
- Start a RIS-based setup by responding to the **F12** network boot prompt. This support is required only if the **F12** prompt is presented by the firmware.
- Boot the computer from the CD drive by responding to the **Press Any Key to Boot from CD** prompt.

When assessing firmware console redirection for use in conjunction with Emergency Management Services, verify that the firmware meets the following criteria:

- Shares the serial port with Emergency Management Services and releases control to Emergency Management Services after the Windows operating system starts.
- Supports VT-UTF8, VT100+, or, at minimum, VT100 terminal emulator conventions. For more information, see "Management Software for Out-of-Band Connections" later in this chapter.
- Preferably, supports the Serial Port Console Redirection (SPCR) table.

An SPCR table is provided with some ACPI-compliant system firmware for specifying how the out-of-band management port is used. For example, if the out-of-band port is a serial port, the SPCR table contains information such as serial port number, baud rate, terminal type, and other settings used for out-of-band communication. When this table exists, Emergency Management Services uses the information in it to ensure a consistent transition between firmware console redirection and Emergency Management Services console redirection. The SPCR table is recommended for use with both 32-bit and 64-bit versions of Windows Server 2003. For more information about the SPCR table and Emergency Management Services, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Using service processors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Service processors provide robust remote management support that is independent of the operating system. Because Emergency Management Services is available only when the loader or kernel is at least partially running, you might need such support when the system experiences severe problems that cause it to stop responding completely. Table 5.3, included earlier in this chapter, shows some of the operating states supported by service processors but not by Emergency Management Services. Consider a service processor if you need a high degree of reliability and availability for your servers or you decide to configure your servers for remote administration.

Typically, service processors are integrated into the system motherboard or into an add-in PCI adapter. Servers that have on-board service processors might offer higher out-of-band throughput by using higher-speed serial or Ethernet connections. Service processors operate independently from the main processor, use their own custom firmware, and sometimes include their own power supply. When you connect to a server through an out-of-band connection, you can communicate directly with the service processor.

Service processor features, client interfaces, and management tools vary by manufacturer. If you plan to use the service processor with Emergency Management Services, it is recommended that the service processor support these functions:

- Console redirection
- Remote power on and power off
- Remote reset
- Access to Emergency Management Services at all times

To be compatible with Emergency Management Services, make sure that the service processor also meets the following requirements:

- If the service process uses the serial port as its interface, it must share the serial port with Emergency Management Services and must release control to Emergency Management Services after the operating system has started.
- The UART interface must be described in the SPCR table, or in the EFI console device path for the 64-bit versions of Windows Server 2003.
- It supports VT-UTF8, VT100+, or, at minimum, VT100 terminal emulator conventions. For more information, see "Management Software for Out-of-Band Connections" later in this chapter.

Manufacturers offer a wide range of additional features. Evaluate the features and tools provided to ensure that they meet your needs. Additional features you might consider include:

- Access to Emergency Management Services through hardware interfaces other than serial, such as modem or RJ-45 Ethernet. The type of connection determines the additional components you need and the security requirements for out-of-band access to your server. For more information about configuring components for a service processor, contact the manufacturer.
- Console redirection of GUI screens.
- Any of a variety of management and troubleshooting tools.
- Client interfaces that range from simple Telnet consoles to complex Web browsers.

# Intelligent UPSs and Intelligent Power Switches

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An uninterruptible power supply (UPS) provides backup power to a server in the event of a power failure. Some UPS units, known as intelligent UPSs, and intelligent power switches can provide limited remote management capabilities such as powering up, powering down, and resetting a server.

If an intelligent UPS or intelligent power switch is integrated with terminal concentrator functionality, it can provide pass-through serial connection between the management computer and the server running Windows Server 2003. In this case, the port on the management computer has a serial connection to an external serial port on the UPS or power switch, which in turn has a serial connection to the server.

The situation just described can provide a more economical solution than an internal service processor: You can access the intelligent UPS, firmware console redirection, and Emergency Management Services through the same communication channel if all these components use the same terminal conventions, such as VT-UTF8. When the components share the same terminal conventions, each component can consistently interpret escape sequences passed to it. For an example of this type of configuration, see "Designing the Hardware Configuration" later in this chapter.

If the intelligent UPS or intelligent power switch shares the same management channel with Emergency Management Services, the UPS or power switch must passively monitor the serial data stream and respond only when it detects VT-UTF8, VT100+, or VT100 escape sequences that apply to it. For more information about using an intelligent UPS or intelligent power switch with Emergency Management Services, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

If you plan to use an intelligent UPS or intelligent power switch with Emergency Management Services, the server running Windows Server 2003 must be configured to start automatically when power is applied.

**Tip**

- The firmware for your server might provide a configuration option for automatically starting the computer when power is applied.

# Management Software for Out-of-Band Connections

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you use terminal emulation software on the management computer to connect to and communicate with a server through an out-of-band connection. The two most common methods are the following:

- Use Telnet — or a secure alternative such as SSH — to connect to a terminal concentrator through an in-band connection, which then connects to the server through an out-of-band connection.
- Use HyperTerminal to connect directly to the server.

If you use a service processor, it might require specific software to work with it and to interact with Emergency Management Services. For example, manufacturers might provide a Web browser or custom software.

Make sure that the terminal emulation software you use supports serial port and terminal definition settings that are compatible with Emergency Management Services, as well as with your service processor or system firmware. If possible, use terminal emulation software that supports the VT-UTF8 protocol because VT-UTF8 support for Unicode provides for multilingual versions of Windows. If English is the only language you need to support, the VT100+ terminal definition is sufficient. At minimum, you can use the VT100 definition, but this terminal definition requires that you manually enter escape sequences for function keys and so forth. For more information about terminal definitions and what they support, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit). For more information about the VT-UTF8 terminal definition, see the Emergency Management Services Design link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

If your hardware and firmware use the same terminal definition settings that Emergency Management Services uses, you can always use the same escape sequences for managing computers, regardless of what is controlling the port — hardware, firmware, or Emergency Management Services. If you use different terminal types, the escape sequences you need to use vary depending on what is controlling the serial port, making it difficult to determine the appropriate sequence to send.

# Examples: Selecting Remote Management Tools

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you define your remote management requirements, you can select the tools and components you need to perform remote management tasks. The following illustrations describe the tools for the business situations and remote management levels described in "Examples: Determining Remote Management Requirements" earlier in this chapter.

**Minimal Remote Management**
Because the branch office in this business situation has low availability requirements and has on-site support, this situation requires no special out-of-band support. Emergency Management Services together with the basic serial port can provide out-of-band management support for the few times when administrators need to perform remote out-of-band tasks. Although this organization decided to use existing hardware, the OEM can provide a BIOS upgrade that supports console redirection. Remote Desktop for Administration provides remote in-band support in this situation.

For this branch office, administrators can perform tasks such as the following remotely:

- All in-band tasks, such as monitoring, configuring, and troubleshooting when the operating system is responding over the network.
- Monitoring operating system startup.
- Troubleshooting when the operating system is low on resources, such as when CPU usage is excessively high.
- Running Recovery Console.
- Monitoring firmware initialization and configuring firmware settings.

Administrators must perform the following types of tasks locally:

- Powering up and powering down.
- Resetting.
- Viewing POST status.
- Troubleshooting when the operating system is unresponsive.

For an illustration of out-of-band hardware configuration for this example, see "Configuring for Direct Serial Connection" later in this chapter.

**Moderate Remote Management**
Because the data center in this business situation has many high-availability servers, the organization does not want to incur the costs of upgrading to new computers to obtain out-of-band management support. The BIOS for some of the existing servers can be upgraded to provide console redirection; for other servers, such an upgrade is not available. Emergency Management Services together with a serial port provides out-of-band support when the Windows Server 2003 operating system is functioning.

This data center is configured with terminal concentrators to consolidate access to many servers by using a single in-band network connection. These terminal concentrators have SSH built in to provide authenticated and encrypted remote console sessions. They also have a built-in intelligent UPS for power backup and remote power functionality.

In this data center, administrators can perform tasks such as the following remotely:

- All in-band tasks, such as monitoring, configuring, and troubleshooting when the operating system is responding over the network.
- Monitoring operating system startup.

- Troubleshooting when the operating system is not responding over the network, such as when CPU usage is excessively high.
- Running Recovery Console.

Administrators must perform the following tasks locally:

- For servers without firmware console redirection, viewing POST results.
- For servers without firmware console redirection, monitoring firmware initialization and configuring firmware settings.
- Troubleshooting when the operating system is not responding to Emergency Management Services or the network.

For an example configuration for this example, see "Configuring for Terminal Concentrator Connections" later in this chapter.

**Maximum Remote Management**
In this business situation, the remotely administered servers support Emergency Management Services and include firmware console redirection and built-in service processors. The servers are configured with a terminal concentrator that has built-in intelligent UPS functionality and built-in SSH for secure communications.

Administrators perform all tasks — except hardware replacement — remotely. The Windows Server 2003 operating system is also installed remotely by using RIS.

For possible out-of-band hardware configurations that are appropriate for this business situation, see "Configuring for Intelligent UPS and Terminal Concentrator" and "Configuring for Network Service Processor" later in this chapter.

# Designing the Hardware Configuration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Because in-band management occurs through the standard network connection to a responding operating system, in-band management tools are typically software applications and tools. Out-of-band management, on the other hand, might require hardware components to access a non-responding server or to consolidate access to multiple servers. After you have determined which tasks you want to perform remotely and which tools and components to use, the next step is to determine how to configure the components, as Figure 5.4 illustrates.

**Figure 5.4 Designing the Hardware Configuration**

This section describes and illustrates ways to configure various out-of-band components. These configurations are only sample solutions. Depending on your hardware, you might require a different solution. For more detailed information about setting up out-of-band connections in an Emergency Management Services installation, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

Although you can use Emergency Management Services with only a serial port or modem to manage most Windows Server 2003 operating states, this minimal configuration is useful only if you are managing just one or two servers. If you are managing many servers, this minimal configuration might be of limited practical application.

When you combine Emergency Management Services with additional components, such as a terminal concentrator, an intelligent UPS or intelligent power switch integrated with terminal concentrator functionality, or a network-enabled service processor, you can use a single network connection from your management computer to manage multiple servers through their out-of-band ports. This configuration can be effective when you need to manage many servers in a single location.

The following configurations are described in order from least to most robust.

# Configuring for Direct Serial Connection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Figure 5.5 illustrates a direct serial connection. Using a null modem cable, you can connect the management computer to the server that has Emergency Management Services enabled. This configuration is the simplest out-of-band configuration.

**Figure 5.5 Direct Serial Connection**

The management computer runs terminal emulation software that preferably supports VT-UTF8 terminal conventions.

Because null modem connections have no built-in security, this configuration depends on physical security. For more information about planning for security, see "Providing Security for Remote Management" later in this chapter.

This type of configuration has the following advantages:

- No need to buy additional hardware
- Easiest to set up and configure
- Good for situations with very few servers to manage

Disadvantages of this type of configuration include:

- Management computer must be in close proximity for physical security
- Least robust configuration
- Logical security is not supported
- Ineffective in situations with many servers to manage

A variant of this configuration might be a server with a service processor that provides the serial connection. If a service processor and firmware console redirection are included in the configuration, you can manage all operating states through the out-of-band connection. If Emergency Management Services is the sole provider of console redirection, you can perform out-of-band management only when the Windows Server 2003 loader or kernel is at least partially running.

With this configuration, you can be ready to quickly connect a laptop to a remotely administered server to perform management tasks.

# Configuring for Remote Serial Connection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Figure 5.6 illustrates a remote serial connection using a modem. The modem is connected to the server that is running Emergency Management Services, and the remote management computer connects over the phone line.

**Figure 5.6 Serial Connection with Modem**

The management computer runs terminal emulation software that preferably supports VT-UTF8 terminal conventions. The modem functionality might be provided by an external modem or by a service processor with built-in modem functionality.

This configuration depends on physical security between the server and the modem and modem-based security for the phone connection. For security, modems that support dial-back are preferred. If you use a service processor, it might provide additional security options.

This type of configuration has the following advantages:

- No need to buy additional hardware
- Easy to set up and configure
- Good for situations with very few servers to manage
- Management computer can be in a remote location

Disadvantages of this type of configuration include:

- Security is not robust
- Ineffective in situations with many servers to manage

This configuration can be used for the minimal remote management example described in "Examples: Selecting Remote Management Tools" earlier in this chapter.

# Configuring for Terminal Concentrator Connections

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Figure 5.7 illustrates a terminal concentrator with direct serial connections to multiple servers running Emergency Management Services. The optional modem connects to the terminal concentrator. The remote management computer can connect to the terminal concentrator over the network for an in-band connection or over the phone line for an out-of-band connection when the network is not available.

**Figure 5.7 Remote Connections with Terminal Concentrator**

The servers running Emergency Management Services connect to the terminal concentrator with serial connections using the VT-UTF8 terminal definition. The serial connections might be provided by null modem cables or by service processors. The number of serial ports provided by the terminal concentrator determines the number of servers that can be supported in this configuration. If the terminal concentrator is integrated with intelligent power switch functionality, you can use this configuration to power servers off and on.

The remote management computer connects to the terminal concentrator over the standard network by using an in-band tool, such as Telnet or SSH, that supports the VT-UTF8 terminal definition.

This configuration requires physical security between the servers and the terminal concentrator. In addition, it is important to provide logical security for the terminal concentrator. Because access to a terminal concentrator provides access to multiple servers, it is important to ensure that only authorized persons can gain access, as described in "Providing Security for Remote Management" later in this chapter, thus protecting the connected servers from denial-of-service attacks. The terminal emulation software supported by the terminal concentrator helps determine the logical security between the management computer and terminal concentrator. For example, some terminal concentrators have SSH built in to provide authentication and encryption. If the terminal emulation software does not support authentication and encryption and the network is accessible to outsiders, an unauthorized person can sniff the network to obtain credentials for your servers. Another solution is to use a private, secondary network for remote management.

The advantages of this type of configuration are:

- Supports remote management for multiple servers
- Combined with firmware console redirection, provides broad functionality
- Supports logical security
- Can support the use of legacy computers

The primary disadvantage of this configuration is that it requires additional hardware.

This configuration is an excellent alternative to service processors. When combined with firmware redirection, this configuration provides functionality comparable to service processors without the additional costs. It provides a way to obtain state-of-the-art technology with legacy computers. For a document to assist you in setting up remotely administered servers in

this type of configuration, see "Headless Server Quick Start" (SDCEMS_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "Headless Server Quick Start" on the Web at http://www.microsoft.com/reskit).

This configuration can be used for the moderate remote management example described in "Examples: Selecting Remote Management Tools" earlier in this chapter.

# Configuring for Intelligent UPS and Terminal Concentrator

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Figure 5.8 illustrates a remote management computer with a network connection to an intelligent UPS that also functions as a terminal concentrator.

**Figure 5.8 Intelligent UPS and Terminal Concentrator**

The servers running Emergency Management Services have two connections to the intelligent UPS/terminal concentrator: an AC power connection and a serial connection that supports the VT-UTF8 convention. The serial connection can be provided by a null modem cable or by a service processor. The number of ports provided by the UPS determines the number of servers that can be supported in this configuration. The remote management computer connects to the UPS over the standard network by using an in-band tool, such as Telnet.

In this configuration, terminal concentrator and intelligent UPS functionality are combined, allowing you to manage multiple servers, as well as remotely control power to them.

This configuration requires physical security between the servers and the intelligent UPS. The network connection requires logical security, as described for the terminal concentrator configuration.

This configuration can provide an economical alternative to internal service processors for legacy computers that do not support service processors.

Advantages of this configuration include:

- Provides much of the functionality of a service processor
- Does not require a new component for each server (as service processors do)
- Supports remote management of multiple servers
- Supports logical security

The primary disadvantage of this configuration is that it requires additional hardware.

This configuration can be used for the moderate remote management example described in "Examples: Selecting Remote Management Tools" earlier in this chapter.

# Configuring for Network Service Processor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Figure 5.9 illustrates a remote management computer connected to servers with network-enabled service processors.

**Figure 5.9 Network Service Processor**

The servers in this configuration each have an internal network-enabled service processor. The service processors might be integrated into the motherboard or on an add-in PCI card.

The remote management computer connects to the servers through the network using an in-band tool such as Telnet or a proprietary tool provided by the service processor manufacturer.

The security in this configuration depends on the service processors. Using the Secure Sockets Layer (SSL) protocol is the preferred method. Using a secondary management network is another option for providing security.

Advantages of this configuration include:

- Does not require physical security for connections to servers
- Supports remote management for multiple servers

The primary disadvantage of this configuration is the cost of service processors, which are needed for each managed server.

This configuration can be used for the maximum remote management example described in "Examples: Selecting Remote Management Tools" earlier in this chapter.

# Configuring Your Infrastructure for Remote Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Remote administration, whether in-band or out-of-band, might require changes to your environment in areas such as network connectivity, memory and processor resources, and security. After you select the tools you plan to use for remote management, assess the impact they have on your environment, and decide how to configure hardware components, the next step is to determine the changes you need to make to your infrastructure to mitigate any potential negative impacts. The place of this step in the process is illustrated in Figure 5.10.

**Figure 5.10 Configuring Your Infrastructure for Remote Management**

For more information about ways that remote administration might affect your environment, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Ensuring Network Connectivity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Remote administration requires a stable, unrestricted connection between the management computer and the server being managed. In some cases, you also might need a high-speed connection. The tools you select and the location of the management computer in relation to the server being managed determine the network connectivity issues you need to address. Issues you need to address include available network bandwidth, the type of connection you plan to use, firewalls that might prevent access, and routers that might prevent access due to IP packet filtering.

**Network bandwidth**
Because remote administration tools can increase network traffic, you need to assess your current traffic levels and the capacity of your network to handle additional traffic that might result from the tools you decide to use. Typically, remote administration tools increase traffic only by a small amount, but some tools can increase traffic significantly. Remote Desktop for Administration, for example, is resource intensive and can create a significant amount of traffic.

**Type of connection**
If you select resource intensive remote management tools, you also need to assess the type of connection you plan to use with the tool. Typically, high-speed connections available on a LAN or WAN can, depending on your current traffic level, accommodate resource intensive tools. Dial-up, digital subscriber line (DSL), or broadband digital cable connections across a VPN, however, are relatively slow compared to LAN and WAN connections and might result in poor performance for some remote management tools.

If you plan to perform remote management tasks across a VPN, you need to configure the networking settings for the connection. For information about specifying these settings, see "VPN remote access for employees" in Help and Support Center for Windows Server 2003.

**Firewalls**
Because firewalls restrict network traffic, they can prevent you from remotely managing computers from outside the firewall. If you plan to use a management computer outside the firewall to manage servers inside the firewall, ensure that you can connect to them remotely through the firewall and that the firewall supports the network protocols and ports used by your tools. You might need to reconfigure firewall settings to permit remote management through the firewall.

For more information about the impact of firewall settings on remote management, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**IP packet filtering**
If you use routers that filter IP packets based on source and destination IP addresses and TCP ports, ensure that you can remotely access the servers you need to manage remotely. You might need to reconfigure IP packet filtering settings on your routers to permit remote management from your management computer.

For more details about configuring your network for remote management, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Ensuring Memory and Processor Resources

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Remote management software tools that run on a management computer use memory, disk, and processor resources. Remote management services that run on a managed server use memory and processor resources. Although you typically do not need to add memory or processor resources for remote management, you might want to ensure that the tools you choose do not degrade server performance, especially on critical servers such as domain controllers.

Remote management tools that support graphical user interfaces use more processor resources than command-line tools do. If you are concerned about the effect of a specific remote management tool on server performance, test the tasks you plan to perform with the tool to ensure that the current memory and processor resources can accommodate remote management. The task you perform with a tool affects processor activity more than the tool itself.

Remote management tools use memory on both the management computer and the server. If the computers meet minimum hardware requirements, remote management tools typically do not cause memory usage performance problems. If you optimize memory by terminating all nonessential services and processes, such as on a Web server, you might want to verify that your remote management tools do not have an impact on performance. For more information about assessing memory usage on remote management computers and servers, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Providing Security for Remote Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Remote administration introduces new security considerations into your environment. When you manage servers remotely, sensitive information that normally is not transmitted across a network is sent over your network. For example, server identifying information, configuration information, and other sensitive management information such as user names and passwords can be transmitted. You need to ensure that your remote management tools and tasks do not expose this sensitive data to someone sniffing or eavesdropping on your network. In addition, when you use serial ports for out-of-band management, the null modem connections between the servers and the management computer or other out-of-band hardware component provide no logical security against unauthorized access.

When planning security solutions for remote management, you need to protect against intentional acts as well as accidents. For in-band remote management, you need to consider solutions such as authentication and encryption. If you plan to use dial-up, DSL, or broadband digital cable connections across a VPN, you also need to plan your firewall configuration. For out-of-band remote management, you need to plan physical security solutions to protect the inherently insecure serial connections. Finally, you need to determine a strategy for user rights and shared folder permissions so that only authorized administrators can perform authorized management tasks.

As you plan your remote management security strategy, you need to make sure that:

- The server allows administrative commands only from an authenticated computer.
- The server accepts administrative commands only from an authenticated administrator.
- Confidential information — including administrative commands and configuration settings — cannot be intercepted, read, or changed by intruders.
- Log files are viewed by using a secure method.

A secondary network built specifically for remote management can increase security, performance, and availability. You can control access to such a management network by using a secure router.

For more detailed information about assessing security risks inherent in remote management and an overview about how to mitigate or eliminate these security vulnerabilities, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Authentication**

When you perform remote administration, you need to log on to the remote computer you want to manage. Remote management tools use several different authentication protocols — some stronger than others — to ensure that only authorized users can access computers remotely. For example, some tools use the Kerberos version 5 authentication protocol and others use the NTLM authentication protocol. Kerberos authentication is more secure than NTLM authentication.

You can mitigate the vulnerabilities of less secure authentication protocols by configuring one or more Group Policy settings. Configure these policy settings for maximum protection if either of the following is true:

- You are administering remote computers in an environment that forces NTLM authentication.
- You are administering remote computers with remote management tools that use NTLM authentication.

For information about environments that force NTLM authentication and the description and location of Group Policy settings you can use with NTLM, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Encryption**

Some remote management tools encrypt data — including passwords — before transmitting it across the network, while others do not. Unencrypted data makes your network vulnerable to eavesdropping and sniffing.

If you decide to use a remote management tool that does not encrypt or otherwise secure data, you can mitigate the security

issue by using Internet Protocol security (IPSec) to encrypt the communication between the management computer and the server. When you use IPSec, IP packets can pass securely through routers or other computers that do not support IPSec. You administer IPSec by using policies, which you can configure for the specific security requirements of individual computers, domains, organizational units, sites, or your entire enterprise. If you plan to support dial-up remote management, consider using IPSec across a VPN connection. For more information about VPN and about using IPSec with VPN, see the *Networking Collection* of the *Windows Server 2003 Technical Reference* (or see the Networking Collection on the Web at http://www.microsoft.com/reskit).

For information about IPSec policies, see "Internet Protocol Security (IPSec)" in Help and Support Center for Windows Server 2003. For more information about IPSec in general, see the *Networking Collection* of the *Windows Server 2003 Technical Reference* (or see the Networking Collection on the Web at http://www.microsoft.com/reskit).

For detailed information about using encryption for remote management, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Physical Security**

Although corporate servers must always be situated in secure locations, out-of-band management introduces another physical security issue: the serial connections between servers and out-of-band management components, such as a remote management computer or a terminal concentrator, need to be protected physically because null modem connections provide no logical security. Some ways to provide physical security include:

- Keeping server rooms locked with secured access, such as keys, smart cards, or passwords.
- Using terminal concentrators or intelligent UPSs to consolidate access to servers and keeping these out-of-band hardware components in the same secured room with the servers.
- Keeping cable lengths short to prevent the possibility of extending them outside the secured room.

**Rights and Permissions**

After you know which servers you plan to manage remotely and which administrators are responsible for specific administrative tasks, you need to set up security groups and assign administrators membership in order to grant them access to remote resources. As you define your security groups, set up administrative tasks with the minimum necessary administrative credentials. By using this technique, you can avoid assigning users a higher security level than they need to perform the tasks for which they are responsible. For recommendations about assigning permissions and user rights, see "Best practices for permissions and user rights" in Help and Support Center for Windows Server 2003.

Two types of security considerations are important in remote administration: user rights and shared folder permissions.

**User rights** User rights control the tasks you can perform on a computer, such as setting up user accounts or installing hardware. Depending on the security model and the group structure you use, you might have to configure user rights on each server and management computer, or you might be able to configure them on the domain controller.

**Shared folder permissions** Shared folder permissions control which users or groups can gain access to the contents of a shared folder remotely over the network, as well as which actions users or groups can perform on the contents of those folders. You can configure shared folder permissions on the server and enable users to gain access to the folders remotely over the network. For example, you can assign Read or Full Control.

You need to configure user rights and shared folder permissions if administrators need to do the following:

- Access the administrative shares on a remote computer.
- Log on to computers remotely by using terminal emulation or command console programs.
- Access files or folders on a remote computer.

You can centrally control remote management by using Group Policy settings related to remote management. Group Policy settings for computer configuration include security settings that restrict how a user can access files, folders, and computers, as well as administrative template settings that change the behavior and appearance of remote management tools and technologies, such as Terminal Services.

**Important**

- Terminal Services is affected by the Internet Explorer Enhanced Security Configuration, which places your server and Microsoft Internet Explorer in a configuration that decreases the exposure of your server to attacks that can occur through Web content and application scripts. As a result, some Web sites might not display or perform as expected. For more information, see "Before Installing Terminal Server" and "Internet Explorer Enhanced Security Configuration" in Help and Support Center for Windows Server 2003.

For information about groups, user rights, permissions, and authorization and access control, see the *Windows Security Collection* of the *Windows Server 2003 Technical Reference* (or see the Windows Security Collection on the Web at http://www.microsoft.com/reskit). For information about configuring user rights and permissions for remote management, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Secondary Management Network**

In addition to authentication, encryption, and user rights, you can add an extra layer of network security by placing your remote management system on a separate network segment and control access by using a secure router, as shown in Figure 5.11. You can use this configuration to control exactly which users and computers are allowed access to the management system.

**Figure 5.11 Secondary Management Network**

In this configuration, the servers are connected to the terminal concentrator with null modem cables, and all these components are located in a secure room. The management computer can access the servers by connecting to the terminal concentrator through the secure router. The management computer can use an in-band connection or a remote access connection through a remote access server.

# Planning for Remote Management Deployment

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you create your remote management strategy and determine your tools and configurations, the remaining step is to plan for deployment, as illustrated in Figure 5.12.

**Figure 5.12 Planning for Remote Management Deployment**

If you decide to use Emergency Management Services for out-of-band management, evaluate your existing server hardware to determine whether it supports the out-of-band functionality you need. After you decide whether to use your existing hardware or to purchase new servers or components, you can decide how you want to install the Windows Server 2003 operating system on your remote servers. Then you need to test your plan in a lab environment and identify the tasks that you need to perform to implement your plan.

# Choosing New or Existing Hardware

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you have older server hardware, it might not support some of the enhanced remote management capabilities provided by newer hardware. For many computers, however, you can purchase hardware components that provide enhanced out-of-band features. If you plan to purchase new servers, you can purchase ones that have been designed for compatibility with Emergency Management Services.

As you compare your existing server hardware with your remote management needs, choose one of the following approaches:

- Use existing servers only
- Use existing servers and purchase new peripherals
- Purchase new servers

These three choices are not mutually exclusive; you can decide the most cost-effective solution for each situation on a case-by-case basis. If you want to eventually replace existing servers with new ones but do not want to incur the entire cost at once, you can also plan to prestage new servers, and gradually deploy them over time.

# Using Existing Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You might be able to use your existing servers, even if they include legacy hardware, but they might provide more limited out-of-band options. If you use existing servers, out-of-band management functionality is limited to Emergency Management Services functionality, which means that you can perform out-of-band management tasks remotely only when the operating system is functioning. You might decide on this option if your servers can be easily and quickly accessed for local management when the operating system is not responding.

If your server was recently manufactured, you might be able to upgrade the system firmware. Firmware that supports console redirection lets you manage remotely before the operating system starts. Upgraded firmware can also make it possible to configure your servers for remote administration. Without firmware that supports console redirection, it is not possible to start your server without a keyboard controller and video adapter. Check with your original equipment manufacturer (OEM) to see if upgraded firmware is available.

If you decide to use existing servers, advantages include the following:

- You save on the cost of purchasing new servers.
- You can gain experience with the technology before investing in new hardware.
- You might be able to upgrade the operating system instead of performing a new installation, and you might not need to reinstall all the applications.

For more information about considerations for upgrading computers, see "Choosing an Automated Installation Method" in *Automating and Customizing Installations* in this kit.

Disadvantages of this approach include the following:

- You have only limited out-of-band functionality: with only Emergency Management Services, you can manage remotely only when the loader or kernel is at least partially running.
- You might experience compatibility issues with older hardware. Check the Windows Server Catalog to verify that all installed devices are listed. To find the Windows Server Catalog, see the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Using Existing Servers with New Peripherals

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You might decide to use your existing servers but purchase out-of-band peripherals to provide enhanced out-of-band functionality. For example, you can purchase an intelligent UPS to provide remote power options or a terminal concentrator to provide access to multiple servers from a network connection. Devices such as a PCI adapter with a service processor are also available.

Advantages of this approach include the following:

- You save on the cost of new hardware because new peripherals cost less than new servers.
- You might be able to upgrade to Windows Server 2003 instead of performing a new installation.
- You can gain experience with the new technology as you phase in new servers and components.
- You can obtain increased out-of-band functionality.

Disadvantages of this approach include the following:

- You incur the cost of new hardware components.
- If your OEM does not provide out-of-band support, your out-of-band functionality is limited.

If your OEM does not provide out-of-band-related hardware upgrades, or does not support use of such devices, then your options are limited to using existing servers or purchasing new ones. If you need out-of-band management support when the operating system is not functioning, you need to purchase new hardware. Newer systems that are compliant with Emergency Management Services typically have some or all of the out-of-band management features described in this chapter.

# Using New Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you plan to purchase new servers as part of an organization-wide Windows Server 2003 deployment and you plan to implement remote out-of-band management, look for features that enhance Emergency Management Services when you purchase the new computers. Newer computers that are compliant with Emergency Management Services typically include firmware that provides console redirection and might include service processors.

Advantages of purchasing new servers include the following:

- You can simplify the hardware configuration if the servers have components such as service processors or intelligent power switches built in.
- You are much less likely to encounter component incompatibilities because the Emergency Management Systems–compliant computers packaged by OEMs are sold as a single entity and tested together for compatibility.
- Servers that are compliant with Emergency Management Services might have features such as console redirection, a service processor, and an intelligent power switch built in, providing immediate access to enhanced out-of-band features.
- Servers that are compliant with Emergency Management Services typically are compatible with in-band Windows Server 2003 remote management technologies, including RIS.
- Remotely administered server configurations are an option.

The primary disadvantage of purchasing new servers is the cost of the new hardware.

# Prestaging Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you prestage servers you gradually replace existing servers in your organization with new ones preconfigured and tested in your lab. With this approach, you can use existing servers for your initial Windows Server 2003 deployment. Then, as servers reach approximately 90 percent usage, a technician can go onsite to replace the existing servers with new ones that are built to support out-of-band management.

Advantages of this approach include the following:

- You can spread out the cost of new hardware over time.
- You can gain experience with the technology before investing in new hardware and refine your buying criteria as you phase out old equipment and replace it with new servers.
- You gradually get increased out-of-band functionality as servers are replaced.
- You might be able to upgrade to Windows Server 2003 during the initial deployment, instead of performing new installations and reinstalling applications.

The primary disadvantage of prestaging is that you have the possibility of interim compatibility issues.

# Selecting the Installation Method

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Your decision to use existing servers or to purchase new ones might influence the method you choose to install Windows Server 2003. If you decide to use existing servers, you might be able to upgrade the operating system.

There are many issues in addition to upgrade or new installation to consider when you choose an installation method. For a complete discussion of the considerations when deciding on a method, see "Choosing an Automated Installation Method" in *Automating and Customizing Installations* of this kit. This section covers only the installation issues involved with Emergency Management Services and remotely administered servers.

# Selecting RIS for Installation

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

On 32-bit and 64-bit systems, you can use Remote Installation Services (RIS) to start a network-based Windows Server 2003 installation on a computer without an operating system. To install the Windows Server 2003 operating system by using RIS, you must have a network adapter that is Pre-Boot eXecution Environment (PXE) capable. A PXE-capable network adapter lets you boot the server from the network.

Special versions of Startrom.com support Emergency Management Services console redirection and let you perform an unattended installation on a server from a remote management computer. These versions of Startrom.com let you perform a remote unattended installation even if the firmware on the server does not provide console redirection. Without the Emergency Management Services version of Startrom.com, you cannot respond to the **Press F12 for network boot** prompt unless the server has firmware that provides console redirection. If you have firmware console redirection, however, it is preferable to rely on it instead of Emergency Management Services console redirection and to use the standard Startrom.com file, because the standard version supports a wider variety of baud rates. The special versions of Startrom.com support only a baud rate of 9600.

**Note**

- If you use one of the special versions of Startrom.com, you must also configure the management computer to use a baud rate of 9600 baud in order to read the redirected output.

For more information about using RIS with Emergency Management Services, see the *Server Management Guide* of the *Windows Server 2003 Technical Reference* on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=4681). For more information about RIS in general, see "Designing RIS Installations" in the *Automating and Customizing Installations* topic.

# Selecting Network-Based Unattended Installations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you want to fully automate Setup and enable Emergency Management Services, you can use a network-based unattended installation. If your firmware supports the Serial Port Console Redirection (SPCR) table, Setup automatically detects the out-of-band port parameters and enables Emergency Management Services. If your firmware does not support the SPCR table or you want to fully automate Setup, you can configure Setup by using the Unattend.txt file. You can also use the Unattend.txt file to disable Emergency Management Services if your firmware supports the SPCR table, but you do not want to enable Emergency Management Services.

When Emergency Management Services is enabled, you can use Emergency Management Services console redirection to remotely monitor text-mode setup. Although you cannot use either firmware or Emergency Management Services console redirection to redirect GUI-mode setup graphics such as windows and cursors, you can avoid pauses for user input by specifying parameters in your Unattend.txt file. For remotely administered computers, you need to use an Unattend.txt file or run Setup by using a Remote Desktop for Administration connection.

If your Unattend.txt file does not contain the information necessary for GUI-mode setup to proceed — such as your accepting the End User License Agreement (EULA), entering a 25-digit product key, and providing an administrator password — you will be prompted through the serial port to provide that input. If the server has a local monitor, a dialog will show that the system is waiting for input through the serial port. You can optionally use the local keyboard to cancel this. If more information is missing from your answer file, a default answer is created so that you are not prompted again. For example, if the computername parameter is missing, the random computer name, "computername=*" is automatically generated. You can then change this information after GUI-mode setup is complete.

A sample Unattend.txt file is on the Windows Server 2003 operating system CD. You can use default settings or create customized installations by modifying or adding parameters. For more details about Emergency Management Server parameters for the Unattend.txt file, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit). For more information about network-based unattended installations, see "Designing Unattended Installations" in the *Automating and Customizing Installations* book of this kit.

# Selecting Unattended CD-Based Installations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If your system supports firmware console redirection, you can enable Emergency Management Services as part of a CD-based installation. If your firmware supports the SPCR table, Setup automatically detects the out-of-band port parameters and enables Emergency Management Services. You can then use Windows Emergency Management Services console redirection to remotely monitor text-mode setup, but you cannot use console redirection to monitor GUI-mode setup. To fully automate a CD-based installation that includes customized parameters, you need to configure an unattended setup by using the Winnt.sif file.

If your firmware supports the SPCR table, console redirection is enabled, and you do not plan to use unattended files during setup, you can use Express Setup. When you boot a remotely administered server from CD and do not use the Winnt.sif file, Setup automatically provides default parameters for the computer configuration so that the GUI-mode phase can complete without displaying any prompts. After Setup is complete, you can use SAC to set parameters such as IP address or view the computer name, if the IP address was assigned using DHCP. Then you can use a Remote Desktop for Administration connection to complete your custom configuration.

To begin a CD-based Windows Server 2003 setup, you must enable firmware console redirection to remotely view and respond to the **Press any key to boot from CD-ROM** prompt that appears when starting the computer by using the Windows Server 2003 operating system CD.

**Tip**

- CD-based setups are most useful for local installations during testing.

For more details about using CD-based setups and configuring the Winnt.sif file for Emergency Management Services, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Selecting Unattended Image-Based Installations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can also use an Unattend.txt file to fully automate Setup and enable Emergency Management Services as part of an image-based installation on remotely administered servers. You can distribute the CD image you create to a remote server, power on that server, and proceed through an unattended GUI-mode setup just as you would proceed through an unattended, network-based installation. You can also use Express Setup if your firmware supports the SPCR table, console redirection is enabled, and you do not plan to use unattended files during setup.

# Enable Emergency Management Services

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Emergency Management Services functionality is built into Windows Server 2003 and is installed, but not enabled, when the operating system is installed. You can enable Emergency Management Services at any of the following times:

- During a new Windows Server 2003 installation, including RIS-based setups.
- During a Windows Server 2003 upgrade (x86-based systems only).
- After you complete a Windows Server 2003 installation.

For information about how to enable Emergency Management Services during or after installation, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Preparing for Deployment of Your Remote Management Solution

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you have followed the planning steps in this chapter to identify your organization's remote management requirements and to design a solution that meets those requirements, you need to test your solution in a lab environment that emulates your production environment as closely as possible. Because out-of-band management and support for remotely administered servers is new to the Windows environment, it is particularly important to test your remotely administered servers and out-of-band configurations. Then develop a list of tasks you need to perform before you can implement your plan. Include tasks for preparing your network, hardware and software configurations, and security.

**Network connectivity**
Identify the steps you need to take to prepare your network infrastructure to ensure connectivity and stable access. Include tasks to accomplish the following:

- Configure your network for increased bandwidth, or establish a secondary network for remote management, if necessary.
- Configure Dial-up Networking settings, if you plan to support dial-up remote management.
- Configure firewall settings, if you plan to remotely manage across a firewall.
- Configure IP packet filter settings, if you plan to remotely manage across a router that filters packets.

**Server resources**
Identify the steps for assessing computer resources and for upgrading them, if necessary, such as:

- Upgrade server and management computer memory and processor, if necessary, to support remote management tools.
- Upgrade or purchase new computers that provide enhanced out-of-band support, if necessary.

**Security**
Identify the steps for ensuring both physical and logical security, for both in-band and out-of-band management, such as:

- Provide secured access to servers.
- Provide physical security for out-of-band serial connections.
- Provide for authentication and encryption protocols.
- Configure Group Policy settings to mitigate vulnerabilities of less secure authentication protocols.
- Configure IPSec policies to provide security if you plan to use tools without encryption or dial-up connections through a VPN.
- Establish a secondary management network or configure secured routers, if necessary.
- Set up security groups and assign membership for administrators.
- Set up shared folders as necessary, and assign permissions.
- Configure Group Policy settings to restrict the types of administrative tasks remote users can perform.

**Configure out-of-band settings**
Identify the steps for configuring computers for out-of-band management:

- Enable firmware console redirection.
- Verify and, if necessary, configure hardware resource settings for serial ports.
- Configure SPCR table settings.
- Configure the service processor, if necessary.
- Select consistent terminal definition settings for firmware, Emergency Management Services, and client terminal software.

For more information about specific settings for Emergency Management Services, see the *Server Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Connect out-of-band hardware components**
Identify the steps for configuring the out-of-band infrastructure:

- Set up serial port null modem connections.
- Connect terminal concentrators, modems, service processors, and intelligent UPSs.

For more information about setting up null modem connections in an Emergency Management Services installation, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

**Install and enable Emergency Management Services**
Identify the steps for installing Windows Server 2003 and enabling Emergency Management Services:

- Build and test files and directories for unattended network, unattended CD, or RIS installations of Windows Server 2003.
- Enable Emergency Management Services during or after Windows Server 2003 installation.

For more information about enabling Emergency Management Services, see the *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit).

# Additional Resources for Remote Server Management

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

These resources contain additional information and tools related to this chapter.

**Related Information**

- The *Storage Technologies Collection* of the *Windows Server 2003 Technical Reference* (or see the Storage Technologies Collection on the Web at http://www.microsoft.com/reskit) for more information about remote management, remote management tools, and configuring and using Emergency Management Services.
- "Deploying a Managed Software Environment" in *Designing a Managed Environment* of this kit for information about software distribution tools.
- "Designing a Group Policy Infrastructure" in *Designing a Managed Environment* of this kit for more information about Group Policy.
- The *Windows Security Collection* of the *Windows Server 2003 Technical Reference* (or see the Windows Security Collection on the Web at http://www.microsoft.com/reskit) for more information about Group Policy, and also for more information about groups, user rights, permissions, and authorization and access control.
- The *Internetworking Collection* of the *Windows Server 2003 Technical Reference* (or see the Internetworking Collection on the Web at http://www.microsoft.com/reskit) for more information about VPN and about using IPSec with VPN.
- "Choosing an Automated Installation Method" in *Automating and Customizing Installations* in this kit for more information about choosing an installation method for the Windows Server 2003 operating system.
- "Designing RIS Installations" in *Automating and Customizing Installations* of this kit for more information about Remote Installation Services (RIS).
- "Designing Unattended Installations" in *Automating and Customizing Installations* of this kit for more information about network-based unattended installations.
- The WMI Software Development Kit (SDK) link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources for more information about developing applications using WMI.

**Related Tools**

- Windows Server 2003 Administration Tools Pack

  This set of tools includes several of the most common tools for remotely managing servers from a Windows XP Professional–based computer. Install the tools pack by running C:\windows\system32\adminpak\adminpak.msi.

**Related Help Topics**

For best results in identifying Help topics by title, in Help and Support Center, under the **Search** box, click **Set search options**. Under **Help Topics**, select the **Search in title only** check box.

- "Special Administration Console (SAC) and SAC commands" in Help and Support Center for Windows Server 2003 for information about SAC commands.
- " !Special Administration Console (!SAC) and !SAC commands" in Help and Support Center for Windows Server 2003 for information about !SAC commands.

- "Windows Server 2003 Administration Tools Pack Overview" in Help and Support Center for Windows Server 2003 for more information about the Administration Tools Pack. This topic is installed when you install the tools.

- "Configure client callback options" in Help and Support Center for Windows Server 2003 for information about configuring modems for callback.

- "VPN remote access for employees" in Help and Support Center for Windows Server 2003 for information about network settings for VPN connections.

- "Best practices for selecting and configuring hardware" in Help and Support Center for Windows Server 2003 for information about selecting hardware components to use with Emergency Management Services.

- "Internet Protocol Security (IPSec)" in Help and Support Center for Windows Server 2003 for information about IPSec policies.

- "Best practices for permissions and user rights" in Help and Support Center for Windows Server 2003 for information about assigning permissions and user rights for remote management.

**Related Job Aids**

For a document to assist you in setting up remotely administered servers with a terminal concentrator, see "Headless Server Quick Start" (SDCEMS_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "Headless Server Quick Start" on the Web at http://www.microsoft.com/reskit).

# Planning for High Availability and Scalability

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Business-critical applications such as corporate databases and e-mail often need to reside on systems and network structures that are designed for high availability. The same is true for retail Web sites and other Web-based businesses. Knowing about high availability concepts and practices can help you to maximize the availability (extremely low downtime) and scalability (the ability to grow as demand increases) of your server systems. Using sound IT practices and fault-tolerant hardware solutions in your deployment can increase availability and scalability. Additionally, the Microsoft® Windows® Server 2003 operating system offers two clustering technologies — server clusters and Network Load Balancing — that provide both the reliability and scalability that most enterprises need.

**In This Chapter**

Overview of Planning for High Availability and Scalability

Defining Availability and Scalability Goals

Using IT Procedures to Increase Availability and Scalability

Evaluating Windows Clustering

Using Clusters to Increase Availability and Scalability

Additional Resources for Planning Server Deployments

**Related Information**

- For more information about planning for server clusters, see "Designing and Deploying Server Clusters" in this book.
- For more information about Network Load Balancing, see "Designing Network Load Balancing" in this book.
- For more information about fault-tolerant storage solutions, see "Planning for Storage" in this book.
- For information about deploying Emergency Management Services for managing remote servers, see "Planning for Remote Server Management" in this book.

# Overview of Planning for High Availability and Scalability

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A highly available system reliably provides an acceptable level of service with minimal downtime. Downtime penalizes businesses, which can experience reduced productivity, lost sales, and lost faith from clients, partners, and customers.

By implementing recommended IT practices, you can increase the availability of key services, applications, and servers. These practices also help you minimize both planned downtime, such as for maintenance or service pack installations, and unplanned downtime, such as downtime caused by a server failure.

Additionally, the clustering technologies available in Windows Server 2003 can provide added levels of availability and scalability. A cluster is a group of independent computers that work together to provide a common set of services. If a cluster node (a computer in a cluster) fails, other nodes in the cluster assume the functions of the failed node. Clusters enhance the availabilityof critical applications and services. Clusters also increase the scalabilityof your deployment by allowing you to scale your solution over time to support additional clients or increased client demands. In most deployments, server clustersprovide availability, and Network Load Balancing clustersincrease scalability.

If you need the highest levels of availability (and if your budget can accommodate the expense), use both recommended IT practices and clustering for a truly comprehensive high availability deployment that is also scalable. If you determine that your organization needs to increase availability and scalability, this chapter can help you create an effective plan for implementing a high availability and scalability solution that meets your organization's current and future needs.

**Note**

- Server clusters are supported by the Microsoft® Windows® Server 2003, Enterprise Edition, and Windows® Server 2003, Datacenter Edition, operating systems. Network Load Balancing is supported by all Windows Server 2003 operating systems, including Windows® Server 2003, Standard Edition, and Windows® Server 2003, Web Edition.

# High Availability and Scalability Planning Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Figure 6.1 illustrates the high availability design process and defines the steps you can take to ensure a deployment that meets your requirements for high availability.

**Figure 6.1 Planning for High Availability and Scalability**

# Basic High Availability and Scalability Concepts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To begin designing a Windows Server 2003 deployment for maximum availability and scalability, familiarize yourself with these fundamental high availability and scalability concepts.

**Basic High Availability Concepts**
An integral part of building large-scale, mission-critical systems that your business and your users can rely on is to ensure that no single point of failure can render a server or network unavailable. There are several types of failures you must plan against to keep your system highly available.

**Storage failures**
There are many ways to protect against failures of individual storage devices using techniques such as Redundant Array of Independent Disks (RAID). Storage vendors provide hardware solutions that support many different types of hardware redundancy for storage devices, allowing devices as well as individual components in the storage controller itself to be exchanged without losing access to the data. Software solutions also provide similar capabilities.

**Network failures**
There are many components to a computer network, and there are many typical network topologies that provide highly available connectivity. All types of networks need to be considered, including client access networks and management networks. In storage area networks (SANs), failures might include the storage fabrics that link the computers to the storage units. For more information about SANs, see "Planning for Storage" and "Designing and Deploying Server Clusters" in this book.

**Computer failures**
Many enterprise-level server platforms provide redundancy inside the computer itself, such as through redundant power supplies and fans. Vendors also allow components such as peripheral component interconnect (PCI) cards and memory to be swapped in and out without removing the computer from service. In cases where a computer fails or needs to be taken out of service for routine maintenance or upgrades, clustering provides redundancy to enable applications or services to continue. This redundancy happens automatically in clustering, either through failover of the application (transferring client requests from one computer to another) or by having multiple instances of the same application available for client requests.

**Site failures**
In extreme cases, a complete site can fail due to a total power loss, a natural disaster, or other unusual occurrences. More and more businesses are recognizing the value of deploying mission-critical solutions across multiple geographically dispersed sites. For disaster tolerance, a data center's hardware, applications, and data can be duplicated at one or more geographically remote sites. If one site fails, the other sites continue offering service until the failed site is repaired. Sites can be *active-active*, where all sites carry some of the load, or *active-passive*, where one or more sites are on standby.

You can prevent most of these failures by using the following methods:

- **Proven IT practices.** IT strategies can help your organization avoid some or all of the above failures. IT practices take on added importance when a clustering solution is not applicable to, or even possible in, your particular deployment. Whether or not you choose to deploy a clustering solution, all Windows deployments should at a minimum follow the guidelines and reference the resources listed in this chapter for fault-tolerant hardware solutions.

- **Clustering.** This chapter introduces Windows Server 2003 clustering technologies and provides an overview of how they work. Different kinds of clusters can be used together to provide a true end-to-end high availability and scalability solution. For more information about end-to-end solutions, see "Using Clusters to Increase Availability and Scalability" later in this chapter. For complete information about designing clusters, see "Designing and Deploying Server Clusters" and "Designing Network Load Balancing" in this book.

**Basic Scalability Concepts**
In general deployments, scalability is the measure of how well a service or application can grow to meet increasing performance demands. When applied to clustering, scalability is the ability to incrementally add systems to an existing cluster when the overall load of the cluster exceeds the cluster's capabilities.

**Scaling up**
*Scaling up* involves increasing system resources (such as processors, memory, disks, and network adapters) to your existing

hardware or replacing existing hardware with greater system resources. Scaling up is appropriate when you want to improve client response time, such as on a Network Load Balancing cluster. If the required number of users are not properly supported, adding random access memory (RAM) or central processing units (CPUs) to the server is one way to meet the demand.

Windows Server 2003 supports single or multiple CPUs that conform to the symmetric multiprocessing (SMP) standard. Using SMP, the operating system can run threads on any available processor, which makes it possible for applications to use multiple processors when additional processing power is required to increase the capability of a system. For more information about scaling up, see "Using Clusters to Increase Availability and Scalability" later in this chapter.

**Scaling out**

*Scaling out* involves adding servers to meet demand. In a server cluster, this means adding nodes to the cluster. Scaling out is also appropriate when you want to improve client response time with your servers, and when you have the hardware budget to purchase additional servers as needed. For more information about scaling out, see "Using Clusters to Increase Availability and Scalability" later in this chapter.

**Testing and Pilot Deployments**

Before you deploy any new solution, whether it is a fault-tolerant hardware or networking component, a software monitoring tool, or a Windows clustering solution, you should thoroughly test the solution before deploying it. After testing in an isolated lab, test the solution in a pilot deployment in which only a few users are affected, and make any necessary adjustments to the design. After you are satisfied with the pilot deployment, perform a full-scale deployment in your production environment. Depending on the number of users you have, you might want to perform your full-scale deployment in stages. After each stage, verify that your system can accommodate the increased processing load from the additional users before deploying the next group of users.

Clusters in particular need to be tested and then deployed in a pilot environment before you deploy them in a production environment. For more information about testing clusters, see "Designing and Deploying Server Clusters" and "Deploying Network Load Balancing" in this book.

For complete information about setting up a test environment for your Windows Server 2003 deployment and implementing a pilot deployment see "Designing a Test Environment" and "Designing a Pilot Project" in *Planning, Testing, and Piloting Deployment Projects* in this kit.

# Defining Availability and Scalability Goals

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Defining availability and scalability goals is the first step toward ensuring that your efforts are focused on the elements of the system that matter the most to your organization. Figure 6.2 shows how to quantify and determine your availability goals.

**Figure 6.2 Defining Availability and Scalability Goals**

Availability goals allow you to accomplish the following tasks:

- Design, operate, and evaluate your systems in relationship to a consistent set of priorities, and place new requests or problems in context.
- Keep efforts focused where they are needed. Without clear goals, efforts can become uncoordinated, or resources can be spread so thin that none of the organization's most important needs are met.
- Limit costs. You can direct expenditures toward the areas where they make the most difference.
- Recognize when tradeoffs must be made, and make them in appropriate ways.
- Clarify areas where one set of goals might conflict with another, and avoid making plans that require a system to handle two conflicting goals simultaneously.
- Provide a way for operators and support staff to prioritize unexpected problems when they arise by referring to the availability goals for that component or service.

# Quantifying Availability and Scalability for Your Organization

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Your goal in quantifying availability is to compare the costs of your current IT environment — including the actual costs of outages — and the cost of implementing high availability solutions. These solutions include training costs for your staff as well as facilities costs, such as costs for new hardware. After you have calculated the costs, IT managers can use these numbers to make business decisions, not just technical decisions, about your high availability solution. For information about monitoring tools that can help you measure the availability of your services and systems, see "Implementing Software Monitoring and Error-Detection Tools" later in this chapter.

Scalability is more difficult to quantify because it is based on future needs and therefore requires a certain amount of estimation and prediction. Remember, though, that scalability is tied to availability because if your system cannot grow to meet increased demand, certain services will become less available to your users.

#### Determining Availability Requirements

Availability can be expressed numerically as the percentage of the time that a service is available for use. The exact level of availability must be determined in the context of the service and the organization that uses the service. Table 6.1 displays common availability levels that many organizations try to achieve. The following formula is used to calculate these levels:

**Percentage of availability = (total elapsed time – sum of downtime)/total elapsed time**

**Table 6.1 Availability Measurements and Yearly Downtime**

| Availability | Yearly Downtime |
|---|---|
| 99.999% | 5 minutes |
| 99.99% | 53 minutes |
| 99.9% | 8 hours, 45 minutes |

Availability requirements can vary depending on the server role. Your users can probably continue to work if a print server is down, for example, but if a server hosting a mission-critical database fails, your business might feel the effects immediately.

#### Determining Reliability Requirements

Reliability is related to availability, and it is generally measured by computing the time between failures. Mean time between failures (MTBF) is calculated by using the following equation:

**MTBF = (total elapsed time – sum of downtime)/number of failures**

A related measurement is mean time to repair (MTTR), which is the average amount of time that it takes to bring an IT service or component back to full functionality after a failure.

A system is more reliable if it is *fault tolerant*. Fault tolerance is the ability of a system to continue functioning when part of the system fails. This is achieved by designing the system with a high degree of hardware redundancy. If any single component fails, the redundant component takes its place with no appreciable downtime. For more information about fault-tolerant components, see "Planning and Designing Fault-Tolerant Hardware Solutions" later in this chapter.

#### Determining Scalability Requirements

You need to consider scalability now to provide your organization a certain amount of flexibility in the future. If you believe your hardware budget will be sufficient, you can plan to purchase hardware at regular intervals to add to your existing deployment. The amount of hardware you purchase depends on the exact increase in demand. If you have budget limitations, purchase servers that you can scale up later by adding RAM or CPUs to meet a rise in users or client requests.

Looking at past growth can help you determine how demand on your IT system might grow. However, because business technology is becoming increasingly complex, and reliance on that technology is growing every year, you must consider other factors as well. If you anticipate growth, realize that some aspects of your deployment may grow at different rates. You might need many more Web servers than print servers, for example, over a certain period of time. For some types of servers, it might be sufficient to add CPU power when network traffic increases, while in other cases, such as with a Network Load Balancing cluster, the most practical scaling solution might be to add more servers.

Recreate your Windows deployment as accurately as possible in a test environment and, either manually or through a

simulation program, put as much workload as possible on different areas of your deployment. Observing your system under such circumstances can help you formulate scaling priorities and anticipate where you might need to scale first.

After your system is deployed, software-monitoring tools can alert you when certain components of your system are near or at capacity. Use these tools to monitor performance levels and system capacity so that you know when a scaling solution is needed. For more information about monitoring performance levels, see "Implementing Software Monitoring and Error-Detection Tools" later in this chapter.

# Analyzing Risk

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When planning a highly available Windows Server 2003 environment, consider all available alternatives and measure the risk of failure for each alternative. Begin with your current organization and then implement design changes that increase reliability to varying degrees. Evaluate the costs of each alternative against its risk factors and the impact of downtime to your organization.

Often, achieving a certain level of availability can be relatively inexpensive, but to go from 98 percent availability to 99 percent, for example, or from 99.9 percent availability to 99.99 percent, can be very costly. This is because bringing your organization to the next level of availabity might entail a combination of new or costly hardware solutions, additional staff, and support staff for non-peak hours. As you determine how important it is to maintain productivity in your IT environment, consider whether those added days, hours, and minutes of availability are worth the price.

Every operations center needs a risk management plan. When assessing risks in your proposed Windows Server 2003 deployment, remember that network and server failures can cause considerable loss to businesses. After you evaluate risks versus costs, and after you design and deploy your system, your IT staff needs sound guidelines and plans of action in case a failure in the system does occur.

For more information about designing a risk management plan for your Windows Server 2003 deployment, see the Microsoft Operations Framework (MOF) link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. The MOF Web page provides complete information about creating and maintaining a flexible risk management plan, with emphasis on change management and physical environment management, in addition to staffing and team role recommendations.

# Developing Availability and Scalability Goals

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Begin establishing goals by reviewing information that is readily available within your organization. Existing Service Level Agreements, for example, define the availability goals for specific IT services or systems. Gather information from those individuals and groups who are most directly affected, such as the users or departments that depend on the services and the people who make decisions about IT staffing.

The following questions provide a starting point for developing a list of availability goals. These goals, and the factors that influence them, vary from organization to organization. By identifying the goals appropriate to your situation, you can clarify your priorities as you work to increase system availability and reliability.

**Organization's Central Purposes**
These fundamental questions will help you prioritize the applications and services that are most important to your organization and the extent to which you rely on your IT infrastructure for certain key tasks.

- What are the organization's central purposes?
- What must the organization accomplish to survive and flourish?

**Details on Record That Help Define Availability Requirements**
The questions in this section can help you quantify your availability needs, which is the first step in addressing those needs.

- If your organization has attempted to evaluate the need for high availability in the past, do you have existing documents that already outline availability goals?
- Do you have current or previous Service Level Agreements, Operating Level Agreements, or similar agreements that define service levels?
- Have you defined acceptable and unacceptable service levels?
- Do you have data about the cost of outages or the effect of service delays or outages (for example, information about the cost of an outage at 9 A.M. versus the cost of an outage at 9 P.M.)?
- Do you have any data from groups that practice incident management, problem management, availability management, or similar disciplines?

**Users of IT Services**
It is important to define the needs of your users to provide them with the availability they need to do their work. There is often a tradeoff between providing high availability and paying the cost of hardware, training, and support. Categorizing your users can make these kinds of business decisions easier.

- Who are the end users? What groups or categories do they fall into? What expertise levels do they have?
- How important is each user group or category to the organization's central goals?

**Requirements and Requests of End Users**
These questions help pinpoint the needs of your users. You can more easily customize your high availability solutions and anticipate scalability issues if you know exactly what your users need.

- Among the tasks that users commonly perform, which are the most important to the organization's central purposes?
- When end users try to accomplish the most important tasks, what do they expect to see on their screens (or access through some other device)? Described another way, what data (or other resources) do users need to access, and what applications or services do they need when working with that data?

- For the users and tasks most important to the organization, what defines a satisfactory level of service?

**Requirements for User Accounts, Networks, or Similar Types of Infrastructure**

It is important to know about supporting services — even services that you do not control — when evaluating availability needs and defining availability goals. Your system will be only as fault tolerant as the systems that support it.

- What types of network infrastructure and directory services are required so that users can accomplish the tasks that you have identified as requirements for end users? In other words, what types of behind-the-scenes services do users require?

- For these behind-the-scenes services, what defines the difference between satisfactory and unsatisfactory results for the organization?

**Time Requirements and Variations**

Keeping support staff on-site to maintain a system can be expensive. Costs can be minimized if support personnel are on-site only during critical periods. Similarly, knowing when workload is highest can help you anticipate when availability is most important, and possibly when a failure is likely to occur.

- Are services needed on a 24-hours-a-day, 7-days-a-week basis, or on some other schedule (such as 9 A.M. to 5 P.M. on weekdays)?

- What are the normal variations in load over time?

- What increments of downtime are significant (for example, five seconds, five minutes, an hour) during peak and nonpeak hours?

# Using IT Procedures to Increase Availability and Scalability

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following sections introduce best practices for optimizing your Windows Server 2003 deployment for high availability and scalability. A well-planned deployment strategy can increase system availability and scalability while reducing the support costs and failure recovery times of a system. Figure 6.3 displays the process for deploying your servers and network infrastructure in a fault-tolerant manner that also provides manageability.

**Figure 6.3 Using IT Procedures to Increase Availability and Scalability**

To aid in this planning, Microsoft recommends the Microsoft Operations Framework (MOF). MOF is a flexible, open-ended set of guidelines and concepts that you can adapt to your specific operations needs. Adopting MOF practices provides greater organization and contributes to regular communication between your IT department, your end users, and other departments in your company that might be affected. For complete information about MOF and how to implement it in your organization, see the Microsoft Operations Framework (MOF) link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Planning and Designing Hardware for High Availability

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

*Fault tolerance* means there can be no single point of failure that can cause system failures. The following sections contain highlights of IT practices for ensuring reliable hardware performance and a fault-tolerant IT infrastructure. Included is a summary of ways to safeguard your servers for optimal performance. For detailed information about IT fault-tolerant hardware strategies and highly available system designs, see the Microsoft Solutions Framework link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Planning and Designing Fault-Tolerant Hardware Solutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An effective hardware strategy can improve the availability of a system. These strategies can range from adopting commonsense practices to using expensive fault-tolerant equipment.

**Using Standardized Hardware**
To ensure full compatibility with Windows operating systems, choose hardware from the Windows Server Catalog only. For more information, see the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

When selecting your hardware from the Windows Server Catalog, adopt one standard for hardware and standardize it as much as possible. To do this, pick one type of computer and use the same kinds of components, such as network cards, disk controllers, and graphics cards, on all your computers. Use this computer type for all applications, even if it is more than you need for some applications. The only parameters that you should modify are the amount of memory, number of CPUs, and the hard disk configurations.

Standardizing hardware has the following advantages:

- Having only one platform reduces the amount of testing needed.
- When testing driver updates or application-software updates, only one test is needed before deploying to all your computers.
- With only one system type, fewer spare parts are required.
- Because only one type of system must be supported, support personnel require less training.

For help choosing standardized hardware for your file and print servers, see "Designing and Deploying File Servers" and "Designing and Deploying Print Servers" in this book.

**Using Spares and Standby Servers**
This chapter discusses clustering as a means of providing high availability for your applications and services to your end users. However, there are two clustering alternatives that provide flexibility or redundancy in your hardware design: spares and standby systems.

**Spares**
Keep spare parts on-site, and include spares in any hardware budget. One of the advantages of using a standard configuration is the reduced number of spares that must be kept on-site. If all of the hard drives are of the same type and manufacturer, for example, you can keep fewer drives in stock as spares. This reduces the cost and complexity associated with providing spares.

The number of spares that you need to keep on hand varies according to the configuration and failure conditions that users and operations personnel can tolerate. Another concern is availability of replacement parts. Some parts, such as memory and CPU, are easy to find years later. Other parts, like hard drives, are often difficult to locate after only a few years. For parts that may be hard to find, and where exact matches must be used, plan to buy spares when you buy the equipment. Consider using service companies or contracts with a vendor to delegate the responsibility, or consider keeping one or two of each of the critical components in a central location.

**Standby Systems**
Consider the possibility of maintaining an entire standby system, possibly even a hot standby to which data is replicated automatically. For file servers, for example, the Windows Server 2003 Distributed File System (DFS) allows you to logically group folders located on different servers by transparently connecting them to one or more hierarchical namespaces. When DFS is combined with File Replication service (FRS), clients can access data even if one of the file servers goes down, because the other servers have identical content. DFS and FRS are discussed in detail in "Designing and Deploying File Servers" in this book.

If the costs of downtime are very high and clustering is not a viable option, you can use standby systems to decrease recovery times. Using standby systems can also be important if failure of the computer can result in high costs, such as lost profits from server downtime or penalties from a Service Level Agreement violation.

A standby system can quickly replace a failed system or, in some cases, act as a source of spare parts. Also, if a system has a catastrophic failure that does not involve the hard drives, it might be possible to move the drives from the failed system to a working system (possibly in combination with using backup media) to restore operations relatively quickly. This scenario does not happen often, but it does happen, in particular with CPU or motherboard component failures. (Note that this transfer of data after a failure is performed automatically in a server cluster.)

One advantage to using standby equipment to recover from an outage is that the failed unit is available for careful after-the-fact diagnosis to determine the cause of the failure. Getting to the root cause of the failure is extremely important in preventing repeated failures.

Standby equipment should be certified and running on a 24-hours-a-day, 7-days-a-week basis, just like the production equipment. If you do not keep the standby equipment operational, you cannot be sure it will be available when you need it.

**Using Fault-Tolerant Components**

Using fault-tolerant technology improves both availability and performance. The following sections describe some basic fault-tolerant considerations in two key areas of your deployment: storage and network components. In both cases you should also consult hardware vendors for details specific to each product, especially if you are considering deploying server clusters. For more information about storage options and strategies for server clusters, see "Designing and Deploying Server Clusters" in this book.

**Storage Strategies**

When planning how to store your data, consider the following points:

- The type and quantity of information that must be stored. For example, will a particular computer be used to store a large database needing frequent reads and writes?

- The cost of the equipment. It does not make sense to spend more money on the storage system than you expect to recover in saved time and data if a failure occurs.

- Specific needs for protecting data or making data constantly available. Do you need to prevent data loss, or do you need to make data constantly available? Or are both necessary? For preventing data loss, a RAID arrangement is recommended. For high availability of an application or service, consider multiple disk controllers, a RAID array, or a Windows clustering solution. (Clustering is discussed later in this chapter.)

- A good backup and recovery plan is essential. Downtime is inevitable, but a sound and proven backup and recovery plan can minimize the time it takes to restore services to your users. For more information, see "Backing up and recovering data" in Help and Support Center for Windows Server 2003.

- Physical memory copying, or memory *mirroring*, provides fault tolerance through memory replication. Memory-mirroring techniques include having two sets of RAM in one computer, each a mirror of the other, or mirroring the entire system state, which includes RAM, CPU, adapter, and bus states. Memory mirroring must be developed and implemented in conjunction with the original equipment manufacturer (OEM).

For more information about storage strategies, see "Planning for Storage" in this book.

**Network Components**

The network adapter is a potential single point of failure. Fortunately, the network adapter is, on average, very reliable. However, other components outside the computer can fail, causing the same effect that you would experience with the loss of the network adapter. These include the network cable to the computer; the switch or hub; the router; and the Dynamic Host Configuration Protocol (DHCP), Domain Name System (DNS), and Windows Internet Name Service (WINS) systems. Any one of these components can fail and cause the failure of one or more servers and, potentially, all the servers.

You can contend with such failures through redundancy in your network design. Many components lend themselves to backup or load-sharing strategies. The following list describes redundancy strategies for the network hardware (hub or switch, network adapter, and wiring), the routers, and DNS or WINS.

**Note**

- The following is a list of general planning considerations for all networks. For more information about network considerations for specific cluster types, see "Designing Network Load Balancing" and "Designing and Deploying Server Clusters" in this book.

**Network hardware** Although hubs, switches, network adapters, and wiring are very reliable, if a service must be guaranteed, it is still important to use redundancy for these components. Consult with the vendors who provide your network hardware and support for recommendations on how to build redundancy into your network. For more information about building redundancy into your network, see "Designing a TCP/IP Network" in *Deploying Network Services* of this kit.

**Routers** Routers do not frequently fail, but when they do, entire computer centers can go down. Having redundant routing capability in the computer center is critical. Your router vendor is a recommended source of information about how to protect against router failures.

**DHCP** For the servers on which you must maintain the highest degree of availability, use fixed IP addresses on servers and do not use DHCP. This prevents an outage due to the failure of the DHCP server. This can improve address resolution by DNS servers that do not handle the dynamic address assignment provided by DHCP. For more information about DHCP, see "Deploying DHCP" in *Deploying Network Services* of this kit.

**DNS and WINS** DNS and WINS infrastructure components are easy to replicate. Both were designed to support replication of their name tables and other information. Make sure that when you use multiple DNS and WINS servers, you place them on different network segments. For information about WINS and DNS servers and replication, see "Deploying DNS" and "Deploying WINS" in *Deploying Network Services* of this kit.

For information about replication options for WINS servers, see "Configuring WINS replication" in Help and Support Center for Windows Server 2003. For information about replicating DNS zones, see "DNS zone replication in Active Directory" in Help and Support Center for Windows Server 2003.

For more information about network infrastructure, see the Microsoft Systems Architecture link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Safeguarding the Physical Environment of the Servers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An important practice for high availability of servers is to maintain high standards for the environment in which the servers must run. The following list contains information to consider if you want to increase the longevity and reliability of your hardware:

- **Temperature and humidity.** Install mission-critical servers in a room set aside for that purpose, where you can carefully control temperature and humidity. Computers perform best at approximately 70 degrees Fahrenheit. In an office, temperature is not normally an issue, but be aware of the effect of a long holiday weekend in the summer with the air conditioning turned off.

- **Dust or contaminants.** Protect servers and other equipment from dust and contaminants where possible, and check for dust periodically. Dust and other contaminants can cause components to short-circuit or overheat, which can cause intermittent failures. Whenever the case of a server is opened for any reason, perform a quick check to determine whether the unit needs cleaning. If so, check all the other units in the area.

- **Power supplies.** Planning for power outages, like any disaster-recovery planning, is best done long before you anticipate outages, and it involves identifying the resources that are most critical to the operation of the company. When possible, provide power from at least two different circuits to the computer room and divide redundant power supplies between the power sources. Ideally, the circuits should originate from two different sources external to the building. Be aware of the maximum amount of power a location can provide. It is possible that a location could have so many servers that there is not sufficient power for any additional servers you might want to install. Consider a backup power supply for use in the event of a power failure in your computer center. It may be necessary to continue providing computer service to other buildings in the area or to areas geographically remote from the computer center. Short outages can be dealt with through uninterruptible power supply (UPS) units. Longer duration outages can be handled using standby generators. Include network equipment, such as routers, when reviewing equipment that requires backup power during an outage.

- **Maintenance of cables.** Prevent physical damage to cables in the computer room by making sure cables are neat and orderly, either with a cable management system or tie wraps. Cables should never be loose in a cabinet, where they can be disconnected by mistake. Make sure all cables are securely attached at both ends where possible, and make sure pull-out, rack-mounted equipment has enough slack in the cables, and that the cables do not bind and are not pinched or scraped. Set up good pathways for redundant sets of cables. If you use multiple sources of power or network communications, try to route the cables into the cabinets from different points. If one cable is severed, the other can continue to function. Do not plug dual power supplies into the same power strip. If possible, use separate power outlets or UPS units (ideally, connected to separate circuits) to avoid a single point of failure.

- **Security of the computer room.** For servers that must maintain high availability, restrict physical access for all but designated individuals. In addition, consider the extent to which you need to restrict physical access to network hardware. The details of how you implement this depend on your physical facilities and your organization's structure and policies. When reviewing the security in place for the computer room, also review your methods for restricting access to remote administration of servers. Make sure that only designated individuals have remote access to your configuration information and your administration tools.

# Implementing Software Monitoring and Error-Detection Tools

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Constant vigilance of your network and applications is essential for high availability. Software-monitoring tools and techniques allow you to determine the health of your system and identify potential trouble spots before an error occurs.

This section assumes that you have selected software that supports the high availability features you require. Not all software supports features such as redundancy or clustering. For an application that requires 99 percent uptime, this might not matter. An application that requires 99.9 percent or greater availability must support such features. Monitoring tools can reveal performance trends and other indications that a potential loss of service is eminent before an error actually occurs. If an error does occur, monitoring tools can provide analytic data that administrators can use to prevent the problem from happening again.

Before deploying software, check the application's hardware requirements and consult the documentation or software vendor to be sure the application supports online backup. When your monitoring tools detect a problem or error in an application, online backup allows you to fix the problem with no disruption of service.

# Planning Long-Term Monitoring for Trend Analysis

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Whenever possible, establish monitoring over the long term so you can carry out trend analysis and capacity planning. The advantages of long-term monitoring include:

- Increasing your ability to predict when expansion of the system is necessary.
- Helping with troubleshooting for problems such as memory leaks or abnormal disk consumption.
- Assisting in identifying strategies for load balancing.

Capacity planning plays an important part in the long-term success of a high availability system. A good capacity plan can limit avoidable failures by anticipating system usage, scalability, and growth requirements. Do not limit capacity planning to items such as disks. Ensure that your plans encompass all parts of a system that could become bottlenecks.

Potential bottlenecks for a server include the CPU, memory, disks, and networking components such as cables, routers, switches, and telecommunications carriers.

**CPU** As a general guideline, provide enough processing power to keep CPU utilization below 75 percent.

**Memory** It is important to understand physical memory and its relation to caching, virtual memory, and disk paging. The goal is to provide enough memory to avoid excessive paging, because paging can never be as efficient as directly transferring information to or from physical memory.

**Disks** A general observation for disks is that utilization above 85 percent tends to cause longer seek times, adding to overall response time. As a general guideline, size your disks, and distribute the load between them, to keep utilization below 85 percent.

**Networking, including cabling, routers, switches, and telecommunications carriers** Create a logical map that includes each type of network component and its location along with servers and user access points. This type of diagram provides an understanding of how information travels back and forth between a given user and a given server. Along with using the diagram, gather and organize as much information as possible about the capacities of your network components and about the network loads generated in your enterprise.

**Domain controller traffic** When monitoring network performance, be sure to consider domain controllertraffic and other services inherent in your networking infrastructure. The number of domain controllers that you deploy and their location in your topology can affect performance. For more information about domain controllers, see "Planning Domain Controller Capacity" in *Designing and Deploying Directory and Security Services* of this kit.

# Choosing Monitoring Tools

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you deploy your software, establish routine and automated monitoring and error detection for your operating system and applications. If you can detect application and system errors immediately after they occur, you have a better chance of responding before a system shutdown. Monitoring can also alert you if scaling is necessary somewhere in your organization. For example, if one or more servers are operating at capacity some or all of the time, you can decide if you need to add more servers or increase the CPUs of existing servers.

You can use the following tools and methods to monitor your programs. For more information about monitoring, consult "Monitoring and status tools" in Help and Support Center for Windows Server 2003.

When choosing software to run in a server cluster or Network Load Balancing cluster, see "Designing Network Load Balancing" and "Designing and Deploying Server Clusters" in this book. For additional information, see "Choosing applications to run on a server cluster" and "Determining which applications to use with Network Load Balancing" in Help and Support Center for Windows Server 2003.

**Windows Management Instrumentation**

Windows Management Instrumentation (WMI) helps you manage your network and applications as they become larger and more complex. With WMI, you can monitor, track, and control system events that are related to software applications, hardware components, and networks. WMI includes a uniform scripting application programming interface (API), which defines all managed objects under a common object framework that is based on the Common Information Model (CIM). Scripts use the WMI API to access information from different sources. WMI can submit queries that filter requests for very specific information, and it can subscribe to WMI events based on your particular interests, rather than being limited to events predefined by the original developers. For more information, see Windows Management Instrumentation overview in Help and Support Center for Windows Server 2003.

**Microsoft Operations Manager 2000**

The Microsoft® Operations Manager 2000 management packs have a full set of features to help administrators monitor and manage both the events and performance of their IT systems based on the Microsoft® Windows® 2000 or Windows Server 2003 operating systems. Microsoft Operations Manager 2000 Application Management Pack improves the availability of Windows-based networks and server applications. Microsoft Operations Manager 2000 and Windows Server 2003 are sold separately. For information about Microsoft Operations Manager 2000 and the Application Management Pack, see the Microsoft Operations Manager (MOM) link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Simple Network Management Protocol**

Simple Network Management Protocol (SNMP) allows you to capture configuration and status information about systems in your network and have the information sent to a designated computer for event monitoring. For more information, see "SNMP" in Help and Support Center for Windows Server 2003.

**Event logs**

When you diagnose a system problem, event logs are often the best place to start. By using the event logs in Event Viewer, you can gather important information about hardware, software, and system problems. Windows Server 2003 records this information in the system log, the application log, and the security log. In addition, some system components such as the Cluster service and FRS also record events in a log. For more information about event logs, see "Checking event logs" in Help and Support Center for Windows Server 2003.

**Service Control Manager**

Service Control Manager (SCM), a tool introduced with the release of the Microsoft® Windows NT® version 4.0 operating system, maintains a database of installed services in the registry. SCM can provide high availability because you can configure it to autorestart services after they have failed. For more information about SCM, see the topic "Service Control Manager" in the Windows Platform SDK documentation.

**Performance Logs and Alerts**

Performance Logs and Alerts collects performance data automatically from local or remote computers. You can collect a variety of information about key resources such as CPU, memory, disk space, and the resources needed by the application. When planning your performance logging, determine the information you need and collect it at regular intervals. Be aware, however, that performance sampling consumes CPU and memory resources, and that excessively large performance logs are hard to store and hard to extract useful information from. For more information about automatically collecting performance

data, see "Performance Logs and Alerts overview" in Help and Support Center for Windows Server 2003.

**Shutdown Event Tracker**

You can document the reasons for shutdowns and save the information in a standard format by using Shutdown Event Tracker. You can use codes to categorize the major and minor reasons for each shutdown and record a comment for the shutdown. For more information, see "Shutdown Event Tracker overview" in Help and Support Center for Windows Server 2003.

# Planning for Unreliable Applications

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An unreliable application is an application, usually proprietary to an organization, that your business cannot do without, but that does not meet high standards for reliability. There are two basic approaches you can take if you must work with such an application:

- Remove the unreliable applications from the servers that are most critical to your enterprise. If an application is known to be unreliable, take steps to isolate it, and do not run the application on a mission-critical server.

- Provide sufficient monitoring, and use automatic restarting options where appropriate. Sufficient monitoring requires taking snapshots of important system performance measurements at regular intervals. You can set up automatic restarting of an application or service by using the Services snap-in. For more information about services, see "Services overview" in Help and Support Center for Windows Server 2003.

# Avoiding Operational Pitfalls

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following sections describe operational practices that can limit the availability of applications and computers, in both clustered and nonclustered environments.

**Supporting multiple versions of the operating system, service packs, and out-of-date applications**
Support of a highly available system becomes much more difficult when multiple combinations of different versions of software (and hardware) are used together in one system or in systems that interact on the network. Older software, protocols, and drivers (and the associated hardware) become impractical when they do not support new technologies.

Set aside resources and time for planning, testing, and installing new operating systems, applications, and (where appropriate) hardware. When planning software upgrades, work with users to identify the features they require. Provide training to ease users through software transitions. In your budget for software and support, provide funds for upgrading applications and operating systems in the future.

**Installing incompatible hardware**
Maintain and follow a hardware standard for new systems, spare parts, and replacement parts.

**Failing to plan for future capacity requirements**
Capacity planning is critical to the success of highly available systems. Study and monitor your system during peak loads to understand how much extra capacity currently exists in the system.

**Performing outdated procedures**
Make sure you remove any outdated procedures from operation and support schedules when a root system problem is fixed. For example, when software is replaced or upgraded, certain procedures might become unnecessary or no longer be valid. Pay special attention to procedures that may have become routine. Be sure that all procedures are necessary and not simply temporary fixes for issues for which the root cause has not been found.

**Failing to monitor the system**
If you do not use adequate monitoring, you might not have the ability to catch problems before they become critical and cause system failures. Without monitoring, an application or server failure may be the only notification you receive of a problem.

**Failing to determine the nature of the problem before reacting**
If the operations staff is not trained and directed to analyze problems carefully before reacting, your personnel can spend large amounts of time responding inappropriately to a problem. They also might not use monitoring tools effectively in the crucial time between the first signs of a problem and an actual failure.

**Treating symptoms instead of root cause**
Symptom treatment is an effective strategy for restoring service when an unexpected failure occurs or when performing short-term preventative maintenance. However, symptom treatments that are added to standard operating procedures can become unmanageable. Support personnel can be overwhelmed with symptom treatment and might not be able to react properly to new failures.

**Stopping and restarting to end error conditions**
Stopping and restarting a computer may be necessary at times. However, if this process temporarily fixes a problem but leaves the root cause untouched, it can create more problems than it solves.

# Evaluating Windows Clustering

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Server 2003 provides two clustering technologies: server clusters and Network Load Balancing. The clustering technologies in Windows Server 2003 provide different availability and scalability solutions, and they can be implemented throughout your organization.

You can also utilize an additional type of clustering, Component Load Balancing (CLB) clusters, in your Windows Server 2003 deployment. CLB clusters, however, are a feature of Microsoft® Application Center 2000, and they are not discussed in detail here.

**Note**

- You can use CLB clusters on Windows Server 2003, provided that you use Application Center 2000 Service Pack 2 or later.

For complete information about CLB clusters, see your Microsoft Application Center 2000 documentation. Figure 6.4 illustrates the high-level process for evaluating clustering technologies.

**Figure 6.4 Evaluating Clustering**

# Evaluating the Benefits of Clustering

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A cluster is two or more computers working together to provide higher availability, reliability, and scalability than can be obtained by using a single system. When failure occurs in a cluster, resources are redirected and the workload is redistributed. Microsoft cluster technologies guard against three specific types of failure:

- Application and service failures, which affect application software and essential services.
- System and hardware failures, which affect hardware components such as CPUs, drives, memory, network adapters, and power supplies.
- Site failures in multisite organizations, which can be caused by natural disasters, power outages, or connectivity outages.

**Benefits of Clustering**

If one server in a cluster stops working, a process called *failover* automatically shifts the workload of the failed server to another server in the cluster. Failover ensures continuous availability of applications and data.

This ability to handle failure allows clusters to meet two requirements that are typical in most data center environments:

- **High availability.** The ability to provide end users with access to a service for a high percentage of time while reducing unscheduled outages.
- **High reliability.** The ability to reduce the frequency of system failure.

Additionally, Network Load Balancing clusters address the need for high scalability, which is the ability to add resources and computers to improve performance.

**Limitations of Clustering**

Server clusters are designed to keep applications available, rather than keeping data available. To protect against viruses, corruption, and other threats to data, organizations need solid data protection and recovery plans. Cluster technology cannot protect against failures caused by viruses, software corruption, or human error.

The Cluster service, the service behind server clusters, depends on compatible applications and services to operate properly. The software must respond appropriately when a failure occurs. Administrators must be able to configure where an application stores its data on the server cluster. Also, clients that are accessing a clustered application or service must be able to reconnect to the cluster virtual server after a failure has occurred and a new cluster node has taken over the application.

Only services and applications that use TCP/IP for client-server communication are supported on Network Load Balancing clusters and server clusters.

You cannot use Windows Server 2003 File Replication service (FRS) on shared cluster storage. You also cannot create domain-based Distributed File System (DFS) roots on shared cluster storage. Finally, without the proper management tools, you also cannot use dynamic disks on shared cluster storage. For more information about using dynamic disks on shared cluster storage, see article 237853, "Dynamic Disk Configuration Unavailable for Server Cluster Resources" In the Microsoft Knowledge Base. To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. DFS and FRS are discussed in detail in "Designing and Deploying File Servers" in this book.

**Clustering vs. Fault-Tolerant Hardware Components**

Both clustering and fault-tolerant hardware protect your system from failures of components such as the CPU, memory, fan, or PCI bus. Fault-tolerant hardware is discussed in the section "Planning and Designing Fault-Tolerant Hardware Solutions" earlier in this chapter. Clustering and fault tolerance can be used together in a complete end-to-end solution, but be aware that the two technologies provide high availability in different ways.

Clustering can protect your system against an application or operating system failure, but a fault-tolerant standby server (or a server that uses *hot-swappable* hardware, which allows a device to be added while the server is running) cannot. It is also possible to upgrade an application or operating system or to install a service pack or hotfix without taking a cluster offline.

Upgrades on standby servers, however, are only possible by taking that hardware offline.

# Evaluating Cluster Technologies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you decide to deploy clustering with Windows Server 2003, choosing a cluster technology depends greatly on the application or service that you want to host on the cluster. Server clusters and Network Load Balancing both provide failover support for IP-based applications and services that require high scalability and availability. Each type of cluster, however, is intended for different kinds of services. Your choice of cluster technologies depends primarily on whether you run *stateful* or *stateless* applications:

- **Server clusters are designed for stateful applications.** Stateful applications have long-running in-memory state, or they have large, frequently updated data states. A database such as Microsoft® SQL Server™ 2000 is an example of a stateful application.

- **Network Load Balancing is intended for stateless applications.** Stateless applications do not have long-running in-memory state. A stateless application treats each client request as an independent operation, and therefore it can load-balance each request independently. Stateless applications often have read-only data or data that changes infrequently. Web front-end servers, virtual private networks (VPNs), and File Transfer Protocol (FTP) servers typically use Network Load Balancing.

**Server Clusters**

Server clusters provide high availability for more complex, stateful applications and services by allowing the failover of resources. Server clusters also maintain client connections to applications and services. If your application is stateful, with frequent changes to data, a server cluster is a more appropriate solution. Server clusters run on Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition.

Server clusters, which use the Cluster service, maintain data integrity and provide failover support and high availability for mission-critical applications and services on your back-end servers, including databases, messaging systems, and file and print services. Organizations can use server clusters to make applications and data available on multiple servers that are linked together in a server cluster configuration. Back-end applications and services, such as messaging applications like Microsoft Exchange or database applications like Microsoft SQL Server, are ideal candidates for server clusters.

In server clusters, nodes share access to data. Nodes can be either active or passive, and the configuration of each node depends on the operating mode (active or passive) and how you configure failover in the cluster. A server that is designated to handle failover must be sized to handle the workload of the failed node in addition to its own workload.

In Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, server clusters can contain up to eight nodes. Each node is attached to one or more cluster storage devices, which allow different servers to share the same data. Because nodes in a server cluster share access to data, the type and method of storage in the server cluster is very important.

For information about server clusters, including resource groups, failover and failover policies, storage configurations, cluster-aware applications, and optimizing your network for server clusters, see "Planning your server cluster" in Help and Support Center for Windows Server 2003 and "Designing and Deploying Server Clusters" in this book.

**Network Load Balancing**

If your application is stateless or can otherwise be cloned with no decline in performance, consider deploying Network Load Balancing. Network Load Balancing provides failover support for IP-based applications and services that require high scalability and availability. Network Load Balancing can run on all editions of Windows Server 2003.

Network Load Balancing addresses bottlenecks caused by front-end services, providing continuous availability for IP-based applications and services that require high scalability. Network Load Balancing clusters are used to provide scalability for Web services and other front-end servers, such as VPN servers and firewalls. Organizations can build groups of clustered computers to support load balancing of TCP and User Datagram Protocol (UDP) traffic requests.

Network Load Balancing clusters are groups of identical, typically cloned computers that, through their numbers, enhance the availability of Web servers, Microsoft® Internet Security and Acceleration (ISA) servers (for proxy and firewall servers), and other applications that receive TCP and UDP traffic. Because Network Load Balancing cluster nodes are usually identical clones of each other and can therefore operate independently, all nodes in a Network Load Balancing cluster are active.

You can scale out Network Load Balancing clusters by adding additional servers. As demand on the cluster increases, you can

scale out Network Load Balancing clusters to as many as 32 servers if necessary. Each node runs a copy of the IP-based application or service that is being load balanced and stores all the data necessary for the application or service to run on local drives.

In clusters, stateless applications are typically cloned, so that multiple instances of the same code are executed on the same dataset. Figure 6.5 shows a cloned application (called "App") deployed in a cluster. Each instance of the cloned application is self-contained, so that a client can make a request to any instance and will always receive the same result.

**Figure 6.5 Cloned Application**

Changes made to one instance of a cloned stateless application can be replicated to the other instances, because the dataset of stateless applications is relatively static. Because stateful applications such as Microsoft Exchange or Microsoft SQL Server are updated with new data frequently, they cannot be easily cloned and they are not good candidates for hosting on Network Load Balancing clusters.

For more information about Network Load Balancing, see "Designing Network Load Balancing" and "Deploying Network Load Balancing" in this book.

**Component Load Balancing**

CLB clusters address the unique scalability and availability needs of middle-tier (business) applications that use the COM+ programming model. Organizations can load balance COM+ components over more than one node to dramatically enhance the availability and scalability of software applications. CLB clusters, however, are a feature of Microsoft Application Center 2000. For information about CLB clusters, see your Microsoft Application Center 2000 documentation.

# Using Clusters to Increase Availability and Scalability

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Different types of clusters provide different benefits. Network Load Balancing clusters are designed to provide scalability because you can add nodes as your workload increases. Server clusters increase availability of stateful applications, and they can also allow you to consolidate servers and save on hardware costs. Figure 6.6 shows the steps for planning cluster deployment.

**Figure 6.6 Planning Cluster Deployment**

**Scaling by Adding Servers**

Scaling by adding servers to a Network Load Balancing cluster is also known as *scaling out*. In Windows Server 2003, Network Load Balancing clusters can contain up to 32 nodes. Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, support server clusters containing up to eight nodes. For this reason, it is recommended that you use Network Load Balancing rather than server clusters to increase scalability. Additional servers allow you to meet increased demand on your Network Load Balancing clusters; however, not every organization has the budget to readily add hardware.

Table 6.2 summarizes the number of servers a cluster can contain, by cluster type and operating system.

**Table 6.2 Maximum Number of Nodes in a Cluster**

| Operating System | Network Load Balancing | Component Load Balancing* | Server Cluster |
|---|---|---|---|
| Microsoft® Windows® 2000 Advanced Server | 32 | 12 | 2 |
| Microsoft® Windows® 2000 Datacenter Server | 32 | 12 | 4 |
| Windows Server 2003, Standard Edition | 32 | 12 | N/A |
| Windows Server 2003, Enterprise Edition | 32 | 12 | 8 |
| Windows Server 2003, Datacenter Edition | 32 | 12 | 8 |

* Component Load Balancing is not included with the Windows Server 2003 operating system and runs only on Windows Application Center 2000. You can use CLB clusters with Windows Server 2003, provided that you use Windows Application Center 2000 Service Pack 2 or later. For complete information about Component Load Balancing, see your Windows Application Center 2000 documentation.

Network Load Balancing Clusters also run on Windows Server 2003, Web Edition; the maximum number of nodes is 32.

**Scaling by Adding CPUs and RAM**

Your options for adding CPUs and RAM, also known as *scaling up*, depend on the server operating system. This is a less expensive scaling option than adding nodes, but you are limited by the capacity of the operating system.

Table 6.3 illustrates the CPU and RAM capacity in Windows 2000 and Windows Server 2003.

**Table 6.3 Maximum Number of Processors and RAM**

| Operating System | Number of Processors | Maximum RAM |
|---|---|---|
| Windows 2000 Advanced Server | 8 | 8 GB |
| Windows 2000 Datacenter Server | 32 | 64 GB |
| Windows Server 2003, Enterprise Edition | 8 | 32 GB |
| Windows Server 2003, Datacenter Edition | 32 | 64 GB |

**Availability and Server Consolidation with Server Clusters**

While Network Load Balancing can meet your scaling needs, server clusters provide high availability for hosted applications by reducing the interruption of service due to unplanned outages and hardware failure.

Increasing the number of nodes in a server cluster proportionally increases the availability of the services and applications running on that server cluster. This is because spreading the workload over a greater number of nodes allows each node to run at a lower capacity. When failover occurs in a server cluster with many nodes, there are more servers available to accept the workload of the failed node. Similarly, when a server running at low capacity takes on additional processing after a failover, the failover is less likely to result in a decline in performance.

The hardware required for server cluster nodes is expensive, however. In some cases, it might be possible for you to save money on hardware by consolidating the number of servers or nodes you have deployed in your server clusters. You can still provide high availability of your mission-critical applications after server consolidation, but be aware that combining clusters to reduce the total number of nodes also reduces availability. This is a tradeoff that your organization should evaluate.

Figure 6.7 shows two clusters before consolidation, where two separate two-node clusters, each with one active and one passive node, provide service for a group of clients.

**Figure 6.7 Two Server Clusters Before Consolidation**

Two clusters, each dedicated to a separate application, generally have higher availability than one cluster hosting both applications. This is depends on, among other factors, the available capacity of each server, other programs that may be running on the servers, and the hosted applications themselves. However, if a potential loss in availability is acceptable to your organization, you can consolidate servers.

Figure 6.8 shows what the clusters in Figure 6.7 would look like if they were consolidated into a single three-node cluster. There is a potential loss in availability because in the event of a failure, both active clusters will fail over to the same passive node, whereas before consolidation, each active node had a dedicated passive node. In this example, if both active nodes were to fail at the same time, the single passive node might not have the capacity to take on the workloads of both nodes simultaneously. Your organization must consider such factors as the likelihood of multiple failures in the server cluster, the importance of keeping the applications in this server cluster available, and if potential loss in services is worth the money saved by server consolidation.

**Figure 6.8 Consolidated Server Cluster**

# Evaluating Combining Cluster Technologies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use several Windows clustering solutions together, depending on the services and applications that you need to make highly available. Each cluster type performs a different role in a multicluster deployment. The most common scenario that combines all three clusters is an e-commerce Web site, where the front-end Web servers are configured in Network Load Balancing clusters that receive client requests, the middle-tier applications (such as the Microsoft® BizTalk® Server) use CLB clusters running on Windows Application Center 2000, and the back-end SQL database servers operate in a server cluster. Figure 6.9 illustrates a typical deployment, utilizing all three Windows clustering technologies.

**Figure 6.9 E-Commerce Clustering Scenario**

# Evaluating Clustering Across Multiple Sites

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Many organizations build disaster recovery and increased availability into their infrastructure by using multiple physical sites. Most designs involve a primary site and one or more remote sites, where a remote site mirrors the primary site. The level at which components are mirrored between sites depends on the Service Level Agreement and the business requirements.

**Geographically Dispersed Clusters**

Geographically dispersed server clusters are possible in Windows Server 2003 by using virtual local area networks (VLANs)to connect SANs over long distances. Majority node set, a new type of quorum resource in Windows Server 2003, makes it easier for cluster servers to be geographically separated while maintaining consistency in the event of a node failure.

A geographically dispersed cluster is a combination of pieces supplied by hardware OEMs and software vendors. The configurations required can be complex, and the clusters must use only components supported by Microsoft. Geographically dispersed clusters should be deployed only in conjunction with vendors who provide qualified configurations.

For more information about geographically dispersed clusters and SANs, see "Designing and Deploying Server Clusters" in this book. For complete information about geographically dispersed clusters, see the Geographically Dispersed Clusters link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**MultiSite Network Load Balancing Clusters**

Like geographically dispersed server clusters, Network Load Balancing clusters that span more than one physical site (sometimes known as *stretch clusters*) are intended to protect data in the event of a disaster. Additionally, multisite configurations can be used to provide local access to clients that are spread nationally or globally. For example, a Network Load Balancing cluster split between a data center on the East Coast and a data center on the West Coast can provide services to users in either location.

Unlike geographically dispersed server clusters, in most cases a single Network Load Balancing cluster is not deployed across multiple sites. Instead, multiple, independent Network Load Balancing clusters are deployed, typically with one cluster at each location. The sites are then combined into a single service using features such as DNS round robinto load balance client requests across the sites. Figure 6.10 illustrates a simple version of this scenario.

**Figure 6.10 Multisite Network Load Balancing Configuration**

In Figure 6.10, the client uses DNS to resolve the service name to an IP address. Depending on the IP address that the client receives, the request is sent to Site 1 or Site 2. In this type of configuration, the sites are essentially clones of each other, and the sites provide the same set of services. A Web site, for example, would be identical at either site, and clients receive the same response to a given query regardless of the site they are directed to. Not only are client requests load-balanced between the sites, but in the event that one site fails, the other site can continue responding to client requests. It is worth noting that when one site goes down, there is potential for a longer response time to individual requests, depending on geographical factors and network demand.

# Additional Resources for Planning Server Deployments

Updated: March 28, 2003

# Designing and Deploying Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Server clusters ensure that applications continue to run in the event of planned service downtime due to maintenance or during unplanned downtime due to hardware or network failure. In order to design server clusters, organizations need to understand the applications that they intend to host on a server cluster, namely the best way to deploy and configure the application in a clustering environment, and they also need to know the server cluster's storage and capacity requirements.

**In This Chapter**

Overview of the Server Clusters Design Process

Analyzing High-Availability Requirements

Determining How to Deploy Applications

Designing the Support Structure for Server Clusters

Protecting Data from Failure or Disaster

Securing Server Clusters

Deploying Server Clusters

Additional Resources for Server Clusters

# Overview of the Server Clusters Design Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Mission-critical applications, such as corporate databases and e-mail, must reside on systems that are designed for high availability and scalability. Deploying server clusters with the Microsoft® Windows® Server 2003, Enterprise Edition or the Windows® Server 2003, Datacenter Edition operating system minimizes the amount of planned and unplanned server downtime. Server clusters can benefit your organization if:

- Your users depend on regular access to mission-critical data and applications to do their jobs.
- Your organization has established a limit on the amount of planned or unplanned service downtime that you can sustain.
- The cost of the additional hardware that server clusters require is less than the cost of having mission-critical data and applications offline during a failure.

Windows Server 2003 provides two different clustering technologies: server clusters (discussed in this chapter) and Network Load Balancing. An overview of these cluster solutions is provided in "Planning for High Availability and Scalability" in this book. For more information about Network Load Balancing, see "Designing Network Load Balancing" and "Deploying Network Load Balancing" in this book. Note that this chapter focuses on using server clusters to make applications highly available. For information about using server clusters with resources such as file and print services, see "Designing and Deploying Print Servers" and "Designing and Deploying File Servers" in this book.

A third clustering technology, Component Load Balancing (CLB), is available in Microsoft® Application Center 2000 but not in Windows Server 2003. CLB clusters enable COM+ applications to be distributed across multiple servers. For more information about CLB, see the documentation for Microsoft Application Center 2000.

If your business is considering server clusters to provide increased availability for one or more applications, and you plan to use Windows Server 2003 — either Enterprise Edition or Datacenter Edition — this chapter will help you evaluate, design, and implement a server cluster compatible with those applications. If you are already running server clusters on Windows NT 4.0 or Windows 2000, this chapter helps you prepare to upgrade those clusters to Windows Server 2003.

# Server Cluster Design and Deployment Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You begin the server cluster design and deployment process by defining your high-availability needs. After you determine the applications or services you want to host on a server cluster, you need to understand the clustering requirements of those applications or services. Next, design your server cluster support network, making sure that you protect your data from failure, disaster, or security risks. After you evaluate and account for all relevant hardware, software, network, and security factors, you are ready to deploy a server cluster. Figure 7.1 illustrates the server cluster design process.

**Figure 7.1 Designing and Deploying Server Clusters**

# Server Cluster Fundamentals

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following sections provide an overview of key clustering concepts and summarize new clustering features that have been added to Windows Server 2003.

A *cluster* is a group of individual computer systems working together cooperatively to provide increased computing power and to ensure continuous availability of mission-critical applications or services. From the client viewpoint, an application that runs on a server cluster is no different than an application that runs on any other server, except that availability is higher.

**Clustering Terms**

The following terms are fundamental clustering concepts that are common to almost every clustering decision. For more information about the following terms and for an overview of server clusters, see "Server Cluster Components" and "Cluster Objects" in Help and Support Center for Windows Server 2003.

**Node** A computer system that is a member of a server cluster. Windows Server 2003 supports up to eight nodes in a server cluster.

**Resource** A physical or logical entity that is capable of being managed by a cluster, brought online, taken offline, and moved between nodes. A resource can be owned only by a single node at any point in time.

**Resource groups** A collection of one or more resources that are managed and monitored as a single unit. Resource groups can be started and stopped independently of other groups (when a resource group is stopped, all resources within the group are stopped). In a server cluster, resource groups are indivisible units that are hosted on one node at any point in time. During failover, resource groups are transferred from one node to another.

**Virtual server** A collection of services that appear to clients as a physical Windows-based server but are not associated with a specific server. A virtual server is typically a resource group that contains all of the resources needed to run a particular application and can be failed over like any other resource group. All virtual servers must include a Network Name resource and an IP Address resource.

**Failover** The process of taking resource groups offline on one node and bringing them back online on another node. When a resource group goes offline, all resources belonging to that group go offline. The offline and online transitions occur in a predefined order. Resources that are dependent on other resources are taken offline before and brought online after the resources upon which they depend.

**Failback** The process of moving resources, either individually or in a group, back to their original node after a failed node rejoins a cluster and comes back online.

**Quorum resource** The quorum-capable resource selected to maintain the configuration data necessary for recovery of the cluster. This data contains details of all of the changes that have been applied to the cluster database. The quorum resource is generally accessible to other cluster resources so that any cluster node has access to the most recent database changes. By default there is only one quorum resource per cluster.

**Cluster Hardware Requirements**

The following are general hardware requirements for building Windows Server 2003 clusters. More detailed information is provided throughout this chapter where applicable. In order for server clusters to be supported by Microsoft, all hardware must be selected from a list of qualified clustering solutions. See the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. For more information about support for server clusters, see article Q309395, "The Microsoft Support Policy for Server Clusters and the Hardware." To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

- Use a minimum of two computers running Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition (computer hardware must also be listed in the Windows Server Catalog). You cannot mix x86-based and Itanium architecture–based computers in the same server cluster.

- Meet minimum storage requirements. Minimum storage requirements depend on a number of factors, such as whether or not your server cluster uses storage area network (SAN) technology, or the type of quorum resource used in the server cluster. For more information about storage solutions, see "Designing the Support Structure for Server Clusters" later in this chapter. Note that all storage solutions must also be listed in the Windows Server Catalog.

- Use a minimum of two network adapters for each node. In recommended configurations, one network adapter connects the node to the other nodes in the cluster for communication and configuration purposes (private network). The second adapter connects the cluster to both an external network (public network) and the private network.

**Important**

- Server clusters do not protect against hardware failures. Microsoft recommends a redundant array of independent disks (RAID) solution for all cluster disks to eliminate disk drives as a potential single point of failure.

**New in Windows Server 2003**

Windows Server 2003 introduces a number of new clustering features that are highlighted below.

**More nodes in a cluster** Windows Server 2003 supports up to eight nodes per cluster.

**Support for 64-bit versions of Windows Server 2003 operating system** The 64-bit versions of Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition support the Cluster service. Note that you cannot use GUID partition table (GPT) disks for shared cluster storage. A GPT disk is an Itanium–based disk partition style in the 64-bit versions of Windows Server 2003. For 64-bit versions of Windows Server 2003, you must partition cluster disks on a shared bus as master boot record (MBR) disks and not as GPT disks.

**Simplified cluster configuration and setup** Server cluster system files are installed by default with Windows Server 2003. New features include the ability to create new server clusters — or add nodes to an existing cluster — remotely. Another new feature, the New Server Cluster Wizard, analyzes hardware and software configurations to identify potential problems before installation.

**Security enhancements** You can reset the Cluster service account password without stopping the Cluster service, allowing you to maintain corporate password policies without compromising availability. In addition, server clusters now support the Kerberos version 5 authentication protocol. For more information, see "Securing Server Clusters" later in this chapter.

**Scripting** An application can be made server cluster-aware through scripting (both VBScript and Jscript are supported), rather than through resource dynamic-link library (DLL) files. Unlike DLLs, scripting does not require knowledge of the C or C++ programming languages, which means scripts are easier for developers and administrators to create and implement. Scripts are also easier to customize for your applications.

**Majority node set clusters** In every cluster, the quorum resource maintains all configuration data necessary for the recovery of the cluster. In majority node set clusters, the quorum data is stored on each node, allowing for, among other things, geographically dispersed clusters. For more information about quorums, see "Designing the Support Structure for Server Clusters" later in this chapter. For more information about majority node set clusters, see "Protecting Data from Failure or Disaster" later in this chapter.

# Analyzing High-Availability Requirements

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After determining that you have mission-critical applications or services that need to be highly available, analyze your business needs to determine if clustering is the best solution. You must then evaluate your applications for compatibility with clustering. Figure 7.2 illustrates the process for determining if server clusters are appropriate for your needs.

**Figure 7.2 Analyzing High-Availability Requirements**

# Analyzing High-Availability Business Needs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This chapter assumes that you have already decided to make one or more applications or services highly available, based on your organization's business needs. You need high availability if users require regular access to data or if your organization cannot tolerate downtime from an application or service for more than a minimal amount of time. Other common business motivations for high availability include contractual obligations, concern about losing sales during the time it takes to rebuild a server, and the potential for lost employee productivity when data is inaccessible.

If your business or organization requires high availability, answer the following questions before you begin designing a server cluster:

- How many users depend on a particular application?
- Are your users located at more than one physical site?
- What is the minimum acceptable downtime for a particular application?
- How many failures does your cluster need to tolerate? One node failure? Two nodes or more?
- How much hardware (particularly cluster nodes) can be dedicated to the server cluster?

Additionally, if you have more than one application that needs to be made highly available, do some applications take priority over other applications that will be running on the server cluster? If the answer is yes, consider prioritizing the applications. For example, if more than one node fails in your server cluster, and the remaining hardware is not sufficient to take on every failed node's workload, which applications and services must continue working?

Understanding the business requirements that must be handled by your server cluster is important, particularly later in the server cluster design process when you design failover policies. For more information about these requirements, see "Determining How to Deploy Applications" later in this chapter.

If a server cluster is the most appropriate high-availability solution for your business or organization, the next step is to make sure your application can run on a server cluster.

# Determining Application Compatibility for Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Not all applications can be adapted to run on a server cluster. If your application meets all the following conditions, it will likely work in a server cluster:

- Your application uses a protocol based on Internet Protocol (IP).
- Your application can specify where application data is stored.
- Your application attempts to reconnect or recover from network failures.

IP-based protocols include Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Distributed Component Object Model (DCOM), named pipes, and remote procedure call (RPC) over TCP/IP. NetBEUI and Internetwork Packet Exchange (IPX) protocols do not work on a server cluster.

**Tip**

- For information about pretesting to determine if your application is cluster ready, or for information about whether your application supports failover, whether clients can survive failure and subsequent restart of your application, and if clients can survive a failure without a restart of your application, see "Choosing applications to run on a server cluster" in Help and Support Center for Windows Server 2003.

Additionally, some applications do not react to cluster events. An application must be *cluster-aware* (must communicate with the Cluster application programming interface) to receive status and notification information from the server cluster. The Cluster application programming interface (API) is a collection of functions that are implemented by the cluster software and used to manage the cluster, cluster objects, and the cluster database.

Most older applications are not cluster-aware, but they can still run in a server cluster and fail over. These applications respond to only the most basic methods of failure detection and shutdown, and they are not capable of the more advanced initialization and cleanup tasks performed by applications that can react to cluster events. For this reason, these applications might not be as highly available in a server cluster as are applications that can interact with the cluster.

For more information about applications that can run on a cluster, see the Software Development Kit (SDK) link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources and search for the help topic "Server Cluster Application Types."

Before designing your server cluster, contact the software vendor or consult the documentation to see if your application can run on a cluster. This information can affect how you install your application in a server cluster, and might also determine the best way to upgrade an application once it is installed in a server cluster.

# Determining How to Deploy Applications

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Some of your deployment decisions are dictated by the application you plan to deploy in the server cluster. Figure 7.3 displays the process for analyzing your application and determining the best way to deploy the application in a server cluster.

**Figure 7.3 Determining How to Deploy Applications**

# Evaluating the Application

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You need a thorough understanding of your application's installation needs before deploying the application in a server cluster. For every application that you intend to install in a server cluster, check the documentation or contact the software vendor about installation issues in general and clustering considerations in particular.

The information you need before deploying an application in a server cluster includes:

- **Setup information.** How the application setup works, such as where the application is installed and where supporting data for the application is installed. When installing Microsoft® Exchange 2000 Server on a server cluster, for example, the log files and database in each storage group must be on the cluster's shared disk. This allows the log files and the storage group databases to fail over to another node if the Exchange virtual server goes offline.

- **Upgrade information.** When it is time to upgrade the application, can the application be upgraded online, or will the server cluster need to be taken offline?

- **Application behavior during failover.** Anticipating application behavior during failover will also help to optimize your deployment. In Microsoft® SQL Server™, Microsoft recommends making all transactions as small as possible because the startup process for SQL virtual servers includes going through the transaction log for each database and rolling transactions back or forward. Therefore, larger transactions, especially with a large volume of transactions, could result in slower failover time.

# Choosing a Method for Deploying an Application on a Server Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The best method for deploying an application on a server cluster depends greatly on what type of application it is. Applications running on a cluster can be characterized in two ways: single-instance and multiple-instance. The way your application behaves in a server cluster depends on which type (single-instance or multiple-instance) it is. This means that your deployment method can also vary by application type.

# Deploying Single-Instance Applications

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

With single-instance applications, only one application instance is running on the cluster at any time, and the application typically has data sets that cannot be partitioned across multiple nodes. The Dynamic Host Configuration Protocol (DHCP) service is an example of a single-instance application. The set of leased IP addresses that the application provides is small, but would be complicated to replicate across a cluster. Therefore the DHCP instance exists as a single instance, and high availability is provided by failing over the instance to another node in the cluster.

Figure 7.4 illustrates a single-instance application, named "App," in a four-node cluster. Only one node is currently hosting the application. If that node fails, the application can fail over to one of the other three nodes (the failover options are represented by dotted lines). All four nodes are connected to the application data source, but only the node currently hosting the application can access the data source.

**Figure 7.4 Single-Instance Application**

# Deploying Multiple-Instance Applications

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

With a multiple-instance application, either multiple instances of the same code, or different pieces of code that cooperate to provide a single service, can run on a cluster. In both cases, the client or end user sees only one partition of an application. Applications can be either *cloned* or *partitioned* to create multiple instances in a cluster.

**Cloned Applications**

In a cloned deployment, multiple instances of the same code are executed on the same data set. Cloned applications are more commonly deployed in Network Load Balancing clusters than in server clusters, because cloning is ideal for *stateless* applications, which are applications with data that is rarely updated or that is read-only. Server clusters are designed for applications such as databases and messaging systems that have frequently updated data. For more information about Network Load Balancing clusters, see "Designing Network Load Balancing" in this book.

**Partitioned Applications**

Server clusters are designed for *stateful* applications, which are applications with frequently updated data sets and long-running in-memory states. Most stateful applications can be partitioned. A large database, for example, can be partitioned so that names beginning with A through L are in one database partition, and those beginning with M through Z are in another database partition. In other applications, functionality — rather than data — is partitioned. After they are partitioned, the different functions are deployed across a set of nodes in a cluster.

In order to represent a single application instance to clients or end users, a partitioned application requires an application-dependent decomposition, routing, and aggregation mechanism that allows a single client request to be distributed across the set of partitions. Then the results from the partitions need to be combined into a single response back to the client. This mechanism depends on the type of application and type of data returned, and is therefore application-specific. The query engine in SQL Server performs this splitting and aggregating. In Exchange 2000 Server clusters, the Exchange front-end server uses the Active Directory® directory service to perform this task.

Figure 7.5 shows an example of a partitioned application in which a database of customer names has been partitioned on a four-node cluster. The solid lines represent each node's connection to its partition of the database; the dotted lines represent the application's access to a given partition as needed.

**Figure 7.5 Data Partitioning for an Application on a Cluster**

When a client issues a query such as "return all records" across multiple instances, the request is split across the instances and — after results are collected — aggregated back into a single result, which is passed back to the client.

A deployment such as the one in Figure 7.5 allows for scalability, because more servers can be added to house additional partitions, but it does not provide high availability. If one of the nodes fails, that part of the data set is no longer accessible.

As mentioned above, an application can also be partitioned by functionality. Figure 7.6 shows a multiple-instance application deployment, where functionality, not data, is shared among the nodes.

**Figure 7.6 Functional Partitions**

When a client request is introduced to the server cluster in Figure 7.6, the request is directed to the appropriate node, depending on the nature of the request. A billing inquiry, for example, is handled by the node designated for that function. The billing node is the only node with access to the billing database.

The deployment of an application across a server cluster depends on the style of application (single-instance versus multiple-instance) and the number of applications that you plan to deploy in the same cluster.

The following sections describe the most common application deployment options.

**One single-instance application** One node in the cluster executes the application, servicing user requests. The remaining nodes are on standby, ready to host the application in the event of failover. This type of deployment is well suited for a two-node active-passive cluster in which one node runs the applications and the second node is on standby. This deployment is not typically used in clusters with three or more nodes, however, because of hardware costs. In a cluster of *N* nodes, only 1/*N* of total processing power is used. Although availability of the single application is high, even in a two-node cluster hardware costs are higher than with other deployment options because of the cost of purchasing standby servers. Some multiple-instance applications, such as SQL Server, can be deployed as a single instance. In the case of SQL Server, when a node in the cluster running SQL Server fails, the entire SQL Server workload is transferred to another, identically configured node.

**Several single-instance applications** Each application is independent from the others, and different applications can fail over to different nodes in the cluster. For more information about defining failover targets, see "Creating Failover Policies" later in this chapter. This type of deployment provides high availability for applications, but careful capacity planning is required to ensure that each node has sufficient processing capacity, memory, and bandwidth to accommodate additional loads in the event of failover.

**One multiple-instance application** The cluster supports only one application, with pieces of the application hosted on different nodes. When there is a failover with a partitioned application, a node can host multiple partitions until failback. In SQL Server and other multiple-instance applications, it is important to make sure that each node has the capacity to take on additional partitions in the event of failover.

**Several multiple-instance applications** Each node hosts one instance of each application. In such a deployment, both capacity planning and defining failover targets become increasingly important and complex.

# Planning for Server Capacity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before deploying your application on a high-availability server cluster, you need to answer some key business questions:

- How many servers are available for your cluster and what is the capacity of each server?
- In the case of a failover, what kind of performance is acceptable until failback returns the cluster to full processing capacity?
- Given that it is possible for more than one node in a cluster to fail, how many failures do you want your cluster to be able to withstand before the application becomes unavailable?

The workload of a server both before and after failover is closely tied to your server resource planning. The way your application adapts to the server cluster depends on how much of the server resources it consumes. The consumption of server resources affects the number of servers you need to ensure high availability for the application, in addition to how many servers are required to pick up the workload for a given node in the event of a failover.

Consider a simple example: a two-node cluster, with Node A and Node B. If Node A fails over, Node B has to continue processing its own jobs in addition to processing the jobs that fail over from Node A. This means that prior to failover, both nodes can operate at a maximum of 50 percent capacity. After failover, Node B operates at 100 percent capacity. When any server operates at maximum capacity, performance is compromised. However, even reduced performance is preferable to completely losing Node A's workload, which is what would happen in a nonclustered environment. In this example, an organization would have to determine if this level of availability is sufficient for its needs, or if an expenditure on more hardware is warranted.

If you add a third node to the above example and all three nodes operate at 50 percent, the two remaining nodes can divide the workload of a failed node. If Node A fails over, Node B and Node C assume Node A's work and operate at 75 percent capacity, which provides better application performance than a single server operating at 100 percent capacity. However, if two nodes in this cluster were to fail over, the remaining node would not have sufficient capacity to assume the processing for the entire cluster.

Windows Server 2003 supports up to eight nodes in a cluster. With additional nodes, you have more options for distributing the workload in a cluster.

**Cluster Server Capacity Examples**

The following illustrations of a simple four-node cluster demonstrate how server load can be balanced across nodes. These examples also demonstrate the relationship between hardware resources, fault tolerance, and availability.

**Important**

- The examples in this section are theoretical and intended for discussion purposes only. Be aware that in an actual server cluster deployment, applications cannot always be distributed as evenly as they are in the following examples.

In Figure 7.7, all four nodes are operational, each running at 25 percent capacity.

**Figure 7.7 Cluster Under Normal Operating Conditions**

Figure 7.8 shows the cluster after one of the nodes fails. The remaining three nodes each receive a share of the failed node's work.

**Figure 7.8 Cluster After a Single Node Failure**

After two nodes fail, shown in Figure 7.9, the remaining two nodes are each operating at approximately 50 percent capacity.

**Figure 7.9 Cluster After Two Failures**

Finally, when three nodes fail, as shown in Figure 7.10, the remaining node has enough capacity to take over the clusters' entire workload (though application performance might be degraded somewhat with the server operating at 100 percent capacity).

**Figure 7.10 Cluster After Three Failures**

**Deployment Considerations**

When determining the appropriate size of your server cluster (the number of nodes and their capacity) and the failover policies for one or more applications, consider the following points:

- The cluster configuration in Figure 7.7 through Figure 7.10 is able to tolerate three failures with no loss of availability for clients and users. The cost of this availability is the price of four servers of sufficient capacity. For example, if the above nodes were running at 50 percent or 75 percent capacity, the same amount of work could be done with fewer nodes (or the same number of nodes could do more work). However, the cluster would then be unable to accommodate three failures; the remaining nodes would already be at full capacity by the time the third node failed. If you don't need to anticipate three failures, you could use fewer nodes running at a higher capacity than 25 percent.

- In Windows Server 2003, Cluster Administrator allows you to designate applications to fail over to specific nodes. If your application cannot afford to lose any performance when it fails over to another node, configure failover distribution so that the application fails over to a node with plenty of room (running at low capacity). Again, this requires a hardware investment in order to have a server standing by for the purpose of failover.

- If some decline in performance is acceptable for your application, specifically during the time it takes to get the failed node restarted, you can fail over the application to a node that is operating at a higher capacity. This means you can use fewer nodes, but the chances are higher that performance on the new node will decrease after failover.

- If some applications are a higher priority than others to your organization, you can use Cluster Administrator to fail over the high-priority applications before the others. This is useful in deployments where multiple failures cannot be tolerated due to capacity limitations. In this case, if both a high-priority application and a lower-priority application fail over and need to find room elsewhere in the cluster, the high-priority application always takes precedence.

- In planning server capacity (and in all other aspects of cluster deployment planning), it is important that you consider scalability and future demands on your cluster. It is very likely that over time your applications will grow, or you will need to deploy more applications on a cluster, or both. When calculating how many servers you will need and how much capacity each server needs to have, a general IT principal is to increase your estimates by 30 percent, and then add capacity for anticipated future growth. The extra 30 percent provides a safety buffer against calculation error or unforeseen load additions.

# Creating Failover Policies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To provide high availability, single-instance applications — and the individual partitions of multiple-instance applications — fail over from one cluster node to another. In a two-node cluster, failover involves transferring the resources of one node to the remaining node. As the number of nodes in a cluster increases, different failover policies are possible.

When you create failover policies, you must perform each of the following tasks:

1. Make key failover policy decisions.
2. Evaluate N+I failover policies.
3. Evaluate random versus customized failover control.

# Making Key Decisions in Failover Policies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You need to make the following decisions when planning and configuring your failover policies:

- How many nodes, such as standby servers, do you deploy for failover?
- What resources do you fail over to which nodes?
- Do you partition applications and services across cluster nodes, or do you distribute the load differently?
- How do you consolidate resources into resource groups? A group is the indivisible unit (a collection of resources) that fails over from one node to another.

**Note**

- A failover policy often involves targeting a specific node for a given application. Such targeting can be configured through Cluster Administrator. For more information about targeting failover nodes, see "Determining failover and move policies for groups" in Help and Support Center for Windows Server 2003.

Many of the key decisions in failover policies involve weighing the benefits of implementing the best possible solution against the cost of purchasing and maintaining hardware. For example, do your applications and services need the highest level of availability, or is your organization willing to settle for a slightly lower level of availability at a greatly reduced cost? If you decide to purchase standby servers that are dedicated to receiving specific applications in the event of failover, be sure your budget can accommodate the additional cost.

# Evaluating N+I Failover Policies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The most common modeling used for failover policies is *N+I,* where *N* nodes are hosting applications and *I* (idle) nodes are standing by as spares. The simplest method for providing failover is to match each node with its own idle failover node: in a three-node cluster that would be 3+3. This design achieves the highest level of availability, but requires an investment in hardware that remains idle much of the time.

A failure on a cluster might result in an impact on users that can range from slow performance to application unavailability. When deploying an N+I solution, extensive testing must be done to ensure that, in the case of a massive failure, one node can run all applications and services with little or no user impact.

N+I configurations are scalable and good for handling multiple failures. An example of an N+I configuration is shown in Figure 7.11.

**Figure 7.11 N+I Configuration**

The configuration shown in Figure 7.11 is a good configuration if your application must continue running without any decrease in performance after failover. This configuration guarantees that the application will fail over to a node with 100 percent available resources and not to a node already in use by another application or another partition (assuming there has not already been another failover in the same server cluster).

Exchange 2000 Server is a good example of an application suited for an N+I server cluster deployment. In a four-node cluster, Microsoft recommends three active nodes and one node on standby (3+1). Because Exchange can have large memory and processing requirements, it is better to have a resource group in an Exchange cluster fail over to a node with 100 percent available resources. The potential drawback is that only one node failure is supported in this scenario.

**Standby Server**

A variation of N+I, a standby server configuration has idle nodes prepared to take on the work of one or more active nodes. Standby servers are effective for maintaining a consistent performance level for your users even after failover. A three-node version of a standby server configuration is illustrated in Figure 7.12.

**Figure 7.12 Standby Server Configuration**

Standby servers are good for larger applications that require a lot of resources such as processing power, memory, and input/output (I/O) bandwidth. In the event of a failure on one node, all applications are still hosted on separate servers. In Figure 7.12, for example, App1 and App2 are large applications. Combining them on the same node might require more processing or capacity than a single node could provide. With a standby server configuration, if Node A were to fail, App1 would move to Node B and the applications would remain on separate nodes. It is easy to plan server capacity for this failover policy; the size of each node is based on the application that it will be running, and the capacity of the spare server is sized to the maximum of the other nodes.

The drawback of this failover policy is that there is a single point of failure. In Figure 7.12, for example, if Node A failed, and App1 moved to Node B, no failover could take place if Node B were to also fail. This type of configuration also does not support multiple failures well. For example, if both Node A and Node C were to fail, Node B would not have sufficient resources to run both applications. This example shows a three-node cluster, however. In larger clusters (up to eight nodes) you can configure a variety of standby combinations to eliminate a single point of failure.

**Failover Pairs**

Failover pairs are another common N+I variation. Failover pairs are often used in clusters with four or more nodes, and they are ideal for ensuring performance consistency after failover. Failover policies can be defined so that each application can fail over between two nodes, such as in the four-node cluster illustrated in Figure 7.13. Here, Node A is paired with Node B, and Node C is paired with Node D.

**Figure 7.13 Failover Pair Server Configuration**

Failover pairs are also good for larger, resource-intensive applications such as databases. For capacity planning, you must ensure that each node in the pair can accommodate the application in question. Compared to a standby server policy, failover pairs have the added benefit of being part of a larger cluster. If the failover node needs to be brought down for maintenance, for example, a different failover node for the application can be assigned dynamically.

The disadvantage of failover pairs is that in simpler configurations, such as the one illustrated in Figure 7.13, only 50 percent of the cluster resources are ever in use. Also, depending on the number of nodes and the specific failover policies configured on the nodes, multiple failures in this kind of cluster might require administrators to manually failback resources when nodes are restored.

# Evaluating Random vs. Customized Failover Control

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Depending on the size and complexity of your server cluster, and the resources at your disposal, you might want to enact precise control over failover policies. Alternatively, you can let Windows Server 2003 determine the failover location for an application randomly.

**Random Failover Policies**
In clusters that run several small application instances, where the capacity of any node is large enough to support several instances at a time, random failover policies work well. Random failover policies are not recommended for large clusters (four or more nodes) because, given the great number of combinations of nodes, resources, and failures, there is no way to prevent some nodes from becoming overloaded while other nodes are underused.

When a resource group has an empty preferred owners list, and the node hosting that group fails, Windows clustering randomizes the failover target for the group. Assuming there are sufficient resources and application instances in a cluster, random failover in a small cluster can actually load balance applications across cluster nodes. Random failover is also well able to handle multiple failures.

The disadvantage of random failover policies is that you might find it difficult to plan capacity because statistically there is no guarantee that applications will be equally divided across nodes. Similarly, the effect on the performance of an application after failover is also difficult to predict. Random failover policies are not recommended in clusters with large, resource-intensive applications.

**Customized Failover Policies**
Targeting specific applications to specific nodes gives the administrator full control over what happens when a failure occurs. It also makes capacity planning easy, because you know which application is going to run on which server.

*Group affinity* is an attribute of a dependency between groups that determines the groups' relative location in the server cluster. For resources and resource groups that have no requirements for specific hardware or configurations, it might not matter where the resource groups are hosted on the cluster. There are circumstances, however, where the location of one group can affect the location of other groups. Groups can be set up to have strong or weak *affinity*. With strong affinity, they will be placed together on the same node, if possible. They can also be set up to have strong or weak *anti-affinity*. With strong anti-affinity, groups will be kept apart if at all possible. Exchange virtual servers are an example of groups that use anti-affinity, because running more than one instance of Exchange on the same node is not recommended.

If you have multiple applications, defining good policies for each can be difficult. In the event of multiple failures, it is difficult to account for all the possible combinations of application and server failures. For more information about configuring group affinity, see article Q296799, "How to Configure Windows Clustering Groups for Hot Spare Support." To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Designing the Support Structure for Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A server cluster depends on network connectivity for communication with clients and end users, and for intra-cluster configuration information between nodes. The other fundamental requirement for a server cluster is storage ¯ the storage of application information that is shared and failed over between nodes, and the storage of cluster configuration data. Note that your storage design, in addition to providing sufficient storage capacity, must be able to deliver information to the cluster in a timely and efficient manner.

Before you design the support structure for your server clusters, assemble the information that you collected during the steps outlined earlier in this chapter, including:

- Usage statistics, such as the number of users and clients who will be using applications running on your clusters.
- The number of clusters you plan to run on your network, and the number of nodes in each cluster.
- The amount of storage your applications need.
- The scalability needs in your organization, particularly projections for anticipated growth in storage needs and network traffic in the near future.

Figure 7.14 shows the high-level process for analyzing your network and infrastructure needs.

**Figure 7.14 Designing the Support Structure for Server Clusters**

**Important**

- All storage and networking solutions for a server cluster must be supported by Microsoft. For more information about qualified storage and networking solutions, see the Windows Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Choosing a Cluster Storage Method

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Currently, the most common storage I/O technologies used with Windows Server 2003 clusters are Parallel SCSI and Fibre Channel.

Beginning with the Windows Server 2003 release, SCSI interconnects are supported only on two-node clusters running the 32-bit version of Windows Server 2003, Enterprise Edition. SCSI is not supported on Windows Server 2003, Datacenter Edition, or any 64-bit version of the Windows Server 2003 family.

SCSI storage and two types of Fibre Channel — arbitrated loops and switched network — are currently qualified storage configurations in the Windows Catalog. Both SCSI and Fibre Channel are discussed later in this section.

**Note**

- This section provides an overview of storage technology and implementation recommendations. The information here is intended to provide deployment guidelines and help administrators make informed deployment decisions. For procedural information about installing or configuring storage in your server cluster, see "Storage configuration options" in Help and Support Center for Windows Server 2003.

In addition to configuring adequate storage for applications, you also need a dedicated disk to use as the quorum device. This disk must have a minimum capacity of 50 megabytes (MB). For optimal NTFS file system performance, it is recommended that the quorum disk have at least 500 MB. For more information about the quorum device, see "Choosing the Cluster Model" later in this chapter. It is recommended that you do not use the quorum disk for storing applications or anything other than quorum data.

# Using RAID in Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

It is strongly recommended that you use a RAID solution for all disks running the Windows Server 2003 operating system. A RAID configuration prevents disk failure from being a single point of failure in your server cluster.

It is possible to use hardware-based RAID with Windows Server 2003. By using a controller provided by the hardware vendor or RAID solution provider, you can configure physical disks into fault-tolerant sets or volumes. The sets can be made visible to clusters either as whole disks or as smaller partitions.

Cluster nodes are unaware of the physical implementation of disks and treat each volume as a physical disk. For an ideal configuration, it is recommended that you associate the logical volume size as closely as possible with the actual physical disk size. This practice avoids taxing the physical disk with too many I/O operations from multiple logical volumes.

If your RAID controller supports dynamic logical unit (LUN) expansion, cluster disks can be extended without rebooting, providing excellent scalability for your organization's needs. The command-line tool DiskPart.exe lets administrators apply the physical extension of the disks to the logical partitions with no disruption of service. For more information about DiskPart.exe, in Help and Support Center for Windows Server 2003, click **Tools**, and then click Command-line reference A-Z.

# Using Storage Interconnects with Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Make sure that all interconnects used on a server cluster are supported by Microsoft by checking the Windows Catalog. This also applies to any software that is used to provide fault tolerance or load balancing for adapters or interconnects. For more information about qualified interconnects and software, see the Windows Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

Consider establishing redundant access routes to stored data. Providing multiple paths to your storage is another way to provide high availability. With versions of Windows operating systems earlier than Windows Server 2003, vendors and storage providers implemented two or more storage fabrics that were configured for load balancing and fault tolerance. The specific solution was designed by the vendor and required specially designed configurations and drivers. With the release of Windows Server 2003, Microsoft developed and supplied vendors with a multipath driver, which they can use in place of customized drivers.

# Using SCSI Storage with Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

SCSI is supported only on two-node clusters running the 32-bit version of Windows Server 2003, Enterprise Edition. Server clusters using SCSI are not supported on the 64-bit version of Windows Server 2003. General guidelines for deploying SCSI in your server cluster are listed below:

- All devices on the SCSI bus, including disks, must have unique SCSI IDs (for example, by default, most SCSI adapters have an ID of 7).
- SCSI hubs are not supported in server clusters.
- The SCSI bus must be terminated. Use physical terminating devices, and do not use controller-based or device-based termination.

# Using Fibre Channel Storage with Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

There are two supported methods of Fibre Channel-based storage in a Windows Server 2003 server cluster: arbitrated loops and switched fabric.

**Important**

- When evaluating both types of Fibre Channel implementation, read the vendor's documentation and be sure you understand the specific features and restrictions of each.

Although the term *Fibre Channel* implies the use of fiber-optic technology, copper coaxial cable is also allowed for interconnects.

**Arbitrated Loops (FC-AL)**

A Fibre Channel arbitrated loop (FC-AL) is a set of nodes and devices connected into a single loop. FC-AL provides a cost-effective way to connect up to 126 devices into a single network. As with SCSI, a maximum of two nodes is supported in an FC-AL server cluster configured with a hub. An FC-AL is illustrated in Figure 7.15.

**Figure 7.15 FC-AL Connection**

FC-ALs provide a solution for two nodes and a small number of devices in relatively static configurations. All devices on the loop share the media, and any packet traveling from one device to another must pass through all intermediate devices.

If your high-availability needs can be met with a two-node server cluster, an FC-AL deployment has several advantages:

- The cost is relatively low.
- Loops can be expanded to add storage (although nodes cannot be added).
- Loops are easy for Fibre Channel vendors to develop.

The disadvantage is that loops can be difficult to deploy in an organization. Because every device on the loop shares the media, overall bandwidth in the cluster is lowered. Some organizations might also be unduly restricted by the 126-device limit.

**Switched Fabric (FC-SW)**

For any cluster larger than two nodes, a switched Fibre Channel fabric (FC-SW) is the only supported storage technology. In an FC-SW, devices are connected in a many-to-many topology using Fibre Channel switches (illustrated in Figure 7.16).

**Figure 7.16 FC-SW Connection**

When a node or device communicates with another node or device in an FC-SW, the source and target set up a point-to-point connection (similar to a virtual circuit) and communicate directly with each other. The fabric itself routes data from the source to the target. In an FC-SW, the media are not shared, any device can communicate with any other device, and communication occurs at full bus speed. This is a fully scalable enterprise solution and, as such, is highly recommended for deployment with server clusters.

FC-SW is the primary technology employed in SANs. Other advantages of FC-SW include ease of deployment, the ability to support millions of devices, and switches that provide fault isolation and rerouting. Also, there are no shared media as there are in FC-AL, allowing for faster communication. However, be aware that FC-SWs can be difficult for vendors to develop, and the switches can be expensive. Vendors also have to account for interoperability issues between components from different vendors or manufacturers.

# Using SANs with Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For any large-scale cluster deployment, it is recommended that you use a SAN for data storage. Smaller SCSI and stand-alone Fibre Channel storage devices work with server clusters, but SANs provide superior fault tolerance.

A SAN is a set of interconnected devices (such as disks and tapes) and servers that are connected to a common communication and data transfer infrastructure (FC-SW, in the case of Windows Server 2003 clusters). A SAN allows multiple server access to a pool of storage in which any server can potentially access any storage unit.

The information in this section provides an overview of using SAN technology with your Windows Server 2003 clusters. For more information about deploying server clusters on SANs, see the Windows Clustering: Storage Area Networks link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Note**

- Vendors that provide SAN fabric components and software management tools have a wide range of tools for setting up, configuring, monitoring, and managing the SAN fabric. Contact your SAN vendor for details about your particular SAN solution.

The following sections provide an overview of SAN concepts that directly affect a server cluster deployment.

**HBAs**

Host bus adapters (HBAs) are the interface cards that connect a cluster node to a SAN, similar to the way that a network adapter connects a server to a typical Ethernet network. HBAs, however, are more difficult to configure than network adapters (unless the HBAs are preconfigured by the SAN vendor).

**Zoning and LUN Masking**

Zoning and LUN masking are fundamental to SAN deployments, particularly as they relate to a Windows Server 2003 cluster deployment. Both methods provide isolation and protection of server cluster data within a SAN, and in most deployments one or the other is sufficient. Work with your hardware vendor to determine whether zoning or LUN masking is more appropriate for your organization.

**Zoning**

Many devices and nodes can be attached to a SAN. With data stored in a single *cloud*, or storage entity, it is important to control which hosts have access to specific devices. Zoning allows administrators to partition devices in logical volumes and thereby reserve the devices in a volume for a server cluster. That means that all interactions between cluster nodes and devices in the logical storage volumes are isolated within the boundaries of the zone; other noncluster members of the SAN are not affected by cluster activity.

Figure 7.17 is a logical depiction of two SAN zones (Zone A and Zone B), each containing a storage controller (S1and S2, respectively).

**Figure 7.17 Zoning**

In this implementation, Node A and Node B can access data from the storage controller S1, but Node C cannot. Node C can access data from storage controller S2.

Zoning needs to be implemented at the hardware level (with the controller or switch) and not through software. The primary reason is that zoning is also a security mechanism for a SAN-based cluster, because unauthorized servers cannot access devices inside the zone (access control is implemented by the switches in the fabric, so a host adapter cannot gain access to a device for which it has not been configured). With software zoning, the cluster would be left unsecured if the software component failed.

In addition to providing cluster security, zoning also limits the traffic flow within a given SAN environment. Traffic between ports is routed only to segments of the fabric that are in the same zone.

**LUN masking**

A LUN is a logical disk defined within a SAN. Server clusters see LUNs and think they are physical disks. LUN masking, performed at the controller level, allows you to define relationships between LUNs and cluster nodes. Storage controllers usually provide the means for creating LUN-level access controls that allow access to a given LUN to one or more hosts. By providing this access control at the storage controller, the controller itself can enforce access policies to the devices.

LUN masking provides a more detailed level of security than zoning, because LUNs provide a means for zoning at the port level. For example, many SAN switches allow overlapping zones, which enables a storage controller to reside in multiple zones. Multiple clusters in multiple zones can share the data on those controllers. Figure 7.18 illustrates such a scenario.

**Figure 7.18 Storage Controller in Multiple Zones**

LUNs used by Cluster A can be masked, or hidden, from Cluster B so that only authorized users can access data on a shared storage controller.

**Requirements for Deploying SANs with Windows Server 2003 Clusters**

The following list highlights the deployment requirements to meet when using a SAN storage solution with your server cluster. For a white paper to provide more complete information about using SANs with server clusters, see the Windows Clustering: Storage Area Networks link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

### Note

- A utility that might be helpful in deploying SANs with server clusters is Mountvol.exe. Mountvol.exe is included with the Windows Server 2003 operating system, and provides a means of creating volume mount points and linking volumes without requiring a drive letter. For more information about Mountvol.exe, see "Mountvol" in Help and Support Center for Windows Server 2003.

  - Each cluster on a SAN must be deployed in its own zone. The mechanism the cluster uses to protect access to the disks can have an adverse effect on other clusters that are in the same zone. By using zoning to separate the cluster traffic from other cluster or noncluster traffic, there is no chance of interference.

  - All HBAs in a single cluster must be the same type and have the same firmware version. Many storage and switch vendors require that all HBAs in the same zone — and, in some cases, the same fabric — share these characteristics.

  - All storage device drivers and HBA device drivers in a cluster must have the same software version.

  - Never allow multiple nodes access to the same storage devices unless they are in the same cluster.

**Caution**

If multiple nodes in different clusters can access a given disk, data corruption will result.

- Never put tape devices into the same zone as cluster disk storage devices. A tape device could misinterpret a bus rest and rewind at inappropriate times, such as during a large backup.

**Guidelines for Deploying SANs with Windows Server 2003 Clusters**

In addition to the SAN requirements discussed in the previous section, the following practices are highly recommended for server cluster deployment:

- In a highly available storage fabric, you need to deploy clustered servers with multiple HBAs. In these cases, always load the multipath driver software. If the I/O subsystem sees two HBAs, it assumes they are different buses and enumerates all the devices as though they were different devices on each bus. The host, meanwhile, is seeing multiple paths to the same disks. Failure to load the multipath driver will disable the second device, because the operating system sees what it thinks are two independent disks with the same signature.

- Hardware snapshots can go either to a server outside the server cluster or to a backup *clone* disk. When the original disk fails, you can replace it in the server cluster with its clone. When using cloned disks, it is very important that only one disk with a given disk signature be exposed to the server cluster at one time. Many controllers provide snapshots at the controller level that can be exposed to the cluster as a completely separate LUN. Cluster performance is degraded when multiple devices have the same signature. If a hardware snapshot is exposed back to the node with the original disk online, the I/O subsystem attempts to rewrite the signature. However, if the snapshot is exposed to another node in the cluster, the Cluster service does not recognize it as a different disk and the result could be data corruption. Although this is not specifically a SAN issue, the controllers that provide this functionality are typically deployed in a SAN environment.

  **Caution**

  - Exposing a hardware snapshot to a node on the cluster might result in data corruption.

# Choosing the Cluster Model

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The term *cluster model* refers to the manner in which the quorum resource is used in the server cluster. Server clusters require a quorum resource, which contains all of the configuration data necessary for recovery of the cluster. The cluster database, which resides in the Windows Server 2003 registry on each cluster node, contains information about all physical and logical elements in a cluster, including cluster objects, their properties, and configuration data. When a cluster node fails and then comes back online, the other nodes update the failed node's copy of the cluster database. It is the quorum resource that allows the Cluster service to keep every active node's database up to date.

The quorum resource, like any other resource, can be owned by only one node at a time. A node can form a cluster only if it can gain control of the quorum resource. Similarly, a node can join a cluster (or remain in an existing cluster) only if it can communicate with the node that controls the quorum resource.

Servers negotiate for ownership of the quorum resource in order to avoid split-brain scenarios, which occur when nodes lose communication with one another and multiple partitions of the cluster converge with a well-defined set of members, each partition believing that it is the one and only instance of the cluster. In such a case, each partition would continue operating in the belief that it had control of any cluster-wide shared resources or state, ultimately leading to data corruption.

The concept of a quorum ensures that only one partition of a cluster survives a split-brain scenario. When the cluster is partitioned, the quorum resource is used as an arbiter. The partition that owns the quorum resource is allowed to continue. The other partitions of the cluster are said to have *lost quorum*, and Cluster service — along with any resources hosted on the nodes that are not part of the partition that has quorum — is terminated.

The Cluster service stores cluster configuration data in a quorum log file. This file is usually located on a shared disk that all nodes in the cluster can access, and it acts as the definitive version of the cluster configuration. It holds cluster configuration information such as which servers are part of the cluster, what resources are installed in the cluster, and the state of those resources (for example, online or offline). Because the purpose of a cluster is to have multiple physical servers acting as a single virtual server, it is critical that each of the physical servers has a consistent view of how the cluster is configured.

A quorum resource can be any resource that:

- Provides a means for arbitration leading to membership and cluster state decisions.
- Provides physical storage to store configuration information.
- Uses NTFS.

The quorum resource you choose is dictated by the server cluster model you deploy (number of servers, number of sites, and so on). Do not build your server cluster around a particular type of quorum resource; instead, design the cluster that best supports your applications, and then choose one of the cluster models described in the following sections.

Three types of cluster models are available for deployment with server clusters:

- Local quorum
- Single quorum device
- Majority node set

For more information about the cluster database and the quorum resource, see "Quorum resource" in Help and Support Center for Windows Server 2003.

**Local Quorum Cluster**

This cluster model is for clusters that consist of only one node. This model is also referred to as a local quorum. It is typically used for:

- Deploying dynamic file shares on a single cluster node, to ease home directory deployment and administration.

- Testing.
- Development.

**Single Quorum Device Cluster**
The most widely used cluster model is the single quorum device cluster (also referred to as the standard quorum model), which is illustrated in Figure 7.19. The definitive copy of the cluster configuration data is on a single cluster storage device connected to all nodes.

**Figure 7.19 Single Quorum Device Cluster**

**Majority Node Set Cluster**
With Windows Server 2003, Microsoft introduces the majority node set cluster. The majority node set quorum model is intended for sophisticated, end-to-end clustering solutions. Each node maintains its own copy of the cluster configuration data. The quorum resource ensures that the cluster configuration data is kept consistent across the nodes. For this reason, majority node set quorums are typically found in geographically dispersed clusters. Another advantage of majority node set quorums is that a quorum disk can be taken offline for maintenance and the cluster will continue to operate.

The major difference between majority node set clusters and single quorum device clusters is that single quorum device clusters can survive with just one node, but majority node set clusters need to have a majority of the cluster nodes survive a failure for the server cluster to continue operating. A majority node set cluster is illustrated in Figure 7.20.

**Figure 7.20 Majority Node Set Cluster**

A majority node set cluster is a good solution for controlled, targeted scenarios as part of a cluster solution offered by an independent software vendor (ISV) or independent hardware vendor (IHV). By abstracting storage from the Cluster service, majority node set clusters provide ISVs with much greater flexibility for designing sophisticated cluster scenarios.

There are strict requirements to adhere to when you deploy majority node set clusters. The deployment of majority node set clusters is appropriate in some specialized configurations that need tightly consistent cluster features and do not have shared disks, for example:

- Clusters that host applications that can fail over, but that use other, application-specific methods to keep data consistent between nodes. Database log shipping and file replication for relatively static data are examples of this kind of application.
- Clusters that host applications that have no persistent data, but that need to cooperate in a tightly coupled manner to provide consistent volatile state.
- Multisite clusters, which span more than one physical site.

For more information about majority node sets and geographically dispersed clusters, see "Protecting Data from Failure or Disaster" later in this chapter.

# Designing the Cluster Network

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A network performs one of the following roles in a cluster:

- A private network carries internal cluster communication.
- A public network provides client systems with access to cluster application services.
- A mixed network (public and private) carries internal cluster communication and connects client systems to cluster application services.

Figure 7.21 shows a typical four-node server cluster deployment with a public (intranet) and private network.

**Figure 7.21 Four-Node Cluster Service Cluster with Private and Public Networks**

A network might have no role in a cluster; this is also known as disabling a network for cluster use. In the case of single quorum device clusters, the Cluster service will not use the network for internal traffic, nor will it bring IP Address resources online. Other cluster-related traffic, such as traffic to and from a domain controller for authentication, might or might not use this network.

Use these guidelines for designing the network segments of the server clusters:

- You can provide fault tolerance in your network by grouping network adapters on multiple ports to a single physical segment. This practice is known as *teaming network adapters* and is described in "Eliminating Single Points of Failure in Your Network Design" later in this chapter.
- You can use any network adapter that complies with Network Driver Interface Specification (NDIS).
- Use only network adapters that comply with specifications for the Peripheral Component Interconnect (PCI) local bus. Do not use network adapters compatible with an Industrial Standard Architecture (ISA) or Extended Industrial Standard Architecture (EISA) bus.
- For each server cluster network, use only identical network adapters on all nodes (that is, the same make, model, and firmware version). This is not a requirement, but it is strongly recommended. Consider the loads on each type of adapter and plan accordingly; for example, the private network adapters can require 10 MB to 100 MB of throughput, although the public network adapters can require 1 gigabyte (GB) of throughput.

# Eliminating Single Points of Failure in Your Network Design

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You must incorporate failsafe measures within the cluster network design. To achieve this end, adhere to the following rules:

- Configure at least two of the cluster networks for internal cluster communication to eliminate a single point of failure. A server cluster whose nodes are connected by only one network is not supported.
- Design each cluster network so that it fails independently of other cluster networks. This requirement implies that the components that make up any two networks must be physically independent. For example, the use of a multiport network adapter to attach a node to two cluster networks does not meet this requirement if the ports share circuitry.
- If using multihoming nodes, make sure the adapters reside on separate subnets.
- Do not connect multiple adapters on one node to the same network; doing so does not provide fault tolerance or load balancing.

  **Note**

  - If a cluster node has multiple adapters attached to one network, the Cluster service will recognize only one network adapter per node per subnet.

The best way to guard against network failure in your server cluster is by teaming network adapters. By grouping network adapters on multiple ports to a single physical segment, you can provide fault tolerance to your cluster network. If a port fails — whether the failure occurs on the adapter, cable, switch port, or switch — another port takes over automatically. To the operating system and other devices on the network, this failover is transparent.

An important consideration, however, is that networks dedicated to internal server cluster communication cannot be teamed. Teaming network adapters is supported only on networks that are not dedicated to internal cluster traffic. Teaming network adapters on all cluster networks concurrently is not supported. There are alternative methods for achieving redundancy on networks that are dedicated to internal cluster traffic. These alternatives include adding a second private network, which avoids the cost of adding network adapters (however, this second network must be for intra-cluster network traffic only).

Teaming network adapters on other cluster networks is acceptable; however, if communication problems occur on a teamed network, it is recommended that you disable teaming.

# Determining Domain Controller Access for Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For Windows Server 2003 clusters to function properly, any node that forms part of the cluster must validate the Cluster service account in the local domain. To do this, each node must be able to establish a secure channel with a domain controller. If a domain controller cannot validate the account, the Cluster service does not start. This is also true for other clustered applications that need account validation, such as SQL Server and Microsoft® Exchange 2000. There are three ways to provide the necessary access, presented here in order of preference:

- Configure cluster nodes as member servers within a Windows domain and give them fast, reliable connectivity to a local domain controller.
- If the connectivity between cluster nodes and domain controllers is slow or unreliable, locate a domain controller within the cluster.
- Configure the cluster nodes as domain controllers, so that the Cluster service account can always be validated.

The security rights applicable to a domain controller administrator are often inappropriate or nonfunctional for a cluster administrator. A domain controller administrator can apply global policy settings to a domain controller that might conflict with the cluster role. Domain controller administrative roles span the network; this model generally does not suit the security model for clusters.

It is strongly recommended that you do not configure the cluster nodes as domain controllers, if at all possible. But if you must configure the cluster nodes as domain controllers, follow these guidelines:

- If one node in a two-node cluster is a domain controller, both nodes must be domain controllers. If you have more than two nodes, you must configure at least two nodes as domain controllers. This gives you failover assurance for the domain controller services.
- A domain controller that is idle can use between 130 MB and 140 MB of Random Access Memory (RAM), which includes running the Cluster service. If these domain controllers have to replicate with other domain controllers within the domain and across domains, replication traffic can saturate bandwidth and degrade overall performance.
- If the cluster nodes are the only domain controllers, they must be Domain Name System (DNS) servers as well. You must address the problem of not registering the private interface in DNS, especially if the interface is connected by a crossover cable (two-node cluster only). The DNS servers must support dynamic updates. You must configure each domain controller and cluster node with a primary — and at least one secondary — DNS server. Each DNS server needs to point to itself for primary DNS resolution and to the other DNS servers for secondary resolution.
- If the cluster nodes are the only domain controllers, they must also be global catalog servers.
- The first domain controller in the forest takes on all single-master operation roles. You can redistribute these roles to each node; however, if a node fails over, the single-master operation roles that the node has taken on are no longer available.
- If a domain controller is so busy that the Cluster service is unable to gain access to the quorum as needed, the Cluster service might interpret this as a resource failure and cause the resource group to fail over to the other node.
- Clustering other applications, such as SQL Server or Exchange 2000, in a scenario where the nodes are also domain controllers can result in poor performance and low availability due to resource constraints. Be sure to test this configuration thoroughly in a lab environment before you deploy it.
- You must promote a cluster node to a domain controller by using the Active Directory Installation Wizard before you create a cluster on that node or add it to an existing cluster.

- Practice extreme caution when demoting a domain controller that is also a cluster node. When a node is demoted from a domain controller, security settings are changed. For example, certain domain accounts and groups revert back to the default built-in accounts and groups originally on the sever. This means the security ID (SID) of the Domain Admins group changes to that of the local Administrators group. As a result, the Administrators entry in the security descriptor for the Cluster service is no longer valid because its SID still matches the Domain Admins group, and not the SID for the local Administrators group.

# Protecting Data from Failure or Disaster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You must take steps to protect and ensure the integrity of your data. If your organization spans more than one physical site, for example, you might want to cluster resources across sites in what is known as a geographically dispersed cluster. Geographically dispersed clusters maintain high availability even when communication with another site is disrupted or lost. And all server clusters, whether in a single site or spread across two sites, need a plan for backing up application data regularly, and for recovering data in the event of a failure or disaster.

Figure 7.22 displays the process for ensuring the data integrity for your server cluster.

**Figure 7.22 Protecting Data from Failure or Disaster**

# Designing a Geographically Dispersed Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Geographically dispersed server clusters ensure that a complete outage at one site does not cause a loss of access to the application being hosted. All nodes hosting an application must exist within the same cluster. Therefore, to provide fault tolerance, a single cluster spans multiple sites.

**Important**

- Windows Server 2003 supports two-site geographically dispersed clusters. However, Microsoft does not provide a software mechanism for replicating application data from one site to another. Instead, Microsoft works with hardware and software vendors to provide a complete solution. For more information about qualified clustering solutions, see the Windows Server Catalog link or the Geographically Dispersed Clusters link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

A geographically dispersed cluster requires multiple storage arrays, at least one in each site, to ensure that in the event of failure at one site, the remaining site will have local copies of the data. In addition, the nodes of a geographic cluster are connected to storage in such a way that when there is a failure at one site or a failure in communication between sites, the functioning nodes can still connect to storage at their own site. For example, in the simple two-site cluster configuration shown in Figure 7.23, the nodes in Site A are directly connected to the storage in Site A, so they can access data with no dependencies on Site B.

**Figure 7.23 Geographically Dispersed Cluster**

In Figure 7.23, Nodes A and B are connected to one array in Storage Controller A, while Node C and Node D are connected to another array in Storage Controller B. These storage arrays present a single view of the disks spanning both arrays. In other words, Disks A and B are combined into a single logical device (by using mirroring, either at the controller level or the host level). Logically, the arrays appear to be a single device that can fail over between Nodes A, B, C, and D.

**Note**

- For a job aid to assist you in gathering your requirements for a multisite server cluster and organizing the necessary, preparatory information, see "Planning Checklist for Geographically Dispersed Clusters" (Sdcclu_1.doc) on the Microsoft® *Windows® Server 2003 Deployment Kit* companion CD (or see "Planning Checklist for Geographically Dispersed Clusters" on the Web at http://www.microsoft.com/reskit).

# Design Requirements for Geographically Dispersed Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Although there are many requirements in setting up a geographically dispersed cluster, at the most fundamental level your design has to meet two requirements:

- Both sites must have independent copies of the same data. The goal of a geographically dispersed cluster is that if one site is lost, such as from a natural disaster, the applications can continue running at the other site. For read-only data, the challenge is relatively simple: the data can be cloned, and one instance can run at each site. However, in a typical stateful application, in which data is updated frequently, you must consider how changes made to the data at one site are replicated to the other site.

- When there is a failure at one site, the application must restart at the other site. Even if the application data is replicated to all sites, you need to know how the application is restarted at an alternate site when the site that was running the application fails.

**Important**

- The hardware and software configuration of a geographically dispersed cluster must be certified and listed in the Windows Server Catalog. Also, be sure to involve your hardware manufacturer in your design decisions. Frequently, third-party software and drivers are required for geographically dispersed clusters to function correctly. Microsoft Product Support Services might not be aware of how these components interact with Windows Clustering. For more information about hardware and software configurations, see the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Network Requirements for Geographically Dispersed Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following network requirements pertain to all server clusters, but are particularly important with regard to geographically dispersed clusters:

- All nodes must be on the same subnet. The nodes in the cluster can be on different physical networks, but the private and public network connections between cluster nodes must appear as a single, nonrouted Local Area Network (LAN). You can do this by creating virtual LANs (VLANs).

- Each VLAN must fail independently of all other cluster networks. The reason for this rule is the same as for regular LANs — to avoid a single point of failure.

- The roundtrip communication latency between any pair of nodes cannot exceed 500 milliseconds. If communication latency exceeds this limit, the Cluster service assumes the node has failed and will potentially fail over resources.

# Data Replication in Geographically Dispersed Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Data can be replicated between sites with different techniques, and at different levels in the clustering infrastructure. At the block level (known as *disk-device-level replication* or *disk-device-level mirroring*), replication is performed by the storage controllers or by mirroring the software. At the file-system level (replication of file system changes), the host software performs the replication. Finally, at the application level, the applications themselves can replicate data. An example of application-level replication is Microsoft SQL Server log shipping.

The method of data replication that is used depends on the requirements of the application and the business needs of the organization that owns the cluster.

**Synchronous vs. Asynchronous Replication**

When planning geographically dispersed clusters, you need to understand your data consistency needs in different failure and recovery scenarios and work with the solution vendors to meet your requirements. Different geographically dispersed cluster solutions provide different replication and redundancy strategies. Determine the support requirements of your applications with regard to replication -- in geographically dispersed server clusters, the type of data replication is just as important as the level at which it occurs. There are two types of data replication: synchronous and asynchronous.

*Synchronous replication* is when an application performs an operation on one node at one site, and then that operation is not completed until the change has been made on the other sites. Using synchronous, block-level replication as an example, if an application at Site A writes a block of data to a disk mirrored to Site B, the I/O operation will not be completed until the change has been made to both the disk on Site A and the disk on Site B. Because of this potential latency, synchronous replication can slow or otherwise detract from application performance for your users.

*Asynchronous replication* is when a change is made to the data on Site A and that change eventually makes it to Site B. In asynchronous replication, if an application at Site A writes a block of data to a disk mirrored to Site B, then the I/O operation is complete as soon as the change is made to the disk at Site A. The replication software transfers the change to Site B (in the background) and eventually makes that change to Site B. With asynchronous replication, the data at Site B can be out of date with respect to Site A at any point in time.

Different vendors implement asynchronous replication in different ways. Some preserve the order of operations and others do not. This is very important, because if a solution preserves ordering, then the disk at Site B might be out of date, but it will always represent a state that existed at Site A at some point in the past. This means Site B is *crash consistent*: the data at Site B represents the data that would exist at Site A if Site A had crashed at that point in time. Conversely, if a solution does not preserve ordering, the I/O operations might be applied at Site B in an arbitrary order. In this case, the data set at Site B might never have existed at Site A. Many applications can recover from crash-consistent states; very few can recover from out-of-order I/O operation sequences.

**Caution**

- Geographically dispersed server clusters must never use asynchronous replication unless the order of I/O operations is preserved. If this order is not preserved, the data that is replicated to the second site can appear corrupt to the application and be totally unusable.

Mirroring and replication solutions are implemented differently, depending on the vendor, the business needs of the organization, and the logistics of the cluster. In general terms, however, for every disk there is a master copy and one or more secondary copies. The master is modified, and then the changes are propagated to the secondary copies.

In the case of disk-device-level replication, the secondary disk might not be visible to the applications. If it is visible, it will be a read-only copy of the device. When there is a failover, a cluster resource typically designates one of the secondary disks to be the new primary, and the old primary becomes a secondary. In other words, most of the mirroring solutions are master-secondary, one-way mirror sets. This is usually on a per-disk basis, so some disks might have the master at one site and others might have the master at another site.

# Majority Node Set Quorum in Geographically Dispersed Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Although geographically dispersed clusters can use a standard quorum, presenting the quorum as a single logical shared drive between sites can create design issues. Majority node set clusters solve these issues by allowing the quorum to be stored on the local hard disk of each node.

Applications in a geographically dispersed cluster are typically set up to fail over in the same manner as those in a single-site cluster; however, the total failover solution is inherently more complex. The Cluster service provides health monitoring and failure detection of the applications, the nodes, and the communications links, but there are cases where it cannot differentiate between various failure modes.

Consider two identical sites, each having the same number of nodes and running the same software. If a complete failure of all communication (both network and storage fabric) occurs between the sites, neither site can continue without human intervention because neither site has sufficient information about the other site's continuity.

As discussed in "Choosing the Cluster Model" earlier in this chapter, the server cluster architecture requires that a single-quorum resource in the cluster be used as the tiebreaker to avoid split-brain scenarios. Although split-brain scenarios can happen in single-site clusters, they are much more likely to occur in geographically dispersed clusters.

If communication between two sites in a geographically dispersed server cluster were to fail, none of the cluster nodes in either site could determine which of the following is true:

- Communication between sites failed and the other site is still alive.
- The other site is dead and no longer available to run applications.

This problem is solved when one of the partitions takes control of the quorum resource. However, with majority node set clusters, the process is different than in a traditional (single-site, single-quorum) server cluster. Traditional clusters can continue as long as one of the nodes owns the quorum disk, and traditional server clusters can therefore continue even if only one node out of the configured set of nodes is running (if that node owns the quorum disk). By contrast, a server cluster running with a majority node set quorum resource will start up (or continue running) only if a majority of the nodes configured for the cluster are running, and if all nodes in that majority can communicate with each other.

When designing your server cluster with a majority node set quorum, consider this difference, because it can affect how majority node set clusters behave when the server cluster is partitioned and during split-brain scenarios. This "more than half" quorum requirement makes the number of nodes in your server cluster very important. For more information about majority node set quorum cluster models, see "Model 3: Majority node set server cluster configuration" in Help and Support Center for Windows Server 2003.

# Single Quorum in Geographically Dispersed Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

It is possible to use a single quorum disk resource in a geographically dispersed cluster, provided the quorum is replicated across sites, such as through disk mirroring. When a single quorum is used across multiple sites, the quorum data must always use synchronous replication, although application data can be replicated either synchronously or asynchronously (assuming there are no application-specific restrictions). This is because the quorum could become corrupt during asynchronous replication, rendering different quorum data on each site, and your server cluster would then fail.

# Backing Up and Restoring Cluster Data

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In order to maintain high availability on your server clusters, it is important to back up server cluster data on a regular basis. The Backup or Restore Wizard in Windows Server 2003 (Ntbackup.exe) has been enhanced to enable backups and restores of the local cluster database, in addition to the capacity to restore configurations locally and to all nodes in a cluster.

**Note**

- In addition to the Backup or Restore Wizard, Ntbackup.exe is also available as a command-line tool. For more information about Ntbackup.exe, in Help and Support Center for Windows Server 2003, click **Tools**, and then click Command-line reference A-Z.

Although there are some scenarios in which you can restore data without having a backup data set available, your options are limited. Providing true high availability to your users is possible only by backing up your data on a regular basis. For information about what you can do to restore your server cluster without a backup, see the Server Cluster (MSCS) Backup and Recovery Best Practices link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

A new backup and restore feature in Windows Server 2003 is Automated System Recovery (ASR), which helps you recover a system that will not start. ASR is a two-part recovery option consisting of ASR backup and ASR restore, both of which are accessed through the Advanced mode of the Backup or Restore Wizard. Note that ASR backs up only the partition used by the operating system. You must back up other partitions by using the standard Backup or Restore Wizard.

You can use ASR to recover a cluster node, the quorum disk, and the signatures on any lost shared disks. You can use ASR to restore a Windows Server 2003 installation when:

- A node cannot start as the result of damaged or missing Windows Server 2003 system files. ASR verifies and replaces damaged critical system files.
- There is a hardware failure, such as disk failure. ASR restores the installation to the state of your most recent ASR backup.
- The Cluster service will not start on the local node because the Cluster database is corrupt or missing.
- The disk signature has changed on one of the shared disks as a result of a disk replacement or other disk-related issue, causing a shared disk to fail to come online.

For more information about ASR, see "Automated System Recovery (ASR) overview" in Help and Support Center for Windows Server 2003.

For specific information about backing up cluster disk signatures and partition layouts, the cluster quorum, and data on cluster nodes, see "Backing up and restoring server clusters" in Help and Support Center for Windows Server 2003. Details include how to restore the cluster database on a local node, how to restore the contents of a cluster quorum disk for all nodes in a cluster, and how to repair a damaged cluster node by using ASR.

Help and Support Center for Windows Server 2003 also includes:

- The specific permissions that a cluster administrator needs in order to perform each backup and restore procedure. For example, to back up the data on cluster nodes or to restore a damaged cluster node using Automated System Recovery, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. For the specific access control permissions you need to perform each backup and restore operation, see "Backing up and restoring server clusters" in Help and Support Center for Windows Server 2003.
- Ten failover and restore scenarios that describe failure from cluster disk data loss, cluster quorum corruption, cluster disk corruption or failure, and complete cluster failure. Scenarios include symptoms that are common indications of a server cluster failure, and methods for recovering from such failures. For more information see "Backing up and restoring server clusters" in Help and Support Center for Windows Server 2003.

**Important**

- For information about backing up applications that run on your server cluster, consult the documentation for the application.

# Securing Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Security considerations must be present in all aspects of your cluster design. After your clustering infrastructure is in place, you need to consider a number of recommended policies and configurations to ensure that your server clusters are secure. Figure 7.24 shows an overview of security deployment considerations.

**Figure 7.24 Securing Your Server Clusters**

Before beginning your security design, see "Best practices for securing server clusters" in Help and Support Center for Windows Server 2003.

**Note**

- Do not weaken the default security settings for clustering objects in the operating system. This includes registry keys, files, and devices.

# Ensuring the Physical Security of Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For servers that must maintain high availability, it is recommended that you restrict physical access to a small number of essential, designated individuals. Locate server clusters and their storage in physically secure locations.

When you review your policies for keeping your computer room secure, be sure to include the following:

- Restrict access to the instruction sheets that you create, such as the directions for server recovery.
- Review your administration practices to ensure that only trusted, authorized personnel have access to restricted data, such as logs and backup and restore media.

# Ensuring a Secure Networking Infrastructure

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Standard security devices — such as firewalls, network probes, and management tools to detect irregular traffic — must be in place before you put sensitive data on server clusters (or any other servers).

**Note**

- Although you can use IP security (IPSec) with server clusters, IPSec was not designed for use in failover situations. You can, however, use IPSec if your business need for secure connectivity outweighs your need for continuous client access during failover. For more information about IPSec and clusters, see article Q306677, "IPSec Is Not Designed for Failover," in the Microsoft Knowledge Base. To find this article, click the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

In order to create a secure environment for your server clusters, begin with the following basic network precautions:

- Secure your network with firewalls and management tools that can detect irregular network traffic.
- Restrict physical access to network hardware (routers, hubs, and switches) to protect them from unauthorized individuals.
- Make sure administrative permissions are adhered to, and that logs and other resources are protected by access control lists (ACLs).
- Ensure that network services such as the Active Directory, DNS, and DHCP, and Windows Internet Name Service (WINS) are protected from compromise. Any compromise of these infrastructure services can lead to a compromise of the Cluster service itself.

# Protecting Server Clusters from Network Flooding

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Cluster service uses User Data Protocol (UDP) port 3343 for intracluster communication. This communication includes heartbeat traffic, which detects node failure, and cluster control operations. Some of this communication (such as heartbeats) is time sensitive. If there is a significant load on the ports due to network flood attacks, the result can be false node-failure detection, which can cause unnecessary failover operations, leading to application downtime. To ensure that node-failure detection cannot be compromised in this way, secure the private network or networks between cluster nodes so that only trusted nodes can send data.

# Protecting Server Clusters from Unauthorized Access

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Cluster service provides remote management capabilities through the Cluster API so that you can manage the cluster from a management workstation. If you are administrating clusters remotely, be sure to use only trusted computers. The Cluster API uses the NTLM authentication protocol to authenticate the administrator on the cluster. This allows the cluster to verify that the administrator has sufficient administrative credentials to manage the cluster; however, it does not provide mutual authentication. In other words, the client has no guarantee that the node or cluster it is connected to is the real cluster.

If an unauthorized computer appears on the network with the same IP address or network name assigned to the cluster (assuming DNS information was compromised), the unauthorized computer can masquerade as the cluster. If that unauthorized computer also appears to implement the Cluster API, the unauthorized computer can intercept any management commands sent to the cluster. In many cases, this might not represent a threat because the administrator simply receives a false positive or negative that an action was performed. However, there are some sensitive operations (such as changing the cluster configuration) during which an unauthorized recipient could potentially collect cluster configuration data that might help to extend the attack surface.

This type of masquerade attack cannot occur until a number of conditions are met:

- The unauthorized computer must be visible on the same subnet as the target cluster and respond to traffic to the cluster IP address (this can be the IP address of the physical computers or the IP address of virtual servers hosted by the computer).
- In a typical environment, the unauthorized computer can take over the IP address only if the cluster node or virtual server is not running.
- The unauthorized computer must appear to implement the Cluster API.
- The administrator or an operational procedure must change the configuration that includes the sensitive data (for example, the administrator must change the Cluster service account password).

To protect against such attacks, the subnets on which the server clusters reside must be protected in the following ways:

- The subnet used by the cluster nodes must not extend beyond the set of nodes that can be physically secured or trusted. You must ensure that unauthorized or potentially compromised computers cannot attach to the subnet that contains the clusters. Because this network typically contains domain controllers, DNS servers, WINS servers, DHCP servers, and other network infrastructure, you must take steps to ensure that these infrastructure servers are also secure.
- Make sure that only nodes in the cluster are visible on a private network (multiple clusters can use the same private network). Make sure that no other network infrastructure servers or other application servers exist on the private subnet. This can be achieved by physically constraining the network itself (for example, ensuring that the private network is a LAN that is only connected to the cluster nodes), or by isolating the private networks by using VLAN-capable switches.

# Protecting the Cluster Disks

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Clustering supports only NTFS on cluster disks. This ensures that file protection can be used to safeguard data on the cluster disks. Because the cluster disks can fail over between nodes, you must use only domain user accounts (or Local System, Network Service, or Local Service) to protect files. Local user accounts on one computer have no meaning on other computers in the cluster.

Cluster disks are periodically checked for health. The Cluster service account must have Write access to the top-level directory of all cluster disks. If the Cluster service account does not have Write access, the disk might be mistakenly declared as failed.

**Evaluating Upgrade Risks**

On the Microsoft® Windows® 2000 Server and Microsoft® Windows NT® version 4.0 operating systems, the default security attributes of the cluster log files in the *windir*\Cluster directory and the default security attributes of the quorum directory allow any authenticated user to read the contents. The security of these directories has been tightened in Windows Server 2003 to stop nonadministrator access altogether, ensuring that unauthorized users cannot gain information about the cluster configuration. However, these security attributes are not modified when you upgrade to Windows Server 2003, so on an upgraded Windows Server 2003 cluster node, all authenticated users might have Read access to these directories. Be sure to manually set the permissions to conform to the minimum access requirements.

### Note

- Be aware that if you install any service packs in the future, the service packs might reset permissions that have been configured manually.

**Protecting the Quorum Disk**

Never store other application data on the quorum disk. The quorum disk should contain only quorum data.

The quorum disk health determines the health of the entire cluster. If the quorum disk fails, the Cluster service becomes unavailable on all cluster nodes. The Cluster service checks the health of the quorum disk and negotiates for exclusive access to the physical drive by using standard I/O operations. These operations are queued to the device along with any other I/O operations to that device. If extremely heavy traffic delays the Cluster service I/O operations, the Cluster service declares the quorum disk as failed and forces a regroup event to bring the quorum back online somewhere else in the cluster.

To protect against malicious applications that could fill up the quorum disk, or flood the quorum disk with I/O operations, restrict access to the quorum disk to the local Administrators group on the local computer and the Cluster service account. If the quorum disk fills up, the Cluster service might be unable to log required data. In this case, the Cluster service fails, potentially on all cluster nodes.

**Protecting the Server Cluster Data Disks**

As it does with the quorum disk, the Cluster service periodically checks the health of the cluster data disks. If malicious applications flood the cluster data disks with I/O operations, the Cluster service health check can fail, thereby causing the disk (and any applications that depend on the disk) to fail over to another cluster node, which can result in a denial-of-service attack. To avoid this possibility, restrict access to the cluster data disks to only those applications that store data on the specific disks.

# Creating Secure Administrative Policies for Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To provide adequate and manageable security for sever clusters, you need to implement appropriate administrative practices and policies. The most important secure administrative policy is to permit only trusted, specially designated workstations to access the Cluster service. Any compromise on computers used to administer the cluster can compromise the cluster. For example, if a workstation from which administrative tools are run can be accessed by unauthorized users, these users can run unreliable or malicious code on the cluster without the knowledge of the cluster administrator. For this reason, it is important to audit both administrative access to the server cluster and changes to the Cluster service account.

The following sections describe best practices for securely administrating a server cluster.

**Note**

- To change the password of the Cluster service account without taking any nodes offline, it is essential that each node in the cluster have the same Cluster service account.

**Verifying Permissions for the Cluster Service Account**

The nodes in a server cluster use authenticated communication mechanisms to ensure that only valid members of the cluster can participate in intra-cluster protocols. Authentication of the communication is based on the Cluster service account. The Cluster service creates and maintains files, devices, registry keys, and other objects in the operating system. The default security setting of these objects ensures that unauthorized users cannot impact the cluster configuration or the applications running on the cluster. Making these security settings less restrictive can lead to the cluster being compromised and application data being corrupted.

For the server cluster to function properly, the Cluster service account must have certain permissions associated with it. During cluster installation, some of these rights are granted directly to the Cluster service account while others are inherited when the Cluster service account is made a member of the local Administrators group. The Cluster service account must have rights that allow it to perform the following actions:

- Act as part of the operating system.
- Back up files and directories.
- Adjust memory quotas for a process.
- Increase scheduling priority.
- Log on as a service.
- Restore files and directories.
- Debug programs.
- Manage auditing and security logs.
- Impersonate a client after authentication.

In Windows Server 2003, the Cluster service can publish virtual servers as computer objects in Active Directory. To ensure correct operation, the Cluster service account needs appropriate permissions to manipulate these objects in the Active Directory Computers container.

**Note**

- Although the Network Name resource publishes a computer object in Active Directory, that computer object must not be used for administrative tasks such as applying Group Policy settings. The only roles for the virtual server computer object are to support Kerberos authentication, and for cluster-aware services that can use Active Directory (such as Message

Queuing) to publish service provider information.

**Administering Clusters**

Cluster administrators can grant permissions to groups or individuals to manage the cluster. There is no fine level of control: Either a user has credentials to administer the cluster, or the user does not. Because of the high degree of impact administrators can have on your system's security, granting administrative credentials to a user must be done with careful consideration.

The security descriptor for the Cluster service contains the accounts that are authorized to administrate the cluster. By default, a cluster node's local Administrators group is added to the Cluster service security descriptor. The service accounts LocalSystem and NetworkService are also added to the security descriptor. The local Administrators group and the two accounts cannot be removed from the security descriptor. Be aware that adding a domain user or global group to the local Administrators group gives cluster administrator permissions to that group or account. If a node is evicted from a cluster, or if the last node is removed, the Cluster service account is not removed from the local Administrators group. When you remove a node from the cluster, you must manually remove the Cluster service account from the local Administrators group.

Cluster administrators can manage all aspects of the cluster configuration, including:

- Taking resources offline and bringing resources online.
- Adding and removing nodes from the cluster.
- Adding and removing resources from the cluster.

In addition, cluster administrators are able to shut down the Cluster service on nodes, provided they are also member of the local Administrators group. Apart from the local Administrators group on a node, all other members of the cluster security descriptor must be either domain user accounts, built-in local accounts such as System or NetworkService, or global groups. This ensures that the account is an identical, well-defined, and authorized account on all nodes in the cluster.

The Cluster service account does not need to be a member of the Domain Admins group, because the Cluster service account does not need domain administrator permissions. As a general security guideline, give all accounts the minimal possible permissions.

If you are deploying multiple clusters in a single domain, you can make administration easier by using the same Cluster service account on all nodes. However, you must balance ease of management against the potential security risks associated with using a single account for many clusters. If the account is compromised, the scope of the impact might exceed the benefits you gain by increasing the ease of management. With Windows Server 2003, the Cluster service account password on multiple clusters can be changed at the same time, as long as every node in the cluster is using the same Cluster service account.

Cluster administrators and the Cluster service need to use different accounts to administer the cluster. This allows more specific auditing and allows policy settings (such as password expiration) to be applied to the Cluster service account and the accounts used to administer the cluster.

If you plan to deploy multiple clusters that have different Cluster service accounts, create a global group or universal group that implements all the policy settings described earlier in this section. Then place each Cluster service account into the group. This eases management of the Cluster service accounts by providing a single container for all Cluster service accounts, and a single point of management for changing account policy settings. For example, you could put all cluster nodes and the Cluster service accounts into a single organizational unit (OU) in Active Directory.

Your OU model depends on your Active Directory implementation. If your Windows Server 2003 clusters reside in a Windows NT 4.0 domain, OUs and universal groups are not available.

Follow these guidelines for ease of use and best security:

- If there are multiple clusters in a single domain, use the same Cluster service account on all nodes to make administration easier.
- If you have password expiration policy settings on your Cluster service account, do not use this account for other services.
- Do not use the Cluster service account for SQL Server or Exchange 2000 if you have password expiration policy settings. When multiple services use the same account, coordinating the password change across the Cluster service and other

services is complex and can cause the entire cluster or service to become unavailable during a password rotation. It is recommended that you use a dedicated account, which can be maintained independently, for each service.

- With Windows Server 2003, the Cluster service account password can be changed online without taking down the cluster, but only if the Cluster service account is not used by other services.

**Caution**

- Be sure to change the Cluster service account password before it expires. The cluster will stop functioning when the password expires, because intra-cluster communication can no longer be successfully authenticated.

# Applying Kerberos Authentication in a Clustered Environment

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Carefully plan your use of Kerberos authentication in a server cluster. By default, Kerberos authentication support for the network name resource is turned off. When Kerberos authentication support is enabled, the Cluster service account must be able to create a virtual computer object in Active Directory.

By default, all users have **Add workstations to the domain** permissions,which allows the creation of computer objects in Active Directory.

**Note**

- By default, authenticated users can join up to ten machine accounts to the domain. This limit does not apply to members of the Administrators or Domain Admins groups, and to those users who have delegated permissions on containers in Active Directory to create and delete computer accounts.

If the **Add workstations to the domain** permission has been removed from the Cluster service account, before enabling Kerberos authentication, a member of the Domain Administrators group must perform one of the following actions:

- Grant the Cluster service account the **Create Computer Objects** permission on the Computers organizational unit in Active Directory.

- Create the computer object manually in Active Directory before enabling Kerberos authentication. If the object is manually created, the Cluster service account must have **Write all properties** access permission to allow it to manipulate the computer object.

**Caution**

- Although the Network Name resource supports the changing of its **Name** property, many services, such as Message Queuing and Microsoft® SQL Server™ 2000, do not support changing the Network Name resource **Name** property. Do not change this property unless you fully understand the implications of doing so. In some cases, changing the Network Name resource **Name** property can lead to loss of data or service failure.

Before you allow clients to access a server cluster, or before failing over the resources to another node, ensure that the domain controllers have replicated newly created computer objects associated with Network Name resources. Until replication is complete, clients might fail to authenticate, or they could authenticate with the default NTLM authentication protocol and not with Kerberos authentication. One way to avoid replication issues with your clients is to not notify clients that the service is available until you are sure replication is complete. The amount of time it takes your directory to replicate information depends on many factors, such as the topology and the amount of network traffic. If you are not sure of the time necessary to allow for replication, replication can be forced with tools such as Ntdsutil.exe. For more information about Ntdsutil.exe, see "Using Ntdsutil" in Help and Support Center for Windows Server 2003.

After you enable Kerberos authentication on a server cluster, do not disable Kerberos authentication on a virtual server without knowing the effects the disabling will have on other services that use that virtual server. Microsoft® Message Queuing (MSMQ), for example, relies on the presence of a virtual computer object and ceases to function if its dependent Network Name resource has Kerberos authentication support disabled.

Use extreme care when you remove Kerberos authentication from a Network Name resource. When you disable Kerberos authentication from a Network Name resource, the computer object is disabled, leaving the system administrator with an explicit decision to delete the computer object. If the object remains in Active Directory, the Network Name resource does not go online. If the computer object is deleted, properties attached by applications that can use Active Directory are also deleted, and the applications might no longer function correctly.

For more information about enabling Kerberos authentication on a virtual server, see "Enable Kerberos authentication for virtual servers" in Help and Support Center for Windows Server 2003, or see articles Q302389, "Description of the Properties of the Cluster Network Name Resource in Windows Server 2003," and Q307532, "How to Troubleshoot the Cluster Service Account When It Modifies Computer Objects," in the Microsoft Knowledge Base. To find these articles, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Deploying Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After your application has been evaluated for server cluster deployment, and your hardware and network are in place, you can deploy your server cluster on Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition. Figure 7.25 illustrates the process for installing or upgrading a server cluster.

**Figure 7.25 Deploying a Server Cluster**

**Important**

- Server clusters have very specific hardware requirements. It is extremely important that you select hardware configurations approved by Microsoft for Windows server clusters. For more information about approved hardware configurations, see the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Installing a New Server Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section is designed as an overview of the new server cluster installation process and is not intended as an installation guide. For detailed information about creating server clusters, see "Checklists: Creating Server Clusters" in Help and Support Center for Windows Server 2003.

Before installing Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition on your cluster nodes, consult "Planning for Deployments" in *Planning, Testing, and Piloting Deployment Projects* in this kit. Information in that chapter includes methods for taking inventory of your current IT environment and how to create a functional specification that you can use to create a clear and thorough cluster deployment plan. In addition, gather the following materials and have them available for reference during installation:

- A list of all services and applications to be deployed on server clusters.
- A plan that defines which applications are to be installed on which nodes.
- Failover policies for each service or application, including resource group planning.
- A selected quorum model.
- A physical and logical security plan for the cluster.
- Specifications for capacity requirements.
- Documentation for your storage system.
- The Windows Server Catalog — approved device drivers for network hardware and storage systems. For more information about support for server clusters, see article Q309395, "The Microsoft Support Policy for Server Clusters and the Hardware Compatibility List." To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.
- Documentation supplied with all cluster hardware and all applications or services that will be deployed on the server cluster.
- An IP addressing scheme for the cluster networks, both private and public.
- A selected cluster name, its length limited by NetBIOS parameters.

Before installing, it is recommended that you complete the checklists in "Installing and upgrading on cluster nodes" in Help and Support Center for Windows Server 2003, Datacenter Edition and Windows Server 2003, Enterprise Edition.

Completing these checklists and reviewing the recommended information in Help and Support Center for Windows Server 2003, Datacenter Edition and Windows Server 2003, Enterprise Edition ensures that your hardware and network components are compatible and supported by Microsoft.

Additionally, be sure to read "Best practices for installing and upgrading cluster nodes" and the conceptual topics under "Installing Windows Server 2003, Enterprise Edition on cluster nodes" in Help and Support Center for Windows Server 2003, Enterprise Edition.

# Upgrading a Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are upgrading an existing server cluster from the Microsoft® Windows NT Server 4.0, Enterprise Edition or Windows® 2000 Advanced Server operating system, you have a choice of the following:

- Take the servers offline, upgrade the operating system, and rebuild the server cluster.
- Perform a rolling upgrade.

A *rolling upgrade* is the process of upgrading cluster nodes by turns while the other nodes continue to provide service. The server cluster downtime is reduced to a few minutes, which is the time needed to move resources from one node to another. Note that you cannot perform a rolling upgrade directly from Windows NT 4.0 to Windows Server 2003, but you can upgrade to Windows 2000 Advanced Server and then upgrade to Windows Server 2003, Enterprise Edition. Rolling upgrades are described in "Rolling Upgrades" later in this chapter.

**Important**

- Consult with the software vendors, or your software documentation, to be certain that all applications and services currently running on your server clusters will be able to function on Windows Server 2003.

# Upgrading by Rebuilding a Server Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The process of upgrading a server cluster by taking the nodes offline, upgrading the operating system, and then rebuilding the cluster requires the same preparation as described in "Installing a New Server Cluster" earlier in this chapter.

**Checklists for Upgrading a Server Cluster**
Before upgrading a Windows NT Server 4.0, Enterprise Edition server cluster or a Windows 2000 Advanced Server cluster, it is recommended that you complete the checklist "Preparation for upgrading a cluster" in Help and Support Center for Windows Server 2003, Datacenter Edition and Windows Server 2003, Enterprise Edition.

- Additionally, be sure to read the relevant conceptual topics under "Upgrading to Windows Server 2003, Enterprise Edition on cluster nodes" in Help and Support Center for Windows Server 2003, Enterprise Edition and "Upgrading to Windows Server 2003, Datacenter Edition on cluster nodes" in Help and Support Center for Windows Server 2003, Enterprise Edition. Also available is information specific to Windows NT 4.0 server clusters running the Microsoft Distributed Transaction Coordinator (DTC) and MSMQ applications, and Windows NT 4.0 server clusters running Internet Information Services (IIS).

- For information about upgrading clusters from Windows 2000 Server, see "Upgrade a cluster from Windows 2000" in Help and Support Center for Windows Server 2003, Enterprise Edition. In Help and Support Center for Windows Server 2003, Datacenter Edition, search for this title to view individual topics about how to upgrade clusters containing IIS and clusters containing Message Queueing.

**Upgrading from Windows NT Server 4.0, Enterprise Edition**
There are extra considerations when upgrading directly to Windows Server 2003, Enterprise Edition from Windows NT Server 4.0, Enterprise Edition. You must be running Windows NT Server 4.0, Enterprise Server, Service Pack 5 or later, and you have to make sure that your server cluster hardware is compatible with Windows Server 2003 (and has enough processing power and memory). Check the Windows Server Catalog to be certain Microsoft will support your Windows NT 4.0 Server cluster after you upgrade to the new operating system.

It is also important to check with your software and service vendors, or the supporting documentation, to be certain that your services and applications still function after you upgrade.

For information about upgrading and reinstating your cluster nodes, see "Upgrade a cluster from Windows NT 4.0" in Help and Support Center for Windows Server 2003, Enterprise Edition. Note that by upgrading directly to Windows Server 2003, there is no way for you to provide service to your users until the upgrade of the entire cluster is complete. For more information about supported hardware for server clusters, see the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

# Rolling Upgrades

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Rolling upgrades allow you to upgrade your server clusters while continuing to provide service to your users. Rolling upgrades can be performed for the following scenarios only:

- From Windows 2000 Advanced Server to Windows Server 2003, Enterprise Edition.
- From the Microsoft® Windows® 2000 Datacenter Server operating system to Windows Server 2003, Datacenter Edition.

You cannot perform a rolling upgrade directly from Windows NT 4.0 to Windows Server 2003. To upgrade from Windows NT 4.0, you can perform a rolling upgrade to Windows 2000 and then perform another rolling upgrade to Windows Server 2003. Consult your Windows 2000 documentation for the best way to upgrade your server cluster to Windows 2000 Advanced Server.

As with a standard (offline) upgrade, before performing a rolling upgrade you have to check the Windows Server Catalog to make sure your cluster hardware is supported, and then you have to confirm that your clustered applications and services will be able to run in a Windows Server 2003 cluster. For more information about cluster hardware support, see the Windows Server Catalog link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

For detailed procedures for performing a rolling upgrade, see "Perform a rolling upgrade from Windows 2000" in Help and Support Center for Windows Server 2003. Also available is specific information for upgrading Windows 2000 clusters running IIS and MSMQ, and for upgrading a print spooler resource.

During the process of a rolling upgrade, some of your nodes will be upgraded to Windows Server 2003 while others will still be running Windows 2000, temporarily resulting in a mixed-version cluster. Although mixed version clusters are supported by Windows Server 2003, Datacenter Edition, this is not a desirable configuration. You should upgrade all nodes to the same operating system as soon as possible.

The operation of a mixed-version cluster is complicated if a resource type that you add to the cluster is supported in one version of the operating system but not in the other. For example, the Cluster service in Windows Server 2003, Datacenter Edition supports the Generic Script resource type. However, older versions of the Cluster service do not support it. A mixed-version cluster can run a Generic Script resource on a node running Windows Server 2003, Datacenter Edition, but not on a node running Windows 2000. The Cluster service transparently sets the possible owners of new resource types to prevent these resources from failing over to a Windows 2000 node of a mixed-version cluster. Consequently, when you view the possible owners of a new resource type, a Windows 2000 node will not be in the list, and you will not be able to add this node to the list. If you create such a resource during the mixed-version phase of a rolling upgrade, the resource groups containing those resources will not fail over to a Windows 2000 node.

For information about which services support rolling upgrades, see "Resource behavior during rolling upgrades" in Help and Support Center for Windows Server 2003. Also, before you perform a rolling upgrade, read Relnotes.htm in the \Docs folder of the Windows Server 2003, Enterprise Edition operating system CD, in addition to the product documentation that comes with each application or resource.

If you have a service that is not fully supported during rolling upgrade, you can still perform a last node rolling upgrade. For more information, see "Perform a last node rolling upgrade from Windows 2000" in Help and Support Center for Windows Server 2003. This process entails moving all the applications and resources on your server cluster that do not support rolling upgrades to a single Windows 2000 node. You then upgrade the remaining nodes in the cluster, transfer the applications and resources to the newly upgraded nodes, and upgrade the final node to Windows Server 2003.

# Testing and Deploying the Cluster Configuration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You must always test a server cluster configuration prior to live deployment. Ensure that your failover policies work and that the receiving nodes have the required capacity for all failover resources. Perform a benchmark on each server upon initial installation, and monitor the servers to ensure they are staying within operational guidelines. Collect performance data at peak and off-peak periods.

For information about ensuring that your server cluster is ready for a test environment, see "Test Cluster Failures and Failover Policies" in Help and Support Center for Windows Server 2003.

After verifying that your servers are running within acceptable tolerances and that failover is properly achieved, pilot test your server clusters in a production environment. A small pilot deployment in a production environment lets you test the effectiveness of your clusters in an environment that simulates the conditions of a full deployment. This allows you to make any necessary adjustments to your cluster design before performing the full deployment.

Complete information about testing and piloting Windows Server 2003 deployments is available in "Designing a Test Environment" and "Designing a Pilot Project" in *Planning, Testing, and Piloting Deployment Projects* of this kit.

# Additional Resources for Server Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Related Information**

# Designing Network Load Balancing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Many of your deployments will include mission-critical applications and services. The servers that host your applications and services must be able to support projected increases in the number of users, and they must ensure that users can access mission-critical applications. To fulfill these requirements, your solution must be highly available and scalable. Network Load Balancing (NLB) improves availability and scalability in your solutions by distributing application load across multiple servers.

**In This Chapter**

Overview of the NLB Design Process

Identifying Applications That Benefit from NLB

Determining the Core Specifications in the NLB Design

Securing NLB Solutions

Scaling NLB Solutions

Ensuring Availability in NLB Solutions

Additional Resources for Designing Network Load Balancing

**Related Information**

- For information about server clusters, see "Designing and Deploying Server Clusters" in this book.

# Overview of the NLB Design Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Improving availability and scalability in your solution depends on the applications and services in your organization. A computer running the Microsoft® Windows® Server 2003 operating system can provide a high level of reliability and scalable performance. However, a Network Load Balancing cluster can achieve the higher levels of availability and performance required by mission-critical servers.

A Network Load Balancing cluster comprises multiple servers running any version of the Windows Server 2003 family, including the Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Datacenter Edition; and Windows® Server 2003, Web Edition operating systems. The servers are combined to provide greater scalability and availability than is possible with an individual server. Network Load Balancing distributes client requests across the servers to improve scalability. If a server fails, client requests are redistributed to the remaining servers to improve availability. Network Load Balancing can improve scalability and availability for applications and services that communicate with clients that use Transmission Control Protocol (TCP) or User Datagram Protocol (UDP).

The Network Load Balancing design process assumes that you are creating new clusters or that you are redesigning existing Windows Load Balancing Service (WLBS) or Network Load Balancing clusters. Upon completion of the Network Load Balancing design process, you will have a solution that meets or exceeds your scalability and availability requirements.

**Note**

- For a list of additional information to assist you in designing Network Load Balancing clusters, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

# NLB Design Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Creating a Network Load Balancing design involves more than documenting Windows Server 2003 and Network Load Balancing settings on the individual application servers. You must identify the applications and services that can benefit from Network Load Balancing, determine the core set of specifications in your design, ensure that your solution is secure, and provide for scalability and availability. The process for creating your Network Load Balancing design is shown in Figure 8.1.

**Figure 8.1 Designing a Network Load Balancing Solution**

As you create your Network Load Balancing design, document your decisions and use that information to deploy your Network Load Balancing solution.

**Note**

- For a Word document to assist you in documenting your Network Load Balancing design decisions, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Microsoft® Windows® Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

# NLB Fundamentals

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To create a successful Network Load Balancing design and to ensure that Network Load Balancing is correct for your solution, you need to know the fundamentals of how Network Load Balancing provides improved scalability and availability, and how Network Load Balancing compares with other strategies for providing scalability and availability.

**How NLB Provides Improved Scalability and Availability**

Network Load Balancing improves scalability and availability by distributing client traffic across the servers that you include in the Network Load Balancing cluster. Each *cluster host* (a server running on a cluster) runs an instance of the applications supported by your cluster. Network Load Balancing transparently distributes client requests among the cluster hosts. Clients access your cluster by using one or more virtual IP addresses. From the perspective of the client, the cluster appears to be a single server that answers the client request.

As the scalability and availability requirements of your solution change, you can add or remove servers from the cluster as necessary. Network Load Balancing automatically distributes client traffic to take advantage of any servers that you add to the cluster. In addition, when you remove a server from the cluster, Network Load Balancing redistributes the client traffic among the remaining servers in the cluster.

As an example, assume that your organization has a Web application farm running Microsoft® Internet Information Services (IIS) version 6.0 that hosts your organization's Internet presence. As seen in Figure 8.2, Network Load Balancing allows your individual Web application servers to service client requests from the Internet by distributing them across the cluster. On each of the servers, you install IIS 6.0 and Network Load Balancing. By combining the individual Web application servers into a Network Load Balancing cluster, you can load balance the requests to improve client response times and to provide improved fault tolerance in the event that one of the Web application servers fails.

**Figure 8.2 Network Load Balancing Cluster in a Web Farm**

Network Load Balancing automatically detects and recovers when the entire server fails or is manually disconnected from the network. However, Network Load Balancing is unaware of the applications and services running on the cluster, and it does not detect failed applications or services. To provide awareness of application or service failures, you need to add management software, such as Microsoft® Operations Manager (MOM), Microsoft® Application Center 2000, a third-part party application, or software developed by your organization.

When your design requires fault tolerance for servers that support your Network Load Balancing cluster, such as servers running Microsoft® SQL Server™ 2000, include Microsoft server clusters. For example, you can improve the availability of the network database (SQLCLSTR-01 in Figure 8.2) by creating a two-node server cluster. For more information about server

clusters, see "Designing and Deploying Server Clusters" in this book.

Network Load Balancing runs as an intermediate network driver in the Windows Server 2003 network architecture. Network Load Balancing is logically situated beneath higher-level application protocols, such as Hypertext Transfer Protocol (HTTP) and File Transfer Protocol (FTP), and above the network adapter drivers. Figure 8.3 illustrates the relationship of Network Load Balancing in the Windows Server 2003 network architecture.

**Figure 8.3 Network Load Balancing in the Windows Server 2003 Network Architecture**

To maximize throughput and to provide high availability in your solution, Network Load Balancing uses a distributed software architecture. A copy of the Network Load Balancing driver runs on each host in the cluster. The Network Load Balancing drivers allow all hosts in the cluster to concurrently receive incoming network traffic for the cluster.

On each host in the cluster, the driver acts as an intermediary between the network adapter driver and the TCP/IP stack. This allows a subset of the incoming network traffic to be received by the host. Network Load Balancing uses this filtering mechanism to distribute incoming client requests among the servers in the cluster.

Network Load Balancing architecture maximizes throughput by using a common media access control (MAC) address to deliver incoming network traffic to all hosts in the cluster. As a result, there is no need to route incoming packets to the individual hosts in the cluster. Because filtering unwanted network traffic is faster than routing packets (which involves receiving, examining, rewriting, and resending), Network Load Balancing delivers higher network throughput than dispatcher-based software load balancing solutions. Also, as you add hosts to your Network Load Balancing cluster, the scalability grows proportionally, and any dependence on a particular host diminishes.

Because Network Load Balancing load balances client traffic across multiple servers, it provides higher availability in your solution. One or more cluster hosts can fail, but the cluster continues to service client requests as long as any cluster hosts are running.

**NLB and Round Robin DNS**

Round robin Domain Name System (DNS) is a software method for distributing workload among multiple servers, but does not prevent clients from detecting server outages. If one of the servers fails, round robin DNS continues sending client requests to the server until a network administrator detects the failure and removes the server from the DNS address list. This results in service disruption for clients.

In contrast, Network Load Balancing automatically detects servers that have been disconnected from the cluster and redistributes client requests to the remaining servers. Unlike round robin DNS, this prevents clients from sending requests to the failed servers.

For more information about methods for improving availability and scalability, see "Planning for High Availability and Scalability" in this book.

# Identifying Applications That Benefit from NLB

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The first step in creating your Network Load Balancing design, as illustrated in Figure 8.4, is to determine if any of your applications can benefit from the improved scalability and availability provided by Network Load Balancing. Your applications include not only applications in the traditional sense, such as Web applications, but also Windows Server 2003 network services, such as virtual private network (VPN) remote access.

**Figure 8.4 Identifying Applications That Benefit from Network Load Balancing**

Beyond using TCP/IP, an application that works well with Network Load Balancing has one or more of the following characteristics:

- Avoids instructing the client to open a subsequent connection that must be serviced by the same cluster host.

  For example, a Web application sends a response instructing a client to open an additional Secure Sockets Layer (SSL) session, and the application expects the SSL session to be established with the same cluster host that originated the response.

- Avoids retaining application state on a specific server in the cluster, such as session state saved by Active Server Pages (ASP).

  For example, some Web applications use a common database, or service, to maintain session state. A cookie is sent to the client on the initial request. On subsequent requests, the client sends the cookie to the cluster. Any cluster host in the cluster is capable of restoring the application session state by using the cookie sent by the client to retrieve the session state from the session database, or service. Applications that use a common database, or service, in conjunction with client-side cookies to maintain session state are more likely to work with Network Load Balancing than those that retain application state on a specific host in the cluster.

Applications and services that are stateless are the most likely to run without modifications on Network Load Balancing. Applications and services are said to be *stateless* when each client request is considered to be a new request that is unrelated to any previous request. Anytime a client request is considered to be a continuation of a previous request, the applications and services maintain *session state*.

Applications that maintain session state are said to be *stateful*. Stateful applications require *affinity* with the cluster host, when the session state is maintained locally.

You can set affinity between the client computer and a specific server within your cluster by using the port rules in Network Load Balancing. For more information about port rules, see "Identifying Applications or Services That Require Custom Port Rules" later in this chapter.

Regardless of which category your application belongs to, always test the application with Network Load Balancing in your lab environment during the proof-of-concept stage in your design. Ensure that your application is compatible with Network Load

Balancing before continuing with the design process.

Some of the common applications and services that run on Network Load Balancing include:

- Web applications running on IIS 6.0

  One of the most common of the solutions that use Network Load Balancing is an IIS 6.0 Web farm. A typical challenge in supporting Web applications occurs when an application must maintain a persistent connection to a specific cluster host. For example, if a Web application uses Hypertext Transfer Protocol Secure (HTTPS), the application should contact the same cluster hosts within the cluster, for efficiency. Connecting to a different cluster host requires establishing a new SSL session, which creates excess network traffic and overhead on the client and server. Network Load Balancing maintains affinity and reduces the possibility that a new SSL session needs to be established.

- VPN remote access running on Routing and Remote Access

  Another solution that uses Network Load Balancing involves using the Routing and Remote Access service in Windows Server 2003 to provide VPN remote connectivity. In the VPN solution, you combine multiple remote access servers running Windows Server 2003 and Routing and Remote Access to create a VPN remote access server farm.

- Web content caching and firewall running on Microsoft® Internet Security and Acceleration (ISA) Server 2000

  You can also use Network Load Balancing in solutions that include ISA Server to provide network security, network isolation, network address translation, or Web content caching. In ISA Server solutions, the design and deployment are integral parts of the ISA Server design and deployment process.

  For more information about creating ISA Server designs and deploying ISA Server in your organization, see "Deploying ISA Server" in *Deploying Network Services* of this kit and see the documentation that accompanies ISA Server.

- Application hosted on Terminal Services

  When you run applications on Terminal Services, the Terminal Services clients can be load balanced across a number of computers running Terminal Services. Network Load Balancing is combined with the Session Directory service in Terminal Server to provide improved scalability and availability for Terminal Services.

  For more information about creating Terminal Services designs to host applications, see "Hosting Applications with Terminal Server" in this book, or see the Session Directory and Load Balancing Using Terminal Server link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

  **Note**

  - Network Load Balancing is an inappropriate solution if you are using Terminal Services to provide remote administration for specific servers, because Network Load Balancing can distribute your administration traffic to any one of the cluster hosts within the cluster. When you want to use Terminal Services to remotely administer cluster hosts, connect to the specific cluster host through the dedicated IP address on the cluster adapter or through a separate management adapter. For more information about the adapters in a cluster host, see "Selecting the Number of Network Adapters in Each Cluster Host" later in this chapter.

- Custom applications

  Network Load Balancing might be an appropriate method of improving scalability and availability for applications that your organization or third-party organizations have developed. Custom applications must adhere to the same criteria listed earlier in this section.

  The considerations for custom applications are similar to those for Web applications running on IIS 6.0. For example, any application behavior that maintains local session state across multiple TCP connections is less likely to benefit from Network Load Balancing. For more information about determining if an application requires cluster host affinity, see "Identifying Applications or Services That Require Custom Port Rules" later in this chapter.

  In addition to being compatible with Network Load Balancing, custom applications must be compatible with Windows

Server 2003. For help in determining if your application is compatible with Windows Server 2003, use the Windows Application Compatibility Toolkit on the *Windows Server 2003 Deployment Kit* companion CD. For more information about the Windows Application Compatibility Toolkit, in Help and Support Center for Windows Server 2003, click **Tools**, and then click Windows Resource Kit Tools Help.

# Determining the Core Specifications in the NLB Design

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you identify applications that can benefit from Network Load Balancing, you are ready to design the core specifications for your Network Load Balancing design. These core specifications form the foundation on which you create your cluster. They include the design process steps that are required for all Network Load Balancing solutions. Figure 8.5 illustrates the current step in the process for creating your Network Load Balancing design. The steps that occur later in the design process depend on the design decisions that you make about these essential aspects of your design.

**Figure 8.5 Determining the Core Specifications in the NLB Design**

# Combining Applications on the Same Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you create your Network Load Balancing design, one of the first steps is to determine if you can combine the applications and services in your solution on the same cluster. One of the primary concerns when combining applications on the same cluster is determining if the applications are compatible with each other. Table 8.1 lists the categories of common applications and services that run on Network Load Balancing, and it describes how you can combine them on the same cluster.

**Table 8.1 Compatibility of Applications and Services on a Cluster**

| Application or Service | Combined on the Same Cluster |
|---|---|
| IIS 6.0 Web applications | • Can be combined on the same cluster; however, might require customized port rules.[1] |
| Terminal Services | • Can run any combination of applications as long as the applications are compatible with Terminal Services.<br>• Avoid combining Terminal Services (when Terminal Services is hosting applications) with other application platforms or services, such as IIS 6.0 or VPN remote access.[2] |
| VPN remote access | • Can be combined with ISA Server to combine remote access server and firewall features in the same server.<br>• Otherwise, avoid combining with other application platforms and services, such as IIS 6.0. |
| ISA Server | • Can be combined with Routing and Remote Access to combine remote access server and firewall features.<br>• Can be combined with IIS 6.0 to provide default Web site redirection to a Web site that is local to the server running ISA Server and IIS 6.0. |
| Custom applications | • Can be combined on the same cluster; however, might require customized port rules.[1] |

[1] For more information, see "Identifying Applications or Services That Require Custom Port Rules" later in this chapter.

[2] If you are not hosting applications with Terminal Services, you can combine Terminal Services with IIS 6.0 Web applications, VPN remote access servers, ISA Server, and your custom applications to provide remote administration of those servers.

As mentioned in Table 8.1, avoid running some applications and services, such as Terminal Services and VPN remote access, on the same cluster. The reasons for not running these applications and services on the same cluster include system resource constraints, security constraints, and ease of management.

In some instances, the cluster hosts might not have sufficient system resources to run the combined applications. For example, if you use Terminal Services to host applications, Terminal Services consumes a significant amount of processor and memory resources. Hosting applications with Terminal Services on the same cluster as IIS 6.0 might cause significant delays in running Web applications. For more information about scaling applications and services on Network Load Balancing clusters, see "Scaling NLB Solutions" later in this chapter.

Also, security considerations might require running the applications and services on separate clusters. For example, you might want to avoid running an FTP site that allows anonymous access on a cluster that also runs a secured e-commerce Web application.

Finally, combining applications on the same cluster can make the applications unmanageable and difficult to administer. The complexity of combining applications can correspondingly increase the complexity of managing and operating the cluster. For more information about creating clusters that are easy to manage and operate, see "Ensuring Ease of Cluster Management and Operations" later in this chapter.

# Example: Combining Applications on the Same Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A fictitious organization, Contoso, is in the process of restructuring its existing network infrastructure and application platforms. Contoso wants to reduce the number of Network Load Balancing clusters required to support its new network infrastructure and application platforms. The company plans to run the following applications and services on Network Load Balancing clusters:

- A VPN remote access server farm, based on Routing and Remote Access
- Three e-commerce Web applications, based on IIS 6.0

  One of the applications is based on static Hypertext Markup Language (HTML) content with Common Gateway Interface (CGI) scripts, another application is an ASP application, and the third application is an ASP.NET application.
- A customer support FTP site, based on IIS 6.0

  The customer support FTP site supports the downloading of information and documents to customers and the uploading of customer documents, files, and other information to the FTP site. The customer support FTP site allows anonymous access for users who want to download and upload files.

For each of these applications and services, Contoso must determine if the application can be combined with other applications and services or if the application requires its own cluster. Table 8.2 lists the clusters required to support the applications and services and the reasons for including those clusters in the design.

**Table 8.2 Clusters Required by Contoso**

| Cluster Required | Applications Running on the Cluster | Reason for Inclusion |
|---|---|---|
| NLBClusterA | VPN remote access server farm | VPN remote access servers should not be combined with other applications platforms or services. |
| NLBClusterB | E-commerce Web applications | The three -commerce Web applications are compatible with one another. |
| NLBClusterC | Customer support FTP site | The customer support FTP site supports anonymous user access and cannot be combined with the e-commerce Web applications. |

# Specifying Cluster and Cluster Host Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For each Network Load Balancing cluster, there are settings that are common to all cluster hosts and there are other settings that are unique to each cluster host. The cluster parameters define the cluster and establish cluster-wide configurations, such as the virtual IP address assigned to the cluster. The cluster host parameters define the cluster host role and identity within the cluster, such as the cluster host's priority within the cluster or the dedicated IP address that is unique to the cluster host.

Specify the cluster and cluster host parameters by completing the following steps:

1. Specify the settings that are common to all cluster hosts within the same cluster.

2. Specify the settings that are unique to each cluster host.

**Note**

- For a Word document to assist you in documenting cluster and cluster host parameters, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

# Specifying the Cluster Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Cluster parameters are the configuration settings that define the cluster and the configuration settings common to all cluster hosts within the cluster. The cluster parameters must be unique within your organization's network.

Specify the cluster parameters by completing the following steps:

1. Specify the cluster IP address.
2. Specify the cluster fully qualified domain name (FQDN).
3. Specify the cluster operation mode.
4. Specify the remote control settings.

**Tip**

- When you configure cluster parameters by using Network Load Balancing Manager, enter the cluster parameters once during the creation of the cluster. As cluster hosts are added to the cluster, Network Load Balancing Manager automatically configures the cluster parameters for the new cluster hosts. When you configure them by using other methods, configure the cluster parameters identically for all cluster hosts within the same cluster. For more information about configuring the cluster parameters, see "Network Load Balancing parameters" in Help and Support Center for Windows Server 2003.

**Specifying the Cluster IP Address**

The cluster IP address is the virtual IP address that is assigned to the cluster. Client requests are sent to the cluster IP address. The cluster IP address has a corresponding subnet mask that is part of the cluster IP address specifications. The criteria for specifying the cluster IP address and subnet mask are the same as for all other IP addresses. When you configure the cluster manually, you must configure the cluster IP address and subnet mask identically on all cluster hosts within the cluster.

**Tip**

- The cluster IP address must appear in the list of IP addresses in the TCP/IP properties. Network Load Balancing Manager automatically configures the TCP/IP properties so that the cluster IP address is in the list. When you configure the TCP/IP properties by other methods, you must ensure that the cluster IP address is in the list of IP addresses in the TCP/IP properties.

**Specifying the Cluster FQDN**

For each cluster, you must designate the FQDN to be assigned to the cluster. The FQDN is registered in DNS later in the deployment process, when the cluster is deployed and ready to service client requests. The cluster FQDN refers to the cluster as a whole.

**Tip**

- You can enter the cluster FQDN in the full Internet name setting. The full Internet name is not automatically registered in DNS or used by other Windows components. As a result, treat the full Internet name setting as a comment that allows administrators to easily identify the cluster's FQDN. If you elect to leave the full Internet name setting blank, the operation of any Windows component, including Network Load Balancing, is not affected.

In addition to the cluster FQDN, designate a FQDN for each application and service running on the cluster. Ultimately these FQDNs become DNS entries as you deploy the corresponding application or service.

**Specify the Cluster Operation Mode**

The cluster operation mode determines the method, *unicast* or *multicast*, that is used to propagate incoming client requests to all the cluster hosts. For more information about determining which method to select for the cluster, see "Selecting the Unicast

or Multicast Method of Distributing Incoming Requests" later in this chapter.

**Specify the Remote Control Settings**

The remote control settings provide the ability to perform certain remote administration tasks, such as starting and stopping a cluster host, from the command line utility Nlb.exe. Because of security-related concerns, avoid enabling the remote control settings. Nlb.exe can only perform limited administrative tasks. Network Load Balancing Manager can perform all administrative tasks, and is the preferred method for administering clusters. Remotely administering a cluster by using Network Load Balancing Manager is not affected by the remote control settings. For more information about specifying the remote control settings, see "Securing NLB Solutions" later in this chapter.

# Specifying the Cluster Host Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The cluster host parameters are the configuration settings that define each cluster host, including the configuration settings that are unique to each cluster host within the cluster. The cluster host parameters must be unique within a cluster and within your organization's network.

Specify the cluster host parameters by completing the following steps:

1. Specify the cluster host priority.
2. Specify the dedicated IP address configuration.
3. Specify the initial host state.

For more information about configuring the cluster host parameters, see "Network Load Balancing parameters" in Help and Support Center for Windows Server 2003.

**Tip**

- Network Load Balancing Manager prevents common cluster host configuration errors, such as duplicate cluster host priorities or duplicate dedicated IP addresses. When you use other methods to configure the cluster host parameters, you must ensure that the cluster host parameters are configured appropriately for all cluster hosts within the cluster.

**Specifying the Cluster Host Priority**

For each cluster host, you must specify a cluster host priority that is unique within the cluster. During cluster convergence, the cluster host with the lowest numeric value for the cluster host priority triggers the end of convergence. For example, if three cluster hosts have the priorities of 3, 16, and 22, 3 is the cluster host with the highest priority and it will trigger the end of convergence.

Specify the cluster host priority for your cluster by using any unique identifier between 1 and 32. Any sequence can be used as long as the cluster host priorities are unique.

**Note**

- If you specify the same cluster host priority for two cluster hosts, the last cluster host that starts fails to join the cluster. An error message describing the problem is written to the Windows system event log. The existing cluster hosts continue to operate as before.

**Specifying the Dedicated IP Address Configuration**

The dedicated IP address is an IP address that is assigned to each cluster host for network traffic that is not associated with the cluster, such as Telnet access to a specific host within a cluster. This IP address is used to individually address each host in the cluster; therefore, it should be unique for each host. Enter this parameter in standard Internet dotted notation (for example, w.x.y.z).

Traffic that is sent to the dedicated IP address is not load balanced by Network Load Balancing. Network Load Balancing ensures that all traffic to the dedicated IP address is unaffected by the Network Load Balancing current configuration, including:

- When a host is running as part of the cluster.
- When Network Load Balancing is disabled as a result of parameter errors in the registry.

**Tip**

- The dedicated IP address must be the first IP address in the list of IP addresses in the TCP/IP properties. Network Load Balancing Manager automatically configures the TCP/IP properties so that the dedicated IP address is first. When you use other methods to configure the TCP/IP properties, you must ensure that the dedicated IP address is the first IP address

listed in the TCP/IP properties.

**Specifying the Initial Host State**

The *initial host state* specifies whether Network Load Balancing starts and whether the cluster host joins the cluster when the operating system starts. You need to determine the correct initial host state for the applications and services running on the cluster.

Network Load Balancing starts very early in the system start sequence. As a result, a cluster host can join the cluster before the applications and services running on the cluster host are ready to handle traffic. In this situation, clients might be directed to the cluster host and experience outages.

In some instances, management software, such as MOM or Applications Center 2000, is responsible for starting Network Load Balancing. The management software monitors the applications and services running on the cluster host and starts Network Load Balancing when the applications are fully operational.

In other instances, you might decide to start Network Load Balancing manually to ensure that applications and services are running before Network Load Balancing starts.

Table 8.3 lists the possible settings for the initial host state and the reasons for selecting the specific initial host state.

**Table 8.3 Selecting the Appropriate Initial Host State**

| Initial Host State | Reasons for Selecting the Initial Host State |
|---|---|
| Started | • The applications and services running on the cluster start before Network Load Balancing.<br>• The length of time between the start of Network Load Balancing and the start of applications and services running on the cluster is negligible. |
| Stopped | • Management software, such as MOM or Application Center 2000, is responsible for starting Network Load Balancing automatically.<br>• The applications and services running on the cluster start after Network Load Balancing, and you want to start the cluster host manually. |
| Suspended | • You have performed maintenance on the cluster host, and you want to prevent the cluster from responding to clients after a restart of the cluster host. |

# Example: Specifying Cluster and Cluster Host Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A fictitious organization, Contoso, is designing a VPN remote access solution, based on Routing and Remote Access and Network Load Balancing. The VPN remote access solution provides remote access to Contoso's private network by establishing Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP) VPN tunnels through the Internet. The VPN remote access server farm contains five servers that have identical system resources.

Table 8.4 lists the cluster parameter design decisions for the VPN remote access server farm and the reasons for making those decisions.

**Table 8.4 Cluster Parameter Settings for the VPN Remote Access Server Farm**

| Decision | Reason for the Decision |
|---|---|
| The cluster IP address and subnet mask is assigned an IP address and subnet mask that is accessible from the Internet. | Remote access users need to access the VPN server farm running on the cluster from the Internet. |
| The cluster is assigned the FQDN of vpn.contoso.com. | The FQDN assigned to the cluster is the name used by remote access users when accessing the VPN server farm running on the cluster. |
| The cluster operation mode is set to unicast. | The network infrastructure supports the unicast cluster operation mode. For more information about the decisions regarding setting this mode, see "Selecting the Unicast or Multicast Method of Distributing Incoming Requests" later in this chapter. |
| The remote control settings are not enabled. | The remote control settings are not required, because Network Load Balancing Manager will be used to administer the cluster. |

Table 8.5 lists the cluster host parameter design decisions for the VPN remote access server farm.

**Table 8.5 Cluster Host Parameter Settings for the VPN Remote Access Server Farm**

| Cluster Host Name | Host Priority | Dedicated IP Address | Initial Host State |
|---|---|---|---|
| NLBClusterA-01 | 1 | Not specified | Started |
| NLBClusterA-02 | 2 | Not specified | Started |
| NLBClusterA-03 | 3 | Not specified | Started |
| NLBClusterA-04 | 4 | Not specified | Started |
| NLBClusterA-05 | 5 | Not specified | Started |

A unique cluster host priority is assigned to each cluster host. The cluster host initial host state is set to Started to ensure that Network Load Balancing starts automatically and that the cluster host automatically joins the cluster.

# Controlling the Distribution of Client Traffic Within the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

One of the intended purposes of Network Load Balancing is to distribute incoming client traffic within the cluster. You can control the distribution of client traffic within the cluster by using Network Load Balancing port rules. Port rules are criteria-based policies that allow you to direct client requests to specific cluster hosts, based on TCP and UDP port numbers.

A default port rule is created during the installation of Network Load Balancing. In many instances, the default port rule is sufficient for some of the applications and services that use Network Load Balancing. When the default port rule is insufficient, you can create custom port rules. For more information about the default port rule, see "Identifying the Behavior of the Default Port Rule" later in this chapter.

The default port rule is sufficient for the following applications and services:

- VPN remote access farms with Routing and Remote Access
- Load-balancing application hosting with Terminal Services

**Tip**

- The ISA Server setup process defines the port rules that are necessary for ISA Server. No custom port rules are necessary for ISA Server.

If the default port rule is sufficient for your solution, and creating custom port rules is unnecessary, see "Specifying Cluster Network Connectivity" later in this chapter.

For IIS 6.0 Web farms or for custom applications, custom port rules might be required.

In some instances, the applications and services might require that the same client traffic be handled differently for the same or different applications and services. The virtual IP address assigned to the cluster can handle client traffic only in one way. However, you can specify a *virtual cluster* for each of the applications, allowing each application to have its own load-balancing behavior. Virtual clusters are a logical construct within the cluster, and they require no additional hardware.

For example, two Web applications might require different load-balancing behavior for HTTP (TCP port 80). You can create a virtual cluster for each Web application that allows different load-balancing behavior for the HTTP client traffic.

You can create a virtual cluster by specifying a virtual IP address in a Network Load Balancing port rule. The virtual IP address that is assigned in the port rule is associated with the application that requires the different load-balancing behavior.

Figure 8.6 illustrates the relationship between a Network Load Balancing cluster and the virtual clusters specified for the cluster. Each of the applications — Web applications A, B, and C — requires different load-balancing behavior. A virtual IP address is assigned to each virtual cluster and associated with each application. A DNS entry associates the virtual IP address with a URL for the corresponding application.

**Figure 8.6 Relationship Between an NLB Cluster and Virtual Clusters**

For more information about including Network Load Balancing port rules in your design, see "Identifying Applications or Services That Require Custom Port Rules" later in this chapter.

Control the distribution of client traffic within a cluster by completing the following steps:

1. Identify the behavior of the default port rule.

2. Identify applications or services that require custom port rules.

3. Specify the client traffic to be affected by the custom port rule.

4. Specify the affinity and load-balancing behavior of the custom port rule.

**Important**

- The port rules applied to each cluster host must be identical, with the exception of the load weight (in the multiple hosts filter mode) and the handling priority (in the single hosts filter mode). If there is a discrepancy between port rules on existing cluster hosts, the cluster will not converge.

# Identifying the Behavior of the Default Port Rule

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When Network Load Balancing is installed on a cluster host, a default port rule is created. Table 8.6 lists the configuration of the default port rule that is created during Network Load Balancing installation.

**Table 8.6 Specifications for the Network Load Balancing Default Port Rule**

| Default Port Rule Setting | Set to This Value |
|---|---|
| Cluster IP address | All |
| Port range: From | 0 |
| Port range: To | 65535 |
| Protocols | Both |
| Filtering Mode | Multiple Hosts with Single affinity and Equal load weight |

Specify that the default port rule be deleted unless the default port rule is:

- Appropriate for the applications and services installed on the cluster.
- Modified for the applications and services installed on the cluster.

# Identifying Applications or Services That Require Custom Port Rules

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As previously mentioned, the default port rule is sufficient for some applications and services. However, many applications running on IIS 6.0 or custom applications that are developed by your organization might require customized port rules.

These applications and services can require customized port rules to influence how load is directed to hosts in the cluster. In addition, the applications and services might require a virtual cluster when the same client traffic must be handled differently for the same or different applications and services. With virtual clusters, you can use different port rules for different Web sites or applications hosted on the cluster, provided each Web site or application has a different virtual IP address.

**Identifying Applications and Services That Need Persistent Sessions**
The applications and services that run on Network Load Balancing include stateful applications (those that maintain session state) and stateless applications. Maintaining session state means that the application or service collects information when first connecting to a cluster host and then retains the information for subsequent requests. During a user session, the same server must handle all the requests from the user in order to access that information. Applications and services that are stateless maintain no user or communication information for subsequent connections.

With a single server, maintaining session state presents no difficulty, because the user always connects to the same server. However, when client requests are load balanced within a cluster, without some type of persistence, the client might not be directed to the same cluster host for a series of client requests.

In Network Load Balancing, you maintain session state with a *port rule affinity* between the client and a specific cluster host. Port rule affinity directs all client requests from the same IP address to the same cluster host. You can use port rules to specify the port rule affinity between clients and cluster hosts. For more information about specifying port rule affinity between clients and cluster hosts, see "Specifying the Affinity and Load-Balancing Behavior of the Custom Port Rule" later in this chapter.

Port rule affinity might be required by the following:

- An application or service running on the cluster
- Session-oriented protocols that are used by the application or service running on the cluster if the session lifetime extends across multiple TCP connections

**Identifying applications that require affinity**
Applications and services require persistent sessions when the application or service retains information established in a client request that is used in subsequent client requests. In some instances, the application or service is aware that load balancing is occurring, and it uses an application-specific method, such as client-side cookies, for maintaining session state. In other instances, the application or service is unaware that load balancing is occurring, and it requires Network Load Balancing to maintain affinity between the client and specific cluster hosts.

An example of an application that maintains session state is a Web application that requires a user to log on to buy products through a shopping cart application. After the application authenticates the user, the user's information, including shipping information, billing information, and items in the shopping cart, is retained for subsequent requests. The session state is maintained until the user completes or cancels the purchase.

Table 8.7 lists common Web application types and their requirements for affinity provided by cluster port rules.

**Table 8.7 Web Applications and Their Requirements for Port Rule Affinity**

| Web Application | Description | Requires Port Rule Affinity |
|---|---|---|

| | | |
|---|---|---|
| Static, HTML-based applications | Application maintains no user information. | |
| Static, HTML-based applications with CGI | CGI portion of the application might retain user information. | • |
| Web application that uses client-side cookies | Application sends a cookie to the client when the application session is initiated. On subsequent requests, the client sends the cookie along as part of the request. The instance of the application running on individual cluster hosts is capable of retrieving application session state by using the cookie in the request. | |
| ASP.NET applications with session state persistence | ASP.NET applications support a method for maintaining session state on a centralized session state server or on a server running SQL Server 2000. Because the session state is managed centrally, any cluster host can recover session state information, and affinity is not required. For more information about ASP.NET application session state, see "Deploying ASP.NET Applications in IIS 6.0" in *Deploying Internet Information Services (IIS) 6.0*, or see "Deploying ASP .NET Applications in IIS 6.0" at the Microsoft Web site. | |
| ASP applications and ASP.NET applications without session state | These applications create session information when the user first starts the application. The session information is managed by the instance of the ASP or ASP.NET dynamic-link libraries (DLLs) running on the cluster host. On subsequent requests, the session state is maintained for the application on that specific cluster host. No session state information is shared among cluster hosts. | • |

For applications that are written by your organization, consult with the application developers to determine if, or how, any session information is retained. When your applications run on Terminal Services, port rule affinity is required.

**Identifying session-oriented protocols that require affinity**

Even when the application or service is stateless, the protocol required by the application or service might be session-oriented. For example, an application might be based on static HTML, but it might use SSL to provide security.

However, other session-oriented protocols, such as SSL, can operate correctly without affinity, but they incur a significant decrease in performance. When an SSL session is established with a cluster host, an SSL session ID is exchanged between the cluster host and the client. If the client makes a subsequent request to the same cluster host, the same session ID can be used.

If the client makes a subsequent request to a different cluster host, a new session ID must be obtained. The overhead for obtaining a new SSL session ID is five times more than for reusing a session ID. By using port rule affinity, SSL session IDs are reused whenever possible.

**Compensating for Differences in System Resources**

During the IT life cycle of your cluster, new cluster hosts might be added to the cluster. These new cluster hosts are typically new computers with improved system resources, such as processor speed, number of processors, or memory. Because of the improved system resources, the new cluster hosts are capable of servicing more clients.

The default port rule, created during the installation of Network Load Balancing, evenly distributes network requests among cluster hosts, regardless of the available system resources on individual cluster hosts. Cluster hosts with inadequate system resources can provide slower response times to clients than other cluster hosts with adequate system resources. You can compensate for differences in available system resources on individual cluster hosts by directing a higher percentage of client requests to the cluster hosts with adequate system resources.

The method of compensating for the differences in system resources is based on the filter mode in the port rule. Only the Multiple Hosts port filter mode supports compensating for differences in cluster host resources. For more information about port rule filter modes and, specifically, the Multiple Hosts port filter mode, see "Specifying the Affinity and Load-Balancing Behavior of the Custom Port Rule" later in this chapter.

**Deciding to Include Virtual Clusters**

In some instances, you might want a cluster to appear logically as multiple Network Load Balancing clusters. In Network Load Balancing, you can define virtual clusters that allow you to apply a unique set of port rules to each virtual cluster.

Include virtual clusters in the following situations:

- An application or service running on a cluster must exhibit different affinity behavior.

  For example, you might have an FTP site hosted on multiple servers running IIS 6.0. You want FTP downloads to be load balanced across all cluster hosts. However, you want FTP uploads to be sent only to one cluster host. You can create a virtual cluster that supports FTP downloads with no affinity and another virtual cluster that directs FTP uploads to a specific cluster host.

- Multiple applications or services running on the same cluster require different affinity behaviors for the same client traffic type (same TCP/UDP port number).

  For example, you might have two Web applications hosted on the same cluster running IIS 6.0. Both applications use HTTP (TCP port 80), but one application maintains session state while the other application does not. You can create a virtual cluster that supports the application that maintains session state with affinity and another virtual cluster that supports the stateless application without affinity.

- The maintenance and operations of an application or service must be independent of other applications and services running on the cluster.

  For example, you might have two applications hosted on the same cluster. For ease of maintenance, upgrade, or other operations tasks, you can create a virtual cluster for the application. You can stop client communication with the virtual cluster and then perform application maintenance without affecting other applications running on the cluster.

  **Tip**

  - You can stop client communications with a virtual cluster by using the **drain** parameter from Nlb.exe or Network Load Balancing Manager, both of which are a part of Windows Server 2003.

Virtual clusters are specialized port rules that require a virtual IP address, which is assigned to the virtual cluster. You define a virtual cluster by specifying one or more port rules that share the same virtual IP address. As with regular port rules, the port rules that define the virtual cluster must be the same for all cluster hosts in the cluster. For more information about port rule specifications, see "Specifying Client Traffic To Be Affected by the Custom Port Rule" later in this chapter.

# Specifying Client Traffic To Be Affected by the Custom Port Rule

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Port rules can be divided into two parts. The first part of a port rule identifies the client traffic to be affected by the port rule. You identify the client traffic affected by the port rule by specifying the cluster IP address and the TCP (or UDP) port range. Network Load Balancing examines all client requests and determines if a port rule applies to the client request.

The second part of a port rule determines the affinity and load-balancing characteristics of the cluster. For more information about the affinity and load-balancing characteristics of the cluster, see "Specifying the Affinity and Load-Balancing Behavior of the Custom Port Rule" later in this chapter.

Specify the client traffic to be affected by the port rule by completing the following steps:

1. Designate the value for the cluster IP address.
2. Specify the port range for the port rule as a starting port number (From) and an ending port number (To).
3. Specify the protocol for the port range that you specified.

**Note**

- For a Word document to assist you in documenting your port rule settings, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

**Designating the Value for the Cluster IP Address**

If you are specifying a:

- Global port rule for a cluster, specify All.
- Port rule for a virtual cluster, specify the virtual IP address for the virtual cluster.

For more information about deciding when to include virtual clusters in your design, see "Identifying Applications or Services That Require Custom Port Rules" earlier in this chapter.

**Specifying the Port Range**

Specify the port range for the port rule:

- Based on the TCP and UDP ports used by the applications and services running on the Network Load Balancing cluster.
- As a starting port number (From) and an ending port number (To).

For example, if your Network Load Balancing cluster supports Web applications that use only TCP port 80, you specify a starting port number of 80 and an ending port number of 80.

**Specifying the Protocol for the Port Range**

If the applications and services are using:

- TCP, specify TCP.
- UDP, specify UDP.
- Both TCP and UDP, specify Both.

# Specifying the Affinity and Load-Balancing Behavior of the Custom Port Rule

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The second part of a port rule affects the affinity and load-balancing behavior of the port rule. The affinity and load-balancing behavior of a port rule are specified by the filter mode of the port rule. Only one filter mode can be selected for each port rule. Table 8.8 describes the filter modes that are available.

**Table 8.8 Selecting the Filter Mode for the Port Rule**

| Filter Mode | Description |
|---|---|
| Multiple Hosts | Permits all cluster hosts to actively respond to client requests. This is the most common filter mode, because it allows the affinity and load-balancing characteristics to be customized. |
| Single Host | Allows only one cluster host in the cluster to actively respond to client requests. Could be useful when providing backup servers. For example, in an FTP site where users upload files, single host mode allows one host to receive FTP uploads. If the host fails, the host with the next highest priority takes over for the failed host. |
| Disable | Prevents the cluster from responding to a specific type of client traffic. |

**Note**

- For a Word document to assist you in documenting your port rule settings, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

#### Specifying Multiple Hosts Filter Mode Settings

The Multiple Hosts filter mode provides load balancing across multiple cluster hosts. One of the complexities introduced by load balancing is persistent relationships (affinity) between clients and cluster hosts. For more information about affinity, see "Identifying Applications or Services That Require Custom Port Rules" earlier in this chapter.

Another complexity introduced by load balancing is compensation for differences in cluster host system resources on the cluster over time. Based on differences in available system resources or applications, specific cluster hosts might not be capable of managing the same number of client requests. For more information about compensating for differences in cluster host system resources, see "Identifying Applications or Services That Require Custom Port Rules" earlier in this chapter.

Specify the settings for the Multiple Hosts filter mode by completing the following steps:

1. Preserve persistent application sessions by specifying the affinity between a client and a specific cluster host.

2. Compensate for differences in system resources by specifying the load weight settings.

#### Selecting the affinity between a client and a specific cluster host

You can override the default behavior by selecting other port rule affinity options. Table 8.9 lists the port rule affinity options and the reasons for selecting them.

**Table 8.9 Including Port Rule Affinity Options in Your Design**

| Option | Reasons for Selecting This Option |
|---|---|

| | |
|---|---|
| None | • You want to ensure even load balancing among cluster hosts.<br>• Client traffic is stateless (for example, HTTP traffic). |
| Single | • You want to ensure that requests from a specific client (IP address) are sent to the same cluster host.<br>• Client state is maintained across TCP connections (for example, HTTPS traffic). |
| Class C | • Client requests from a Class C IP address range (instead of a single IP address) are sent to the same cluster host.<br>• Clients use multiple proxy servers to access the cluster, and they appear to have multiple IP addresses within the same Class C IP address range.<br>• Client state is maintained across TCP connections (for example, HTTPS traffic). |

Single affinity is the most common selection when applications require that information about the user state be maintained across TCP connections. Examples of these types of applications include applications that use SSL or applications that retain user information, such as e-commerce shopping cart applications.

Applications that use SSL with Single affinity are efficient because the SSL session IDs are reused. Negotiating a new SSL session ID requires five times the amount of overhead as reusing a SSL session ID. Although negotiating the SSL session ID is transparent to the client, the cumulative increase in overhead could degrade the performance of the cluster.

Applications that retain user information can resolve the affinity requirement by using Network Load Balancing affinity or by using a common session state database or server. Applications that have a common session state database or server are combined with cookie-based affinity to allow any cluster host to restore the appropriate session state. If an application has a common session state database or server, you can select a port rule affinity of **None** if SSL is not part of the solution.

If an application retains user information by requiring that client transactions are completed on the same cluster host, select a port rule affinity of Single. For a discussion of when an application requires persistent connections to specific cluster hosts, along with an explicit discussion regarding SSL, see "Identifying Applications or Services That Require Custom Port Rules" earlier in this chapter.

Class C is used when Internet clients connect through proxy servers with different IP addresses within the same Class C IP address range. Some Internet service providers, such as America Online (AOL) in the United States, have proxy servers with different Class C IP addresses. Using different Class C IP addresses on the proxy servers can break the affinity between the client and the cluster host. In situations like this, other methods might be required to preserve cluster host affinity. For example, Application Center 2000 supports cookie-based affinity, which solves the problem of proxy servers with different Class C IP addresses. Alternatively, the application can be redesigned to maintain application session state in a common database or session state server, such as that provided by IIS 6.0 and ASP.NET. When possible, allow the application to maintain session state in this manner because the application will be more robust and scalable.

**Specifying the load weight settings for each cluster host**

The default port rule that is created during the installation of Network Load Balancing uses equal load weights. To override the default behavior, you can specify a custom load weight to be handled by each cluster host, as shown in Table 8.10.

**Table 8.10 Selecting the Method for Distributing Client Requests**

| Method | Description |
|---|---|
| Equal | Evenly distributes client requests across all cluster hosts when the available system resources are the same. |
| Load weight | Distributes client requests based on the available system capacity because of differences in the:<br>• Hardware configuration of each cluster host.<br>• Applications and services running on each cluster host. |

Specify the amount of client requests to be handled by each cluster host by completing one of the following steps:

- Specify Equal to ensure that client requests are evenly distributed across all cluster hosts, unless the cluster hosts do not have the same available system capacity.

- Otherwise, specify the load weight value for the cluster host.

  The load weight value can range from 0 (zero) to 100. You can prevent a cluster host from handling any client requests by specifying a load weight of 0.

  The percentage of client requests that are handled by each cluster host is computed by dividing the local load weight by the sum of all load weights across the cluster. Table 8.11 shows an example of the relationship between load weight and the percentage of client requests that are handled by each cluster host.

  **Table 8.11 Using Load Weights and Client Request Percentages**

| Cluster Host | Load Weight | Percentage of Client Requests |
|---|---|---|
| ClusterHost-A | 50 | 40% |
| ClusterHost-B | 50 | 40% |
| ClusterHost-C | 25 | 20% |

**Specifying Single Host Filter Mode Settings**

As with the cluster host priority setting for Network Load Balancing, which is discussed in "Specifying the Cluster Host Parameters" earlier in this chapter, you must specify the handling priority value for each cluster host that has the port rule.

Specify the handling priority for Single Host filter mode by completing the following steps:

1. Specify a value of 1 as the priority for the cluster host that will always handle the client traffic designated in the port rule criteria.

2. Increase the value assigned to the previous cluster host by 1, assign that value to the next cluster host, and repeat the process until you have specified the handling priority for all cluster hosts.

### Important

- If you specify the same handling priority for two cluster hosts, the last cluster host that starts will fail to join the cluster. An error message describing the problem will be written to the Windows system event log. The existing cluster hosts will continue to operate as before if cluster convergence completed previously. Otherwise, convergence must complete before traffic is handled by the cluster.

**Specifying Disable Filter Mode Settings**

As previously mentioned, the Disabled filter mode means that the client traffic corresponding to the port rule is blocked. Unlike the other filter modes, after you select this mode, no additional settings or values are required.

# Example: Controlling the Distribution of Client Traffic Within the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization implements the following solutions, which include Network Load Balancing, to reduce outages and improve performance:

- VPN remote access, based on Routing and Remote Access
- E-commerce Web applications, based on IIS 6.0
- A customer support FTP site, based on IIS 6.0

**VPN remote access solution with Routing and Remote Access**
The VPN remote access solution, based on Routing and Remote Access, provides remote access to the organization's private network by establishing PPTP and L2TP VPN tunnels through the Internet.

The VPN remote access server farm contains five servers that have identical system resources. Network Load Balancing is enabled on the network adapters connected to the Internet. A cluster IP address has been configured for the cluster, and the appropriate DNS entries have been determined but not yet created.

Because the default port rule provides the appropriate affinity and load balancing, no custom port rules are required for the cluster.

**E-commerce Web application solution with IIS 6.0**
The e-commerce Web application solution, based on IIS 6.0, includes the following applications:

- Web-based, e-commerce application built with static HTML
- Web-based, e-commerce application built with ASP

Both applications use:

- HTTPS (TCP port 443)
- HTTP (TCP Port 80)

The application that uses ASP maintains user session information after the user is authenticated.

The two e-commerce Web application solutions are combined on the same IIS 6.0 Web farm and, subsequently, the same Network Load Balancing cluster. The IIS 6.0 Web farm contains four computers that have identical system resources. Network Load Balancing is enabled on the network adapters connected to the Internet. A cluster IP address is configured for the cluster, and the appropriate DNS entries have been determined but not yet created.

To facilitate the combination of the two e-commerce Web applications into a single Web farm and cluster, each e-commerce application is assigned to a virtual cluster. By assigning each e-commerce application to a virtual cluster, client access can be stopped individually to allow operations tasks, such as upgrades, to be performed without disrupting client access to the other e-commerce application.

Table 8.12 lists the cluster, virtual cluster, and cluster hosts in the organization's e-commerce solution.

**Table 8.12 Network Load Balancing Clusters and Cluster Hosts in the E-Commerce Solution**

| Cluster Name | Solution | Type | Cluster Host |
|---|---|---|---|

| | | | |
|---|---|---|---|
| NLBCluster-B | Web-based, e-commerce applications | Cluster | • NLBClusterB-01<br>• NLBClusterB-02<br>• NLBClusterB-03<br>• NLBClusterB-04 |
| VirCluster-A | IIS 6.0 and HTML | Virtual cluster | Same as NLBCluster-B |
| VirCluster-B | IIS 6.0 and ASP | Virtual cluster | Same as NLBCluster-B |

Table 8.13 lists the port rules that meet the requirements of the e-commerce Web application solution that includes IIS 6.0 and Network Load Balancing.

**Table 8.13 Port Rules for IIS 6.0 E-Commerce Solution on NLBCluster-B**

| Cluster IP Address | Start | End | Protocol | Filtering Mode | Load Weight | Affinity |
|---|---|---|---|---|---|---|
| VirtualIP-A | 80 | 80 | TCP | Multiple | Equal | None |
| VirtualIP-A | 443 | 443 | TCP | Multiple | Equal | Single |
| VirtualIP-B | 80 | 80 | TCP | Multiple | Equal | Single |
| VirtualIP-B | 443 | 443 | TCP | Multiple | Equal | Single |

Because the port rules, listed in Table 8.13, have a specified load weight of Equal, the same port rules are used for all the cluster hosts. The virtual clusters, VirtualIP-A and VirtualIP-B, are dedicated to the respective e-commerce applications. Because both applications use HTTP (TCP port 80) and HTTPS (TCP port 443), port rules must be specified for each protocol in each virtual cluster.

**Customer support FTP site solution with IIS 6.0**

The customer support FTP site solution:

- Is based on IIS 6.0.
- Provides secured and unsecured access to files.
- Allows users to upload files to specified areas on the FTP site.
- Requires file uploads that are centralized on one FTP server to avoid users uploading duplicate files.
- Uses TCP port 20 for FTP.
- Uses TCP port 21 for FTP.

The customer support FTP site runs on an IIS 6.0 farm and, subsequently, a Network Load Balancing cluster. The IIS 6.0 farm contains three computers that have identical system resources. Network Load Balancing is enabled on the network adapters connected to the Internet. A cluster IP address has been configured for the cluster, and the appropriate DNS entries have been determined but not yet created.

To support the number of simultaneous users who are performing FTP downloads, all FTP download requests must be load balanced across the entire IIS 6.0 farm. However, to ensure that users upload files to only one location, FTP uploads must be directed to only one server in the IIS 6.0 farm.

To facilitate the differences in cluster host affinity between FTP uploads and downloads, each direction of FTP transfer is assigned to a different virtual cluster. By assigning FTP uploads to a virtual cluster and FTP downloads to another virtual cluster, the organization ensures that FTP downloads can be load balanced across all cluster hosts, while FTP uploads are sent to only one cluster host in the cluster.

Table 8.14 lists the cluster, virtual cluster, and cluster hosts selected in the organization's customer support FTP site solution.

**Table 8.14 Clusters and Cluster Hosts in the Customer Support FTP Site Solution**

| Cluster Name | Solution | Type | Cluster Host |
|---|---|---|---|
| NLBCluster-C | FTP site | Cluster | • NLBClusterC-01<br>• NLBClusterC-02<br>• NLBClusterC-03 |
| VirCluster-C | FTP download | Virtual cluster | All cluster hosts can be used for download. |
| VirCluster-D | FTP upload | Virtual cluster | NLBClusterC-03 is to be used for upload. |

Table 8.15 lists the port rules that meet the requirements of the organization's customer support FTP site solution, which includes IIS 6.0 and Network Load Balancing.

**Table 8.15 Port Rules for an IIS 6.0 FTP Site Solution on NLBCluster-C**

| Cluster IP Address | Start | End | Protocol | Filtering Mode | Load Weight | Affinity | Handling Priority |
|---|---|---|---|---|---|---|---|
| VirtualIP-C | 20 | 21 | TCP | Multiple Hosts | Equal | Single | NA |
| VirtualIP-D | 20 | 21 | TCP | Single Host | | | • NLBClusterC-03 = 1<br>• NLBClusterC-01 = 2<br>• NLBClusterC-02 = 3 |

The port rules that define VirCluster-C are identical for all the cluster hosts in NLBCluster-C. The port rules that define VirCluster-D are unique for each cluster host in NLBCluster-C, because the handling priority for each cluster host is unique. NLBClusterC-03 is the cluster host that is designated for FTP uploads, and it is assigned a handling priority of 1 to ensure that all file uploads are sent to NLBClusterC-03. The handling priority for NLBClusterC-01 and for NLBClusterC-02 must be unique and of a lower priority than for NLBClusterC-03.

# Specifying Cluster Network Connectivity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The scalability and availability improvements provided by your cluster depend on the network connectivity that is provided to the cluster. An improperly designed network infrastructure can cause client response-time problems and application outages. Specify the connections between the cluster and the client computers, the other servers within your organization's network, and the operation consoles to achieve the connectivity goals of your network.

The goals of network connectivity to the cluster are to provide:

- High-capacity network connectivity to ensure adequate client response time.
- Redundant routing and switching infrastructure.
- Restricted management of the cluster and cluster resources.
- Valid IP configuration for each network interface in each cluster host.

Specify the cluster network connectivity by completing the following steps:

1. Select the number of network adapters in each cluster host.
2. Select the unicast method or the multicast method of distributing incoming client requests to cluster hosts.
3. Include support for teaming network adapters.
4. Determine the network infrastructure requirements.

After you have specified the cluster network connectivity, document your decisions on your organization's network diagram (for example, on a Microsoft® Visio® drawing).

**Note**

- For a Word document to assist you in documenting your decisions, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

# Selecting the Number of Network Adapters in Each Cluster Host

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

At a minimum, you must connect each cluster host in your cluster to a network segment that has connectivity to the client computers. In most solutions, you need to connect each cluster host to other servers and to management and operations consoles in your organization.

With the appropriate cluster network connectivity, your solution will be properly secured, highly available, highly scalable, and easy to manage. Any design deficiencies in the cluster network connectivity portion of the design can compromise the security, availability, scalability, and manageability of the cluster.

Select the number of network adapters in each cluster host by completing the following steps:

1. Identify a network interface, referred to as the *cluster adapter*, which provides connectivity to the client computers.

   Include the appropriate IP configuration (IP address, subnet mask, and so forth) for the cluster adapter, so that the cluster host is on the same physical subnet or virtual subnet.

   All hosts of the same cluster must be on the same physical or virtual LAN (VLAN). In instances where the cluster hosts are not connected to the same physical subnet, ensure that the cluster hosts are connected to a virtual subnet. If all hosts are not connected to the same physical subnet, make sure that your routing and switch infrastructure supports virtual subnets.

2. Specify a network interface, referred to as the *management adapter*, which will provide connectivity to other servers within your organization and to management and operations consoles within your organization.

   Include the appropriate IP configuration (IP address, subnet mask, and so forth) for the management adapter.

**Important**

- To prevent unauthorized altering of the Network Load Balancing configuration, enable Network Load Balancing administration only on the management adapter. This is done by restricting traffic through your firewalls or routers.

In instances where only the cluster adapter is included and your applications require peer-to-peer communications between cluster hosts (beyond the cluster heartbeat traffic), see the discussion on unicast mode and multicast mode in "Selecting the Unicast or Multicast Method of Distributing Incoming Requests" later in this chapter.

Figure 8.7 illustrates cluster network connectivity that includes connectivity to clients, other servers in an organization, and management and operations consoles.

# Selecting the Unicast or Multicast Method of Distributing Incoming Requests

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

All cluster hosts in a cluster receive all incoming client requests that are destined for the virtual IP address that is assigned to the cluster. The Network Load Balancing load-balancing algorithm, which runs on each cluster host, is responsible for determining which cluster host processes and responds to the client request.

You can distribute incoming client requests to cluster hosts by using unicast or multicast methods. Both methods send the incoming client requests to all hosts by sending the request to the cluster's MAC address.

When you use the unicast method, all cluster hosts share an identical unicast MAC address. Network Load Balancing overwrites the original MAC address of the cluster adapter with the unicast MAC address that is assigned to all the cluster hosts.

When you use the multicast method, each cluster host retains the original MAC address of the adapter. In addition to the original MAC address of the adapter, the adapter is assigned a multicast MAC address, which is shared by all cluster hosts. The incoming client requests are sent to all cluster hosts by using the multicast MAC address.

Select the unicast method for distributing client requests, unless only one network adapter is installed in each cluster host and the cluster hosts must communicate with each other. Because Network Load Balancing modifies the MAC address of all cluster hosts to be identical, cluster hosts cannot communicate directly with one another when using unicast. When peer-to-peer communication is required between cluster hosts, include an additional network adapter or select multicast mode. When the unicast method is inappropriate, select the multicast method.

For more information about the interaction between the method of distributing incoming requests and layer 2 switches, see article Q193602, "Configuration Options for WLBS Hosts Connected to a Layer 2 Switches," in the Microsoft Knowledge Base. To find this article, see the Microsoft Knowledge Base link on the Web Resources page at www.microsoft.com/windows/reskits/webresources.

**Selecting the Unicast Method**

In the unicast method:

- The cluster adapters for all cluster hosts are assigned the same unicast MAC address.
- The outgoing MAC address for each packet is modified, based on the cluster host's priority setting, to prevent upstream switches from discovering that all cluster hosts have the same MAC address.

  The modification of the outgoing MAC address is appropriate for switches. When a hub is used to connect the cluster hosts, disable the modification of the outgoing MAC address. On Windows Server 2003, you can disable modification of outgoing addresses by setting the value of the registry entry **MaskSourceMAC**, of data type REG_DWORD, to 0x0. **MaskSourceMAC** is located in HKLM\SYSTEM\CurrentControlSet\Services\WLBS\Parameters\Interface*Adapter-GUID* (where *Adapter-GUID* is the long GUID assigned to the network adapter in the server).

  **Caution**

  - Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Windows Server 2003 Resource Kit Registry Reference on the *Microsoft Windows Server 2003 Deployment Kit* companion CD or at http://www.microsoft.com/reskit.
- The unicast MAC address is derived from the cluster's IP address to ensure uniqueness outside the cluster hosts.
- Communication between cluster hosts, other than Network Load Balancing–related traffic (such as heartbeat), is only available when you install an additional adapter, because the cluster hosts all have the same MAC address.

Although the unicast method works in all routing situations, it has the following disadvantages:

- A second network adapter is required to provide peer-to-peer communication between cluster hosts.
- If the cluster is connected to a switch, incoming packets are sent to all the ports on the switch, which can cause switch flooding.

**Selecting the Multicast Method**

In the multicast method:

- The cluster adapter for each cluster host retains the original hardware unicast MAC address (as specified by the hardware manufacture of the network adapter).
- The cluster adapters for all cluster hosts are assigned a multicast MAC address.
- The multicast MAC is derived from the cluster's IP address.
- Communication between cluster hosts is not affected, because each cluster host retains a unique MAC address.

By using the multicast method with Internet Group Membership Protocol (IGMP), you can limit switch flooding, if the switch supports IGMP *snooping*. IGMP snooping allows the switch to examine the contents of multicast packets and associate a port with a multicast address. Without IGMP snooping, switches might require additional configuration to tell the switch which ports to use for the multicast traffic. Otherwise, switch flooding occurs, as with the unicast method.

The multicast method has the following disadvantages:

- Upstream routers might require a static Address Resolution Protocol (ARP) entry. This is because routers might not accept an ARP response that resolves unicast IP addresses to multicast MAC addresses.
- Without IGMP, switches might require additional configuration to tell the switch which ports to use for the multicast traffic.
- Upstream routers might not support mapping a unicast IP address (the cluster IP address) with a multicast MAC address. In these situations, you must upgrade or replace the router. Otherwise, the multicast method is unusable.

# Including Support for Teaming Network Adapters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Many hardware vendors support *teaming network adapters* to increase network bandwidth capacity and to provide an additional level of network redundancy. Teaming network adapters are multiple network adapters in the same computer that logically act as a single, virtual network adapter. The virtual network adapter can provide load balancing of traffic between the physical network adapters or automatic failover in the event that one of the network adapters fails.

Teaming network adapter drivers and Network Load Balancing both try to manipulate the MAC addresses of the network adapters. As a result, teaming network adapters might work only in limited configurations. As a general rule, avoid including teaming network adapters in your Network Load Balancing solutions.

**Note**

- Because each implementation of teaming network adapters is vendor-specific, the support for teaming network adapters is provided by the hardware vendor, and it is beyond the scope of Microsoft Product Support Services. For more information about teaming network adapters in your Network Load Balancing solution, consult the teaming network adapter hardware recommendations.

# Determining the Network Infrastructure Requirements

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The network infrastructure affects your Network Load Balancing solution more than any other component. No matter how much Network Load Balancing enables you to scale out your solution, an inadequate routing and switching infrastructure can create a number of problems.

Even if you optimize the Network Load Balancing cluster, an inadequate routing and switching infrastructure can restrict available network throughput and prevent clients from achieving any improvement in response times. Additionally, an inadequate routing and switching infrastructure can allow a single failure in a router, switch, or network path to disrupt communications with the cluster.

Determine the network infrastructure requirements for your cluster by completing the following steps:

1. Determine the IP subnet requirements for the cluster.

2. Determine how the cluster handles inbound and outbound traffic.

3. Determine when to include switches or hubs to connect cluster hosts to one another.

For more information about how the network infrastructure affects availability, see "Ensuring Availability in NLB Solutions" later in this chapter. For more information about how the network infrastructure affects scalability, see "Scaling NLB Solutions" later in this chapter.

**Determining Cluster IP Subnet Requirements**

Network Load Balancing requires that all cluster hosts be on the same IP subnet or virtual IP subnet (VLAN). This is because all cluster hosts share the cluster's virtual IP address. The routing infrastructure sends client requests to all cluster hosts by using a virtualized unicast MAC address or a multicast MAC address. For more information about unicast and multicast addressing, see "Selecting the Unicast or Multicast Method of Distributing Incoming Requests" earlier in this chapter.

**Determining How the Cluster Handles Inbound and Outbound Traffic**

Network Load Balancing cluster traffic is handled differently for inbound and outbound traffic. The differences between inbound client requests and outbound responses affect the network infrastructure and the use of switches and hubs.

Inbound cluster traffic is sent to all cluster hosts by using broadcasts or multicast traffic, which is required so that all cluster hosts can receive the inbound traffic. Switches learn where to send packets by watching the source packets that are sent from the computers directly connected to the switch. After the switch learns a computer's location, the switch sends subsequent packets to the same switch port.

From an inbound-traffic perspective, the behavior of the switch is similar to a hub, because inbound cluster traffic is sent to all switch ports. However, from an outbound-traffic perspective, the switch provides isolation by preventing other cluster hosts from seeing a response to a client from the cluster host that services the client request.

For more information about the behavior of Network Load Balancing traffic, see the Network Load Balancing Technical Overview link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources.

**Determining When to Include Switches or Hubs for Interconnecting Cluster Hosts**

For most networks, switches are the preferred technology for connecting network devices to one another. Although many existing network infrastructures have hubs, switches are typically used in new deployments.

Although Network Load Balancing works in most configurations of switches and hubs, some configurations allow for optimal performance, and they provide ease of maintenance and operations. The recommended configuration is to use switches for interconnecting cluster hosts. Configurations that include hubs are also supported, but they require more complex network infrastructure and configuration.

The supported configurations for switches and hubs include:

- Cluster hosts connected to a switch that is dedicated to the cluster.

- Cluster hosts connected to a switch that is shared with other devices.

- Cluster hosts connected to a hub that is connected to a switch.

**Cluster hosts connected to a switch that is dedicated to the cluster**
In this configuration, the cluster hosts connect to a switch that is dedicated to the cluster. Because the inbound cluster traffic is sent to all ports on the switch, the primary advantage of a switch for inbound traffic — segregating traffic to a limited number of switch ports — is lost.

However, for outbound traffic, only the cluster host responding to the client request is aware of the traffic, because the switch isolates the outbound traffic to the port connected to the responding cluster host. This reduces the congestion of traffic for all the cluster hosts that are connected to the switch.

**Cluster hosts connected to a switch that is shared with other devices**
In this configuration, the cluster hosts are connected to a switch that is shared with other devices. The switch sends inbound cluster traffic to the other devices as well, creating unnecessary traffic for the other devices.

You can isolate the inbound cluster traffic to only the cluster hosts by establishing a VLAN comprising the ports that connect to the cluster hosts. After you establish the VLAN, inbound cluster traffic is sent only to the cluster hosts and not to the other devices that are attached to the same switch. Using a VLAN to segregate inbound client traffic works for the unicast or multicast method of distributing incoming requests. You can also use the multicast method with IGMP to limit inbound cluster traffic only to the cluster hosts.

Because outbound cluster traffic is sent directly to the client that originated the request, only the cluster host responding to the request sees the outbound cluster traffic. All other cluster hosts, and the other devices connected to the same switch, are unaware of the outbound cluster traffic.

**Cluster hosts connected to a hub that is connected to a switch**
From the perspective of inbound cluster traffic, a switch provides no additional benefit over a hub, except for being able to define a VLAN that isolates inbound traffic from other devices attached to the switch. Because all cluster hosts receive the inbound cluster traffic, the switch sends all inbound traffic to all ports that are attached to the switch (or ports that are assigned to the same VLAN).

From the perspective of outbound cluster traffic, a switch provides a greater advantage, because it reduces the network contention for outbound cluster traffic. With a switch, only the cluster host originating the outbound cluster traffic is aware of the traffic, because outbound traffic is switched. Using a hub causes network contention for all cluster hosts. With a hub, all cluster hosts receive, and subsequently determine if they need to process, the outbound cluster traffic.

To eliminate the network contention caused by using a hub, install an additional network adapter in each cluster host for the purpose of responding to client traffic. Inbound requests are received through the cluster adapters in each cluster host, while the outbound responses are sent to the clients through the additional network adapter.

Because of the increased complexity of configuration (adding an additional network adapter to each cluster host) and network infrastructure (adding an additional switch to connect all the additional network adapters to the clients), this is not a recommended configuration. Because a switch is required for the additional network adapters, it is easier to eliminate the additional network adapters and connect the cluster adapters to a switch.

If you are considering adding network adapters to improve cluster performance, consider increasing the data rate of the cluster network adapters and corresponding network infrastructure, instead of adding network adapters. For example, to increase available network bandwidth, specify 100 megabits per second (Mbps) network adapters instead of 10 Mbps network adapters (along with the appropriate upgrades to intermediary switches and routers). For more information about increasing the available network bandwidth to the cluster, see "Increasing Available Network Bandwidth to the Cluster" later in this chapter.

# Example: Specifying Cluster Network Connectivity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization has e-commerce Web applications that are accessed by users on the Internet. The organization's design includes Network Load Balancing to eliminate any application outages and improve performance. The e-commerce Web applications, running on IIS 6.0 and Windows Server 2003, will reside in the organization's perimeter network, which is located between the Internet and the organization's private network.

Figure 8.8 illustrates the existing firewalls, Internet connectivity, and connectivity to the organization's private network.

**Figure 8.8 Existing Network Diagram Before the E-Commerce Web Application Solution**

The e-commerce Web application requires support for 1,500 simultaneous users and an acceptable data transfer rate of 10 kilobits per second (Kbps) for each user, for a total aggregate data rate of 15 Mbps.

The organization has conducted lab testing on the devices in the organization's design, including routers, switches, network segments, and servers, and it has determined their capacity as listed in Table 8.16.

**Table 8.16 Device Capacity Results from Lab Testing**

| Device | Results Verified in the Lab |
|---|---|
| IIS server | • Supports 200 simultaneous users.<br>• Provides total aggregate data rates up to 50 Mbps. |
| Router | • Supports virtual IP subnets (VLANs).<br>• Provides total aggregate data rate of 20 Mbps.<br>• Requires manual ARP registration of a unicast IP address with a multicast MAC address. |
| Switch | • Supports virtual IP subnets (VLANs).<br>• Provides total aggregate data rate of 60 Mbps. |

Figure 8.9 illustrates the organization's network infrastructure after including the e-commerce Web solution.

**Figure 8.9 E-Commerce Web Solution with Network Load Balancing**

Table 8.17 lists the design decisions in specifying cluster network connectivity and the reasons for making the decisions.

**Table 8.17 Cluster Network Connectivity Design Decisions and Their Justification**

| Decision | Reason for the Decision |
|---|---|
| Include eight IIS servers (cluster hosts). | Each IIS server supports a maximum of 200 users, and eight servers are required to achieve 1,500 simultaneous users. |
| Specify unicast mode for distributing incoming client requests. | Network infrastructure supports unicast mode. |
| Specify VLAN-01 between Switch-01 and Switch-02. | All hosts on the cluster must belong to the same IP subnet. |
| Place cluster hosts on Switch-01 and Switch-02. | Bandwidth of a single switch is insufficient to handle cluster host traffic. |

# Ensuring Ease of Cluster Management and Operations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After your Network Load Balancing cluster is deployed, the operations staff in your organization takes primary responsibility for the day-to-day operations of the cluster. In addition to normal administration tasks required to maintain the operating system, such as applying service packs and upgrading the operating system, over the IT life cycle of your cluster, the operations team also maintains and upgrades applications on the cluster.

Follow the guidelines presented in Table 8.18 to help create Network Load Balancing clusters that are easier to manage and operate.

**Table 8.18 Guidelines for Designing NLB Clusters for Easy Management**

| Guideline | Explanation |
|---|---|
| Include sufficient cluster hosts to support maintenance and failover needs. | Cluster management is easier if enough cluster hosts exist to support client requests when one of the hosts is offline due to maintenance, upgrade, or failure. During lab testing, determine the number of cluster hosts required to support the required client traffic, and then add at least one additional cluster host. |
| Create a network infrastructure design that can accommodate a change in the number of cluster hosts. | The network infrastructure design must be flexible enough to allow the removal and addition of cluster hosts. When creating the supporting network infrastructure design, include additional ports on the switches or hubs connecting cluster hosts to support the addition of cluster hosts, as required.<br><br>By adding additional network infrastructure support, cluster hosts can be added easily by the operations team without redesigning or recabling the existing network infrastructure. |

During the IT life cycle of the cluster, upgrades are performed on the cluster by the operations team. The operations team typically performs these as *rolling upgrades*, by upgrading individual cluster hosts, one at a time, until the entire cluster is upgraded. For more information about performing rolling upgrades, see "Deploying Network Load Balancing" in this book.

Scaling out improves cluster performance by adding cluster hosts to the cluster and distributing client traffic across more cluster hosts. For more information about scaling your cluster, see "Scaling NLB Solutions" later in this chapter.

# Example: Ensuring Ease of Cluster Management and Operations

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization has five mission-critical applications that must be run by remote users. These remote users connect to the organization's private network through a VPN tunnel. The remote users run the applications on servers running Terminal Services.

Because of the number of simultaneous remote users, three servers running Terminal Services are required. The number of servers was determined during the lab-testing phase of the solution. To provide load balancing and fault tolerance, the servers are part of a Network Load Balancing cluster.

The number of remote users that simultaneously access the Terminal Services farm is expected to increase over the lifetime of the farm. Also, the applications running on the farm need to be upgraded periodically, and this requires that the servers be restarted.

Table 8.19 lists the design decisions for ensuring the cluster is easier to maintain and operate and the reasons for making the decisions.

**Table 8.19 Cluster Maintenance and Operations Decisions and Their Justification**

| Decision | Reason for the Decision |
|---|---|
| Include an additional cluster host. | Ensures that the upgrades to individual servers in the Terminal Services farm can be performed without affecting client response times. |
| Provide unused ports on Switch-01. | Provides expansion for the addition of cluster hosts (servers running Terminal Services). |

Figure 8.10 illustrates the network infrastructure after the optimization of the design to ensure ease of cluster management and operations.

**Figure 8.10 Infrastructure Optimized for Ease of Cluster Management and Operations**

# Securing NLB Solutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The fact that your solution requires Network Load Balancing indicates that the applications and services are critical to the operations of your organization. The stability and integrity of your solution depend on how secure you make the resources that are used by the applications services. Besides protecting confidential data, the security that you include in your design ensures the stability of your applications and services. Use the features of Windows Server 2003 to protect the resources and applications running on cluster hosts. Plan security for your network load balancing solution immediately after determining the core specifications for your Network Load Balancing design, as illustrated in Figure 8.11.

**Figure 8.11 Securing Network Load Balancing Solutions**

**Note**

- For a Word document to assist you in documenting your security settings, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

One of the most important methods of protecting resources and applications on Network Load Balancing clusters is to ensure that only authorized users can remotely manage your clusters. To remotely manage clusters, users must be members of the local Administrators group on every cluster host in the cluster.

**Note**

- Users who are members of the local Administrators group can administer Network Load Balancing locally, regardless of other restrictions.

Ensure that only authorized users can remotely manage clusters by following these practices:

- Specify that remote management by using Nlb.exe be disabled on all cluster hosts.

  By default, remote management through Nlb.exe is disabled on clusters. Remote administration by using Nlb.exe is not recommended, because this method presents many security risks, including the possibility of data tampering, denial-of-service attacks, and information disclosure.

  If you choose to enable remote control for Nlb.exe, restrict access by specifying a strong remote-control password. Also, include a firewall to protect the Network Load Balancing UDP ports (the ports that receive remote control commands) by allowing access only to authorized client computers.

- Specify that Network Load Balancing Manager be used for all administration.

- Specify that administration be performed only from a secure, trusted computer that is within your organization's private

network or that is connected through a VPN remote access connection.

In addition to the security provided by restricting the administration of Network Load Balancing, you can further protect the applications, services, and confidential data on the cluster by using other Windows Server 2003 security features. These security features are specific to the applications and services running on the cluster. For more information about the security features provided by the applications and services running on the cluster, see the security content for the documents listed in "Additional Resources for Deploying Network Load Balancing" later in this chapter.

# Example: Securing NLB Solutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization has e-commerce Web applications that are accessed by Internet users. The design includes Network Load Balancing to eliminate any application outages and improve performance. The e-commerce Web applications, running on IIS 6.0 and Windows Server 2003, resides in the organization's perimeter network, which is located between the Internet and the organization's private network.

Figure 8.12 illustrates the e-commerce Web farm network design after the placement of the following components:

- Network infrastructure, including firewalls, routers, switches, and network segments
- IIS 6.0 servers into the perimeter network
- Active Directory® directory service domain controllers
- A computer running Windows Server 2003 and SQL Server 2000 on a server cluster
- A computer running Windows Server 2003 and file services on a server cluster

**Figure 8.12 IIS 6.0 E-Commerce Web Farm Solution**

Table 8.20 lists the design decisions that were made to protect the applications and resources on the cluster and the reasons for making those decisions.

**Table 8.20 Cluster Security Design Decisions**

| Decision | Reason for the Decision |
|---|---|
| IIS 6.0 servers are placed behind Firewall-01 and Firewall-02. | Prevents unwanted client traffic by filtering unnecessary client traffic. |
| Isolated network for communication is placed between the cluster and other servers in organization. | Prevents users outside the organization from viewing communications between the cluster and other servers in the organization. |

| | |
|---|---|
| Remote management is disabled. | Prevents unauthorized users from managing the cluster. |

# Scaling NLB Solutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

One of the primary reasons for including Network Load Balancing in your network design solution is to provide the ability to scale out your network by adding additional servers. Any other methods of improving client response times are not directly related to Network Load Balancing, but rather to the network infrastructure and system hardware associated with the cluster. Figure 8.13 illustrates the steps involved in incorporating scaling options in your Network Load Balancing solution.

**Figure 8.13 Scaling Network Load Balancing Solutions**

Also, you can ensure the scalability of applications and services by using methods that are specific to the applications and services running on the cluster. For more information about improving the scalability of services running on Network Load Balancing, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

**Note**

- Document your design on your organization's network diagram. For a Word document to assist you in documenting your Network Load Balancing design decisions, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

# Scaling Up the Solution by Adding System Resources

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

During the lab testing and pilot testing of your Network Load Balancing design, you might discover that the cluster hosts are not responding within the requirements for your solution. Also, as you anticipate the increase in growth that your design must support, the cluster hosts need to continue to respond in accordance with your solution requirements. When a cluster becomes unable to respond the client requests within a specified time, you can improve the performance by *scaling up* your solution.

Take the following actions to scale up your solution:

- Increase system resources (such as processors, memory, disks, and network adapters) for the existing cluster host.
- Replace the existing cluster host with another system that has greater resources.

Scaling up is appropriate in the following situations:

- You want to reduce the total cost of ownership (TCO) by including fewer, more powerful cluster hosts in your design.
- The client response time is insufficient for a cluster host that is supporting the required number of users.

Scale up your solution by adding system resources by completing the following steps:

1. Identify the applications or services running on the Network Load Balancing cluster.
2. Identify the system resources that are consumed by the applications or services running on the cluster.

   Because Network Load Balancing requires only minimal system resources, the applications and services running on the cluster determine the system resources that are consumed first. For more information about the system resource requirements for services running on Network Load Balancing, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.
3. Verify the system resource estimates in your deployment lab.
4. Modify the system resource requirements based on the data from your testing in the deployment lab.
5. Document the system requirements in your design.

**Note**

- You can reduce the system resource requirements for your cluster hosts and avoid scaling up by eliminating any unnecessary applications or services. For more information about the required applications or services in your solution, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

# Scaling Out the Solution by Adding Cluster Hosts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Another method that you can use to improve client response time is *scaling out*. You scale out your solution when you add cluster hosts to existing clusters.

Scaling out your solution is appropriate in the following situations:

- You want to reduce TCO by including more, less-expensive cluster hosts in your design.
- You cannot further upgrade the system resources of the existing cluster hosts.

**Tip**

- To further improve client response time, consider scaling up the cluster host system resources as you scale out.

Scale out your solution by adding cluster hosts to the cluster and completing the following steps:

1. Identify the applications or services that require scaling out.
2. Identify any port rules that are associated with the application or services.
3. Include the additional cluster hosts in the cluster.
4. When appropriate, divide the cluster hosts into separate clusters and use round robin DNS to distribute client traffic across the clusters.

# Scaling Out Within a Single Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Determine the number of cluster hosts that are required in your design by estimating the number of clients each host can support and then testing your estimates in your lab. The maximum number of clients that each cluster host can support depends on the applications and services running on the host. For more information about capacity planning for the applications and services running on Network Load Balancing clusters, see "Additional Resources for Designing Network Load Balancing" later in this chapter.

The maximum number of cluster hosts in a cluster depends on a number of factors, such as the network infrastructure or protocols used by the applications and services running on the cluster, in addition to any Network Load Balancing limitations.

The only method of determining the maximum number of hosts in a cluster is by testing your configuration in a lab. When your lab tests indicate that you are unable to support the number of simultaneous clients by scaling out within a single cluster, scale out by using multiple clusters.

Network infrastructure devices, such as routers or switches, can also limit the network throughput to the cluster and ultimately affect how much you can scale out a cluster. To overcome this limitation, you can increase the network infrastructure capacity by changing the number and placement of routers and switches. However, the changes to the network infrastructure capacity might prevent you from keeping the cluster hosts on the same subnet or VLAN. Because all the cluster hosts must be on the same subnet or VLAN, scaling out with a single cluster is inadequate and you must scale out by using multiple clusters on separate subnets or VLANs.

# Scaling Out by Using Multiple Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are unable to scale out your applications on a single cluster, you can scale out by using multiple clusters. Then distribute the client traffic across the multiple clusters by using round robin DNS.

For example, an organization is getting ready to deploy a new high-volume Web site for its Internet presence. To support the required number of client requests, 72 cluster hosts are necessary. In lab testing, the organization determines that the network infrastructure can support only 9 clusters hosts per VLAN. As a result, eight clusters are required to scale out the organization's Web farm. Table 8.21 lists the clusters and the IP addresses that are assigned to each cluster.

**Table 8.21 Clusters and Their IP Addresses in Round-Robin DNS**

| Network Load Balancing Cluster | Assigned IP Address |
|---|---|
| IISNLB-01 | 10.0.1.100 |
| IISNLB-02 | 10.0.2.100 |
| IISNLB-03 | 10.0.3.100 |
| IISNLB-04 | 10.0.4.100 |
| IISNLB-05 | 10.0.5.100 |
| IISNLB-06 | 10.0.6.100 |
| IISNLB-07 | 10.0.7.100 |
| IISNLB-08 | 10.0.8.100 |

Figure 8.14 illustrates an IIS 6.0 Web farm in which client traffic is distributed across multiple Network Load Balancing clusters by using round robin DNS.

**Figure 8.14 Using Round Robin DNS to Distribute Client Traffic Across Clusters**

The DNS name of the IIS 6.0 application Web farm is www.contoso.com. The DNS zone for contoso.com contains multiple

entries for www.contoso.com, as required by round robin DNS. Each DNS entry corresponds to a Network Load Balancing cluster in the IIS 6.0 application Web farm. Round robin DNS distributes client traffic to the clusters, and then Network Load Balancing distributes client traffic within the cluster.

One of the assumptions in combining Network Load Balancing and round robin DNS is that an entire cluster is never taken offline. When an entire cluster is offline, DNS still directs client requests to the offline cluster and some clients will experience service outages, as they do when round robin DNS entries point to an individual server that is offline. To prevent clients from experiencing service outages, take only individual cluster hosts offline for maintenance or for other reasons.

For more information about round robin DNS, see "Deploying DNS" in *Deploying Network Services* of this kit.

# Increasing Available Network Bandwidth to the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Other steps in improving client response time directly affect the cluster hosts themselves. However, even with a highly optimized cluster, inadequate network bandwidth between the clients and the cluster can increase client response times to unacceptable levels.

Increase the available bandwidth between clients and the cluster by completing the following steps:

1. Identify the intermediary network segments, routers, and switches between the clients and the clusters.

2. Calculate the aggregate bandwidth requirements for the maximum number of simultaneous users.

3. Determine the intermediary network segments, routers, and switches between the clients and the clusters that are unable to support the aggregate bandwidth requirements.

4. Modify your design to increase the available bandwidth, based on the information in Table 8.22.

**Table 8.22 Increasing Bandwidth Based on Network Infrastructure Limitations**

| Available Bandwidth Limited By | Increase Bandwidth by One or More of These Methods |
|---|---|
| Network segment available capacity | • Increase the data rate of the network segment. (Upgrade from Integrated Services Digital Network (ISDN) to digital subscriber line (DSL) or T1.)<br>• Include additional network segments, and distribute the network traffic across the network segments. |
| Switch capacity | • Increase the data rate of the switch and the devices that are connected to the switch. (Upgrade from 10BaseT to 100BaseT or 1000BaseT.)<br>• Include additional switches, and distribute the computers that are connected to the original switch across the switches. |
| Router capacity | • Increase the data rate of the router and the devices that are connected to the router. (Upgrade from 10BaseT to 100BaseT or 1000BaseT.)<br>• Include additional routers, and create redundant routes to load balance the network traffic between the routers. |

# Example: Scaling NLB Solutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization provides VPN remote access to the organization's users through the Internet. The design includes Network Load Balancing to eliminate any application outages and to improve performance. The VPN remote access servers, which run Routing and Remote Access and Windows Server 2003, reside in the organization's perimeter network, which is located between the Internet and the organization's private network.

Pilot testing of the VPN remote access solution indicates the need for an increase in remote access client performance. Figure 8.15 illustrates the Routing and Remote Access VPN design to be tested.

**Figure 8.15 VPN Solution Pilot Test Environment**

Table 8.23 lists the results of the pilot test for each portion of the design that is illustrated in Figure 8.15.

**Table 8.23 Results of VPN Pilot Test**

| Design Portion Tested | Results |
|---|---|
| Network infrastructure | • Router-01 was saturated with client traffic.<br>• Switch-01 was saturated with client traffic.<br>• The network segment between Switch-01 and Router-01 was saturated.<br>• The connection to the Internet was saturated. |
| Cluster hosts hardware | • Individual cluster hosts lacked sufficient memory to handle the required number of simultaneous users.<br>• The total number of cluster hosts was insufficient to handle total number of simultaneous users. |

After the pilot test, the organization modifies the VPN remote access design. Figure 8.16 illustrates the modified version of the VPN design.

**Figure 8.16 Revised VPN Remote Access Design**

The organization made the following design decisions to improve scalability for the cluster:

- Add Firewall-02 and Router-02 to provide additional network bandwidth to the Internet and to solve the saturation problem on Router-01.
- Add Switch-02 to provide additional network bandwidth to the Internet and to solve the saturation problem on Switch-01.
- Add memory for all cluster hosts to ensure sufficient system resources for the hosts.
- Add VPN-07 and VPN-08 to support the maximum number of simultaneous users.

# Ensuring Availability in NLB Solutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By including multiple cluster hosts that provide the same applications and services, Network Load Balancing inherently provides fault tolerance. However, to provide a complete high-availability solution, your design must include more than just Network Load Balancing. The network infrastructure and system hardware that are associated with the cluster also affect the availability of the applications and services running on the cluster. In addition, include application-level monitoring, such as the monitoring provided by MOM or Application Center 2000, to ensure that applications are operating correctly. Ensuring availability is the final task in designing a network load balancing solution, as shown in Figure 8.17.

**Figure 8.17 Ensuring Availability in Network Load Balancing Solutions**

Include the following items to ensure high availability for clients that access applications and services on the cluster:

- Cluster hosts with fault-tolerant hardware
- Signed device drivers and software only
- Fault-tolerant network infrastructure

Also, you can improve the availability of applications and services by using methods that are specific to the applications and services running on the cluster. For more information about improving the availability of services running on Network Load Balancing, see "Additional Resources for Designing Network Load Balancing" later in this chapter.

**Note**

- After you design the specifications for ensuring availability, document your decisions. For a Word document to assist you in recording your decisions, see "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

#### Including Fault-Tolerant Hardware on Cluster Hosts

The cluster host hardware that you specify in your design can affect the uptime of the applications and services in your solution. Including system hardware with a longer mean time between failure (MTBF) can ensure that you experience fewer cluster host failures. In addition, including cluster hosts with fault-tolerant hardware can prevent unnecessary outages in your cluster.

For more information about including fault-tolerant hardware in your design, see "Planning for High Availability and Scalability" in this book.

#### Including Signed Device Drivers and Software Only

Another method of improving application and services uptime is to include only signed device drivers and software on the cluster hosts. Drivers and software that are signed have been certified by Microsoft, your organization, or third-party

companies that your organization trusts. Because unstable drivers and software can affect cluster uptime, including only signed device drivers and software helps ensure the stability of the cluster.

You can specify Group Policy settings in Active Directory to centrally configure the cluster hosts for the appropriate driver signing settings. When you are unable to specify driver signing by using Active Directory, specify the Local Security policies for each cluster host.

For more information about signed device drivers and software, see "Driver signing for Windows" in Help and Support Center for Windows Server 2003. For more information about specifying Group Policy settings, see "Designing a Group Policy Infrastructure in *Designing a Managed Environment* of this kit.

**Including a Fault-Tolerant Network Infrastructure**

Even if you perform all the previous steps to ensure fault tolerance for improving application and services uptime, your solution is not complete. Even with a highly optimized cluster, failures in the network infrastructure between the clients and the cluster can reduce uptime for applications and services.

To include a fault-tolerant network infrastructure between the clients and the cluster, complete the following steps:

1. Identify the intermediary network segments, routers, and switches between the clients and the cluster.

2. Determine if any of the intermediary network segments, routers, and switches between the clients and the cluster are potential points of failure that can cause application and services outages.

3. Modify your design to provide a fault-tolerant network infrastructure, based on the information in Table 8.24.

**Table 8.24 Providing Network Infrastructure Fault Tolerance Based on Limitations**

| Potential Failure Points | Include Any of These Fault-Tolerance Solutions |
|---|---|
| Network connection failure | Redundant network connections to provide fault tolerance in the event that a network connection fails. For example, if you are connected to the Internet by a single T1 connection, a failure of the T1 connection would prevent clients from accessing the cluster. Specify a redundant T1 connection to help prevent this type of failure. |
| Switch failure | Redundant switches to provide fault tolerance in the event that a switch fails. |
| Router failure | Redundant routers and redundant routes to provide fault tolerance in the event that a router fails. |

# Example: Ensuring Availability in NLB Solutions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization provides VPN remote access to the organization's users through the Internet. The organization's design includes Network Load Balancing to eliminate any application outages and improve performance. The VPN remote access servers, running Routing and Remote Access and Windows Server 2003, reside in the organization's perimeter network, which is located between the Internet and the organization's private network.

The design includes ISA Server, which protects the VPN remote access servers in the perimeter network. The ISA Server servers are in a cluster (ISANLB-01) that provides load balancing and fault tolerance.

During the pilot testing of the Web content caching solution, with ISA Server, the deployment team experiences a number of outages that affect the entire solution. Figure 8.18 illustrates the Web content caching design, incorporating ISA Server, that is tested.

**Figure 8.18 VPN Remote Access Test Environment**

Table 8.25 lists the results of the pilot test for each portion of the design that is illustrated in Figure 8.18.

**Table 8.25 Results of VPN Pilot Test**

| Design Portion Tested | Results |
|---|---|
| Network infrastructure | • A failure of Router-01 resulted in total outage of VPN services.<br>• A failure of Switch-01 resulted in total outage of VPN services.<br>• A total outage of VPN services occurred for failure of the network segment between Router-01 and the Internet, or between Switch-01 and Router-01. |

| | |
|---|---|
| Cluster host hardware | • A failure of a disk drive in a cluster host resulted in a total cluster host failure.<br>• Network adapters in the cluster hosts have unsigned device drivers. |

After the pilot test, the VPN remote access design is modified. Figure 8.19 illustrates the modified version of the VPN design.

**Figure 8.19 Revised VPN Remote Access Design**

Table 8.26 lists the design decisions that the organization makes to improve the uptime for the VPN remote access solution and the reasons for making those decisions.

**Table 8.26 Improving VPN Solution Uptime Design Decisions and Their Justification**

| Decision | Reason for the Decision |
|---|---|
| Added Router-02 and additional Internet connection. | Provides a redundant route path to the Internet in the event that Router-01 or the corresponding Internet connection fails. |
| Added Switch-02. | Provides redundant paths in the event that Switch-01 fails. |
| RAID disk controllers were used in each cluster host. | Provide disk fault tolerance to help prevent disk failures and cluster host failures. |
| Group Policy was established to allow cluster hosts to load signed device drivers. | Provides trusted software to help ensure a stable environment, and prevents cluster host failure. |

# Additional Resources for Designing Network Load Balancing

Updated: March 28, 2003

# Deploying Network Load Balancing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After completing the design for the applications and services in your Network Load Balancing cluster, you are ready to deploy the cluster running the Microsoft® Windows® Server 2003 operating system in your pilot and production network environments. A successful deployment ensures that your Network Load Balancing cluster meets or exceeds the specifications in the design. In addition, you must ensure that the deployment of your Network Load Balancing cluster does not disrupt the operation of any existing applications or services.

**In This Chapter**

Overview of the NLB Deployment Process

Selecting the Automated Deployment Method

Implementing a New Cluster

Upgrading Existing Clusters

Migrating Existing Clusters

Additional Resources for Deploying Network Load Balancing

**Related Information**

- For more information about the Network Load Balancing design process, see "Designing Network Load Balancing" in *Planning Server Deployments* of this kit.
- For more information about designing server clusters, see "Designing and Deploying Server Clusters" in *Planning Server Deployments*.

# Overview of the NLB Deployment Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A Network Load Balancing cluster comprises multiple servers running any version of the Windows Server 2003 family of operating systems, including Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Datacenter Edition; and Windows® Server 2003, Web Edition.

Clustering allows you to combine application servers to provide a level of scaling and availability that is not possible with an individual server. Network Load Balancing distributes incoming client requests among the servers in the cluster to more evenly balance the workload of each server and prevent overload on any one server. To client computers, the Network Load Balancing cluster appears as a single server that is highly scalable and fault tolerant.

The Network Load Balancing deployment process assumes that your design team has completed the design of the Network Load Balancing solution for your organization and has performed limited testing in a lab. After the design team tests the design in the lab, your deployment team implements the Network Load Balancing solution first in a pilot environment and then in your production environment.

Upon completing the deployment process presented here, your Network Load Balancing solution (the Network Load Balancing cluster and the applications and services running on the cluster) will be in place. For more information about the procedures for deploying Network Load Balancing on individual servers, see "New ways to do familiar tasks" in Help and Support Center for Windows Server 2003, and then click "Network Load Balancing Manager".

**Note**

- As you implement your Network Load Balancing design, use the information for each cluster host recorded by your design team in the "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

# NLB Deployment Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Deploy your Network Load Balancing solution by implementing the decisions made by the design team. The process for deploying Network Load Balancing clusters is shown in Figure 9.1.

**Figure 9.1 Deploying Network Load Balancing**

During the Network Load Balancing design process, the design team created and documented the design of the network configuration by using drawing and diagramming software (such as Microsoft® Visio®), and the "NLB Cluster Host Worksheet" job aid that your design team completed for each cluster host. (This worksheet is associated with "Designing Network Load Balancing" in *Planning Server Deployments* of this kit.) The Network Load Balancing design documents describe the number of Network Load Balancing clusters, the placement of the Network Load Balancing clusters in your network environment, the number of Network Load Balancing cluster hosts, and other specifications.

Before deploying Network Load Balancing in your production environment, test your deployment solution in a lab and in a pilot deployment. For more information about testing your design, see "Planning for Deployment" in *Planning, Testing, and Piloting Deployment Projects* of this kit.

After you test your design, you can use different options for deploying each Network Load Balancing cluster, based on the requirements of your organization. Table 9.1 lists deployment requirements and the corresponding options for deploying Network Load Balancing clusters. For each cluster in the Network Load Balancing design, select one of these options for deploying Network Load Balancing clusters.

**Table 9.1 Deployment Requirements and Corresponding Options for Deploying NLB Clusters**

| Deployment Requirements | Implement | Upgrade | Migrate |
|---|---|---|---|
| Fresh installation of Windows Server 2003 is required | • | | • |
| Clusters are to be deployed on new cluster hardware | • | | • |
| Two or more existing clusters to be consolidated into a single cluster | | | • |
| A corresponding cluster currently exists in the network environment | | • | • |
| Existing hardware is capable of running Windows Server 2003 | | • | |

| | | | |
|---|---|---|---|
| Existing Windows registry settings to be retained | | ● | |

When your Network Load Balancing solution includes multiple Network Load Balancing clusters, you might need to use more than one method for deploying Network Load Balancing clusters. For each Network Load Balancing cluster in your solution, read the corresponding section in this chapter for the deployment method you select:

- Implementing New Clusters
- Upgrading Existing Clusters
- Migrating Existing Clusters

# Selecting the Automated Deployment Method

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Begin the deployment of your Network Load Balancing solution by determining how to automate your Network Load Balancing deployment. Automate the deployment of your Network Load Balancing solution to ensure the consistency of installation, to reduce the time required to deploy your solution, and to assist in restoring failed Network Load Balancing cluster hosts. Manually deploy your Network Load Balancing solution only if creating and testing the automation files and scripts would take more time than manually configuring the cluster. Figure 9.2 shows the process for determining the best method to automate the deployment of your Network Load Balancing solution.

**Figure 9.2 Selecting the Automated Deployment Method**

You can automate the deployment of Windows Server 2003 and Network Load Balancing cluster hosts by using one of the following methods:

- Unattended installation
- Sysprep
    - Remote Installation Services (RIS)

Table 9.2 compares the characteristics of the various automated deployment methods.

**Table 9.2 Comparing Automated Deployment Methods**

| Deployment Characteristics | Unattended Installation | Sysprep | RIS |
|---|---|---|---|
| Uses images to deploy installation | | ● | ● |
| Uses scripts to customize installation | ● | ● | |
| Supports post installation scripts to install applications | ● | ● | ● |
| Deployed by using local drives on the target server | ● | ● | |

| | | | |
|---|---|---|---|
| Initiated by remotely administered servers | | | ● |
| Deployed from a network share | ● | ● | |

Depending on the requirements of each cluster, more than one method might be required to deploy all your Network Load Balancing clusters. For more information about these methods, see "Designing Unattended Installations" "Designing Image-based Installations with Sysprep" and "Designing RIS Installations" in *Automating and Customizing Installations* of this kit.

The unattended installation and Sysprep methods require that you create script files to automate the deployment. The Network Load Balancing–specific installation and configuration information is required in two sections of the unattended and Sysprep script files: the [MS_WLBS parameters] and [MS_TCPIP parameters] sections.

For more information about the process for configuring the script files, see the *Microsoft® Windows® Server 2003 Corporate Deployment Tools User's Guide* (Deploy.chm). Deploy.chm is included in the Deploy.cab file in the Support folder on the Windows Server 2003 operating system CD. For more information about the parameters used by the script files, see the Windows Preinstallation Environment link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. There are no special considerations for automating Network Load Balancing deployment by using the RIS method.

For Network Load Balancing, you need to perform specific tasks when creating the unattended installation and Sysprep script files:

- Review the content in the Microsoft Windows Preinstallation Reference that relates to the [*MS_WLBS parameters*] section.

  WLBS stands for "Windows NT Load Balancing Service," the name of the load balancing service used in Microsoft® Windows NT® Server version 4.0. For reasons of backward compatibility, WLBS continues to be used in certain instances.

- Ensure that the IP addresses for the cluster and all virtual clusters are entered in the IPAddress parameter under the [*MS_TCPIP parameters*] section.

  Typically, Network Load Balancing Manager automatically adds the cluster and virtual cluster IP addresses to the list of IP addresses. Both unattended installation and Sysprep require that you add the addresses to the IPAddress parameter under the [*MS_TCPIP parameters*] section of the script.

# Implementing a New Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Many of the mission-critical applications deployed within your organization will be new applications, which require you to deploy new Network Load Balancing clusters. The process for implementing a new cluster involves more than installing Windows Server 2003 and Network Load Balancing on the individual application servers. Implementing a new cluster might require additional network infrastructure, network services, file services, database services, and security services. Figure 9.3 shows the steps that you must complete before and after the implementation of the new cluster.

**Figure 9.3 Implementing a New Cluster**

# Preparing to Implement the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Your new cluster is dependent upon the network infrastructure and other network services in your total solution. Ensure that these network infrastructure and other network services are deployed prior to implementing your cluster.

Prepare for the implementation of the new cluster by using the information documented in the "NLB Cluster Host Worksheet" and other documentation (such as Visio drawings of the network environment) that your design team completed for a specific cluster host during the design process. Coordinate with the operations team during this step in the process to review the changes that will occur in your organization's network environment.

To prepare for the implementation of the new cluster, complete the following tasks:

1. Implement the network infrastructure required by the cluster and by the applications and services running on the cluster.
2. Implement any networking services required by the applications and services running on the cluster.
3. Select the method for automating any additional Network Load Balancing configuration.

**Implementing the Network Infrastructure**

Before you implement the cluster, you must implement the network infrastructure that connects the cluster to client computers, to other servers within your organization, and to management consoles. The network infrastructure components include:

- Network cables
- Hubs
- Switches
- Routers
- Firewalls

**Note**

- Any references to switches in this chapter refer to Layer 2 switches.

When implementing the network infrastructure, make sure to have specifications about your current network environment available. Specifically, your hardware and software inventory and a map of network topology can be helpful. For more information about creating those documents, see "Planning for Deployment in *Planning, Testing, and Piloting Deployment Projects* of this kit.

**Implementing Any Required Networking Services**

Network Load Balancing is independent of the other Windows Server 2003 network services. As a result, you do not need to implement networking services for Network Load Balancing.

However, the applications and services running on the cluster can be dependent on other Windows Server 2003 networking services. For more information about requirements for implementing networking services used by the services and applications running on the cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

**Automating Additional Configurations**

In many instances, it is possible that Windows Server 2003, Network Load Balancing, or the applications and services running on a particular cluster might require additional configuration after the installation is complete. You can use any combination of the following methods for automating these additional configurations:

- Microsoft Visual Basic Scripting Edition (VBScript)

- Windows Management Instrumentation (WMI)
- Active Directory Service Interfaces (ADSI)

# Example: Preparing to Implement the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization is deploying a new Web application that will be accessed by a large volume of Internet users. Because of scaling and availability considerations, the organization will deploy the new, high-volume Web application on a Network Load Balancing cluster. Figure 9.4 illustrates the organization's network environment prior to the implementation of the new cluster.

**Figure 9.4 Network Environment Before Implementing New Cluster**

In addition to deciding that the new Web farm will run on a Network Load Balancing cluster, the design team also made the following configuration decisions:

- No single router, switch, or Internet Information Services (IIS) Web farm server failure will prevent users from running the Web application.
- Web application will store data in a clustered SQL server running Microsoft® SQL Server™ 2000 on a server cluster.
- Web application executables Active Server Pages (ASP), Hypertext Markup Language (HTML) pages, and other executable code will be stored on a file server running on a server cluster.
- Accounts used for authenticating Internet users will be stored in Active Directory® directory service.

As the first step in the organization's deployment of the Web application, the IIS 6.0 Web farm, and Network Load Balancing, the organization must restructure the network infrastructure to support the new Web farm and cluster. Figure 9.5 illustrates the organization's network environment after preparing for the implementation.

**Figure 9.5 Network Environment After Preparing to Implement a New Cluster**

Table 9.3 lists the deployment steps that were performed prior to the implementation of the new cluster and the reasons for performing those steps.

**Table 9.3 Deployment Steps Prior to Implementation of the New Cluster**

| Deployment Step | Reason |
|---|---|
| Add Firewall-02 and Firewall-03 | Provide redundancy and load balancing. |
| Add Switch-01 and Switch-02 | Provide redundancy and load balancing. |
| Add network segments on Switch-01 and Switch-02 | Connect the IIS 6.0 Web farm to the network. |
| Configure Switch-01 and Switch-02 to belong to the same VLAN | Provide load balancing of client requests by using Network Load Balancing. |
| Add SQLCLUSTR-01 | Provide database support for the Web application on a Microsoft server cluster. |
| Add FILECLUSTR-01 | Provide secured storage for the Web application executables and content on a Microsoft server cluster. |
| Add DC-01 and DC-01 | Provide storage and management of user accounts used in authenticating Internet users. |

# Implementing the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To implement the new cluster, complete the following tasks:

1. Install and configure the hardware and Windows Server 2003 for each cluster host.
2. Install and configure the first Network Load Balancing cluster host.
3. Install and configure additional Network Load Balancing cluster hosts.

**Note**

- When your Network Load Balancing solution includes multiple Network Load Balancing clusters with round robin DNS, complete these tasks for each Network Load Balancing cluster in the solution. For more information about combining multiple Network Load Balancing clusters with round robin DNS, see "Scaling NLB Solutions" in "Designing Network Load Balancing" in this book.

# Installing and Configuring the Hardware and Windows Server 2003

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The first step in performing the implementation of the new cluster is to install and configure the hardware and Windows Server 2003 for each cluster host. Install and configure all cluster host hardware at the same time to ensure that you eliminate any configuration errors prior to installing and configuring the Network Load Balancing cluster.

To install and configure Windows Server 2003 on the cluster host hardware, you must be logged on as a user account that is a member of the local administrators group on all cluster hosts. Install and configure the cluster host by using the information documented in the "NLB Cluster Host Worksheet" that your design team completed for that host during the design process.

To install and configure the hardware and Windows Server 2003 on each cluster host in the new cluster, complete the following tasks:

1. Install the cluster host hardware in accordance with the manufacturer's recommendations.

2. Connect the cluster host hardware to the network infrastructure.

3. Install Windows Server 2003 with the default options and specifications from the worksheet for the cluster host.

4. Install any additional services (such as IIS 6.0 or Routing and Remote Access) by using the design specifications for the service.

   For detailed instructions on installing additional services, see the resources related to the corresponding service in "Additional Resources for Deploying Network Load Balancing" later in this chapter.

5. Configure the TCP/IP property settings and verify connectivity for the cluster adapters.

   **Caution**

   - Configure the dedicated IP address at this time. The cluster IP address and any virtual IP addresses for port rules are added later in the deployment process through Network Load Balancing Manager.

6. If a separate management network is used, configure the TCP/IP property settings and verify connectivity for the management adapter.

   Although not required, it is recommended that you use a separate management network adapter to provide a communication path that is isolated both from the cluster adapter and from the clients. For more information about the benefits of including a management network adapter in your design, see "Selecting the Number of Network Adapters in Each Cluster Host" in "Designing Network Load Balancing" in this book.

7. Configure each server to be a member server in a domain created specifically for managing the cluster and other related servers.

   Although not required, creating a domain for management of the cluster provides a centralized method of controlling security to the cluster. Management of clusters installed in a workgroup is more difficult and time-consuming. When the cluster resides in a perimeter network, create a separate forest for the exclusive purpose of managing servers (including cluster hosts) in the perimeter network.

# Installing and Configuring the First Cluster Host

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you have installed and configured the hardware for the cluster, you are ready to install and configure the first cluster host. The first cluster host acts as a master copy when you use an image-based deployment method (such as RIS, Sysprep, or a third-party product) to deploy the remaining cluster hosts.

An image-based deployment is faster and ensures consistency when implementing the remaining cluster hosts, by reducing or eliminating manual configuration. In addition, the same image-based deployment method can be reused after the deployment to restore failed cluster hosts.

Depending on the type of image-based deployment, different methods are used to customize the cluster host after the image has been restored. For example, Sysprep can allow you to interactively customize the image or use a configuration file — sysprep.inf — to customize the image. For more information about customizing the restored image, see "Designing Unattended Installations," "Designing Image-based Installations with Sysprep," and "Designing RIS Installations" in *Automating and Customizing Installations* of this kit.

Perform the following task on the first cluster host by using the "NLB Cluster Host Worksheet" that your design team completed for the first cluster host:

1. If you did not use the automated installation process to create the new cluster, start Network Load Balancing Manager and create a new cluster.

   **Tip**

   - You can start Network Load Balancing Manager by running Nlbmgr.exe.

2. Install the applications and services on the first cluster host.

   Examples of Windows Server 2003 services to be installed at this time include IIS or Terminal Services. For more information about installing Windows Server 2003 services, see the chapters that discuss those services in the *Microsoft® Windows® Server 2003 Deployment Kit*.

   Examples of applications to be installed at this time include, Web applications or Windows applications that run on Terminal Services. For more information about installing the applications running on your cluster, see the documentation that accompanies your application.

3. Enable monitoring and health checking on the first cluster host.

   A Microsoft Operations Manager (MOM) Management Pack exists for Network Load Balancing. When your organization uses MOM to monitor and manage the servers within your organization, include the MOM Management Pack for Network Load Balancing on the cluster hosts.

   For location of additional information about monitoring and health checking the applications and services running on the cluster, review the resources in "Additional Resources for Deploying Network Load Balancing" later in this chapter.

4. Verify that the first Network Load Balancing cluster host responds to client queries by directing requests to the cluster IP address.

   Test the first cluster host by specifying the cluster IP address or a virtual cluster IP address in the client software that is used to access the application or service running on the cluster. For example, a client accessing an IIS application would put the cluster IP address or virtual cluster IP address in the Web browser address line.

**Important**

- Create an entry in DNS for the cluster only after you have completed the deployment of the entire cluster. Prematurely

publishing the applications and services in DNS might result in overwhelming the cluster hosts before all cluster hosts are installed

# Installing and Configuring Additional Cluster Hosts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you have installed and configured the first cluster host, you are ready to install and configure the remaining cluster hosts in the cluster. The first cluster host acts as a master copy when you use an image-based deployment method (such as RIS, Sysprep, or a third-party product) to deploy the remaining cluster hosts.

Perform the following tasks on the remaining cluster hosts by using the "NLB Cluster Host Worksheet" that your design team completed for each cluster host:

1. Create an image of the first cluster host that has just been deployed (discussed in the previous section) as required by one of the following image-based automated installation methods:

   - Sysprep

     For more information about creating Sysprep images, see "Designing Image-based Installations with Sysprep" in *Automating and Customizing Installations* of this kit.

   - RIS

     For more information about creating RIS images, see "Designing RIS Installations" in *Automating and Customizing Installations*.

   - Third-party products

     For more information about creating images with third-party products, see the documentation provided with the third-party image deployment software.

2. Restore the image of the first cluster host (created in step 1) to one of the remaining cluster host, following the directions provided in the documentation for the image-base installation method you used.

3. Configure any computer specific information (such as computer name and IP address) on the newly deployed cluster host.

4. Enable monitoring and health checking for the additional cluster host.

   Use the same methods as described for the first cluster host.

5. Verify that the additional cluster host responds to client requests.

   Use the same methods as described for the first cluster host.

6. Complete steps 2 through 5 for each remaining cluster host in the Network Load Balancing cluster.

7. Ensure that the cluster is load balancing requests across all cluster hosts (based on the port rules of the cluster).

The time required to create and test the images used in an image-based deployment can be prohibitive. It might take you less time to install and configure the remaining cluster hosts in the same way that you installed and configured the first Network Load Balancing cluster host. For example, you could deploy a cluster that consists of three cluster hosts. If you decide to deploy the cluster hosts using a method other than image-based deployment, you must ensure that you can restore a failed cluster host.

# Example: Implementing the New Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The organization mentioned in "Example: Preparing to Implement the Cluster" earlier in this chapter is now ready to implement the new IIS 6.0 Web farm that uses Network Load Balancing for load balancing and fault tolerance. The network infrastructure and additional networking services have been deployed in preparation for the implementation.

In this step, the organization installed and configured the first cluster host as a model for the remaining cluster hosts. Then the organization deployed the remaining cluster hosts by using an image-based deployment method. Figure 9.6 illustrates the network environment after the implementation of the new IIS 6.0 Web farm and Network Load Balancing.

**Figure 9.6 Network Environment After Installing the New Cluster**

Table 9.4 lists the deployment steps that were performed to implement the new cluster and the reasons for performing those steps.

**Table 9.4 Deployment Steps for Implementing the New NLB Cluster**

| Deployment Step | Reason |
|---|---|
| Add IIS-01, IIS-02, IIS-03, IIS-04, IIS-05, IIS-06, IIS-07, and IIS-08 server hardware. | Server hardware needs to be connected to network infrastructure in preparation for Network Load Balancing deployment. |
| Install Windows Server 2003 and Network Load Balancing on IIS-01 by using unattended installation. | Unattended setup is chosen because of the limited number of hosts to be deployed. |
| Create an image of IIS-01 to use as a model for RIS deployment. | RIS allows the servers to be reimaged in the event of a server failure. |
| Deploy the image on IIS-02, IIS-03, IIS-04, IIS-05, IIS-06, IIS-07, and IIS-08. | Image deployment ensures a consistent configuration on all servers in the Network Load Balancing cluster. |
| Verify the Web farm responds to client requests. | Verification ensures that the Web farm is properly configured and that Network Load Balancing is load balancing. |

# Verifying the Cluster and Enabling Client Access

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The final step in implementing your new Network Load Balancing cluster is to ensure that you have properly implemented and configured your cluster. In "Installing and Configuring the First Cluster Host" earlier in this chapter, you verified your implementation of individual servers. Now you must ensure that the entire cluster is secure and is properly monitored and health checked.

To verify the cluster and enable client access, complete the following tasks:

1. Verify the cluster host restoration process.
2. Verify that identified security threats are mitigated.
3. Perform monitoring and health checking on the complete cluster.
4. Verify proper operation of applications and services running on the cluster.
5. Enable client access to the cluster.

# Verifying the Cluster Host Restoration Process

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before placing the cluster into a pilot or production environment, you need to verify cluster host restoration to ensure that you can properly restore a cluster host that has failed.

To verify the cluster host restoration process, complete the following tasks:

1. Remove a cluster host from the cluster by performing a drainstop on the cluster host.

   A drainstop prevents a cluster host from handling new client requests. While draining, a cluster host continues to complete any outstanding requests and remains in the cluster until all active requests are completed. Then the cluster host stops all cluster operation.

2. Remove all disk volumes and disk partitions on the cluster host.

3. Restore the cluster host based on the installation method selected earlier in the deployment process.

4. Restart the cluster host.

5. Verify that the System event log of each cluster host contains no errors and that the restored cluster host responds properly to client requests.

# Verifying That Identified Security Threats are Mitigated

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You need to verify that all the identified security threats are properly handled in your new Network Load Balancing solution.

To verify that the identified security threats are mitigated, complete the following tasks:

1. Connect a client computer to the network such that the clients access the cluster by using the same route path that a typical client computer would use to connect to the cluster.

   For example, when clients connect to the cluster through a series of firewalls and routers to connect to the cluster over the Internet, ensure the client computer used for testing connects to the cluster through the same firewalls and routers.

2. Log on to the client computer with the user rights identified in your security threats.

3. For each identified security threat, reproduce the steps that result in the security compromise of the cluster.

4. Document the results and report the findings to the design team.

5. With the assistance of the design team, resolve any outstanding security issues.

   **Important**

   - Resolve all security threats before proceeding further in the deployment process.

# Monitoring and Health Checking the Complete Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Your next step in completing the implementation of your new cluster is to enable monitoring and health checking on the entire cluster. In "Installing and Configuring the First Cluster Host" and "Installing and Configuring Additional Cluster Hosts" earlier in this chapter, you enabled monitoring and health checking on individual cluster hosts. However, in this step you are ensuring that the cluster is monitored as a complete unit. Enable monitoring and health checking on the cluster before allowing users to access the cluster in a pilot or production environment.

As clients begin to access the applications and services in your cluster, continue to provide monitoring and health checking as described in "Installing and Configuring the First Cluster Host" earlier in this chapter. Verify that the cluster performs as expected with live client traffic.

After the deployment process is complete, ensure that your operations staff continues the monitoring and health checking process in their long-term operations processes as part of your ongoing operations.

# Verifying Proper Operations of Applications and Services

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before placing the complete cluster into a pilot or production environment, you need to verify that applications and services are running correctly on the cluster.

To verify proper operations of applications and services on the new cluster, complete the following tasks:

1. Temporarily connect a client computer to the same switch used by the cluster.
2. From the client computer, verify that the applications respond to client requests as expected.
3. Disconnect the client computer from the switch.

# Enable Client Access to the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Your last step in the implementation of your new cluster is to allow clients access to the applications and services running on the cluster. Be sure that you successfully complete all previous steps in the process before enabling users to access the cluster in a pilot or production environment.

Enable client access to the applications and the services in the cluster by creating DNS entries. Users will access your applications and services by using user-friendly names or Uniform Resource Locaters (URLs), such as http://www.microsoft.com, which correspond to the individual applications or services on the Network Load Balancing cluster. The DNS entries allow the translation of the user-friendly name to at least one IP address. When round robin DNS is used for load balancing between clusters, you must create a DNS entry for each cluster.

Table 9.5 lists the criteria for determining the number of DNS entries required for your new cluster.

**Table 9.5 Criteria for Determining the DNS Entries for Your Cluster**

| Solution Includes One of the Following | Required DNS Entries |
|---|---|
| Only one Network Load Balancing cluster. | A DNS entry for the cluster and a DNS entry for each virtual cluster. |
| More than one Network Load Balancing cluster with client traffic distributed across Network Load Balancing clusters by using round robin DNS. | A round robin DNS entry for each cluster and a round robin DNS entry for each virtual cluster. |

# Example: Verifying the Cluster and Enabling Client Access

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The organization mentioned in the examples earlier in this chapter is now ready to complete the implementation of the new IIS 6.0 Web farm. The Web farm servers are implemented and basic connectivity is provided to the Web farm. The organization has verified that Network Load Balancing is distributing client traffic evenly and that all cluster hosts are servicing client requests.

In this step, the organization verifies that the Web farm and the cluster function as a whole. Although operation of each cluster host was verified during the implementation process, now the organization must ensure that the new Web farm meets or exceeds the design specifications established by your design team before enabling client access to the applications.

Figure 9.7 illustrates the network environment after the implementation of the new IIS 6.0 Web farm and Network Load Balancing.

**Figure 9.7 Network Environment After Implementing the New Cluster**

Table 9.6 lists the deployment steps that were performed to verify the new cluster and enable client access.

**Table 9.6 Verifying the New Cluster and Enabling Client Access**

| Deployment Step | Reason |
|---|---|
| IIS-03 taken off line. | Automatic failover to other Web servers must be proven. |
| IIS-02 restored. | Restoration process for Web servers must be proven. |
| Client attached to the Internet and security attacks performed. | Mitigation of security threats must be proven. |
| Monitoring and health checking enabled on IIS-01, IIS-02, IIS-03, IIS-04, IIS-05, IIS-06, IIS-07 and IIS-08. | • Proper operation of the IIS 6.0 Web farm must be verified during and after the implementation process to ensure that load balancing is occurring and that system resources are adequate for client requests. |

| | |
|---|---|
| A DNS entry created for the cluster IP address of NLBCluster-01. | Clients must have a DNS entry to access the Web applications running on the cluster. |

# Upgrading Existing Clusters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If your organization has applications and services that currently run on the Windows NT 4.0 or Microsoft® Windows® 2000 operating systems, you can upgrade your existing WLBS or Network Load Balancing clusters to take advantage of the improved security and performance of Windows Server 2003 and Network Load Balancing. Figure 9.8 shows the process for upgrading an existing cluster.

**Figure 9.8 Upgrading an Existing Cluster**

The Network Load Balancing upgrade process assumes the following conditions:

- Your applications are running on an existing IIS 4.0 (on Windows NT 4.0) or IIS 5.0 (on Windows 2000).
- You are upgrading the operating system and services running on your existing application servers.
- The system resources of the computers in your existing application farm are sufficient, or can be upgraded, to support Windows Server 2003 and IIS 6.0.

You can upgrade a cluster by taking the entire cluster offline and upgrading all the hosts, or you can leave the cluster on line and perform a *rolling upgrade*. A rolling upgrade entails taking individual cluster hosts offline one at a time, upgrading each host, and returning the host to the cluster. You continue upgrading individual cluster hosts until the entire cluster is upgraded. A rolling upgrade allows the cluster to continue running during the upgrade.

The decision to use rolling upgrades is based on the applications and services running on your existing cluster. If the applications and services support rolling upgrades, then perform a rolling upgrade on the existing cluster. Otherwise, perform the upgrade process recommended for the applications and services running on the cluster. For more information on the upgrade process for the applications and services running on your cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

Upgrade the cluster by using the information documented in the "NLB Cluster Host Worksheet" that your design team completed for each cluster host during the design process.

# Preparing to Upgrade the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Network Load Balancing runs independently of other networking services provided by Windows Server 2003. On the other hand, the applications and services running on the cluster can be dependent upon the network infrastructure and other network services in your existing environment. Prior to upgrading the existing cluster, deploy any network infrastructure components or networking services that are required by the applications and services running on the cluster.

Prepare to upgrade the cluster by performing the following tasks:

1. Verify that applications and services running on the cluster are compatible with Windows Server 2003.
2. Upgrade the network infrastructure as required by the applications and services running on the cluster.
3. Upgrade any networking services as required by the applications and services running on the cluster.

**Verifying Applications and Services Are Compatible with Windows Server 2003**
Before you upgrade the existing cluster, ensure that the applications and services running on the cluster are compatible with Windows Server 2003. For help in determining if your application is compatible with Windows Server 2003, use the Windows Application Compatibility Toolkit. To download the toolkit, see the Windows Application Compatibility link on the Web Resources page at http://www.microsoft.com/reskits/webresources.

**Upgrading Necessary Network Infrastructure**
Before you upgrade the existing cluster, ensure that the final configuration of the cluster can be supported by the network infrastructure that connects the cluster to client computers, to other servers within your organization, and to management consoles. Perform only the network infrastructure upgrades required by the applications and services running on the cluster. Avoid performing upgrades to the network infrastructure for other reasons at the same time that you are upgrading the cluster. This minimizes the number of changes to the environment and reduces the likelihood of problems occurring during the upgrade process.

The network infrastructure to upgrade includes the following components:

- Network cabling
- Hubs
- Switches
- Routers
- Firewalls

**Note**

- When performing this step, make sure to have specifications about your current network environment available for use. Specifically, your hardware and software inventory, and a map of network topology can be helpful. For more information about creating those documents, see "Planning for Deployment" in *Planning, Testing, and Piloting Deployment Projects* of this kit.

**Upgrading Any Required Networking Services**
Network Load Balancing is independent of the other Windows Server 2003 network services. As a result, no networking services upgrades are required for Network Load Balancing.

However, the applications and services running on the cluster can be dependent on other Windows Server 2003 networking services. For more information about requirements that the services and applications running on the cluster might have for upgrading networking services, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

# Example: Preparing to Upgrade the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An organization is upgrading their existing virtual private network (VPN) remote access solution. The existing solution has a VPN remote access server farm that supports Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP). Currently the VPN remote access server farm is running WLBS on Windows NT 4.0. Figure 9.9 illustrates the organization's network environment prior to preparing for the upgrade of the existing WLBS cluster that hosts the VPN remote access server farm.

**Figure 9.9 Network Environment Before Preparing to Upgrading the Cluster**

As the first step in upgrading the existing VPN remote access server farm, the organization installs any networking services required by the VPN remote access server farm. No networking infrastructure or networking services upgrades are required for the upgrade.

In the future, the organization plans to deploy Internet Authentication Service (IAS) servers to provide centralized management of remote access policies. However, the deployment of IAS is scheduled to occur after the upgrade to Windows Server 2003 to prevent any unnecessary complications during the upgrade process.

# Upgrading the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The upgrade of your existing cluster can be done one cluster host at a time (a rolling upgrade) or by taking the cluster offline to upgrade all the hosts at the same time (a nonrolling upgrade). It is recommended that you perform a rolling upgrade. Otherwise, perform the upgrade process recommended for the applications and services running on the cluster. For more information about the upgrade process for the applications and services running on your cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

Determine if you can perform a rolling upgrade in your lab prior to your pilot or production deployments. If you can perform rolling upgrades, ensure that you perform the post-upgrade processes described in this section for each individual cluster host.

To perform a rolling upgrade on existing WLBS or Network Load Balancing clusters, complete the following tasks:

1. Prevent clients from accessing the cluster host to be upgraded by performing a drainstop on the cluster host.
2. Monitor client activity on the cluster host until all client activity ceases.
3. Upgrade the cluster host.
4. Verify that the applications and services are running correctly on the upgraded cluster host.
5. Add the cluster host back to the cluster.
6. Upgrade the remaining cluster hosts by performing steps 1 though 5 for each cluster host.

# Preventing Clients From Accessing the Cluster Host

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you upgrade a cluster host, you must ensure that no clients have active sessions running on the cluster host. During the upgrade process, the cluster host is still connected to the network infrastructure.

However, to prevent new clients from starting sessions or applications on the cluster host, perform a drainstop on the cluster host to be upgraded. Performing a drainstop prevents new clients from accessing the cluster while allowing existing clients to continue until they have completed their current operations.

In addition, configure the **Default state** of the **Initial host state** to **Stopped**. Configuring the cluster host in this manner ensures the cluster host cannot rejoin the cluster during the upgrade process. Because the upgrade process requires the cluster host to restart, you need to verify that the upgrade completed successfully before adding the cluster host back to the cluster.

**Tip**

- You can configure the Initial host state through Network Load Balancing Manager or the property settings of the cluster network adapter.

For more information about performing a drainstop on the source cluster and changing the **Default state** of cluster host, see "Create and Manage Network Load Balancing Clusters" in Help and Support Center for Windows Server 2003.

# Monitoring Client Activity on the Cluster Host

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you run the drainstop on the cluster host, monitor client activity on the cluster host to determine when clients are no longer using the cluster host. The method for determining when clients are no longer using the cluster host is specific to the applications and services running on the cluster host.

For example, for a VPN remote access solution, monitor for active VPN connections to the cluster host. When there are no active VPN connections, the cluster host is ready to be upgraded.

For more information about monitoring the applications and services running on the cluster for client activity, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

# Upgrading the Cluster Host

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you ensure that no clients are accessing the cluster host, upgrade the cluster host to Windows Server 2003. Ensure that during the upgrade process you apply the latest service packs and hotfixes.

After the upgrade is complete, check the upgrade logs (Setuperr.log in the *windir* folder of the system volume) to identify any problems that occurred during the upgrade process. Many applications and services running on the cluster have log files that identify problems that occur during the upgrade process. For example, IIS 6.0 creates a separate log that documents the upgrade process for IIS components. Make certain that you review any upgrade logs for the applications and services running on the cluster.

For more information about these upgrade logs, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

# Verifying the Applications and Services are Running Correctly

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After the upgrade of the cluster host is complete, you need to verify that the applications and services are running correctly on the cluster host. You need to do this before starting the cluster service again in order to allow the cluster host to rejoin the cluster. The process presented here is specific to Network Load Balancing. This process might apply to the applications and services running on the cluster, however, the applications and services running on the cluster might have a different verification process. For more information about the verification process for specific applications and services running on the cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

To verify that the applications and services are running correctly after you upgrade the cluster host, complete the following tasks:

1. Temporarily connect a client computer to the same switch used by the cluster.

2. From the client computer, verify that the applications respond to client requests as they did prior to the upgrade.

3. Verify that the identified security threats are mitigated.

   The only action you need to take to mitigate Network Load Balancing–specific security threats is to ensure that unauthorized clients cannot remotely administer the cluster. Unless the network infrastructure, including firewalls or routers, changed significantly since the start of the upgrade, the Network Load Balancing security threats should still be mitigated.

   However, you must mitigate security threats that are unique to the applications and services running on the cluster. For more information about mitigating security threats for specific applications and services running on the cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

4. Enable monitoring and health checking, if they are not already enabled.

   A Microsoft Operations Manager (MOM) Management Pack exists for Network Load Balancing. When your organization uses MOM to monitor and manage the servers within your organization, include the MOM Management Pack for Network Load Balancing on the cluster hosts.

   For more information about monitoring and health checking the applications and services running on the cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

5. Disconnect the client computer from the switch.

# Adding the Cluster Host Back to the Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you complete the upgrade and verify that the applications and services are running correctly, add the cluster host back to the cluster. Because the cluster host is still connected by cable to the existing network infrastructure, adding the cluster host back to the cluster requires you to start Network Load Balancing on the cluster host.

To add the cluster host back to the cluster, use Network Load Balancing Manager to start the Network Load Balancing service on the cluster host. In addition, configure the **Default state** of the **Initial host state** to match the setting that existed prior to the upgrade process. Configuring the cluster host in this manner ensures that the clients accessing the applications and services running on the cluster do not encounter problems when you restart the cluster host and return it to the cluster.

The reason to configure the cluster host with the same settings, instead of selecting **Started**, is that Network Load Balancing loads very early in the operating system boot process. The cluster host can join the cluster before other services are running. This means the cluster host might receive load before other services, such as IIS, are started. Allowing Network Load Balancing to start before other services could result in the denial of service to users until the service starts.

You can use management software, such as MOM, to monitor the services running on the host and to start Network Load Balancing when the appropriate services are running. Using management software to start Network Load Balancing is recommended to prevent users from experiencing outages in service.

For more information on performing a drainstop on the source cluster and changing the **Initial host state** of cluster host, see "Create and Manage Network Load Balancing Clusters" in Help and Support Center for Windows Server 2003.

# Example: Upgrading the Existing NLB Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The organization mentioned in the examples earlier in this chapter is now ready to upgrade the existing VPN server farms. In this step, the organization performs a rolling upgrade on each cluster host in the VPN remote access server farm.

Each of the VPN remote access servers were upgraded in turn until the entire VPN remote access server farm was upgraded. Figure 9.10 illustrates the organization's network environment after the upgrade of the cluster.

**Figure 9.10 Network Environment After Upgrading the Cluster**

To upgrade the VPN remote access server farm, the following tasks were performed:

1. Prevented client access on the VPN-01 cluster host by performing a drainstop on VPN-01.
2. Monitored client activity on VPN-01 until all client activity ceased.
3. Upgraded VPN-01.
4. Verified that the applications and services are running correctly on VPN-01.
5. Added VPN-01 back to the cluster.
6. Performed steps 1 through 5 on the remaining VPN remote access servers.

# Migrating Existing Clusters

Updated: December 21, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Your organization might have applications and services that currently run on Windows NT 4.0 or Windows 2000 clusters. If you want these applications and services to take advantage of the improved security and performance of Windows Server 2003, and if you also want to run these applications on newly installed Windows Server 2003 servers, you can migrate the applications and servers from existing clusters to newly installed Network Load Balancing clusters.

| **Note** |
| --- |
| For information about upgrading an existing Network Load Balancing Cluster from Windows Server 2003 to Windows Server 2008 or Windows Server 2008 R2, see Upgrading an Existing Network Load Balancing Cluster. |

The migration process is appropriate in the following situations:

- You want to migrate one WLBS or Network Load Balancing cluster to a target Network Load Balancing cluster.
- You want to consolidate multiple WLBS or Network Load Balancing clusters onto a target Network Load Balancing cluster.

Migrating WLBS clusters from Windows NT 4.0 or Network Load Balancing clusters from Windows 2000 requires only minimal effort for Network Load Balancing. The majority of the migration effort involves the applications and services running on the cluster. The process for migrating an existing cluster to a target Network Load Balancing cluster running Windows Server 2003 is shown in Figure 9.11.

**Figure 9.11 Migrating Existing Clusters**

Migrate your WLBS or Network Load Balancing cluster by using the information documented in the "NLB Cluster Host Worksheet" that your design team completed for each cluster host during the design process.

**Network Load Balancing Migration Assumptions**

The Network Load Balancing migration process to Windows Server 2003 assumes the following conditions:

- Your applications and services are running on an existing cluster running WLBS (on Windows NT 4.0) or Network Load Balancing (on Windows 2000).
- You are installing a new Network Load Balancing cluster as the target cluster.

- Your applications and services are compatible with Windows Server 2003.

In addition to compatibility with Network Load Balancing, the applications and services must be compatible with Windows Server 2003. For help in determining if your application is compatible with Windows Server 2003, use the Windows Application Compatibility Toolkit on the *Windows Server 2003 Deployment Kit* companion CD.

For information about the migration process for the application or service running on your cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

**Network Load Balancing Migrations and Consolidations**

In addition to migrating an existing cluster to the target cluster, you can use the Network Load Balancing migration process to consolidate multiple existing clusters to the target cluster. The consolidation process is identical to the migration process, except that, for each migration, you are migrating applications and services that formerly ran on multiple clusters onto a single target cluster.

As a part of consolidation, the port rules and cluster virtual IP addresses from all the source clusters must be created on the target cluster. For each cluster that you migrate, you must create port rules on the target cluster that handle the client traffic in the same manner as the traffic was handled on the source cluster. For more information about the migration of port rules, see "Migrating to the Target Cluster" later in this chapter.

# Implementing the Target Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The first step in the migration process is to implement the target Network Load Balancing cluster. If the target Network Load Balancing cluster already exists, proceed to the next step in the process, described in "Migrating to the Target Cluster" later in this chapter

The process for implementing the target is identical to the process for installing a new Network Load Balancing cluster. Complete the process described in "Implementing a New Cluster" earlier in this chapter. Ensure that implementing the target cluster does not disrupt applications running on the source cluster. For example, avoid modifying the network infrastructure that actively connects to the source cluster and avoid modifying DNS entries that direct clients to the source cluster.

# Example: Implementing the Target Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Contoso Pharmaceuticals is consolidating existing IIS Web farms onto a new IIS 6.0 Web farm. There are four independent IIS Web farms that need to be migrated. Two of the Web farms are running IIS 4.0 and WLBS on Windows NT 4.0. The other two Web farms are running IIS 5.0 and Network Load Balancing on Windows 2000.

During the migration, Contoso plans to consolidate the separate Web farms into one Web farm that supports all of their Web applications. Figure 9.12 illustrates Contoso's network environment prior to the migration of the existing WLBS and Network Load Balancing clusters that host the IIS Web farms.

**Figure 9.12 Network Environment Before Migrating the IIS Web Farms**

As the first step in Contoso's migration of the Web application server farm, Contoso restructured the network infrastructure to support the new IIS and Network Load Balancing deployment. Additional networking services were deployed in preparation for the implementation.

Then Contoso installed and configured the first server in the Web farm as a model for the remaining servers. Contoso deployed the remaining servers by using an image-based deployment method. Figure 9.13 illustrates Contoso's network environment after the implementation of the target IIS 6.0 Web farm (Network Load Balancing cluster).

**Figure 9.13 Network Environment After Installing the Target Cluster**

During the implementation of the new target cluster, the existing clusters were not affected. Clients continued to access the applications and services running on the existing cluster during the implementation of the target cluster.

# Migrating to the Target Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As discussed in "Implementing the Target Cluster" earlier in this chapter, the only part of Network Load Balancing to be migrated is the port rules. All other aspects of the migration of the cluster are specific to the applications and services running on the cluster. For more information about migrating applications and services running on the cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter.

Because the number of port rules on a cluster is small, the existing port rules can be easily recreated on the target cluster. If you are consolidating multiple clusters to a target cluster, the creation of port rules is slightly different from the creation of port rules if you are migrating a single cluster to a target cluster. Primarily, when consolidating, you need to ensure that consolidated port rules do not conflict with one another.

Migrate or consolidate the port rules on the source cluster to the target cluster by completing the following steps:

1. Document the port rules on the source cluster.
2. Identify any differences between port rules that exist on the target cluster and the port rules on the source cluster.
3. Create the port rule on the target cluster, as required, with new or different virtual IP addresses.
4. Migrate the applications and services running on the source cluster.
5. Enable client access to the applications on the target cluster.

# Documenting Port Rules on the Source Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Document the port rules on the source cluster by completing the following steps:

1. View the port rules in Network Load Balancing Manager or by running Nlb.exe at a command prompt.

   To view port rules in Network Load Balancing Manager:

   a. Start **Network Load Balancing Manager**.

   b. On the **Host** menu, click **Properties**.

   c. On the **Port Rules** tab, view the port rules in the **Defined port rules** box.

   To view port rules by running Nlb.exe, in the command prompt, type **Nlb display *cluster_IP_address*** (where *cluster_IP_address* is the cluster IP address of the source cluster), and then press **Enter**.

   For more information about viewing port rules in Network Load Balancing Manager or by using Nlb.exe, see "Create and Manage Network Load Balancing Clusters" in Help and Support Center for Windows Server 2003.

2. Record the port rules on the job aid "NLB Cluster Host Worksheet" (Sdcnlb_1.doc) on the *Windows Server 2003 Deployment Kit* companion CD (or see "NLB Cluster Host Worksheet" on the Web at http://www.microsoft.com/reskit).

# Identifying Differences Between Port Rules

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When migrating a source cluster to a target cluster, create port rules that are identical to the source cluster. When consolidating two or more clusters to a target cluster, create port rules that are identical to the source cluster unless port rules exist on the target cluster that specify the same TCP/UDP port number that is specified by a port rule on the source cluster.

During consolidation, two clusters might have port rules that relate to the same TCP/UDP port number, but have different affinity or load weight. In these situations you must differentiate between the different affinity or load weight behaviors by associating each of the source port rules with a different virtual cluster.

For example, you are migrating two clusters, Cluster A and Cluster B, to the same target cluster. Cluster A has a port rule for HTTP (TCP port 80) traffic that specifies no affinity, while Cluster B has a port rule for HTTP traffic that specifies Single affinity. The applications on these servers expect the affinity behavior. To ensure these applications behave as they did on the source servers, specify a port rule, with unique virtual IP address, for each of the affinity behaviors.

# Creating Port Rules on the Target Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Create the port rules on the target cluster by using Network Load Balancing Manager. Network Load Balancing Manager is recommended because it ensures that the port rules remain consistent across all the cluster hosts. Other methods require you to manually ensure that the port rules are consistent.

To create the port rules on the target cluster by using Network Load Balancing Manager:

1. Start **Network Load Balancing Manager**.
2. If **Network Load Balancing Manager** does not already list the cluster, connect to the cluster.
3. Right-click the cluster, and then click **Cluster Properties**.
4. Click the **Port Rules** tab.
5. Click **Add**.
6. Using the port rules documented in previous steps, specify values for the following:
   - **Cluster IP address**, which is the virtual IP address that you want this rule to apply to. Enter a specific virtual IP address to create a virtual cluster, or check **All** to apply the rule to all virtual IP addresses.
   - **Port range**
   - **Protocols**
   - **Filtering mode** and as appropriate, values for **Affinity**, and **Load weight**, and then click **OK**.
7. Repeat steps 5 and 6 until all port rules are created.

For more information about creating port rules in Network Load Balancing Manager, see "Create and Manage Network Load Balancing Clusters" in Help and Support Center for Windows Server 2003.

# Migrating the Applications and Services Running on the Source Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For information about the specific migration steps for the applications and services running on the source cluster, see "Additional Resources for Deploying Network Load Balancing" later in this chapter. After you migrate the applications and services, ensure that the applications and services are running correctly before enabling client access to the applications and services on the target cluster.

# Enabling Client Access to the Applications on the Target Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After you have migrated the cluster port rules, applications, and services from the source cluster to the target cluster, you are ready to enable client access to the applications on the target cluster. Enable client access to the target cluster while maintaining the DNS entries to the source cluster. Over a period of time, remove the DNS entries that point to the source cluster.

Enable client access to the applications on the target cluster by completing the following steps:

1. Create the appropriate DNS entries for the applications running on the target cluster.

   For more information about how to create DNS entries for your applications see "Managing resource records" in Help and Support Center for Windows Server 2003.

2. Monitor client traffic to determine if clients are accessing the target cluster.

3. Over a period of time, such as a few hours or a day, confirm clients accessing target cluster are experiencing normal response times and application responses.

4. Remove the DNS entries pointing to the source cluster.

   For more information about how to remove DNS entries for your applications see "Managing resource records" in Help and Support Center for Windows Server 2003.

5. Prevent new clients from accessing the source cluster by performing a drainstop on the source cluster.

   For more information about how to perform a drainstop, see "Create and Manage Network Load Balancing Clusters" in Help and Support Center for Windows Server 2003.

6. Monitor client traffic to the source cluster to determine when clients are no longer accessing the source cluster.

7. When clients no longer access the source cluster, decommission the source cluster hardware.

# Example: Migrating to the Target Cluster

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The fictitious organization Contoso, mentioned in examples earlier in this chapter, is now ready to migrate their existing applications running on the four IIS Web farms to the target IIS 6.0 Web farm (and subsequently the target Network Load Balancing cluster). Contoso's target Web farm has been installed and their applications have been verified to work with Windows Server 2003 and Network Load Balancing.

Figure 9.14 illustrates Contoso's network environment after the migration of the existing applications to the target Web farm and Network Load Balancing cluster.

**Figure 9.14 Network Environment After Migrating Applications and Services**

Table 9.7 lists the applications, the Web farms that run the applications, and the DNS entries that correspond to the Web applications.

**Table 9.7 Applications, Web Farms, and DNS Entries**

| Application | Runs on | DNS Entries |
|---|---|---|
| Organization's Internet presence | • IISNLB-01<br>• IISNLB-02 | • www.contoso.com 10.0.0.111<br>• www.contoso.com 10.0.0.121 |
| Customer support site | • IISNLB-03 | • support.contoso.com 10.0.0.131 |
| E-commerce site | • IISNLB-03 | • sales.contoso.com 10.0.0.132 |
| Nonprofit third-party organization's Internet presence | • IISNLB-04 | • www.treyresearch.net 10.0.0.141 |

In this step, Contoso creates the port rules on the target cluster based on the port rules from each of the existing clusters

(IISNLB-01, IISNLB-02, IISNLB-03, and IISNLB-04). Table 9.8, Table 9.9, Table 9.10, and Table 9.11 lists the port rules for the existing clusters.

**Table 9.8 Port Rules for IIS Applications on IISNLB-01**

| Cluster IP Address | Start | End | Protocol | Filtering Mode | Load Weight | Affinity |
|---|---|---|---|---|---|---|
| All | 80 | 80 | TCP | Multiple | Equal | None |
| All | 443 | 443 | Both | Multiple | Equal | Single |

**Table 9.9 Port Rules for IIS Applications on IISNLB-02**

| Cluster IP Address | Start | End | Protocol | Filtering Mode | Load Weight | Affinity |
|---|---|---|---|---|---|---|
| All | 80 | 80 | TCP | Multiple | Equal | None |
| All | 443 | 443 | Both | Multiple | Equal | Single |

**Table 9.10 Port Rules for IIS Applications on IISNLB-03**

| Cluster IP Address | Start | End | Protocol | Filtering Mode | Load Weight | Affinity |
|---|---|---|---|---|---|---|
| All | 80 | 80 | TCP | Multiple | Equal | Single |
| All | 443 | 443 | Both | Multiple | Equal | Single |

**Table 9.11 Port Rules for IIS Applications on IISNLB-04**

| Cluster IP Address | Start | End | Protocol | Filtering Mode | Load Weight | Affinity |
|---|---|---|---|---|---|---|
| All | 80 | 80 | TCP | Multiple | Equal | None |

The port rules are recorded for each of the source clusters. Because each of the clusters has different port rules, virtual clusters are created to facilitate the consolidation of the applications onto the target cluster IISNLB-05. Table 9.12 lists the port rules that were created to support the applications on IISNLB-05.

**Table 9.12 Port Rules Created for IIS Applications on IISNLB-05**

| Cluster IP Address | Start | End | Protocol | Filtering Mode | Load Weight | Affinity | Created to Support |
|---|---|---|---|---|---|---|---|
| All | 80 | 80 | TCP | Multiple | Equal | None | All source clusters |
| All | 443 | 443 | Both | Multiple | Equal | Single | All source clusters |
| 10.0.0.153 | 80 | 80 | TCP | Multiple | Equal | Single | IISNLB-03 |

The port rules on IISNLB-01 and IISNLB-02 are combined into a pair of port rules on IISNLB-05 because IISNLB-01 and IISNLB-02 support the same application. The two clusters, IISNLB-01 and IISNLB-02, were created to provide scaling in the original design. Because the application — www.contoso.com — is being consolidated onto one Web farm on a single cluster, the port rules can be consolidated as well.

The virtual clusters on IISNLB-03 are created on IISNLB-05 to provide separate virtual IP addresses for support.contoso.com and sales.contoso.com.

A virtual cluster, 10.0.0.154, was created to support the application on IISNLB-04, www.treyresearch.net.

After the applications are migrated to the target cluster, IISNLB-05, and are verified for proper operation, DNS entries are created to direct clients to the applications running on the target cluster. Table 9.13 lists the applications, the Web farms that run the applications, and the DNS entries that correspond to the Web applications that include the target cluster, IISNLB-05.

**Table 9.13 Applications, Web Farms, and DNS Entries**

| Application | Runs on | DNS Entries |
|---|---|---|
| Organization's Internet presence | • IISNLB-01<br>• IISNLB-02<br>• IISNLB-05 | • www.contoso.com 10.0.0.111<br>• www.contoso.com 10.0.0.121<br>• www.contoso.com 10.0.0.151 |
| Customer support site | • IISNLB-03<br>• IISNLB-05 | • support.contoso.com 10.0.0.131<br>• support.contoso.com 10.0.0.152 |
| E-commerce site | • IISNLB-03<br>• IISNLB-05 | • sales.contoso.com 10.0.0.132<br>• sales.contoso.com 10.0.0.153 |
| Nonprofit third-party organization's Internet presence | • IISNLB-04<br>• IISNLB-05 | • www.treyresearch.net 10.0.0.141<br>• www.treyresearch.net 10.0.0.154 |

After a few days of operation, clients are experiencing no difficulty with IISNLB-05, so Contoso modifies the DNS entries to remove the original Web servers (IISNLB-01, IISNLB-02, IISNLB-03, and IISNLB-04). Table 9.14 reflects the DNS entries after the removal of the original Web servers.

**Table 9.14 Applications, Web Farms, and DNS Entries**

| Application | Runs on | DNS Entries |
|---|---|---|
| Organization's Internet presence | • IISNLB-05 | • www.contoso.com 10.0.0.151 |
| Customer support site | • IISNLB-05 | • support.contoso.com 10.0.0.152 |
| E-commerce site | • IISNLB-05 | • sales.contoso.com 10.0.0.153 |
| Nonprofit third-party organization's Internet presence | • IISNLB-05 | • www.treyresearch.net 10.0.0.154 |

To finalize the completion of the migration, Contoso performs the following tasks:

1. Contoso monitors the source clusters for client traffic.

2. After all client traffic ceases on the source clusters, Contoso decommissions the computers in the source clusters.

# Additional Resources for Deploying Network Load Balancing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Example: Migrating to the Target Cluster

# Windows Server 2003 Performance Counters Reference

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This searchable online file provides a reference to the performance counters used by System Monitor and Performance Logs and Alerts, hosted by the Performance console in Windows Server 2003. These counters collect and display information about system performance when you configure a graph, log, or alert.

This reference contains the following topics:

| Topic | Description |
|---|---|
| Overview of Performance Data Collection | Defines performance objects, counters, and instances. |
| Counters by Feature | Describes the performance counters that are associated with optional services or features. |
| Counters by Object | Describes performance counters, grouped by object. |
| Bottleneck-Detection Counters | Describes performance counters that you can use to identify bottlenecks in your system. |

# Overview of Performance Data Collection

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Windows Server 2003 family defines the performance data it collects in terms of *objects*, *counters*, and *instances*. A *performance object* is any resource, application, or service that can be measured. Using System Monitor and Performance Logs and Alerts, you can select performance objects, counters, and instances to collect and present data about the performance of system components or installed software.

Each object has *performance counters* that are used to measure various aspects of performance, such as transfer rates for disks or, for processors, the amount of processor time consumed. The object may also have an *instance*, which is a unique copy of a particular object type; not all object types support multiple instances.

This Help file describes objects, counters, and instances using the following syntax:

```
\\Computer_name\Object(ParentInstance/ObjectInstance#InstanceIndex)\Counter
```

- The \\Computer element is optional; it specifies the name of the computer. The default is the local computer.
- The \Object element specifies the performance object that contains one or more performance counters. If this object has a variable list of instances, then an instance string is included.
- The (ParentInstance/ObjectInstance#InstanceIndex) element is only required if the object supports multiple instances. The format of the string depends on the object type. If the object has single instances, the format is the instance name enclosed in parentheses. For example:

  ```
  (Explorer)
  ```

  For objects with multiple instances, the parent instance name comes before the object instance, and is separated by a forward slash ( / ) character. For example:

  ```
  (Explorer/0)
  ```

  If the object has multiple instances that have the same name string, they can be indexed sequentially by specifying the instance index (a number starting with "1") preceded by a pound sign. Instance indexes are zero-based, so all instances have an implicit zero index. For example:

  ```
  (Explorer/0#1)
  ```

- The \Counter element is required; it specifies the performance counter.

An instance called *_Total instance* is available on most objects and represents the sum of the values for all instances of the object for a specific counter.

In addition to the counter descriptions provided in this Help file, to display counter descriptions you can click **Explain** in the **Add Counters** dialog box in System Monitor or Performance Logs and Alerts. You can also click **Explain** in the **Add Objects** dialog box in Performance Counter Logs to display performance object descriptions.

# Counter Types

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Each counter is assigned a counter type. The counter type determines how the counter data is calculated, averaged, and displayed. The Performance console supports more than 35 counter types, although many of the available counter types are not implemented in the counters installed with the Windows Server 2003 family. All supported counter types are described, including the following information.

**Counter type name** The name of the counter type. The System Monitor counter descriptions in this Help file include the name of the counter type. You can click the counter name in the description to see a definition of the counter.

**Description** A brief description of the counter type, including a description of the formula by which counters of that type are calculated and displayed.

**Generic type** The general category that represents the display format counter. Generic types include:

- Average. These counters measure a value over time and display the average of the last two measurements.
- Difference. These counters subtract the last measurement from the previous one and display the difference, if it is positive; if negative, they display a zero.
- Instantaneous. These counters display the most recent measurement.
- Percentage. These counters display calculated values as a percentage.
- Rate. Similar to an average counter, these counters sample an increasing count of events over time. The count is divided by the change in time to display a rate of activity.

**Formula** Describes how to convert the raw data and other components, such as performance frequency, to arrive at the formatted counter value for display in the Performance console. The variables N and D appear in the formula to describe the two distinct data components, such as raw data and performance frequency, used to calculate the displayed counter values.

For each counter type, the notation of the formula can include the following variables:

| Variable | Description |
|---|---|
| B | A base-value variable. Some counter types require the use of a counter base that supplies a stored value for calculating their formatted value. That base value is the denominator in the formula for the counter type. When describing counter types with multiple samplings, B is shown with numbered subscripts, such as $B_0$ for the oldest sampling, $B_1$ for the next most recent sampling, and $B_n$ for the latest sampling. |
| N | The numerator, typically the first variable. For the purposes of the calculation formulas in this section, N is used to describe the raw counter data. |
| D | The denominator, typically the second variable, as needed. |

The following table describes the types of counter bases and the counter types that they support.

| Base Type | Description | Corresponding Counter Types |
|---|---|---|
| PERF_AVERAGE_BASE | Stores the denominator for calculating a counter to present "time per operation" or "count per operation." | PERF_AVERAGE_BULK<br>PERF_AVERAGE_TIMER |

| | | |
|---|---|---|
| PERF_COUNTER_MULTI_BASE | Indicates the number of items sampled. It is used as the denominator in the calculations to get an average among the items sampled when taking timings of multiple, but similar, items. | PERF_100NSEC_MULTI_TIMER<br>PERF_100NSEC_MULTI_TIMER_INV<br>PERF_COUNTER_MULTI_TIMER<br>PERF_COUNTER_MULTI_TIMER_INV |
| PERF_RAW_BASE | Stores the denominator of a counter that presents a general arithmetic fraction. | PERF_RAW_FRACTION |
| PERF_SAMPLE_BASE | Stores the number of sampling interrupts taken and is used as a denominator in the sampling fraction. The sampling fraction is the number of samples that were 1 (or TRUE) for a sample interrupt. | PERF_SAMPLE_FRACTION |

**Average** The mathematical formula used to calculate averages of the formatted counter data.

**Example** An example of the specified counter type. Click the counter name in the example to see a description of that counter.

# PERF_100NSEC_MULTI_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the active time of one or more components as a percentage of the total time of the sample interval. It measures time in 100 nanosecond units.<br>This counter type is a multitimer. Multitimers are designed to monitor more than one instance of a component, such as a processor or disk. |
| Generic type | Percentage. |
| Formula | $((N_1 - N_0) / (D_1 - D_0)) \times 100 / B$, where the denominator (D) represents the total elapsed time of the sample interval, the numerator (N) represents the portions of the sample interval during which the monitored components were active, and the variable B represents the base count for the monitored components. |
| Average | $((N_x - N_0) / (D_x - D_0)) \times 100 / B$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_100NSEC_MULTI_TIMER_INV

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the active time of one or more components as a percentage of the total time of the sample interval. Counters of this type measure time in 100 nanosecond units.<br><br>This counter type is an inverse multitimer. Multitimers are designed to monitor more than one instance of a component, such as a processor or disk. Inverse counters measure the time that a component is *not* active and derive its active time from the measurement of inactive time. |
| Generic type | Percentage. |
| Formula | $(B - ((N_1 - N_0) / (D_1 - D_0))) \times 100$, where the denominator (D) represents the total elapsed time of the sample interval, the numerator (N) represents the time during the interval when monitored components were inactive, and the variable B represents the number of components being monitored. |
| Average | $(B - ((N_x - N_0) / (D_x - D_0))) \times 100$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

**Concepts**
PERF_100NSEC_MULTI_TIMER

# PERF_100NSEC_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the active time of a component as a percentage of the total elapsed time of the sample interval. It measures time in units of 100 nanoseconds. Counters of this type are designed to measure the activity of one component at a time. |
| Generic type | Percentage. |
| Formula | $(N_1 - N_0) / (D_1 - D_0) \times 100$, where the denominator (D) represents the total elapsed time of the sample interval, and the numerator (N) represents the portions of the sample interval during which the monitored components were active. |
| Average | $(N_x - N_0) / (D_x - D_0) \times 100$ |
| Example | Processor\ % User Time |

# PERF_100NSEC_TIMER_INV

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the average percentage of active time observed during the sample interval. This is an inverse counter. Inverse counters are calculated by monitoring the percentage of time that the service was inactive and then subtracting that value from 100 percent. |
| Generic type | Percentage. |
| Formula | $(1- ((N_1 - N_0) / (D_1 - D_0))) \times 100$, where the denominator (D) represents the total elapsed time of the sample interval, and the numerator (N) represents the time during the interval when the monitored components were inactive. |
| Average | $(1- ((N_x - N_0) / (D_x - D_0))) \times 100$ |
| Example | Processor\ % Processor Time |

# PERF_AVERAGE_BASE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter is used as the base data (denominator) in the computation of time or count averages for the PERF_AVERAGE_BULK and PERF_AVERAGE_TIMER counter types. This counter type collects the last observed value only. |
| Generic type | Instantaneous |
| Formula | None. This counter uses raw data in factional calculations without displaying an output. |
| Average | SUM (N) / x |
| Example | There are no counters of this type installed with Windows Server 2003 family. However, counters of this type can be used by the Windows Server 2003 family to calculate the Average Disk Transfer counters. |

# PERF_AVERAGE_BULK

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval. |
| Generic type | Average. |
| Formula | $(N_1 - N_0) / (D_1 - D_0)$, where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. |
| Average | $(N_x - N_0) / (D_x - D_0)$ |
| Example | PhysicalDisk\ Avg. Disk Bytes/Transfer |

# PERF_AVERAGE_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds. |
| Generic type | Average. |
| Formula | $((N_1 - N_0) / F) / (D_1 - D_0)$, where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval. |
| Average | $((N_x - N_0) / F) / (D_x - D_0)$ |
| Example | PhysicalDisk\ Avg. Disk sec/Transfer |

# PERF_COUNTER_100NS_QUEUELEN_TYPE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type measures the queue-length space-time product using a 100-nanosecond time base. |
| Generic type | Rate. |
| Formula | $(TB(X_1-X_0)) / (Y_1-Y_0)$, where TB represents the performance frequency time base, the denominator (Y) represents the performance time measurement, and the numerator (X) represents counter data. |
| Average | $(TB(X_1-X_0)) / (Y_1-Y_0)$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_BULK_COUNT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the average number of operations completed during each second of the sample interval. Counters of this type measure time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds. This counter type is the same as the PERF_COUNTER_COUNTER type, but it uses larger fields to accommodate larger values. |
| Generic type | Difference. |
| Formula | $(N_1 - N_0) / ( (D_1 - D_0) / F$, where the numerator (N) represents the number of operations performed during the last sample interval, the denominator (D) represent the number of ticks elapsed during the last sample interval, and the variable F is the frequency of the ticks. |
| Average | $(N_x - N_0) / ((D_x - D_0)/ F)$ |
| Example | System\File Read Bytes/sec |

# PERF_COUNTER_COUNTER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the average number of operations completed during each second of the sample interval. Counters of this type measure time in ticks of the system clock. The F variable represents the number of ticks per second. The value of F is factored into the equation so that the result can be displayed in seconds. |
| Generic type | Difference. |
| Formula | $(N_1 - N_0) / ( (D_1 - D_0) / F)$, where the numerator (N) represents the number of operations performed during the last sample interval, the denominator (D) represents the number of ticks elapsed during the last sample interval, and F is the frequency of the ticks. |
| Average | $(N_x - N_0) / ((D_x - D_0) / F)$ |
| Example | System\File Read Operations/sec |

# PERF_COUNTER_DELTA

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the change in the measured attribute between the two most recent sample intervals. |
| Generic type | Difference. |
| Formula | $N_1 - N_0$ |
| Average | $(N_x - N_0) / x$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_LARGE_DELTA

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the change in the measured attribute between the two most recent sample intervals. It is the same as the PERF_COUNTER_DELTA counter type, except that it uses larger fields to accommodate larger values. |
| Generic type | Difference. |
| Formula | $N_1 - N_0$ |
| Average | $(N_x - N_0) / x$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_LARGE_QUEUELEN_TYPE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type monitors the average length of a queue to a resource over time. Counters of this type display the difference between the queue lengths observed during the last two sample intervals, divided by the duration of the interval. This counter type is the same as the PERF_COUNTER_QUEUELEN_TYPE counter type, except that it uses larger fields to accommodate larger values. |
| Generic type | Average. |
| Formula | $(N_1 - N_0) / (D_1 - D_0)$, where the numerator (N) represents the number of items in a queue, and the denominator (D) represents the time elapsed during the sample interval. |
| Average | $(N_x - N_0) / (D_x - D_0)$ |
| Example | PhysicalDisk\ Avg. Disk Queue Length |

# PERF_COUNTER_LARGE_RAWCOUNT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the last observed value only, not an average. It is the same as the PERF_COUNTER_RAWCOUNT counter type, except that it uses larger fields to accommodate larger values. |
| Generic type | Instantaneous. |
| Formula | None. Shows raw data as collected. |
| Average | SUM (N) / x |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_LARGE_RAWCOUNT_HEX

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the last observed value, in hexadecimal format. It is the same as the PERF_COUNTER_RAWCOUNT_HEX counter type, except that it uses larger fields to accommodate larger values. |
| Generic type | Instantaneous. |
| Formula | None. Shows raw data as collected. |
| Average | SUM (N) / x |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_MULTI_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type is a multitimer. Multitimers collect data from more than one instance of a component, such as a processor or disk. Counters of this type display the active time of one or more components as a percentage of the total time of the sample interval. Because the numerator records the active time of components operating simultaneously, the resulting percentage can exceed 100 percent.<br><br>This counter type differs from PERF_100NSEC_MULTI_TIMER in that it measures time in units of ticks of the system performance timer, rather than in 100 nanosecond units. |
| Generic type | Percentage. |
| Formula | $((N_1 - N_0) / (D_1 - D_0)) \times 100$, where the denominator (D) represents the total elapsed time of the sample interval, and the numerator (N) represents the portions of the sample interval during which the monitored components were active. They are multiplied by 100 to display the value as a percentage. |
| Average | $(N_x - N_0) / (D_x - D_0) \times 100$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_MULTI_TIMER_INV

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the active time of one or more components as a percentage of the total time of the sample interval.<br><br>This counter type is an inverse multitimer. Multitimers monitor more than one instance of a component, such as a processor or disk. Inverse counters measure the time that a component is *not* active, and derive the active time from that measurement.<br><br>This counter differs from PERF_100NSEC_MULTI_TIMER_INV in that it measures time in units of ticks of the system performance timer, rather than in 100 nanosecond units. |
| Generic type | Percentage. |
| Formula | (B- ((N$_1$ - N$_0$) / (D$_1$ - D$_0$))) x 100, where the denominator (D) represents the total elapsed time of the sample interval, the numerator (N) represents the time during the interval when monitored components were inactive, and the variable B represents the number of components being monitored. |
| Average | (B- ((N$_x$ - N$_0$) / (D$_x$ - D$_0$))) x 100 |
| Example | There are no counters of this type installed with Windows Server 2003 family. |

# PERF_COUNTER_OBJ_QUEUELEN_TYPE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type measures the queue-length space-time product using an object-specific time base. |
| Generic type | Percentage. |
| Formula | $(X_1-X_0) / (Y_1-Y_0)$, where the denominator (Y) represents the performance time measurement, and the numerator (X) represents counter data. |
| Average | $(X_1-X_0) / (Y_1-Y_0)$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_QUEUELEN_TYPE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type is designed to monitor the average length of a queue to a resource over time. It shows the difference between the queue lengths observed during the last two sample intervals divided by the duration of the interval. |
| Generic type | Average. |
| Formula | $(N_1 - N_0) / (D_1 - D_0)$, where the numerator (N) represents the number of items in the queue, and the denominator (D) represents the time elapsed during the last sample interval. |
| Average | $(N_x - N_0) / (D_x - D_0)$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_RAWCOUNT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the last observed value only. It does not display an average. |
| Generic type | Instantaneous. |
| Formula | None. Shows raw data as collected. |
| Average | SUM (N) / x |
| Example | Memory\Available Bytes |

# PERF_COUNTER_RAWCOUNT_HEX

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the most recently observed value, in hexadecimal format. It does not display an average. |
| Generic type | Instantaneous. |
| Formula | None. Shows raw data as collected. |
| Average | SUM (N) / x |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_TEXT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows a variable-length text string. It does not display calculated values. |
| Generic type | Text. |
| Formula | None. |
| Average | None. |
| Example | There are no counters of this type installed with Windows Server 2003 family. |

# PERF_COUNTER_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the average time that a component was active as a percentage of the total sample time. |
| Generic type | Percentage |
| Formula | $(N_1 - N_0) / (D_1 - D_0)$, where the denominator (D) represents the total elapsed time of the sample interval, and the numerator (N) represents the portions of the sample interval during which the monitored components were active. |
| Average | $(N_x - N_0) / (D_x - D_0)$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_COUNTER_TIMER_INV

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This is an inverse counter type. Inverse counters measure the time that a component is *not* active, and derive the active time from that measurement. Counters of this type display the average percentage of active time observed during sample interval. The value of these counters is calculated by monitoring the percentage of time that the service was inactive and then subtracting that value from 100 percent.<br><br>This counter type is the same as the PERF_100NSEC_TIMER_INV counter type, except that it measures time in units of ticks of the system performance timer, rather than in 100 nanosecond units. |
| Generic type | Percentage. |
| Formula | $(1- ((N_1 - N_0) / (D_1 - D_0))) \times 100$, where the denominator (D) represents the total elapsed time of the sample interval, and the numerator (N) represents the time during the interval when the monitored components were inactive. |
| Average | $(1- ((N_x - N_0) / (D_x - D_0))) \times 100$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_ELAPSED_TIME

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds. |
| Generic type | Difference. |
| Formula | $(D_0 - N_0) / F$, where the denominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. |
| Average | $(D_x - N_0) / F$ |
| Example | System\System Up Time |

# PERF_LARGE_RAW_BASE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type collects the last observed value. It is the same as the PERF_RAW_BASE counter type except that it uses larger fields to accomaodate larger values. |
| Generic type | Instantaneous |
| Formula | None. Uses raw data in factional calculations without displaying an output. |
| Average | SUM (N) / x |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_OBJ_TIME_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This 64-bit counter type is a timer that displays in object-specific units. |
| Generic type | Percentage. |
| Formula | $(X_1-X_0) / (Y_1-Y_0)$, where the denominator (Y) represents the performance time measurement, and the numerator (X) represents counter data. |
| Average | $(X_1-X_0) / (Y_1-Y_0)$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_PRECISION_100NS_TIMER

Updated: September 12, 2007

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows a value that consists of two counter values: the count of the elapsed time of the event being monitored, and the "clock" time from a private timer in the same units. It measures time in 100 nanosecond units. This counter type differs from other counter timers in that the clock tick value accompanies the counter value eliminating any possible difference due to latency from the function call. Precision counter types are used when standard system timers are not precise enough for accurate readings. |
| Generic type | Percentage. |
| Formula | $N1 - N_0 / D_1 - D_0$, where the numerator (N) represents the counter value, and the denominator (D) is the value of the private timer. The private timer has the same frequency as the 100 nanosecond timer. |
| Average | $N1 - N_0 / D_1 - D_0$ |
| Example | PhysicalDisk\% Disk Time |

# PERF_PRECISION_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows a value that consists of two counter values: the count of the elapsed time of the event being monitored, and the frequency from the system performance timer. This counter type differs from other counter timers in that the clock tick value accompanies the counter value, eliminating any possible difference due to latency from the function call. Precision counter types are used when standard system timers are not precise enough for accurate readings. |
| Generic type | Percentage. |
| Formula | $N_x - N_0 / D_1 - D_0$, where the numerator (N) represents the counter value, and the denominator (D) represents the value of the system performance timer. |
| Average | $N_x - N_0 / D_1 - D_0$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_PRECISION_OBJECT_TIMER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows a value that consists of two counter values: the count of the elapsed time of the event being monitored, and the frequency specified in the PerfFreq field of the object header. This counter type differs from other counter timers in that the clock tick value accompanies the counter value so as to eliminate any possible difference due to latency from the function call. Precision counter types are used when standard system timers are not precise enough for accurate readings. |
| Generic type | Percentage. |
| Formula | $N_x$ - $N_0$ / $D_1$ - $D_0$, where the numerator (N) represents the counter value and the denominator (D) represents the value of the private timer. |
| Average | $N_x$ - $N_0$ / $D_1$ - $D_0$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_RAW_BASE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type collects the last observed value only. |
| Generic type | Instantaneous |
| Formula | None. Uses raw data in factional calculations without displaying an output. |
| Average | SUM (N) / x |
| Example | There are no counters of this type installed with the Windows Server 2003 family. However, this type of counter is used to calculate the Disk Queue Length counters. |

# PERF_RAW_FRACTION

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the ratio of a subset to its set as a percentage. For example, it compares the number of bytes in use on a disk to the total number of bytes on the disk. Counters of this type display the current percentage only, not an average over time. |
| Generic type | Instantaneous, Percentage. |
| Formula | ($N_0$ / $D_0$), where the denominator (D) represents a measured attribute, and the numerator (N) represents one component of that attribute. |
| Average | SUM (N / D) /x |
| Example | Paging File\% Usage Peak |

# PERF_SAMPLE_COUNTER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the average number of operations completed in one second. It measures time in units of ticks of the system performance timer. The variable F represents the number of ticks that occur in one second. The value of F is factored into the equation so that the result is displayed in seconds. |
| Generic type | Average. |
| Formula | $(N_1 - N_0) / ((D_1 - D_0) / F)$, where the numerator (N) represents the number of operations completed, the denominator (D) represents elapsed time in units of ticks of the system performance timer, and the variable F represents the number of ticks that elapse in one second. |
| Average | $(N_x - N_0) / ((D_x - D_0) / F)$ |
| Example | There are no counters of this type installed with the Windows Server 2003 family. |

# PERF_SAMPLE_FRACTION

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

| | |
|---|---|
| Description | This counter type shows the average ratio of hits to all operations during the last two sample intervals. |
| Generic type | Percentage; Hits % |
| Formula | $(N_1 - N_0) / (D_1 - D_0)$, where the numerator (N) represents the number of successful operations during the last sample interval, and the denominator (D) represents the change in the number of all operations (of the type measured) completed during the sample interval. |
| Average | $(N_x - N_0) / (D_x - D_0)$ (See Note below) |
| Example | Cache\Pin Read Hits % |

**Note**

- The Hit % counters are best displayed in System Monitor in chart view. Hits often appear in short bursts that are not visible in reports. Also, the average displayed for Hit % on the status bar in chart view might not match the average displayed in report view because they are calculated differently. In chart view, the Hit % is an average of all changes in the counter during the test interval; in report view, it is the average of the difference between the first and last counts during the test interval.

# Counters by Feature

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Some Windows Server 2003 family features or services install one or more performance objects to measure the activity of the feature or service. The following is a list of features or services and their corresponding performance objects:

- Active Directory
    - NTDS Object
- File Replication Service
    - FileReplicaConn Object
    - FileReplicaSet Object
- Indexing Service
    - Indexing Service Object
    - Indexing Service Filter Object
    - Http Indexing Service Object
- Internet Information Services (IIS)
    - Active Server Pages Object
    - FTP Service Object
    - Web Service Object
    - Internet Information Services Global Object
- Message Queuing
    - MSMQ Session Object
    - MSMQ Queue Object
    - MSMQ Service Object
- Quality of Service (QoS) Admission Control
    - ACS/RSVP Service Object
    - ACS/RSVP Interfaces Object
    - ACS Policy Object
- Remote Access Service (RAS)
    - RAS Port Object

    - RAS Total Object
- Terminal Services
    - Terminal Services Session Object
- Windows System Resource Manager (WSRM)
    - WSRM Policy Object
    - WSRM Process Object
    - WSRM Process Matching Criteria Object

# Counters by Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section includes all of the performance objects installed with the Windows Server 2003 family, grouped alphabetically. If objects are installed on your computer, they appear in the performance tools user interfaces (UI). You typically install an object at the same time that you install its associated service or feature.

# ACS Policy Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Quality of Service (QoS) ACS Policy performance object provides data about the operation of Microsoft Identity Local Policy Module. Network administrators should monitor the counters provided by this object when the QoS Admission Control Service (ACS) or Resource Reservation Protocol (RSVP) is enabled on a subnet. The QoS ACS Policy object is available only if the QoS ACS or RSVP has won the Designated Subnet Bandwidth Manager (DSBM) election and is running the Policy-based Admission Control. The Subnet Bandwidth Manager is a QoS signaling technique supported by the Windows Server 2003 family that is used to manage bandwidth on shared media such as 802.1 local area network (LAN) topologies.

There is one object for each subnet being managed by this QoS ACS host.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bad User Identity Policy Elements | Shows the number of user Identity Policy Elements that could not be identified by Microsoft Identity Local Policy Module. | PERF_COUNTER_RAWCOUNT |
| DS Cache Size | Shows the number of entries in the directory service cache. | PERF_COUNTER_RAWCOUNT |
| Flow Count PATH Rejections | Shows the number of PATH messages rejected due to flow count policy. | PERF_COUNTER_RAWCOUNT |
| Flow Count RESV Rejections | Shows the number of RESV messages rejected due to flow count policy. | PERF_COUNTER_RAWCOUNT |
| Flow Duration PATH Rejections | Shows the number of PATH messages rejected due to flow duration policy. | PERF_COUNTER_RAWCOUNT |
| Flow Duration RESV Rejections | Shows the number of RESV messages rejected due to flow duration policy. | PERF_COUNTER_RAWCOUNT |
| Flow Rate PATH Rejections | Shows the number of PATH messages rejected due to flow rate policy. | PERF_COUNTER_RAWCOUNT |
| Flow Rate RESV Rejections | Shows the number of RESV messages rejected due to flow rate policy. | PERF_COUNTER_RAWCOUNT |
| Other Policy PATH Rejections | Shows the number of PATH messages rejected due to other policies on the subnet. | PERF_COUNTER_RAWCOUNT |
| Other Policy RESV Rejections | Shows the number of RESV messages rejected due to other policies on the subnet. | PERF_COUNTER_RAWCOUNT |
| PATH Message Changes Admitted | Shows the number of changes to PATH messages admitted. | PERF_COUNTER_RAWCOUNT |
| PATH Messages Admitted | Shows the number of PATH messages admitted. | PERF_COUNTER_RAWCOUNT |
| Peak Rate PATH Rejections | Shows the number of PATH messages rejected because their peak rate exceeded peak rate policy. | PERF_COUNTER_RAWCOUNT |
| Peak Rate RESV Rejections | Shows the number of RESV messages rejected because their peak rate exceeded peak rate policy. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| RESV Message Changes Admitted | Shows the number of changes to RESV messages admitted. | PERF_COUNTER_RAWCOUNT |
| RESV Messages Admitted | Shows the number of RESV messages admitted. | PERF_COUNTER_RAWCOUNT |
| Total Flow Rate PATH Rejections | Shows the number of PATH messages rejected because their total peak rate exceeded total flow rate policy. | PERF_COUNTER_RAWCOUNT |
| Total Flow Rate RESV Rejections | Shows the number of RESV messages rejected because their total peak rate exceeded the total flow rate policy. | PERF_COUNTER_RAWCOUNT |
| Total Peak Rate PATH Rejections | Shows the number of PATH messages rejected because their total peak rate exceeded the total peak rate policy. | PERF_COUNTER_RAWCOUNT |
| Total Peak Rate RESV Rejections | Shows the number of RESV messages rejected because their total peak rate exceeded the total peak rate policy. | PERF_COUNTER_RAWCOUNT |
| User ID Change PATH Rejections | Shows the number of PATH messages rejected because the user ID changed. | PERF_COUNTER_RAWCOUNT |
| User ID Change RESV Rejections | Shows the number of RESV messages rejected because the user ID changed. | PERF_COUNTER_RAWCOUNT |

# Active Server Pages Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Active Server Pages performance object consists of counters that monitor errors, requests, sessions, and other data generated by Active Server Pages (ASP pages) applications.

| Counter Name | Description | Counter Type |
|---|---|---|
| Debugging Requests | Shows the number of ASP pages sent to the script debugger. | PERF_COUNTER_RAWCOUNT |
| Errors During Script Runtime | Shows the number of requests that fail due to run-time errors. | PERF_COUNTER_RAWCOUNT |
| Errors From ASP Preprocessor | Shows the number of requests that fail due to preprocessor errors. | PERF_COUNTER_RAWCOUNT |
| Errors From Script Compilers | Shows the total number of requests that fail due to script compilation errors. | PERF_COUNTER_RAWCOUNT |
| Errors/sec | Shows the number of errors that occur per second. | PERF_COUNTER_COUNTER |
| Request Bytes In Total | Shows the total size of all requests. | PERF_COUNTER_RAWCOUNT |
| Request Bytes Out Total | Shows the total size of all responses sent to clients. This does not include the standard Hypertext Transfer Protocol (HTTP) response headers. | PERF_COUNTER_RAWCOUNT |
| Request Execution Time | Shows the time, in milliseconds, that it took to execute the most recent request. | PERF_COUNTER_RAWCOUNT |
| Request Wait Time | Shows the time, in milliseconds, that the most recent request was waiting in the queue. | PERF_COUNTER_RAWCOUNT |
| Requests Disconnected | Shows the number of requests that were disconnected due to a communications failure. | PERF_COUNTER_RAWCOUNT |
| Requests Executing | Shows the number of requests that are currently being executed. | PERF_COUNTER_RAWCOUNT |
| Requests Failed Total | Shows the total number of requests that fail due to errors, authorization failure, or rejections. | PERF_COUNTER_RAWCOUNT |
| Requests Not Authorized | Shows the number of requests that fail due to insufficient access rights. | PERF_COUNTER_RAWCOUNT |
| Requests Not Found | Shows the number of requests for files that were not found. | PERF_COUNTER_RAWCOUNT |
| Requests Queued | Shows the number of requests waiting for service from the queue. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Requests Rejected | Shows the total number of requests that were not executed due to insufficient resources for processing the requests. This may be due to configuration problems or a memory limitation. | PERF_COUNTER_RAWCOUNT |
| Requests Succeeded | Shows the number of requests that were successfully executed. | PERF_COUNTER_RAWCOUNT |
| Requests Timed Out | Shows the number of requests that timed out. | PERF_COUNTER_RAWCOUNT |
| Requests Total | Shows the total number of requests since the service was started. | PERF_COUNTER_RAWCOUNT |
| Requests/sec | Shows the number of requests that were executed per second. This value is important for monitoring server performance. | PERF_COUNTER_COUNTER |
| Script Engines Cached | Shows the number of script engines that are in the cache. | PERF_COUNTER_RAWCOUNT |
| Session Duration | Shows the time, in milliseconds, that the most recent session lasted. | PERF_COUNTER_RAWCOUNT |
| Sessions Current | Shows the number of sessions that are being serviced. | PERF_COUNTER_RAWCOUNT |
| Sessions Timed Out | Shows the number of sessions that have timed out. | PERF_COUNTER_RAWCOUNT |
| Sessions Total | Shows the total number of sessions that have been opened since the service was started. | PERF_COUNTER_RAWCOUNT |
| Templates Cached | Shows the number of templates that are currently in the ASP page file cache. | PERF_COUNTER_RAWCOUNT |
| Template Cache Hit Rate | Shows the percentage of requests found in the template cache over the sample interval. | PERF_COUNTER_RAWCOUNT |
| Template Notifications | Shows the number of templates invalidated in the cache due to change notification. | PERF_COUNTER_RAWCOUNT |
| Transactions Aborted | Shows the number of transactions that were aborted (rolled back). | PERF_COUNTER_RAWCOUNT |
| Transactions Committed | Shows the number of transactions that were committed. | PERF_COUNTER_RAWCOUNT |
| Transactions Pending | Shows the number of transactions that have not yet been committed. | PERF_COUNTER_RAWCOUNT |
| Transactions Total | Shows the total number of transactions since the service was started. This counter reports the sum of the values of Transactions Aborted, Transactions Committed, and Transactions Pending. | PERF_COUNTER_RAWCOUNT |
| Transactions/sec | Shows the number of transactions started per second. | PERF_COUNTER_COUNTER |

# Apple Talk Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The AppleTalk performance object consists of counters that monitor traffic on the AppleTalk network.

| Counter Name | Description | Counter Type |
|---|---|---|
| AARP Packets/sec | Shows the rate, in incidents per second, at which AppleTalk Address Resolution Protocol (AARP) packets were received on this port. | PERF_COUNTER_COUNTER |
| ATP ALO Response/sec | Shows the rate, in incidents per second, at which AppleTalk Transaction Protocol (ATP) At-Least-Once transaction responses were received on this port. | PERF_COUNTER_COUNTER |
| ATP Packets/sec | Shows the rate, in incidents per second, at which ATP packets were received on this port. | PERF_COUNTER_COUNTER |
| ATP Recvd Release/sec | Shows the rate, in incidents per second, at which ATP transaction release packets were received on this port. | PERF_COUNTER_COUNTER |
| ATP Response Timeouts | Shows the number of ATP release timers that have expired on this port since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| ATP Retries Local | Shows the number of ATP requests that were retransmitted on this port since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| ATP Retries Remote | Shows the number of ATP requests that were retransmitted to this port since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| ATP XO Response/sec | Shows the rate, in incidents per second, at which ATP Exactly-Once transaction responses were received on this port. | PERF_COUNTER_COUNTER |
| Average Time/AARP Packet | Shows the average time, in milliseconds, that was needed to process an AARP packet on this port. | PERF_AVERAGE_BULK |
| Average Time/ATP Packet | Shows the average time, in milliseconds, that was needed to process an ATP packet on this port. | PERF_AVERAGE_BULK |
| Average Time/DDP Packet | Shows the average time, in milliseconds, that was needed to process a Data Delivery Protocol (DDP) packet on this port. | PERF_AVERAGE_BULK |
| Average Time/NBP Packet | Shows the average time, in milliseconds, that was needed to process a Name Binding Protocol (NBP) packet on this port. | PERF_AVERAGE_BULK |
| Average Time/RTMP Packet | Shows the average time, in milliseconds, that was needed to process a Routing Table Maintenance Protocol (RTMP) packet on this port. | PERF_AVERAGE_BULK |

| | | |
|---|---|---|
| Average Time/ZIP Packet | Shows the average time, in milliseconds, that was needed to process a Zone Information Protocol (ZIP) packet on this port. | PERF_AVERAGE_BULK |
| Bytes In/sec | Shows the rate, in incidents per second, at which bytes were received on this port. | PERF_COUNTER_BULK_COUNT |
| Bytes Out/sec | Shows the rate, in incidents per second, at which bytes were sent on this port. | PERF_COUNTER_BULK_COUNT |
| Current Nonpaged Pool | Shows the current amount of nonpaged memory resources that were used by AppleTalk. | PERF_COUNTER_RAWCOUNT |
| DDP Packets/sec | Shows the rate, in incidents per second, at which DDP packets were received on this port. | PERF_COUNTER_COUNTER |
| NBP Packets/sec | Shows the rate, in incidents per second, at which NBP packets were received on this port. | PERF_COUNTER_COUNTER |
| Packets Dropped | Shows the number of packets that were dropped due to resource limitations on this port since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| Packets In/sec | Shows the rate, in incidents per second, at which packets were received on this port. | PERF_COUNTER_COUNTER |
| Packets Out/sec | Shows the rate, in incidents per second, at which packets were sent on this port. | PERF_COUNTER_COUNTER |
| Packets Routed In/sec | Shows the rate, in incidents per second, at which packets were routed on this port. | PERF_COUNTER_COUNTER |
| Packets Routed Out/sec | Shows the rate, in incidents per second, at which packets were routed out on this port. | PERF_COUNTER_COUNTER |
| RTMP Packets/sec | Shows the rate, in incidents per second, at which RTMP packets were received on this port. | PERF_COUNTER_COUNTER |
| ZIP Packets/sec | Shows the rate, in incidents per second, at which ZIP packets were received on this port. | PERF_COUNTER_COUNTER |

# Battery Status Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Battery Status performance object reports the battery status on laptops and on other computers that use batteries, based on Windows Management Instrumentation (WMI). Battery Status is only displayed in Performance Console when batteries are available in your computer and the WMI Driver is installed.

| **Counter Name** | **Description** | **Counter Type** |
|---|---|---|
| Charge Rate | Shows the rate of battery charge in milliwatts (mW). If the battery is not charging, or is discharging, then this value will be 0. | WMI-Based Driver |
| Discharge Rate | Shows the rate of battery discharge in milliwatts (mW). If the battery is not discharging, or is charging, then this value will be 0. | WMI-Based Driver |
| Remaining Battery Capacity | Shows the amount of charge remaining in the battery in milliwatts per hour (mWh). | WMI-Based Driver |
| Battery Tag | Shows the number of times that the battery has been changed. | WMI-Based Driver |
| Voltage | Shows the voltage of the battery in milliwatts (mW). | WMI-Based Driver |

# Browser Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Browser performance object consists of counters that measure the rates of announcements, enumerations, and other browser transmissions.

| Counter Name | Description | Counter Type |
|---|---|---|
| Announcements Domain/sec | Shows the rate at which a domain has announced itself to the network. | PERF_COUNTER_BULK_COUNT |
| Announcements Server/sec | Shows the rate at which the servers in this domain have announced themselves to the server. | PERF_COUNTER_BULK_COUNT |
| Announcements Total/sec | Shows the sum of the values of Announcements Domain/sec and Announcements Server/sec. | PERF_COUNTER_BULK_COUNT |
| Duplicate Master Announcements | Shows the number of times that the master browser has detected another master browser on the same domain. | PERF_COUNTER_RAWCOUNT |
| Election Packets/sec | Shows the rate at which browser election packets have been received by the workstation. | PERF_COUNTER_COUNTER |
| Enumerations Domain/sec | Shows the rate at which domain browse requests have been processed by this workstation. | PERF_COUNTER_COUNTER |
| Enumerations Other/sec | Shows the rate of browse requests processed by this workstation that are not domain or server browse requests. | PERF_COUNTER_COUNTER |
| Enumerations Server/sec | Shows the rate at which server browse requests have been processed by this workstation. | PERF_COUNTER_COUNTER |
| Enumerations Total/sec | Shows the rate at which browse requests have been processed by this workstation. This value is the sum of the values of Enumerations Domain/sec, Enumerations Other/sec, and Enumerations Server/sec. | PERF_COUNTER_COUNTER |
| Illegal Datagrams/sec | Shows the rate at which incorrectly formatted datagrams have been received by the workstation. | PERF_COUNTER_BULK_COUNT |
| Mailslot Allocations Failed | Shows the number of times that the datagram receiver has failed to allocate a buffer to hold a user mailslot write. | PERF_COUNTER_RAWCOUNT |
| Mailslot Opens Failed/sec | Shows the rate at which this workstation received mailslot messages to be delivered to mailslots that are not present on this workstation. | PERF_COUNTER_COUNTER |
| Mailslot Receives Failed | Shows the number of mailslot messages that could not be received due to transport failures. | PERF_COUNTER_RAWCOUNT |
| Mailslot Writes Failed | Shows the total number of mailslot messages that have been successfully received, but could not be written to the mailslot. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Mailslot Writes/sec | Shows the rate at which mailslot messages have been successfully received. | PERF_COUNTER_COUNTER |
| Missed Mailslot Datagrams | Shows the number of mailslot datagrams that have been discarded due to configuration or allocation limits. | PERF_COUNTER_RAWCOUNT |
| Missed Server Announcements | Shows the number of server announcements that have been missed due to configuration or allocation limits. | PERF_COUNTER_RAWCOUNT |
| Missed Server List Requests | Shows the number of times a request to retrieve a list of browser servers was received by this workstation, but could not be processed. | PERF_COUNTER_RAWCOUNT |
| Server Announce Allocations Failed/sec | Shows the rate at which server (or domain) announcements have failed due to lack of memory. | PERF_COUNTER_COUNTER |
| Server List Requests/sec | Shows the rate at which requests to retrieve a list of browser servers have been processed by this workstation. | PERF_COUNTER_COUNTER |

# Cache Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Cache performance object consists of counters that monitor the file system cache, an area of physical memory that stores recently used data as long as possible to permit access to the data without having to read from the disk. Because applications typically use the cache, the cache is monitored as an indicator of application input/output (I/O) operations. When memory is plentiful, the cache can grow, but when memory is scarce, the cache can become too small to be effective.

| **Counter Name** | **Description** | **Counter Type** |
|---|---|---|
| Async Copy Reads/sec | Shows the rate at which read operations from pages of the file system cache involve a memory copy of the data from the cache to the application's buffer. The application regains control immediately, even if the disk must be accessed to retrieve the page. | PERF_COUNTER_COUNTER |
| Async Data Maps/sec | Shows the rate at which an application that uses a file system (such as the NTFS file system) to map a page of a file into the file system cache does not wait for the page to be retrieved, if the page is not in main memory. | PERF_COUNTER_COUNTER |
| Async Fast Reads/sec | Shows the rate at which read operations from the file system cache bypass the installed file system and retrieve the data directly from the cache. Normally, file I/O requests invoke the file system to retrieve data from a file, but this path permits data to be retrieved from the cache directly (without file system involvement) if the data is in the cache. Even if the data is not in the cache, one invocation of the file system is avoided. If the data is not in the cache, the request does not wait until the data has been retrieved from the disk, but gets control immediately. | PERF_COUNTER_COUNTER |
| Async MDL Reads/sec | Shows the rate at which read operations from the file system cache use a memory descriptor list (MDL) to access the pages. The MDL contains the physical address of each page in the transfer, thus permitting direct memory access (DMA) of the pages. If the accessed pages are not in main memory, the calling application program does not wait for the pages to be retrieved from disk through a page fault. | PERF_COUNTER_COUNTER |
| Async Pin Reads/sec | Shows the rate at which data is read into the file system cache before writing the data back to disk. Pages read in this fashion are "pinned" in memory at the completion of the read. *Pinned* pages are those that are read into the file system cache before the system writes data back to the disk at the completion of the read. The file system regains control immediately, even if the disk must be accessed to retrieve the page. While pinned, a page's physical address is not altered. | PERF_COUNTER_COUNTER |
| Copy Read Hits % | Shows the percentage of cache copy read requests that did not require a disk read to access the page in the cache. A *copy read* is a file read operation that is satisfied by a memory copy from a page in the cache to the application's buffer. The LAN redirector uses this method for retrieving information from the cache, as does the LAN server for small transfers. This method is also used by the disk file systems. | PERF_SAMPLE_FRACTION |
| Copy Reads/sec | Shows the rate at which read operations from pages of the file system cache involve a copy read. | PERF_COUNTER_COUNTER |
| Data Flush Pages/sec | Shows the rate at which the file system cache has flushed its contents to disk in response to a request to flush, or to satisfy a write-through file write request. More than one page can be transferred on each flush operation. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Data Flushes/sec | Shows the rate at which the file system cache has flushed its contents to disk in response to a request to flush, or to satisfy a write-through file write request. | PERF_COUNTER_COUNTER |
| Data Map Hits % | Shows the percentage of data maps in the file system cache that can be resolved without having to retrieve a page from the disk, because the page is already in physical memory. | PERF_SAMPLE_FRACTION |
| Data Map Pins/sec | Shows the rate at which data maps in the file system cache resulted in pinning a page in main memory. | PERF_SAMPLE_FRACTION |
| Data Maps/sec | Shows the rate at which a file system, such as NTFS, maps a page of a file into the file system cache to read the page. | PERF_COUNTER_COUNTER |
| Fast Read Not Possibles/sec | Shows the rate at which an application programming interface (API) function call attempts to bypass the file system to get to data in the file system cache that required invoking the file system. | PERF_COUNTER_COUNTER |
| Fast Read Resource Misses/sec | Shows the rate at which cache misses occur because there are not enough resources to satisfy the request. | PERF_COUNTER_COUNTER |
| Fast Reads/sec | Shows the rate at which read operations from the file system cache bypass the installed file system and retrieve the data directly from the cache. | PERF_COUNTER_COUNTER |
| Lazy Write Flushes/sec | Shows the rate at which the Lazy Writer thread writes to disk. | PERF_COUNTER_COUNTER |
| Lazy Write Pages/sec | Shows the rate at which the Lazy Writer thread has written to disk. | PERF_COUNTER_COUNTER |
| MDL Read Hits % | Shows the percentage of MDL read requests to the file system cache that did not have to access the disk to provide memory access to the page or pages in the cache. | PERF_SAMPLE_FRACTION |
| MDL Reads/sec | Shows the rate at which read operations from the file system cache use an MDL to access the data. The LAN server uses this method for large transfers out of the server. | PERF_COUNTER_COUNTER |
| Pin Read Hits % | Shows the percentage of pin read requests that did not have to access the disk to provide access to the page in the file system cache. | PERF_SAMPLE_FRACTION |
| Pin Reads/sec | Shows the rate at which data is read into the file system cache before writing the data back to disk. Pages read in this fashion are pinned in memory at the completion of the read. | PERF_COUNTER_COUNTER |
| Read Aheads/sec | Shows the rate at which read operations from the file system cache detect sequential access to a file. *Read aheads* permit data to be transferred in larger blocks than those being requested by the application, reducing the overhead per access. | PERF_COUNTER_COUNTER |
| Sync Copy Reads/sec | Shows the rate at which read operations from pages of the file system cache involve a memory copy of the data from the cache to the application's buffer. The file system does not regain control until the copy operation is complete, even if the disk must be accessed to retrieve the page. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Sync Data Maps/sec | Shows the rate at which a file system (such as NTFS) maps a page of a file into the file system cache to read the page, and — if the page is not in main memory — waits for it to be retrieved. | PERF_COUNTER_COUNTER |
| Sync Fast Reads/sec | Shows the rate at which read operations from the file system cache bypass the installed file system and retrieve the data directly from the cache. | PERF_COUNTER_COUNTER |
| Sync MDL Reads/sec | Shows the rate at which read operations from the file system cache use an MDL to access the pages. | PERF_COUNTER_COUNTER |
| Sync Pin Reads/sec | Shows the rate at which data is read into the file system cache before it is written back to disk. Pages read in this fashion are pinned in memory at the completion of the read. | PERF_COUNTER_COUNTER |

Windows Server 2003 System Performance Counters

# Client Service for NetWare Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Client Service for NetWare performance object consists of counters that measure packet transmission rates, logon attempts, and connections.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Received/sec | Shows the rate at which bytes are coming in to the redirector from the network. This counter includes all application data in addition to network protocol information (such as packet headers). | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the rate at which the redirector is processing data bytes. This counter includes all application and file data in addition to network protocol information (such as packet headers). | PERF_COUNTER_BULK_COUNT |
| Bytes Transmitted/sec | Shows the rate at which bytes are leaving the redirector to the network. This counter includes all application data in addition to network protocol information (such as packet headers). | PERF_COUNTER_BULK_COUNT |
| Connect NetWare 2.x | Shows the number of connections to NetWare 2.*x* servers. | PERF_COUNTER_RAWCOUNT |
| Connect NetWare 3.x | Shows the number of connections to NetWare 3.*x* servers. | PERF_COUNTER_RAWCOUNT |
| Connect NetWare 4.x | Shows the number of connections to NetWare 4.*x* servers. | PERF_COUNTER_RAWCOUNT |
| File Data Operations/sec | Shows the rate at which the redirector is processing data operations. In general, one operation includes many bytes, although this may not always be the case because of operation overhead. You can determine the efficiency of this path by dividing the value of Bytes/sec by the value of File Data Operations/sec to determine the average number of bytes transferred per operation. | PERF_COUNTER_COUNTER |
| File Read Operations/sec | Shows the rate at which applications are asking the redirector for data. Each call to a file system (or similar application programming interface (API) call) counts as one operation. | PERF_COUNTER_COUNTER |
| File Write Operations/sec | Shows the rate at which applications are sending data to the redirector. Each call to a file system (or similar API call) counts as one operation. | PERF_COUNTER_COUNTER |
| Packet Burst IO/sec | Shows the sum of the values of Packet Burst Read NCP Count/sec and Packet Burst Write NCP Count/sec. | PERF_COUNTER_COUNTER |
| Packet Burst Read NCP Count/sec | Shows the rate at which NetWare Core Protocol (NCP) requests packet burst reads. The windowing Packet Burst Protocol is built on top of Internetwork Packet Exchange (IPX). It can speed the transfer of multiple-packet NCP file reads and writes. | PERF_COUNTER_COUNTER |
| Packet Burst Read Timeouts/sec | Shows the rate at which the Client Service for NetWare was required to retransmit a packet burst read request because the NetWare server took too long to respond. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Packet Burst Write NCP Count/sec | Shows the rate at which NCP requests packet burst writes. | PERF_COUNTER_COUNTER |
| Packet Burst Write Timeouts/sec | Shows the rate at which the Client Service for NetWare was required to retransmit a burst write request because the NetWare server took too long to respond. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate at which the redirector receives packets, also called server message blocks (SMBs). Network transmissions are divided into packets. The average number of bytes received in a packet can be obtained by dividing the value of Bytes Received/sec by the value of Packets Received/sec. Some packets received might not contain incoming data (for example, an acknowledgment to a write operation made by the redirector would count as an incoming packet). | PERF_COUNTER_BULK_COUNT |
| Packets Transmitted/sec | Shows the rate at which the redirector sends packets. The average number of bytes transmitted in a packet can be obtained by dividing the value of Bytes Transmitted/sec by the value of Packets Transmitted/sec. | PERF_COUNTER_BULK_COUNT |
| Packets/sec | Shows the rate at which the redirector processes data packets. In general, one packet includes many bytes, although this may not always be the case because each packet has protocol overhead. The average number of bytes transferred in a packet can be obtained by dividing the value of Bytes/sec by the value of Packets/sec. You can also divide this counter by the value of Operations/sec to determine the average number of packets per operation, another measure of efficiency. | PERF_COUNTER_BULK_COUNT |
| Read Operations Random/sec | Shows the rate at which, on a file-by-file basis, nonsequential read operations are made. If a read is made using a particular file handle, and then is followed by another read that is not the next contiguous byte, this counter is incremented by one. | PERF_COUNTER_COUNTER |
| Read Packets/sec | Shows the rate at which read packets are being placed on the network. Each time a single packet is sent with a request to read data remotely, this counter is incremented by one. | PERF_COUNTER_COUNTER |
| Server Disconnects | Shows the number of times that a server has disconnected the redirector. | PERF_COUNTER_RAWCOUNT |
| Server Reconnects | Shows the number of times that the redirector reconnected to a server to complete a new active request. The redirector may be disconnected by the server if it remains inactive for too long. Even if all of your remote files are closed, the redirector keeps your connections intact on your local computer for about 10 minutes. Such inactive connections are called dormant connections. Reconnecting may take a substantial period of time. | PERF_COUNTER_RAWCOUNT |
| Server Sessions | Shows the total number of security objects managed by the redirector. Logging on to a server followed by a network access to the same server establishes one connection, but two sessions. Each session corresponds to one security object. | PERF_COUNTER_RAWCOUNT |
| Write Operations Random/sec | Shows the rate at which, on a file-by-file basis, nonsequential write operations are made. If a write is made using a particular file handle, and then is followed by another write that is not the next contiguous byte, this counter is incremented by one. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Write Packets/sec | Shows the rate at which write operations are sent to the network. Each time a single packet is sent with a request to write remote data, this counter is incremented by one. | PERF_COUNTER_COUNTER |

# Database Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Database performance object consists of counters that describe the activity of the Extensible Storage Engine (ESE), a transacted database management system that stores all Microsoft Active Directory objects. The objects in the ESE database can access the Database performance object, which provides counters to measure the activity of the ESE. The Database object is not installed by default; use Lodctr.exe in the Microsoft Platform Software Development Kit (SDK) to install it. For more information about the Platform SDK, see the Software Development Kit (SDK) information in the MSDN Library link on the Web Resources page.

These counters provide performance statistics only for processes that use the ESE. This section does not describe counters that are for developer use only.

| Counter Name | Description | Counter Type |
|---|---|---|
| Cache % Hit | Shows the percentage of database file page requests that were fulfilled by the database cache manager without causing a file operation. If this percentage is too low, the database cache size may be too small. | PERF_SAMPLE_FRACTION |
| Cache Page Fault Stalls/sec | Shows the number of page faults that cannot be serviced because there are no pages available for allocation from the database cache. If this counter is nonzero most of the time, the clean threshold may be too low. | PERF_COUNTER_COUNTER |
| Cache Page Faults/sec | Shows the number of database file page requests that require the database cache manager to allocate a new page from the database cache. If this rate is too high, the database cache size may be too small. | PERF_COUNTER_COUNTER |
| Cache Size | Shows the amount of system memory used by the database cache manager to hold commonly used information from the database file(s), in order to reduce the number of file operations the system must perform. If the database cache size seems to be too small for optimal performance and there is very little available memory on the system (see Memory\Available Bytes), adding more memory to the system may increase performance. If there is a lot of available memory on the system and the database cache size does not grow beyond a certain point, the database cache size may be too small. Increasing this limit may increase performance. | PERF_COUNTER_RAWCOUNT |
| File Bytes Read/sec | Shows the rate at which bytes are read from the database file(s) into the database cache. If this rate is too high, the database cache size may be too small. | PERF_COUNTER_COUNTER |
| File Bytes Written/sec | Shows the rate at which bytes are written to the database file(s) from the database cache. If this rate is too high, the database cache size may be too small. | PERF_COUNTER_COUNTER |
| File Operations Pending | Shows the number of reads and writes issued by the database cache manager to the database file(s) that are currently being processed by the operating system. A large number of pending file operations can increase system throughput but will increase response time for individual operations. Typically, a larger number means that file operations to the database file(s) may be a bottleneck. | PERF_COUNTER_RAWCOUNT |
| File Operations/sec | Shows the number of reads and writes issued by the database cache manager to the database file(s). If this rate is too high, the database cache size may be too small. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Log Record Stalls/sec | Shows the number of log records that cannot be added to the log buffers because the buffers are full. If this counter is nonzero most of the time, the log buffer size may be a bottleneck. | PERF_COUNTER_COUNTER |
| Log Threads Waiting | Shows the number of threads waiting for their data to be written to the log during a database update. If this number is too high, the log may be a bottleneck. | PERF_COUNTER_RAWCOUNT |
| Log Writes/sec | Shows the number of times that the contents of the log buffers are written to the log. If this number approaches the maximum write rate for the media holding the log, the log may be a bottleneck. | PERF_COUNTER_COUNTER |
| Table Open Cache % Hit | Shows the percentage of database tables opened by using cached schema information. If this percentage is too low, the table cache size may be too small. | PERF_SAMPLE_FRACTION |
| Table Open Cache Hits/sec | Shows the number of database tables opened by using cached schema information. If this rate is too low, the table cache size may be too small. | PERF_COUNTER_COUNTER |
| Table Open Cache Misses/sec | Shows the number of database tables opened without using cached schema information. If this rate is too high, the table cache size may be too small. | PERF_COUNTER_COUNTER |
| Table Opens/sec | Shows the number of database tables opened. | PERF_COUNTER_COUNTER |

# DHCP Server Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The DHCP Server performance object consists of counters that monitor DHCP service activity. The DHCP service enables the server to perform as a DHCP server and configure DHCP-enabled client computers on your network, as described in the DHCP standard. This object is available when the service is running.

| Counter Name | Description | Counter Type |
|---|---|---|
| Acks/sec | Shows the rate at which DHCP acknowledgements have been sent by the DHCP server. A sudden or abnormal increase in this number indicates that a large number of clients are being renewed by the DHCP server. This may indicate that scope lease times are too short. | PERF_COUNTER_COUNTER |
| Active Queue Length | Shows the number of packets in the processing queue of the DHCP server. This number equals the number of unprocessed messages received by the server. A large number may indicate heavy server traffic. | PERF_COUNTER_RAWCOUNT |
| Conflict Check Queue Length | Shows the number of packets waiting in the DHCP server queue due to conflict detection. This queue holds messages that cannot be responded to while the DHCP server performs address conflict detection. A large value may indicate that the DHCP server property **Conflict detection attempts** has been set too high, or that there is heavy lease traffic on the server. | PERF_COUNTER_RAWCOUNT |
| Declines/sec | Shows the rate at which DHCP declines have been received by the DHCP server. A high value indicates that several clients have found their addresses to be in conflict, possibly indicating network trouble. You may want to enable conflict detection on the DHCP server. Conflict detection should only be used temporarily on the server. | PERF_COUNTER_COUNTER |
| Discovers/sec | Shows the rate at which DHCP discovers have been received by the DHCP server. A sudden or abnormal increase indicates that a large number of clients are probably attempting to initialize and obtain an IP address lease from the server, such as when a number of client computers are started at one time. | PERF_COUNTER_COUNTER |
| Duplicates Dropped/sec | Shows the rate at which the DHCP server received duplicate packets. A large number indicates that clients are probably timing out too fast or that the server is not responding very fast. | PERF_COUNTER_COUNTER |
| Informs/sec | Shows the rate at which DHCP informs have been received by the DHCP server. DHCP inform messages are used when the DHCP server queries for the directory service for the enterprise root, and when dynamic update updates are being done on behalf of clients by the server. | PERF_COUNTER_COUNTER |
| Milliseconds per Packet (Avg). | Shows the average time per packet taken by the DHCP server to send a response. This number can vary depending on the server hardware and its input/output (I/O) subsystem. A sudden or unreasonable increase may indicate a problem, either with the I/O subsystem slowing or because of intrinsic processing overhead on the server computer. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Nacks/sec | Shows the rate at which DHCP negative acknowledgments (Nacks) have been sent by the DHCP server. A very high value may indicate potential network problems, such as misconfiguration of clients or the server. One possible cause of server problems is a deactivated scope. For clients, a very high value could be caused by computers moving between subnets, such as portable computers or other mobile devices. | PERF_COUNTER_COUNTER |
| Offers/sec | Shows that rate at which DHCP offers have been sent out by the DHCP server. A sudden or abnormal increase in this number indicates heavy traffic on the server. | PERF_COUNTER_COUNTER |
| Packets Expired/sec | Shows the rate at which packets expire in the DHCP server message queue. Packets expire because they are in the server's internal message queue for too long. A large number indicates that the server is either taking too long to process some packets while other packets are queued and becoming stale, or traffic on the network is too high for the DHCP server to handle. This could suggest a disk or memory bottleneck. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate at which packets are received by the DHCP server. A large number indicates heavy DHCP-related message traffic to the server. | PERF_COUNTER_COUNTER |
| Releases/sec | Shows the rate at which DHCP releases have been received by the DHCP server. This number is only incremented when a client manually releases its address, such as when the **ipconfig /release** command is used at the client computer. Because clients rarely release their addresses, this counter should not be high for most networks and configurations. | PERF_COUNTER_COUNTER |
| Requests/sec | Shows the rate at which DHCP requests have been received by the DHCP server. A sudden or abnormal increase in this number indicates that a large number of clients are probably trying to renew their leases with the DHCP server. This may indicate that scope lease times are too short. | PERF_COUNTER_COUNTER |

# Distributed Transaction Coordinator Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The performance object provides statistics about Microsoft Distributed Transaction Coordinator (MS DTC), part of Component Services (formerly known as Microsoft Transaction Server) that coordinates external (two-phase) transactions. Among other things, MS DTC is used to coordinate two-phase transactions by Message Queuing.

| Counter Name | Description | Counter Type |
|---|---|---|
| Aborted Transactions | Shows the number of transactions that were aborted. | PERF_COUNTER_RAWCOUNT |
| Aborted Transactions/sec | Shows the rate, in incidents per second, at which transactions were aborted. | PERF_COUNTER_RAWCOUNT |
| Active Transactions | Shows the number of transactions that were active during the sample period. | PERF_COUNTER_RAWCOUNT |
| Active Transactions Maximum | Shows the maximum number of transactions that were ever concurrently active. | PERF_COUNTER_RAWCOUNT |
| Committed Transactions | Shows the number of transactions that were committed. | PERF_COUNTER_RAWCOUNT |
| Committed Transactions/sec | Shows the rate, in incidents per second, at which transactions were committed. | PERF_COUNTER_RAWCOUNT |
| Force Aborted Transactions | Shows the number of transactions that were aborted by the system administrator. | PERF_COUNTER_RAWCOUNT |
| Force Committed Transactions | Shows the number of transactions that were committed by the system administrator. | PERF_COUNTER_RAWCOUNT |
| In Doubt Transactions | Shows the number of transactions that were in doubt; that is, neither committed nor aborted. | PERF_COUNTER_RAWCOUNT |
| Response Time – Average | Shows the average time between when transactions were begun and when they were committed. | PERF_COUNTER_RAWCOUNT |
| Response Time – Maximum | Shows the maximum time between when transactions were begun and when they were committed. | PERF_COUNTER_RAWCOUNT |
| Response Time – Minimum | Shows the minimum time between when transactions were begun and when they were committed. | PERF_COUNTER_RAWCOUNT |
| Transactions/sec | Shows the rate, in incidents per second, at which transactions were performed. | PERF_COUNTER_RAWCOUNT |

# DNS Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Domain Name System (DNS) is an Internet and TCP/IP standard name service. The DNS performance object consists of counters for monitoring various areas of performance of the DNS service, which enables client computers on your network to register and resolve DNS domain names. These names are used to find and access resources offered by other computers on your network or other networks, such as the Internet. The data reported by the DNS object includes the number of overall queries and responses processed by a DNS server, the number of DNS queries and responses processed using either the User Datagram Protocol (UDP) or the Transmission Control Protocol (TCP), the number of queries and responses that used recursion to look up and fully resolve DNS names on behalf of requesting clients, and the number of queries and responses made to servers using the WINS lookup integration features of the DNS service.

| Counter Name | Description | Counter Type |
|---|---|---|
| AXFR Request Received | Shows the total number of full zone transfer requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| AXFR Request Sent | Shows the total number of full zone transfer requests that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| AXFR Response Received | Shows the total number of full zone transfer responses that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| AXFR Success Received | Shows the total number of successful full zone transfers that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| AXFR Success Sent | Shows the total number of successful full zone transfers that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Caching Memory | Shows the total amount of caching memory that was used by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Database Node Memory | Shows the total amount of database node memory that was used by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Dynamic Update NoOperation | Shows the total number of NoOperation/empty dynamic update requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Dynamic Update NoOperation/sec | Shows the rate, in incidents per second, at which NoOperation/empty dynamic update requests were received by the DNS server. | PERF_COUNTER_COUNTER |
| Dynamic Update Queued | Shows the total number of dynamic updates that were queued by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Dynamic Update Received | Shows the total number of dynamic update requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Dynamic Update Received/sec | Shows the rate, in incidents per second, at which dynamic update requests were received by the DNS server. | PERF_COUNTER_COUNTER |
| Dynamic Update Rejected | Shows the total number of dynamic updates that were rejected by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Dynamic Update TimeOuts | Shows the total number of dynamic update timeouts of the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Dynamic Update Written to Database | Shows the total number of dynamic updates that were written to the database by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Dynamic Update Written to Database/sec | Shows the rate, in incidents per second, at which dynamic updates were written to the database by the DNS server. | PERF_COUNTER_COUNTER |
| IXFR Request Received | Shows the total number of incremental zone transfer requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| IXFR Request Sent | Shows the total number of incremental zone transfer requests that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| IXFR Response Received | Shows the total number of incremental zone transfer responses that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| IXFR Success Received | Shows the total number of successful incremental zone transfers that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| IXFR Success Sent | Shows the total number of successful incremental zone transfers that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| IXFR TCP Success Received | Shows the total number of successful TCP incremental zone transfers that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| IXFR UDP Success Received | Shows the total number of successful UDP incremental zone transfers that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Nbstat Memory | Shows the total amount of Nbstat memory that was used by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Notify Received | Shows the total number of notifies that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Notify Sent | Shows the total number of notifies that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Record Flow Memory | Shows the total record flow memory that was used by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Recursive Queries | Shows the total number of recursive queries that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Recursive Queries/sec | Shows the rate, in incidents per second, at which recursive queries were received by the DNS server. | PERF_COUNTER_COUNTER |
| Recursive Query Failure | Shows the total number of failures that occurred while processing recursive queries, since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Recursive Query Failure/sec | Shows the rate, in incidents per second, of failures while processing recursive queries. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Recursive Send TimeOuts | Shows the total number of recursive queries sending timeouts since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Recursive TimeOut/sec | Shows the rate, in incidents per second, of recursive queries sending timeouts. | PERF_COUNTER_COUNTER |
| Secure Update Failure | Shows the total number of secure update failures of the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Secure Update Received | Shows the total number of secure update requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Secure Update Received/sec | Shows the rate, in incidents per second, at which secure update requests were received by the DNS server. | PERF_COUNTER_COUNTER |
| TCP Message Memory | Shows the total amount of TCP message memory that was used by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| TCP Query Received | Shows the total number of TCP queries that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| TCP Query Received/sec | Shows the rate, in incidents per second, at which TCP queries were received by the DNS server. | PERF_COUNTER_COUNTER |
| TCP Response Sent | Shows the total number of TCP responses that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| TCP Response Sent/sec | Shows the rate, in incidents per second, at which TCP responses are were sent by the DNS server. | PERF_COUNTER_COUNTER |
| Total Query Received | Shows the total number of queries that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Query Received/sec | Shows the rate, in incidents per second, at which queries were received by the DNS server. | PERF_COUNTER_COUNTER |
| Total Response Sent | Shows the total number of responses that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Response Sent/sec | Shows the rate, in incidents per second, at which responses were sent by the DNS server. | PERF_COUNTER_COUNTER |
| UDP Message Memory | Shows the total amount of UDP message memory that was used by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| UDP Query Received | Shows the total number of UDP queries that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| UDP Query Received/sec | Shows the rate, in incidents per second, at which UDP queries were received by the DNS server. | PERF_COUNTER_COUNTER |
| UDP Response Sent | Shows the total number of UDP responses that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| UDP Response Sent/sec | Shows the rate, in incidents per second, at which UDP responses were sent by the DNS server. | PERF_COUNTER_COUNTER |
| WINS Lookup Received | Shows the total number of WINS lookup requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| WINS Lookup Received/sec | Shows the rate, in incidents per second, at which WINS lookup requests were received by the DNS server. | PERF_COUNTER_COUNTER |
| WINS Response Sent | Shows the total number of WINS lookup responses that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| WINS Response Sent/sec | Shows the rate, in incidents per second, at which WINS lookup responses were sent by the server. | PERF_COUNTER_COUNTER |
| WINS Reverse Lookup Received | Shows the total number of WINS reverse lookup requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| WINS Reverse Lookup Received/sec | Shows the rate, in incidents per second, at which WINS reverse lookup requests were received by the DNS server. | PERF_COUNTER_RAWCOUNT |
| WINS Reverse Response Sent | Shows the total number of WINS reverse lookup responses that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| WINS Reverse Response Sent/sec | Shows the rate, in incidents per second, at which WINS reverse lookup responses were sent by the server. | PERF_COUNTER_COUNTER |
| Zone Transfer Failure | Shows the total number of failed zone transfers that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Zone Transfer Request Received | Shows the total number of zone transfer requests that were received by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Zone Transfer SOA Request Sent | Shows the total number of zone transfer start of authority (SOA) requests that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Zone Transfer Success | Shows the total number of successful zone transfers that were sent by the DNS server since the service was last started. | PERF_COUNTER_RAWCOUNT |

# Fax Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Shared Fax Service performance object tracks fax activity while the Fax service is running. It is recommended that you use the counters in conjunction with event log data about fax events to assess service performance. The following counters can indicate system problems that prevent the fax from being sent or received, such as installation of the wrong modem driver.

| Counter Name | Description | Counter Type |
|---|---|---|
| Inbound Bytes | Shows the number of inbound bytes received by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Inbound Failed Receptions | Shows the number of faxes that were not received, such as a call that was answered without a fax being received. | PERF_COUNTER_RAWCOUNT |
| Inbound Faxes | Shows the number of inbound faxes received by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Inbound Minutes Receiving | Shows the amount of time, in minutes, spent receiving inbound messages. | PERF_COUNTER_RAWCOUNT |
| Inbound Pages | Shows the number of inbound pages received by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Outbound Bytes | Shows the number of outbound bytes sent by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Outbound Failed Connections | Shows the number of faxes that were not sent because there was no dial tone, no answer, busy, or another unknown error. | PERF_COUNTER_RAWCOUNT |
| Outbound Failed Transmissions | Shows the number of faxes that could not be sent. | PERF_COUNTER_RAWCOUNT |
| Outbound Faxes | Shows the number of outbound faxes sent by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Outbound Minutes Sending | Shows the amount of time, in minutes, spent sending outbound messages. | PERF_COUNTER_RAWCOUNT |
| Outbound Pages | Shows the number of outbound pages sent by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Total Bytes | Shows the total number of bytes sent and received by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Total Faxes | Shows the total number of faxes sent and received by Fax Service. | PERF_COUNTER_RAWCOUNT |
| Total Minutes Sending/Receiving | Shows the total amount of time, in minutes, spent sending and receiving. | PERF_COUNTER_RAWCOUNT |
| Total Pages | Shows the total number of pages sent and received by Fax Service. | PERF_COUNTER_RAWCOUNT |

# FileReplicaConn Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The FileReplicaConn performance object displays performance statistics of the Replicaconn object that defines replica connections to Distributed File System (DFS) roots.

| Counter Name | Description | Counter Type |
|---|---|---|
| Authentications | Shows the number of authentications that were performed. | PERF_COUNTER_COUNTER |
| Authentications in Error | Shows the number of authentications that were performed in error. | PERF_COUNTER_COUNTER |
| Bindings | Shows the number of bindings that were completed. | PERF_COUNTER_COUNTER |
| Bindings in Error | Shows the number of bindings that were completed in error. | PERF_COUNTER_COUNTER |
| Communication Timeouts | Shows the number of communications that were timed out. | PERF_COUNTER_COUNTER |
| Fetch Blocks Received | Shows the number of fetch blocks that were received. | PERF_COUNTER_COUNTER |
| Fetch Blocks Received in Bytes | Shows the number of fetch blocks, in bytes, that were received. | PERF_COUNTER_BULK_COUNT |
| Fetch Blocks Sent | Shows the number of fetch blocks that were sent. | PERF_COUNTER_COUNTER |
| Fetch Blocks Sent in Bytes | Shows the number of fetch blocks, in bytes, that were sent. | PERF_COUNTER_BULK_COUNT |
| Fetch Requests Received | Shows the number of fetch requests that were received. | PERF_COUNTER_COUNTER |
| Fetch Requests Sent | Shows the number of fetch requests that were sent. | PERF_COUNTER_COUNTER |
| Inbound Change Orders Dampened | Shows the number of inbound change orders that were dampened. | PERF_COUNTER_COUNTER |
| Join Notifications Received | Shows the number of join notifications that were received. | PERF_COUNTER_COUNTER |
| Join Notifications Sent | Shows the number of join notifications that were sent. | PERF_COUNTER_COUNTER |
| Joins | Shows the number of joins. | PERF_COUNTER_COUNTER |
| Local Change Orders Sent | Shows the number of local change orders that were sent. | PERF_COUNTER_COUNTER |
| Local Change Orders Sent At Join | Shows the number of local change orders that were sent at join. | PERF_COUNTER_COUNTER |
| Outbound Change Orders Dampened | Shows the number of outbound change orders that were dampened. | PERF_COUNTER_COUNTER |
| Packets Sent | Shows the number of packets that were sent. | PERF_COUNTER_COUNTER |
| Packets Sent in Bytes | Shows the number of packets, in bytes, that were sent. | PERF_COUNTER_BULK_COUNT |

| | | |
|---|---|---|
| Packets Sent in Error | Shows the number of packets that were sent in error. | PERF_COUNTER_COUNTER |
| Remote Change Orders Received | Shows the number of remote change orders that were received. | PERF_COUNTER_COUNTER |
| Remote Change Orders Sent | Shows the number of remote change orders that were sent. | PERF_COUNTER_COUNTER |
| Unjoins | Shows the number of unjoins. | PERF_COUNTER_COUNTER |

FileReplicaSet Object
Counters by Feature

# FileReplicaSet Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The FileReplicaSet performance object displays performance statistics of the Replicaset object that defines a *replica set* (one or more *replicas*, shared volumes or directories that store duplicates of the contents of an original share). The object reports statistics for the computer that constitutes the original share. For example, in a bidirectional ring topology of three computers A, B, and C, where computer A and computer C both replicate from computer B, the FileReplicaSet counters would provide data for computer B.

| Counter Name | Description | Counter Type |
|---|---|---|
| Authentications | Shows the number of authentications that were performed. | PERF_COUNTER_COUNTER |
| Authentications in Error | Shows the number of authentications that were performed in error. | PERF_COUNTER_COUNTER |
| Bindings | Shows the number of bindings that were completed. | PERF_COUNTER_COUNTER |
| Bindings in Error | Shows the number of bindings that were completed in error. | PERF_COUNTER_COUNTER |
| Bytes of Files Installed | Shows the number of bytes of files that were installed. | PERF_COUNTER_BULK_COUNT |
| Bytes of Staging Fetched | Shows the number of bytes of staging that were fetched. Staging is the temporary storage of files prior to replication. | PERF_COUNTER_BULK_COUNT |
| Bytes of Staging Generated | Shows the number of bytes of staging that were generated. | PERF_COUNTER_BULK_COUNT |
| Bytes of Staging Regenerated | Shows the number of bytes of staging that were regenerated. | PERF_COUNTER_BULK_COUNT |
| Change Orders Aborted | Shows the number of change orders that were aborted. | PERF_COUNTER_COUNTER |
| Change Orders Evaporated | Shows the number of change orders that were evaporated. | PERF_COUNTER_COUNTER |
| Change Orders Issued | Shows the number of change orders that were issued. | PERF_COUNTER_COUNTER |
| Change Orders Morphed | Shows the number of change orders that were morphed. | PERF_COUNTER_COUNTER |
| Change Orders Propagated | Shows the number of change orders that were propagated. | PERF_COUNTER_COUNTER |
| Change Orders Received | Shows the number of change orders that were received. This is an important counter to monitor. In an idle state this counter should be zero. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Change Orders Retired | Shows the number of change orders that were retired. | PERF_COUNTER_COUNTER |
| Change Orders Retried | Shows the number of change orders that were retried. | PERF_COUNTER_COUNTER |
| Change Orders Retried at Fetch | Shows the number of change orders that were retried at fetch. | PERF_COUNTER_COUNTER |
| Change Orders Retried at Generate | Shows the number of change orders that were retried at generate. | PERF_COUNTER_COUNTER |
| Change Orders Retried at Install | Shows the number of change orders that were retried at install. | PERF_COUNTER_COUNTER |
| Change Orders Retried at Rename | Shows the number of change orders that were retried at rename. | PERF_COUNTER_COUNTER |
| Change Orders Sent | Shows the number of change orders that were sent. This is an important counter to monitor. In an idle state this counter should be zero. | PERF_COUNTER_COUNTER |
| Communication Timeouts | Shows the number of communications that were timed out. | PERF_COUNTER_COUNTER |
| DS Bindings | Shows the number of directory service bindings. | PERF_COUNTER_COUNTER |
| DS Bindings in Error | Shows the number of directory service bindings that were in error. | PERF_COUNTER_COUNTER |
| DS Objects | Shows the number of directory service objects. | PERF_COUNTER_COUNTER |
| DS Objects in Error | Shows the number of directory service objects that were in error. | PERF_COUNTER_COUNTER |
| DS Polls | Shows the number of directory service polls. | PERF_COUNTER_COUNTER |
| DS Polls with Changes | Shows the number of directory service polls with changes. | PERF_COUNTER_COUNTER |
| DS Polls without Changes | Shows the number of directory service polls without changes. | PERF_COUNTER_COUNTER |
| DS Searches | Shows the number of directory service searches. | PERF_COUNTER_COUNTER |
| DS Searches in Error | Shows the number of directory service searches that were in error. | PERF_COUNTER_COUNTER |
| Fetch Blocks Received | Shows the number of fetch blocks that were received. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Fetch Blocks Received in Bytes | Shows the number of fetch blocks, in bytes, that were received. | PERF_COUNTER_BULK_COUNT |
| Fetch Blocks Sent | Shows the number of fetch blocks that were sent. | PERF_COUNTER_COUNTER |
| Fetch Blocks Sent in Bytes | Shows the number of fetch blocks, in bytes, that were sent. | PERF_COUNTER_BULK_COUNT |
| Fetch Requests Received | Shows the number of fetch requests that were received. | PERF_COUNTER_COUNTER |
| Fetch Requests Sent | Shows the number of fetch requests that were sent. | PERF_COUNTER_COUNTER |
| Files Installed | Shows the number of files that were installed. This is an important counter to monitor. In an idle state this counter should be zero. | PERF_COUNTER_COUNTER |
| Files Installed with Error | Shows the number of files that were installed with error. | PERF_COUNTER_COUNTER |
| Inbound Change Orders Dampened | Shows the number of inbound change orders that were dampened. | PERF_COUNTER_COUNTER |
| Join Notifications Received | Shows the number of join notifications that were received. | PERF_COUNTER_COUNTER |
| Join Notifications Sent | Shows the number of join notifications that were sent. | PERF_COUNTER_COUNTER |
| Joins | Shows the number of joins. | PERF_COUNTER_COUNTER |
| KB of Staging Space Free | Shows the number of kilobytes (KB) of staging space that were free. This is an important counter to monitor. In an idle state, this counter should be 660 KB. | PERF_COUNTER_LARGE_RAWCOUNT |
| KB of Staging Space In Use | Shows the number of kilobytes (KB) of staging space that were in use. This is an important counter to monitor. If all available staging space is in use, then replication stops. | PERF_COUNTER_LARGE_RAWCOUNT |
| Local Change Orders Aborted | Shows the number of local change orders that were aborted. | PERF_COUNTER_COUNTER |
| Local Change Orders Issued | Shows the number of local change orders that were issued. | PERF_COUNTER_COUNTER |
| Local Change Orders Morphed | Shows the number of local change orders that were morphed. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Local Change Orders Propagated | Shows the number of local change orders that were propagated. | PERF_COUNTER_COUNTER |
| Local Change Orders Retired | Shows the number of local change orders that were retired. | PERF_COUNTER_COUNTER |
| Local Change Orders Retried | Shows the number of local change orders that were retried. | PERF_COUNTER_COUNTER |
| Local Change Orders Retried at Fetch | Shows the number of local change orders that were retried at fetch. | PERF_COUNTER_COUNTER |
| Local Change Orders Retried at Generate | Shows the number of local change orders that were retried at generate. | PERF_COUNTER_COUNTER |
| Local Change Orders Retried at Install | Shows the number of local change orders that were retried at install. | PERF_COUNTER_COUNTER |
| Local Change Orders Retried at Rename | Shows the number of local change orders that were retried at rename. | PERF_COUNTER_COUNTER |
| Local Change Orders Sent | Shows the number of local change orders that were sent. | PERF_COUNTER_COUNTER |
| Local Change Orders Sent At Join | Shows the number of local change orders that were sent at join. | PERF_COUNTER_COUNTER |
| Outbound Change Orders Dampened | Shows the number of outbound change orders that were dampened. | PERF_COUNTER_COUNTER |
| Packets Received | Shows the number of packets (change notifications, file data, or other command packets) that were received. This is an important counter to monitor. In an idle state, there should be no packets received unless a computer is having trouble joining with other computers in the replica set. | PERF_COUNTER_COUNTER |
| Packets Received in Bytes | Shows the number of packets, in bytes, that were received. | PERF_COUNTER_BULK_COUNT |
| Packets Received in Error | Shows the number of packets received that were in error. | PERF_COUNTER_COUNTER |
| Packets Sent | Shows the number of packets that were sent. This is an important counter to monitor. | PERF_COUNTER_COUNTER |
| Packets Sent in Bytes | Shows the number of packets, in bytes, that were sent. | PERF_COUNTER_BULK_COUNT |

| | | |
|---|---|---|
| Packets Sent in Error | Shows the number of packets that were sent in error. | PERF_COUNTER_COUNTER |
| Remote Change Orders Aborted | Shows the number of remote change orders that were aborted. | PERF_COUNTER_COUNTER |
| Remote Change Orders Issued | Shows the number of remote change orders that were issued. | PERF_COUNTER_COUNTER |
| Remote Change Orders Morphed | Shows the number of remote change orders that were morphed. | PERF_COUNTER_COUNTER |
| Remote Change Orders Propagated | Shows the number of remote change orders that were propagated. | PERF_COUNTER_COUNTER |
| Remote Change Orders Received | Shows the number of remote change orders that were received. | PERF_COUNTER_COUNTER |
| Remote Change Orders Retired | Shows the number of remote change orders that were retired. | PERF_COUNTER_COUNTER |
| Remote Change Orders Retried | Shows the number of remote change orders that were retried. | PERF_COUNTER_COUNTER |
| Remote Change Orders Retried at Fetch | Shows the number of remote change orders that were retried at fetch. | PERF_COUNTER_COUNTER |
| Remote Change Orders Retried at Generate | Shows the number of remote change orders that were retried at generate. | PERF_COUNTER_COUNTER |
| Remote Change Orders Retried at Install | Shows the number of remote change orders that were retried at install. | PERF_COUNTER_COUNTER |
| Remote Change Orders Retried at Rename | Shows the number of remote change orders that were retried at rename. | PERF_COUNTER_COUNTER |
| Remote Change Orders Sent | Shows the number of remote change orders that were sent. | PERF_COUNTER_COUNTER |
| Replica Sets Created | Shows the number of replica sets that were created. | PERF_COUNTER_COUNTER |
| Replica Sets Deleted | Shows the number of replica sets that were deleted. | PERF_COUNTER_COUNTER |
| Replica Sets Removed | Shows the number of replica sets that were removed. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Replica Sets Started | Shows the number of replica sets that were started. | PERF_COUNTER_COUNTER |
| Staging Files Fetched | Shows the number of staging files that were fetched. | PERF_COUNTER_COUNTER |
| Staging Files Generated | Shows the number of staging files that were generated. | PERF_COUNTER_COUNTER |
| Staging Files Generated with Error | Shows the number of staging files that were generated with error. | PERF_COUNTER_COUNTER |
| Staging Files Regenerated | Shows the number of staging files that were regenerated. | PERF_COUNTER_COUNTER |
| Threads exited | Shows the number of threads that were exited. | PERF_COUNTER_COUNTER |
| Threads started | Shows the number of threads that were started. | PERF_COUNTER_COUNTER |
| Unjoins | Shows the number of unjoins. | PERF_COUNTER_COUNTER |
| USN Reads | Shows the number of update sequence number (USN) reads. | PERF_COUNTER_COUNTER |
| USN Records Accepted | Shows the number of USN records that were accepted. This is an important counter to monitor. Replication is triggered by entries to the NTFS USN journal. A high value on this counter, such as one every five seconds, indicates heavy replication traffic and may result in replication latency. | PERF_COUNTER_COUNTER |
| USN Records Examined | Shows the number of USN records that were examined. | PERF_COUNTER_COUNTER |
| USN Records Rejected | Shows the number of USN records that were rejected. | PERF_COUNTER_COUNTER |

FileReplicaConn Object
Counters by Feature

# FTP Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The FTP Service performance object consists of counters that show data about the Internet Information Services (IIS) FTP service.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Received/sec | Shows the rate at which data bytes are received by the FTP service at the application layer. This value does not include protocol headers or control bytes associated with the data received. | PERF_COUNTER_BULK_COUNT |
| Bytes Sent/sec | Shows the rate at which data bytes are sent by the FTP service at the application layer. This value does not include protocol headers or control bytes associated with the data sent. | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the rate at which data bytes are sent and received by the FTP service at the application layer. This value does not include protocol headers or control bytes associated with the data transmitted. Bytes Total/sec is the sum of the values of Bytes Sent/sec and Bytes Received/sec. | PERF_COUNTER_BULK_COUNT |
| Current Anonymous Users | Shows the number of anonymous connections to the FTP service. *Anonymous connections* are connections whose requests either did not contain a user name and password, or whose user name and password were ignored because authentication is not permitted on the server. If anonymous connections are not permitted on the server, the value of Current Anonymous Users is zero. Current Anonymous Users shows successful connections only. If a client request for an anonymous connection is rejected and the client responds with valid authenticating data, the connection is counted as nonanonymous. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |
| Current Connections | Shows the number of connections to the FTP service. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |
| Current NonAnonymous Users | Shows the number of nonanonymous connections to the FTP service. *Nonanonymous connections* are connections whose requests contain a valid user name and password, or other authentication that is required by a custom authentication scheme. If authentication is not enabled on the server, and none of the applications that run on the server request or require authentication, the value of Current NonAnonymous Users is zero. Current NonAnonymous Users shows successful connections only. If a client request for an anonymous connection is rejected and the client responds with valid authenticating data, the connection is counted as nonanonymous. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |
| Maximum Anonymous Users | Shows the largest number of anonymous connections to the FTP service maintained simultaneously since the FTP service was started. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Maximum Connections | Shows the largest number of connections to the FTP service simultaneously maintained since the FTP service started. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |
| Maximum NonAnonymous Users | Shows the largest number of nonanonymous connections to the FTP service maintained simultaneously since the FTP service was started. Maximum NonAnonymous Users shows successful connections only. If a client request for an anonymous connection is rejected and the client responds with valid authenticating data, the connection is counted as nonanonymous. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |
| Total Anonymous Users | Shows the number of anonymous connections to the FTP service that have been established since the FTP service was started. Total Anonymous Users shows successful connections only. If a client request for an anonymous connection is rejected and the client responds with valid authenticating data, the connection is counted as nonanonymous. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |
| Total Connection Attempts | Shows the total number of connections to the FTP service that have been established since the service was started. The value of this counter either remains the same or increases over time. This value does not include failed attempts to connect to the FTP server. To monitor all connection attempts, use the Connection counters on the TCP performance object. To monitor the number of connections to the FTP server that are currently active, use the FTP Service\Current Connections counter. | PERF_COUNTER_RAWCOUNT |
| Total Files Received | Shows the total number of files received by the FTP service since the service was started. | PERF_COUNTER_RAWCOUNT |
| Total Files Sent | Shows the total number of files sent by the FTP service since the service was started. | PERF_COUNTER_RAWCOUNT |
| Total Files Transferred | Shows the total number of files transmitted by the FTP service since the service was started. Total Files Transferred is the sum of the values of Total Files Sent and Total Files Received. | PERF_COUNTER_RAWCOUNT |
| Total Logon Attempts | Shows the total number of times a user logged on successfully to the FTP service since the service was started. This counter is incremented when a connection satisfies the criteria for logging on to FTP, such as providing user authentication requirements. The FTP service supports clear-text logon authentication. The value of Total Logon Attempts does not include failed attempts to log on to the FTP service. However, the value of Total Logon Attempts is a subset of the value of Total Connection Attempts. Failed logon attempts (situations where clients were able to connect but not to log on) can be calculated by subtracting the value of Total Logon Attempts from the value of Total Connection Attempts. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Total NonAnonymous Users | Shows the number of nonanonymous connections to the FTP service that have been established since the FTP service was started. Total NonAnonymous Users shows successful connections only. If a client request for an anonymous connection is rejected and the client responds with valid authenticating data, the connection is counted as nonanonymous. There might be a lag between the counter value and the exact number of connections: new and closed connections might not be reflected immediately in the counter value. | PERF_COUNTER_RAWCOUNT |

# Http Indexing Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Http Indexing Service object reports statistics about queries run by the Indexing Service through Internet Information Services (IIS). Unlike other Indexing Service counters, which can report values even if the Indexing Service is not being used in conjunction with a Web server, these counters only report values when Indexing Service queries are executed through the Web server.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Cache Hits | Shows the percentage of queries that were found in the cache, out of the total number of times the cache was queried since the Indexing Service was lasted started. | PERF_RAW_FRACTION |
| % Cache Misses | Shows the percentage of times that queries were not found in the cache, out of the total number of times the cache was queried since the Indexing Service was lasted started. | PERF_RAW_FRACTION |
| Active Queries | Shows the current number of running queries since the Indexing Service was lasted started. | PERF_COUNTER_RAWCOUNT |
| Cache Items | Shows the number of completed queries that are stored in the cache since the Web Service was last started and the first query was posted. | PERF_COUNTER_RAWCOUNT |
| Current Requests Queued | Shows the current number of query requests that are pending. | PERF_COUNTER_RAWCOUNT |
| Queries per Minute | Shows the rate, in incidents per minute, of queries by the server. This counter can be used to determine server usage. | PERF_COUNTER_RAWCOUNT |
| Total Queries | Shows the total number of queries run since the service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Requests Rejected | Shows the total number of query requests that were rejected because the server was too busy. If this value begins to increase steadily, a bottleneck is developing. To alleviate this condition, reconfigure the server by adding more RAM, or use less resource-intensive queries. | PERF_COUNTER_RAWCOUNT |

# IAS Accounting Clients Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The IAS Accounting Clients performance object is installed by the Internet Authentication Service (IAS). IAS uses the Remote Authentication Dial-In User Service (RADIUS) protocol to perform remote authentication. IAS performance objects report activity for servers or clients, including user authentication, authorization, and accounting (usage).

When selecting counters for this object, note that each client is a separate instance.

| Counter Name | Description | Counter Type |
|---|---|---|
| Accounting-Requests | Shows the number of packets received from this client on the accounting port. | PERF_COUNTER_RAWCOUNT |
| Accounting-Requests/sec | Shows the rate, in seconds, at which packets were received from this client on the accounting port. | PERF_COUNTER_COUNTER |
| Accounting-Responses | Shows the number of RADIUS Accounting-Response packets sent to this client. | PERF_COUNTER_RAWCOUNT |
| Accounting-Responses/sec | Shows the rate in seconds at which duplicate RADIUS Accounting-Request packets were received from this client. | PERF_COUNTER_COUNTER |
| Bad Authenticators | Shows the number of packets that contained invalid Signature attributes. | PERF_COUNTER_RAWCOUNT |
| Bad Authenticators/sec | Shows the rate, in seconds, at which packets that contained invalid Signature attributes were received. | PERF_COUNTER_COUNTER |
| Dropped Packets | Shows the number of incoming packets silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_RAWCOUNT |
| Dropped Packets/sec | Shows the rate in seconds at which incoming packets were silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_COUNTER |
| Duplicate Accounting-Requests | Shows the number of duplicate RADIUS Accounting-Request packets received from this client. | PERF_COUNTER_RAWCOUNT |
| Duplicate Accounting-Requests/sec | Shows the rate, in seconds, at which duplicate RADIUS Accounting-Request packets were received from this client. | PERF_COUNTER_COUNTER |
| Malformed Packets | Shows the number of malformed packets received. Bad authenticators or unknown types are not included. | PERF_COUNTER_RAWCOUNT |
| Malformed Packets/sec | Shows the rate, in seconds, at which malformed packets were received. | PERF_COUNTER_COUNTER |
| No Record | Shows the number of RADIUS Accounting-Request packets that were received and responded to but not recorded. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| No Record/sec | Shows the rate, in seconds, at which RADIUS Accounting-Request packets were received and responded to but not recorded. | PERF_COUNTER_COUNTER |
| Packets Received | Shows the number of packets received. | PERF_COUNTER_RAWCOUNT |
| Packets Received/sec | Shows the rate, in seconds, at which packets were received. | PERF_COUNTER_COUNTER |
| Packets Sent | Shows the number of packets sent. | PERF_COUNTER_RAWCOUNT |
| Packets Sent/sec | Shows the rate, in seconds, at which packets were sent. | PERF_COUNTER_COUNTER |
| Unknown Type | Shows the number of packets of unknown type that were received. An unknown type is a RADIUS packet that contains an unrecognized entry in the **Code** field, used to identify the packet type. Consequently IAS does not support packets of unknown type. | PERF_COUNTER_RAWCOUNT |
| Unknown Type/sec | Shows the rate, in seconds, at which packets of unknown type were received. | PERF_COUNTER_COUNTER |

# IAS Accounting Proxy Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The IAS Accounting Proxy performance object is installed by Internet Authentication Service (IAS). IAS uses the Remote Authentication Dial-In User Service (RADIUS) protocol. IAS performance objects report activity for servers or clients, including user authentication, authorization, and accounting (use).

| Counter Name | Description | Counter Type |
|---|---|---|
| Accounting-Requests | Shows the number of packets received from this client on the accounting port. | PERF_COUNTER_RAWCOUNT |
| Accounting-Requests/sec | Shows the rate, in incidents per second, at which packets were received from this client on the accounting port. | PERF_COUNTER_COUNTER |
| Accounting-Responses | Shows the number of RADIUS Accounting-Response packets sent to this client. | PERF_COUNTER_RAWCOUNT |
| Accounting-Responses/sec | Shows the rate, in incidents per second, at which RADIUS Accounting-Response packets were sent to this client. | PERF_COUNTER_COUNTER |
| Bad Authenticators | Shows the number of packets that contained invalid Message-Authenticator attributes. | PERF_COUNTER_RAWCOUNT |
| Bad Authenticators/sec | Shows the rate, in incidents per second, at which packets that contained invalid Message-Authenticator attributes were received. | PERF_COUNTER_COUNTER |
| Dropped Packets | Shows the number of incoming packets that were silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_RAWCOUNT |
| Dropped Packets/sec | Shows the rate, in incidents per second, at which incoming packets were silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_COUNTER |
| Invalid Addresses | Shows the number of packets received from unknown addresses. | PERF_COUNTER_RAWCOUNT |
| Invalid Addresses/sec | Shows the rate, in incidents per second, at which packets were received from unknown addresses. | PERF_COUNTER_COUNTER |
| Malformed Packets | Shows the number of malformed packets received. Bad authenticators or unknown types are not included. | PERF_COUNTER_RAWCOUNT |
| Malformed Packets/sec | Shows the rate, in incidents per second, at which malformed packets were received. Bad authenticators or unknown types are not included. | PERF_COUNTER_COUNTER |
| Packets Received | Shows the number of packets received. | PERF_COUNTER_RAWCOUNT |
| Packets Received/sec | Shows the rate, in incidents per second, at which packets were received. | PERF_COUNTER_COUNTER |
| Pending Requests | Shows the number of requests destined for this server that have not yet timed out or received a response. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Request Timeouts | Shows the number of requests to this server that have timed out. | PERF_COUNTER_RAWCOUNT |
| Request Timeouts/sec | Shows the rate, in incidents per second, at which requests to this server have timed out. | PERF_COUNTER_COUNTER |
| Retransmissions | Shows the number of requests that were retransmitted to this server. | PERF_COUNTER_RAWCOUNT |
| Retransmissions/sec | Shows the rate, in incidents per second, at which requests were retransmitted to this server. | PERF_COUNTER_COUNTER |
| Unknown Type | Shows the number of packets of unknown type that were received. | PERF_COUNTER_RAWCOUNT |
| Unknown Type/sec | Shows the rate, in incidents per second, at which packets of unknown type were received. | PERF_COUNTER_COUNTER |

# IAS Remote Accounting Servers Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS Remote Accounting Servers Object**

The IAS Remote Accounting Servers performance object is installed by Internet Authentication Service (IAS). IAS uses the Remote Authentication Dial-In User Service (RADIUS) protocol. IAS performance objects report activity for servers or clients, including user authentication, authorization, and accounting (use).

| Counter Name | Description | Counter Type |
|---|---|---|
| Accounting-Requests | Shows the number of packets received from this client on the accounting port. | PERF_COUNTER_RAWCOUNT |
| Accounting-Requests/sec | Shows the rate, in seconds, at which packets were received from this client on the accounting port. | PERF_COUNTER_COUNTER |
| Accounting-Responses | Shows the number of RADIUS Accounting-Response packets sent to this client. | PERF_COUNTER_RAWCOUNT |
| Accounting-Responses/sec | Shows the rate, in seconds, at which RADIUS Accounting-Response packets were sent to this client. | PERF_COUNTER_COUNTER |
| Bad Authenticators | Shows the number of packets that contained invalid Message-Authenticator attributes. | PERF_COUNTER_RAWCOUNT |
| Bad Authenticators/sec | Shows the rate, in seconds, at which packets that contained invalid Message-Authenticator attributes were received. | PERF_COUNTER_COUNTER |
| Dropped Packets | Shows the number of incoming packets that were silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_RAWCOUNT |
| Dropped Packets/sec | Shows the rate, in seconds, at which incoming packets were silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_COUNTER |
| Duplicate Accounting-Requests | Shows the number of duplicate RADIUS Accounting-Request packets that were received from this client. | PERF_COUNTER_RAWCOUNT |
| Duplicate Accounting-Requests/sec | Shows the rate, in seconds, at which duplicate RADIUS Accounting-Request packets were received from this client. | PERF_COUNTER_COUNTER |
| Invalid Requests | Shows the number of packets received from unknown addresses. | PERF_COUNTER_RAWCOUNT |
| Invalid Requests/sec | Shows the rate, in seconds, at which packets were received from unknown addresses. | PERF_COUNTER_COUNTER |
| Malformed Packets | Shows the number of malformed packets received. Bad authenticators or unknown types are not included. | PERF_COUNTER_RAWCOUNT |
| Malformed Packets/sec | Shows the rate, in seconds, at which malformed packets were received. Bad authenticators or unknown types are not included. | PERF_COUNTER_COUNTER |
| No Record | Shows the number of RADIUS Accounting-Request packets that were received and responded to but not recorded. | PERF_COUNTER_RAWCOUNT |
| No Record/sec | Shows the rate in seconds at which RADIUS Accounting-Request packets were received and responded to but not recorded. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Packets Received | Shows the number of packets received. | PERF_COUNTER_RAWCOUNT |
| Packets Received/sec | Shows the rate, in seconds, at which packets were received. | PERF_COUNTER_COUNTER |
| Packets Sent | Shows the number of packets sent. | PERF_COUNTER_RAWCOUNT |
| Packets Sent/sec | Shows the rate, in seconds, at which packets were sent. | PERF_COUNTER_COUNTER |
| Server Reset Time | Shows the time elapsed, in hundredths of a second, since the server configuration was reset. | PERF_COUNTER_RAWCOUNT |
| Server Up Time | Shows the time elapsed, in hundredths of a second, since the server process was started. | PERF_COUNTER_COUNTER |
| Unknown Type | Shows the number of packets of unknown type that were received. | PERF_COUNTER_RAWCOUNT |
| Unknown Type/sec | Shows the rate, in seconds, at which packets of unknown type were received. | PERF_COUNTER_COUNTER |

# IAS Remote Authentication Servers Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The IAS Remote Authentication Servers performance object is installed by Internet Authentication Service (IAS). IAS uses the Remote Authentication Dial-In User Service (RADIUS) protocol to perform remote administration. IAS performance objects report activity for servers or clients, including user authentication, authorization, and accounting (usage).

| Counter Name | Description | Counter Type |
|---|---|---|
| Access-Accepts | Shows the number of RADIUS Access-Accept packets sent to this server. | PERF_COUNTER_RAWCOUNT |
| Access-Accepts/sec | Shows the rate, in incidents per second, at which RADIUS Access-Accept packets were sent to this server. | PERF_COUNTER_COUNTER |
| Access-Challenges | Shows the number of Access-Challenge packets sent to this server. | PERF_COUNTER_RAWCOUNT |
| Access-Challenges/sec | Shows the rate, in incidents per second, at which Access-Challenge messages were processed. | PERF_COUNTER_COUNTER |
| Access-Rejects | Shows the number of RADIUS Access-Rejects packets sent to this server. | PERF_COUNTER_RAWCOUNT |
| Access-Rejects/sec | Shows the rate, in incidents per second, at which Access-Reject messages were processed. | PERF_COUNTER_COUNTER |
| Access-Requests | Shows the number of packets that were received on the authentication port from this server. | PERF_COUNTER_RAWCOUNT |
| Access-Requests/sec | Shows the rate, in incidents per second, at which packets were received on the authentication port from this server. | PERF_COUNTER_COUNTER |
| Bad Authenticators | Shows the total number of packets that contained invalid Message-Authenticator attributes. | PERF_COUNTER_RAWCOUNT |
| Bad Authenticators/sec | Shows the rate, in incidents per second, at which packets that contained invalid Message-Authenticator attributes were received. | PERF_COUNTER_COUNTER |
| Dropped Packets | Shows the number of incoming packets that were silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_RAWCOUNT |
| Dropped Packets/sec | Shows the rate, in incidents per second, at which incoming packets were silently discarded for a reason other than being malformed, bad authenticators, or unknown types. | PERF_COUNTER_COUNTER |
| Last Round-Trip Time | Shows the time interval, to the hundredths of a second, between the most recent request and the response that matched it from this server. | PERF_COUNTER_RAWCOUNT |
| Malformed Packets | Shows the number of malformed packets received. Bad authenticators or unknown types are not included. | PERF_COUNTER_RAWCOUNT |
| Malformed Packets/sec | Shows the rate, in incidents per second, at which malformed packets were received. Bad authenticators or unknown types are not included. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Packets Received | Shows the number of packets received. | PERF_COUNTER_RAWCOUNT |
| Packets Received/sec | Shows the rate, in incidents per second, at which packets were received. | PERF_COUNTER_COUNTER |
| Pending Requests | Shows the number of requests destined for this server that have not yet timed out or received a response. | PERF_COUNTER_RAWCOUNT |
| Port Number | Shows UDP port the proxy is using to send requests to this server. | PERF_COUNTER_RAWCOUNT |
| Request Timeouts | Shows the number of requests to this server that timed out. | PERF_COUNTER_RAWCOUNT |
| Request Timeouts/sec | Shows the rate, in incidents per second, at which requests to this server timed out. | PERF_COUNTER_COUNTER |
| Retransmissions | Shows the number of requests retransmitted to this server. | PERF_COUNTER_RAWCOUNT |
| Retransmissions/sec | Shows the rate, in incidents per second, at which requests to this server were retransmitted. | PERF_COUNTER_COUNTER |
| Unknown Type | Shows the number of packets of unknown type that were received. | PERF_COUNTER_RAWCOUNT |
| Unknown Type/sec | Shows the rate, in incidents per second, at which packets of unknown type were received. | PERF_COUNTER_COUNTER |

# ICMP Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The ICMP performance object consists of counters that measure the rates at which Internet Control Message Protocol (ICMP) messages are sent and received by using ICMP. It also includes counters that monitor ICMP errors.

| Counter Name | Description | Counter Type |
|---|---|---|
| Messages Outbound Errors | Shows the number of ICMP messages that were not sent due to problems within ICMP, such as lack of buffers. This value does not include errors that were discovered outside the ICMP layer, such as those recording the failure of IP to route the resultant datagram. In some implementations, none of the error types are included in the value of this counter. | PERF_COUNTER_RAWCOUNT |
| Messages Received Errors | Shows the number of ICMP messages that were received but had errors, such as bad ICMP checksums, bad length, etc. | PERF_COUNTER_RAWCOUNT |
| Messages Received/sec | Shows the rate, in incidents per second, at which ICMP messages were received. The rate includes messages received in error. | PERF_COUNTER_COUNTER |
| Messages Sent/sec | Shows the rate, in incidents per second, at which the server attempted to send messages. The rate includes messages sent in error. | PERF_COUNTER_COUNTER |
| Messages/sec | Shows the total rate, in incidents per second, at which ICMP messages were sent and received by the entity. The rate includes messages received or sent in error. | PERF_COUNTER_COUNTER |
| Received Address Mask | Shows the number of ICMP Address Mask Request messages that were received. | PERF_COUNTER_RAWCOUNT |
| Received Address Mask Reply | Shows the number of ICMP Address Mask Reply messages that were received. | PERF_COUNTER_RAWCOUNT |
| Received Dest. Unreachable | Shows the number of ICMP Destination Unreachable messages that were received. | PERF_COUNTER_RAWCOUNT |
| Received Echo Reply/sec | Shows the rate, in incidents per second, at which ICMP Echo Reply messages were received. | PERF_COUNTER_COUNTER |
| Received Echo/sec | Shows the rate, in incidents per second, at which ICMP Echo messages were received. | PERF_COUNTER_COUNTER |
| Received Parameter Problem | Shows the number of ICMP Parameter Problem messages that were received. | PERF_COUNTER_RAWCOUNT |
| Received Redirect/sec | Shows the rate, in incidents per second, at which ICMP Redirect messages were received. | PERF_COUNTER_COUNTER |
| Received Source Quench | Shows the number of ICMP Source Quench messages that were received. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Received Time Exceeded | Shows the number of ICMP Time Exceeded messages that were received. | PERF_COUNTER_RAWCOUNT |
| Received Timestamp Reply/sec | Shows the rate, in incidents per second, at which ICMP Timestamp Reply messages were received. | PERF_COUNTER_COUNTER |
| Received Timestamp/sec | Shows the rate, in incidents per second, at which ICMP Timestamp Request messages were received. | PERF_COUNTER_COUNTER |
| Sent Address Mask | Shows the number of ICMP Address Mask Request messages that were sent. | PERF_COUNTER_RAWCOUNT |
| Sent Address Mask Reply | Shows the number of ICMP Address Mask Reply messages that were sent. | PERF_COUNTER_RAWCOUNT |
| Sent Destination Unreachable | Shows the number of ICMP Destination Unreachable messages that were sent. | PERF_COUNTER_RAWCOUNT |
| Sent Echo Reply/sec | Shows the rate, in incidents per second, at which ICMP Echo Reply messages were sent. | PERF_COUNTER_COUNTER |
| Sent Echo/sec | Shows the rate, in incidents per second, at which ICMP Echo messages were sent. | PERF_COUNTER_COUNTER |
| Sent Parameter Problem | Shows the number of ICMP Parameter Problem messages that were sent. | PERF_COUNTER_RAWCOUNT |
| Sent Redirect/sec | Shows the rate, in incidents per second, at which ICMP Redirect messages were sent. | PERF_COUNTER_COUNTER |
| Sent Source Quench | Shows the number of ICMP Source Quench messages that were sent. | PERF_COUNTER_RAWCOUNT |
| Sent Time Exceeded | Shows the number of ICMP Time Exceeded messages that were sent. | PERF_COUNTER_RAWCOUNT |
| Sent Timestamp Reply/sec | Shows the rate, in incidents per second, at which ICMP Timestamp Reply messages were sent. | PERF_COUNTER_COUNTER |
| Sent Timestamp/sec | Shows the rate, in incidents per second, at which ICMP Timestamp Request messages were sent. | PERF_COUNTER_COUNTER |

# Image Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Image performance object consists of counters that monitor virtual address usage of images executed by processes on the computer. This object contains "costly" counters for which data collection is typically either processor-intensive or memory-intensive. Costly counters cannot be selected with System Monitor but can be accessed by using Showperf.exe, a tool included in the Windows Resource Kit Tools Help for Windows Server 2003.

| Counter Name | Description | Counter Type |
|---|---|---|
| Exec Read Only | Shows memory that can be executed as well as read. Image Space is the virtual address space used by the selected image with this protection. | PERF_COUNTER_RAWCOUNT |
| Exec Read/Write | Shows memory that can be executed by programs, in addition to being read and written. | PERF_COUNTER_RAWCOUNT |
| Exec Write Copy | Shows memory that can be executed by programs, in addition to being read and written. This type of protection is used when memory needs to be shared between processes. If the sharing processes only read the memory, they all use the same memory. If a sharing process wants to have write access to this shared memory, a copy of this memory is made for that process. | PERF_COUNTER_RAWCOUNT |
| Executable | Shows memory that can be executed by programs, but cannot be read or written. This type of protection is not supported by all processor types. | PERF_COUNTER_RAWCOUNT |
| No Access | Prevents a process from writing or reading these pages, and generates an access violation if either is attempted. | PERF_COUNTER_RAWCOUNT |
| Read Only | Prevents the contents of these pages from being modified. Any attempt to write or modify these pages generates an access violation | PERF_COUNTER_RAWCOUNT |
| Read/Write | Allows a process to read, modify and write to these pages. | PERF_COUNTER_RAWCOUNT |
| Write Copy | Used when memory is shared for reading but not for writing. If the sharing processes only read this memory, they all use the same memory. If a sharing process wants read/write access to this shared memory, a copy of this memory is made for that process. | PERF_COUNTER_RAWCOUNT |

# Indexing Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Indexing Service performance object reports statistics about the creation of indexes, and about the merging and querying of indexes by the Indexing Service.

| Counter Name | Description | Counter Type |
|---|---|---|
| # Documents Indexed | Shows the number of documents indexed since the current indexing session started. This does not include the documents indexed in prior sessions of the Indexing Service. | PERF_COUNTER_RAWCOUNT |
| Deferred for Indexing | Shows the number of documents that need to be indexed but cannot because they were in use. | PERF_COUNTER_RAWCOUNT |
| Files to be Indexed | Shows the minimum number of documents that were known to need indexing. | PERF_COUNTER_RAWCOUNT |
| Index Size (MB) | Shows the size, in megabytes (MB), of the content index. | PERF_COUNTER_RAWCOUNT |
| Merge Progress | Shows the percentage of the current merge that has been completed. | PERF_COUNTER_RAWCOUNT |
| Running Queries | Shows the number of queries that were running. | PERF_COUNTER_RAWCOUNT |
| Saved Indexes | Shows the number of indexes that were saved. | PERF_COUNTER_RAWCOUNT |
| Total # Documents | Shows the total number of documents known to the index. | PERF_COUNTER_RAWCOUNT |
| Total # of Queries | Shows the total number of queries made since the index was mounted. | PERF_COUNTER_RAWCOUNT |
| Unique Keys | Shows the number of unique words in the index. | PERF_COUNTER_RAWCOUNT |
| Word Lists | Shows the number of word lists in the index. | PERF_COUNTER_RAWCOUNT |

# Indexing Service Filter Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Indexing Service Filter object monitors the filtering activity of the Indexing Service.

| Counter Name | Description | Counter Type |
|---|---|---|
| Binding Time (msec) | Shows the average time, in milliseconds (msec), for the Indexing Service to bind to a filter file. | PERF_COUNTER_RAWCOUNT |
| Indexing Speed (MB/hr) | Shows the speed, in megabytes per hour (MB/hr), at which documents were indexed. This does not include generating abstracts. | PERF_COUNTER_RAWCOUNT |
| Total Indexing Speed (MB/hr) | Shows the speed, in megabytes per hour (MB/hr), at which documents were indexed. This includes generating abstracts. | PERF_COUNTER_RAWCOUNT |

# Internet Information Services Global Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Internet Information Services Global performance object consists of counters that apply jointly to the Hypertext Transport Protocol (HTTP) service and File Transfer Protocol (FTP) service.

| Counter Name | Description | Counter Type |
|---|---|---|
| Active Flushed Entries | Shows the number of cached file handles that will be closed when all current transfers are completed. | PERF_COUNTER_RAWCOUNT |
| BLOB Cache Flushes | Shows the number of flushes of the binary large object (BLOB) cache since the service was started. | PERF_COUNTER_RAWCOUNT |
| BLOB Cache Hits | Shows the total number of successful lookups in the BLOB cache. | PERF_COUNTER_RAWCOUNT |
| BLOB Cache Hits % | Shows the ratio of BLOB cache hits to total cache requests. | PERF_RAW_FRACTION |
| BLOB Cache Misses | Shows the total number of unsuccessful lookups in the BLOB cache. | PERF_COUNTER_RAWCOUNT |
| Current BLOBs Cached | Shows the number of BLOB information blocks currently in the cache for HTTP and FTP services. | PERF_COUNTER_RAWCOUNT |
| Current Blocked Async I/O Requests | Shows the number of current requests temporarily blocked due to bandwidth throttling settings. Blocked requests are held in a buffer and then unblocked if more bandwidth becomes available (unless a timeout limit is reached). | PERF_COUNTER_RAWCOUNT |
| Current File Handles Cached | Shows the number of open file handles currently in the cache for HTTP and FTP services. | PERF_COUNTER_RAWCOUNT |
| Current URIs Cached | Shows Uniform Resource Identifier (URI) information blocks currently in the cache for HTTP and FTP services. | PERF_COUNTER_RAWCOUNT |
| File Handle Cache Flushes | Shows the number of file handle cache flushes since the service was started. | PERF_COUNTER_RAWCOUNT |
| File Handle Cache Hits | Shows the total number of successful lookups in the file handle cache. | PERF_COUNTER_RAWCOUNT |
| File Handle Cache Hits % | Shows the ratio of file handle cache hits to total cache requests. | PERF_RAW_FRACTION |
| File Handle Cache Misses | Shows the total number of unsuccessful lookups in the file handle cache. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Measured Async I/O Bandwidth Usage | Shows the amount of measured bandwidth of asynchronous input/output (I/O) averaged over a minute. This is a measure of the total amount of user traffic on the server. | PERF_COUNTER_RAWCOUNT |
| Total Allowed Async I/O Requests | Shows the total number of requests allowed by bandwidth throttling settings since the service was started. When you throttle bandwidth, the number of allowed user requests will be restricted. | PERF_COUNTER_RAWCOUNT |
| Total BLOBs Cached | Shows the total number of BLOB information blocks added to the cache for HTTP and FTP services | PERF_COUNTER_RAWCOUNT |
| Total Blocked Async I/O Requests | Shows the total number of requests temporarily blocked due to bandwidth throttling settings since the service was started. Blocked requests are held in a buffer and then unblocked if more bandwidth becomes available (unless a timeout limit is reached). | PERF_COUNTER_RAWCOUNT |
| Total File Handles Cached | Shows the total number of file handles added to the cache for HTTP and FTP services | PERF_COUNTER_RAWCOUNT |
| Total Flushed BLOBs | Shows the number of BLOB information blocks that have been removed from the cache since the service was started. | PERF_COUNTER_RAWCOUNT |
| Total Flushed Files | Shows the number of file handles that have been removed from the cache since the service was started. | PERF_COUNTER_RAWCOUNT |
| Total Flushed URIs | Shows the number of URI information blocks that have been removed from the cache since the service was started. | PERF_COUNTER_RAWCOUNT |
| Total Rejected Async I/O Requests | Shows the total requests rejected due to bandwidth throttling settings since the service was started. Unlike a blocked request, a rejected request is not held in a buffer. | PERF_COUNTER_RAWCOUNT |
| Total URIs Cached | Shows the total number of URI information blocks added to the cache for HTTP and FTP services. | PERF_COUNTER_RAWCOUNT |
| URI Cache Flushes | Shows the total number of URI cache flushes since the service was started. | PERF_COUNTER_RAWCOUNT |
| URI Cache Hits | Shows the total number of successful lookups in the URI cache. | PERF_COUNTER_RAWCOUNT |
| URI Cache Hits % | Shows the ratio of URI cache hits to total cache requests. | PERF_RAW_FRACTION |
| URI Cache Misses | Shows the total number of unsuccessful lookups in the URI cache. | PERF_COUNTER_RAWCOUNT |

# IP Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The IP performance object includes counters that describe the rates at which Internet Protocol (IP) datagrams are transmitted by a computer using the IP protocol. It also describes various IP error counts.

| Counter Name | Description | Counter Type |
|---|---|---|
| Datagrams Forwarded/sec | Shows the rate, in incidents per second, at which attempts were made to find routes to forward input datagrams to their final destination, because the local server was not the final IP destination. In servers that do not act as IP gateways, this rate includes only packets that were source-routed via this entity where the source-route option processing was successful. | PERF_COUNTER_COUNTER |
| Datagrams Outbound No Route | Shows the number of IP datagrams that were discarded because no route could be found to transmit them to their destination. This counter includes any packets counted in Datagrams Forwarded/sec that meet this "no route" criterion. | PERF_COUNTER_RAWCOUNT |
| Datagrams Outbound Discarded | Shows the number of output IP datagrams that were discarded even though no problems were encountered to prevent their transmission to their destination (for example, lack of buffer space). This counter includes datagrams counted in Datagrams Forwarded/sec that meet this criterion. | PERF_COUNTER_RAWCOUNT |
| Datagrams Received Address Errors | Shows the number of input IP datagrams that were discarded because the IP address in their IP header destination field was not valid for the computer. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP gateways and do not forward datagrams, this counter includes datagrams that were discarded because the destination was not a local address. | PERF_COUNTER_RAWCOUNT |
| Datagrams Received Delivered/sec | Shows the rate, in incidents per second, at which input IP datagrams were successfully delivered to IP user-protocols, including Internet Control Message Protocol (ICMP). | PERF_COUNTER_COUNTER |
| Datagrams Received Discarded | Shows the number of input IP datagrams that were discarded even though problems prevented their continued processing (for example, lack of buffer space). This counter does not include any datagrams discarded while awaiting reassembly. | PERF_COUNTER_RAWCOUNT |
| Datagrams Received Header Errors | Shows the number of input IP datagrams that were discarded due to errors in the IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered while processing their IP options, etc. | PERF_COUNTER_RAWCOUNT |
| Datagrams Received Unknown Protocol | Shows the number of locally-addressed datagrams that were successfully received but were discarded because of an unknown or unsupported protocol. | PERF_COUNTER_RAWCOUNT |
| Datagrams Received/sec | Shows the rate, in incidents per second, at which IP datagrams were received from the interfaces, including those in error. Datagrams Received/sec is a subset of Datagrams/sec. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Datagrams Sent/sec | Shows the rate, in incidents per second, at which IP datagrams were supplied for transmission by local IP user-protocols (including ICMP). This counter does not include datagrams counted in Datagrams Forwarded/sec. Datagrams Sent/sec is a subset of Datagrams/sec. | PERF_COUNTER_COUNTER |
| Datagrams/sec | Shows the rate, in incidents per second, at which IP datagrams were received from or sent to the interfaces, including those in error. Forwarded datagrams are not included in this rate. | PERF_COUNTER_COUNTER |
| Fragment Reassembly Failures | Shows the number of failures detected by the IP reassembly algorithm, such as time outs, errors, etc. This is not necessarily a count of discarded IP fragments since some algorithms (notably RFC 815) lose track of the number of fragments by combining them as they are received. | PERF_COUNTER_RAWCOUNT |
| Fragmentation Failures | Shows the number of IP datagrams that were discarded because they needed to be fragmented but could not be (for example, because the "Don't Fragment" flag was set). | PERF_COUNTER_RAWCOUNT |
| Fragmented Datagrams/sec | Shows the rate, in incidents per second, at which datagrams were successfully fragmented. | PERF_COUNTER_COUNTER |
| Fragments Created/sec | Shows the rate, in incidents per second, at which IP datagram fragments were generated as a result of fragmentation. | PERF_COUNTER_COUNTER |
| Fragments Reassembled/sec | Shows the rate, in incidents per second, at which IP fragments were successfully reassembled. | PERF_COUNTER_COUNTER |
| Fragments Received/sec | Shows the rate, in incidents per second, at which IP fragments that need to be reassembled at this entity were received. | PERF_COUNTER_COUNTER |

# Job Object Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Job Object performance object reports the accounting and processor usage data collected by each active job object. A job object provides a means of managing groups of processes with respect to their processor usage and other factors.

| Counter Name | Description | Counter Type |
|---|---|---|
| Current % Kernel Mode Time | Shows the percentage of time that the processes in the job object spent executing code in kernel or privileged mode, during the sample interval. | PERF_100NSEC_TIMER |
| Current % Processor Time | Shows the percentage of time that the processes in the job object spent executing code during the sample interval. | PERF_100NSEC_TIMER |
| Current % User Mode Time | Shows the percentage of time that the processes in the job object spent executing code in user mode during the sample interval. | PERF_100NSEC_TIMER |
| Pages/sec | Shows the page fault rate, in incidents per second, of all the processes in the job object during the sample interval. | PERF_COUNTER_COUNTER |
| Process Count - Active | Shows the number of processes that were associated with the job object during the sample interval. | PERF_COUNTER_RAWCOUNT |
| Process Count - Terminated | Shows the number of processes that were terminated because of a limit violation during the sample interval. | PERF_COUNTER_RAWCOUNT |
| Process Count - Total | Shows the total number of processes, both active and terminated, that were associated with the job object during the sample interval. | PERF_COUNTER_RAWCOUNT |
| This Period mSec - Kernel Mode | Shows the amount of user mode processor time, in milliseconds, that was used by all the processes in the job object during the sample interval. This includes processes that have terminated, or that were no longer associated with the job object because of a time limit on the job. | PERF_COUNTER_LARGE_RAWCOUNT |
| This Period mSec - Processor | Shows the amount of processor time, in milliseconds, that was used by all the processes in the job object during the sample interval. This includes processes that have terminated, or that were no longer associated with the job object because of a time limit on the job. | PERF_COUNTER_LARGE_RAWCOUNT |
| This Period mSec - User Mode | Shows the amount of user mode processor time, in milliseconds, that was used by all the processes in the job object during the sample interval. This includes processes that have terminated, or that were no longer associated with the job object because of a time limit on the job. | PERF_COUNTER_LARGE_RAWCOUNT |

| | | |
|---|---|---|
| Total mSec - Kernel Mode | Shows the total amount of kernel mode processor time, in milliseconds, that was used by all the processes in the job object since it was created. This includes processes that have terminated, or that are no longer associated with the job object. | PERF_COUNTER_LARGE_RAWCOUNT |
| Total mSec - Processor | Shows the total amount of processor time, in milliseconds, that was used by all the processes in the job object since it was created. This includes processes that have terminated, or that are no longer associated with the job object. | PERF_COUNTER_LARGE_RAWCOUNT |
| Total mSec - User Mode | Shows the total amount of user mode processor time, in milliseconds, that was used by all the processes in the job object since it was created. This includes processes that have terminated, or that are no longer associated with the job object. | PERF_COUNTER_LARGE_RAWCOUNT |

Job Object Details

# Job Object Details

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Job Object Details performance object counters show detailed performance information about the active processes that make up a job object.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Privileged Time | Shows the percentage of elapsed time that the process threads have spent executing code in privileged mode. When a Windows 2000 system service is called, the service will often run in privileged mode to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults or interrupts. Unlike some early operating systems, Windows 2000 uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. Some work done by Windows 2000 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |
| % Processor Time | Shows the percentage of elapsed time that all of the process threads used the processor to execute instructions. An instruction is the basic unit of execution in a computer, a thread is the object that executes instructions, and a process is the object created when a program is run. Code executed to handle some hardware interrupts and trap conditions are included in this count. | PERF_100NSEC_TIMER |
| % User Time | Shows the percentage of elapsed time that the process threads spent executing code in user mode. Applications, environment subsystems, and integral subsystems execute in user mode. Code executing in user mode cannot damage the integrity of the Windows 2000 executive, kernel, and device drivers. Unlike some early operating systems, Windows 2000 uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. Some work done by Windows 2000 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |
| Creating Process ID | Shows the Process ID of the process that created the process. The creating process may have terminated, so this value may no longer identify a running process. | PERF_COUNTER_LARGE_RAWCOUNT |
| Elapsed Time | Shows the time, in seconds, that this process has been running. | PERF_ELAPSED_TIME |
| Handle Count | Shows the total number of handles currently open by this process. This is the sum of the handles currently open by each thread in this process. | PERF_COUNTER_RAWCOUNT |
| ID Process | Shows the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process. | PERF_COUNTER_LARGE_RAWCOUNT |
| IO Data Bytes/sec | Shows the rate that the process is reading and writing bytes in I/O operations. It counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |

| | | |
|---|---|---|
| IO Data Operations/sec | Shows the rate at which the process is issuing read and write I/O operations. This counter counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Other Bytes/sec | Shows the rate at which the process is issuing bytes to I/O operations that don't involve data such as control operations. It counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Other Operations/sec | Shows the rate at which the process is issuing I/O operations that are neither read nor write operations (for example, a control function). It counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Read Bytes/sec | Shows the rate at which the process is reading bytes from I/O operations. It counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Read Operations/sec | Shows the rate at which the process is issuing read I/O operations. It counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Write Bytes/sec | Shows the rate at which the process is writing bytes to I/O operations. It counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Write Operations/sec | Shows the rate at which the process is issuing write I/O operations. It counts all I/O activity generated by the process to include file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| Page Faults/sec | Shows the rate of page faults by the threads executing in this process. A page fault occurs when a thread refers to a virtual memory page that is not in its working set in main memory. This will not cause the page to be fetched from disk if it is on the standby list and already in main memory, or if it is in use by another process that is sharing the page. | PERF_COUNTER_COUNTER |
| Page File Bytes | Shows the current number of bytes this process has used in the paging file(s). Paging files are used to store pages of memory used by the process that are not contained in other files. Paging files are shared by all processes; lack of space in paging files can prevent other processes from allocating memory. | PERF_COUNTER_LARGE_RAWCOUNT |
| Page File Bytes Peak | Shows the maximum number of bytes this process has used in the paging file(s). | PERF_COUNTER_LARGE_RAWCOUNT |
| Pool Nonpaged Bytes | Shows the size, in bytes, in the nonpaged pool, an area of system memory (physical memory used by the operating system) for objects that cannot be written to disk, but must remain in physical memory as long as they are allocated. Memory\Pool Nonpaged Bytes is calculated differently than Process\Pool Nonpaged Bytes, and might not equal Process(_Total)\Pool Nonpaged Bytes This counter displays the last observed value only; it is not an average. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Bytes | Shows the size, in bytes, in the paged pool. Memory\Pool Paged Bytes is calculated differently than Process\Pool Paged Bytes, so it might not equal Process(_Total)\Pool Paged Bytes. This counter displays the last observed value only; it is not an average. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Priority Base | Shows the current base priority of this process. Threads within a process can raise and lower their own base priority relative to the base priority of the priority. | PERF_COUNTER_RAWCOUNT |
| Private Bytes | Shows the current size, in bytes, that this process has allocated that cannot be shared with other processes. | PERF_COUNTER_LARGE_RAWCOUNT |
| Thread Count | Shows the number of threads currently active in this process. An instruction is the basic unit of execution in a processor, and a thread is the object that executes instructions. Every running process has at least one thread. | PERF_COUNTER_RAWCOUNT |
| Virtual Bytes | Shows the current size, in bytes, of the virtual address space the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and by using too much, the process can limit its ability to load libraries. | PERF_COUNTER_LARGE_RAWCOUNT |
| Virtual Bytes Peak | Shows the maximum number of bytes of virtual address space the process has used at any one time. | PERF_COUNTER_LARGE_RAWCOUNT |
| Working Set | Shows the current size, in bytes, in the Working Set of this process. The Working Set is the set of memory pages touched recently by the threads in the process. If free memory in the computer is above a threshold, pages are left in the Working Set of a process even if they are not in use. When free memory falls below a threshold, pages are trimmed from Working Sets. If they are needed, they will be soft-faulted back into the Working Set before leaving main memory. | PERF_COUNTER_RAWCOUNT |
| Working Set Peak | Shows the maximum size, in bytes, in the Working Set of this process at any point in time. | PERF_COUNTER_RAWCOUNT |

Job Object Object

# LogicalDisk Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The LogicalDisk performance object consists of counters that monitor logical partitions of hard or fixed disk drives. System Monitor identifies logical disks by their drive letter, such as "C."

| Counter Name | Description | Counter Type |
|---|---|---|
| % Disk Time | Shows the percentage of time that the selected disk drive was busy servicing read or write requests. | PERF_PRECISION_100NS_TIMER |
| % Disk Read Time | Shows the percentage of time that the selected disk drive was busy servicing read requests. | PERF_PRECISION_100NS_TIMER |
| % Disk Write Time | Shows the percentage of time that the selected disk drive was busy servicing write requests. | PERF_PRECISION_100NS_TIMER |
| % Free Space | Shows the percentage of the total usable space on the selected logical disk drive that was free. | PERF_RAW_FRACTION |
| Avg. Disk Bytes/Read | Shows the average number of bytes transferred from the disk during read operations. | PERF_AVERAGE_BULK |
| Avg. Disk Bytes/Transfer | Shows the average number of bytes transferred to or from the disk during write or read operations. | PERF_AVERAGE_BULK |
| Avg. Disk Bytes/Write | Shows the average number of bytes transferred to the disk during write operations. | PERF_AVERAGE_BULK |
| Avg. Disk Queue Length | Shows the average number of both read and write requests that were queued for the selected disk during the sample interval. | PERF_COUNTER_LARGE_QUEUELEN_TYPE |
| Avg. Disk Read Queue Length | Shows the average number of read requests that were queued for the selected disk during the sample interval. | PERF_COUNTER_LARGE_QUEUELEN_TYPE |
| Avg. Disk sec/Read | Shows the average time, in seconds, of a read operation from the disk. | PERF_AVERAGE_TIMER |
| Avg. Disk sec/Transfer | Shows the time, in seconds, of the average disk transfer. | PERF_AVERAGE_TIMER |
| Avg. Disk sec/Write | Shows the average time, in seconds, of a write operation to the disk. | PERF_AVERAGE_TIMER |
| Avg. Disk Write Queue Length | Shows the average number of write requests that were queued for the selected disk during the sample interval. | PERF_COUNTER_LARGE_QUEUELEN_TYPE |

| | | |
|---|---|---|
| Current Disk Queue Length | Shows the number of requests outstanding on the disk at the time that the performance data is collected. It also includes requests in service at the time of the collection. This is a snapshot, not an average over a time interval. Multispindle disk devices can have multiple requests that are active at one time, but other concurrent requests are awaiting service. This counter might reflect a transitory high or low queue length, but if there is a sustained load on the disk drive, it is likely that this will be consistently high. Requests experience delays that are proportional to the length of this queue, minus the number of spindles on the disks. For good performance, this difference should average less than two. | PERF_COUNTER_RAWCOUNT |
| Disk Bytes/sec | Shows the rate, in incidents per second, at which bytes were transferred to or from the disk during write or read operations. | PERF_COUNTER_BULK_COUNT |
| Disk Read Bytes/sec | Shows the rate, in incidents per second, at which bytes were transferred from the disk during read operations. | PERF_COUNTER_BULK_COUNT |
| Disk Reads/sec | Shows the rate, in incidents per second, at which read operations were performed on the disk. | PERF_COUNTER_COUNTER |
| Disk Transfers/sec | Shows the rate, in incidents per second, at which read and write operations were performed on the disk. | PERF_COUNTER_COUNTER |
| Disk Write Bytes/sec | Shows the rate, in incidents per second, at which bytes were transferred to the disk during write operations. | PERF_COUNTER_BULK_COUNT |
| Disk Writes/sec | Shows the rate, in incidents per second, at which write operations were performed on the disk. | PERF_COUNTER_COUNTER |
| Free Megabytes | Shows the unallocated space, in megabytes, on the disk drive. One megabyte is equal to 1,048,576 bytes. | PERF_COUNTER_RAWCOUNT |

# MacFile Server Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The MacFile Server performance object consists of counters that provide information about a system running File Server for Macintosh.

| Counter Name | Description | Counter Type |
|---|---|---|
| Current Files Open | Shows the number of internal files currently open in the MacFile server. This count does not include files opened on behalf of Macintosh clients. | PERF_COUNTER_RAWCOUNT |
| Current Paged Memory | Shows the current amount of paged memory resources used by the MacFile server. | PERF_COUNTER_RAWCOUNT |
| Current Nonpaged Memory | Shows the current amount of nonpaged memory resources used by the MacFile Server. | PERF_COUNTER_RAWCOUNT |
| Current Sessions | Shows the number of sessions currently connected to the MacFile Server. This counter reports current server activity. | PERF_COUNTER_RAWCOUNT |
| Failed Logons | Shows the number of failed attempts to log on to the MacFile server. These values can indicate that password-guessing programs are being used to undermine the security on the server. | PERF_COUNTER_RAWCOUNT |
| Max Nonpaged Memory | Shows the maximum amount of nonpaged memory resources used by the MacFile Server. | PERF_COUNTER_RAWCOUNT |
| Max Paged Memory | Shows the maximum amount of paged memory resources used by the MacFile Server. | PERF_COUNTER_RAWCOUNT |
| Maximum Files Open | Shows the maximum number of internal files open at one time in the MacFile Server. This count does not include files opened on behalf of Macintosh clients. | PERF_COUNTER_RAWCOUNT |
| Maximum Sessions | Shows the maximum number of sessions connected at one time to the MacFile Server. This counter indicates the level of usage of the server. | PERF_COUNTER_RAWCOUNT |
| Data Read/sec | Shows the rate, in incidents per second, at which bytes were read from the disk. | PERF_COUNTER_BULK_COUNT |
| Data Written/sec | Shows the rate, in incidents per second, at which bytes were written to the disk. | PERF_COUNTER_BULK_COUNT |
| Data Received/sec | Shows the rate, in incidents per second, at which bytes were received from the network. This counter indicates how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Data Transmitted/sec | Shows the rate, in incidents per second, at which bytes were sent on the network. This counter indicates how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Current Queue Length | Shows the number of outstanding work items waiting to be processed. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Maximum Queue Length | Shows the maximum number of outstanding work items waiting at one time. | PERF_COUNTER_RAWCOUNT |
| Current Threads | Shows the current number of threads used by the MacFile Server. This counter indicates how busy the server is. | PERF_COUNTER_RAWCOUNT |
| Maximum Threads | Shows the maximum number of threads used by the MacFile Server. This counter indicates the peak usage level of the server. | PERF_COUNTER_RAWCOUNT |

# Memory Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Memory performance object consists of counters that describe the behavior of physical and virtual memory on the computer. Physical memory is the amount of RAM on the computer. Virtual memory consists of space in physical memory and on disk. Many of the memory counters monitor paging, which is the movement of pages of code and data between disk and physical memory. Excessive paging is a symptom of a memory shortage and can cause delays that interfere with all system processes.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Committed Bytes In Use | Shows the ratio of Committed Bytes to the Commit Limit. Committed memory is physical memory in use, for which space has been reserved in the paging file(s) so that it can be written to disk. The commit limit is determined by the size of the paging file. If the paging file is enlarged, the commit limit increases, and the ratio is reduced. | PERF_RAW_FRACTION |
| Available Bytes | Shows the amount of physical memory, in bytes, immediately available for allocation to a process or for system use. It is equal to the sum of memory assigned to the standby (cached), free, and zero page lists. | PERF_COUNTER_RAWCOUNT |
| Available KBytes | Shows the amount of physical memory, in Kilobytes, immediately available for allocation to a process or for system use. It is equal to the sum of memory assigned to the standby (cached), free, and zero page lists. | PERF_COUNTER_RAWCOUNT |
| Available MBytes | Shows the amount of physical memory, in Megabytes, immediately available for allocation to a process or for system use. It is equal to the sum of memory assigned to the standby (cached), free, and zero page lists. | PERF_COUNTER_RAWCOUNT |
| Cache Bytes | Shows the sum of the values of System Cache Resident Bytes, System Driver Resident Bytes, System Code Resident Bytes, and Pool Paged Resident Bytes. | PERF_COUNTER_RAWCOUNT |
| Cache Bytes Peak | Shows the maximum number of bytes used by the file system cache since the system was last started. This might be larger than the current size of the cache. | PERF_COUNTER_RAWCOUNT |
| Cache Faults/sec | Shows the rate, in incidents per second, at which faults occured when a page that was sought in the file system cache was not found and was be retrieved either from elsewhere in memory (a soft fault) or from disk (a hard fault). This counter shows the total number of faults, without regard for the number of pages faulted in each operation. | PERF_COUNTER_COUNTER |
| Commit Limit | Shows the amount of virtual memory, in bytes, that can be committed without having to extend the paging file(s). Committed memory is physical memory that has space reserved on the disk paging file(s). There can be one or more paging files on each physical drive. If the paging file(s) are expanded, this limit increases accordingly. | PERF_COUNTER_RAWCOUNT |
| Committed Bytes | Shows the amount of committed virtual memory, in bytes. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Demand Zero Faults/sec | Shows the average rate, in incidents per second, at which page faults required a zeroed page to satisfy the fault. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. Zeroed pages (pages emptied of previously stored data and filled with zeroes) prevent processes from seeing data stored by earlier processes that used the same memory space. This counter displays the number of faults, without regard to the number of pages retrieved to satisfy the fault. | PERF_COUNTER_COUNTER |
| Free System Page Table Entries | Shows the number of page table entries not in use by the system. | PERF_COUNTER_RAWCOUNT |
| Page Faults/sec | Shows the average number of pages faulted per second, which is equal to the number of page fault operations because only one page is faulted in each fault operation. This counter includes both hard faults (those that require disk access) and soft faults (where the faulted page is found elsewhere in physical memory). Most processors can handle large numbers of soft faults without significant consequence. However, hard faults can cause delaysbecause they require disk access.. | PERF_COUNTER_COUNTER |
| Page Reads/sec | Shows the rate, in incidents per second, at which the disk was read to resolve hard page faults. This counter shows numbers of read operations, without regard to the number of pages retrieved in each operation. Hard page faults occur when a process references a page in virtual memory that must be retrieved from disk because it is not in its working set or elsewhere in physical memory. This counter is a primary indicator for the kinds of faults that cause system-wide delays. It includes read operations to satisfy faults in the file system cache (usually requested by applications) and in noncached mapped memory files. Compare the value of Page Reads/sec to the value of Pages Input/sec to find an average of how many pages were read during each read operation. | PERF_COUNTER_COUNTER |
| Page Writes/sec | Shows the rate, in incidents per second, at which pages were written to disk to free up space in physical memory. Pages are written to disk only if they are changed while in physical memory, so they are likely to hold data, not code. This counter shows write operations, without regard to the number of pages written in each operation. | PERF_COUNTER_COUNTER |
| Pages Input/sec | Shows the rate, in incidents per second, at which pages were read from disk to resolve hard page faults. Hard page faults occur when a process refers to a page in virtual memory that must be retrieved from disk because it is not in its working set or elsewhere in physical memory. When a page is faulted, the system tries to read multiple contiguous pages into memory to maximize the benefit of the read operation. Compare Pages Input/sec to Page Reads/sec to find the average number of pages read into memory during each read operation | PERF_COUNTER_COUNTER |
| Pages Output/sec | Shows the rate, in incidents per second, at which pages were written to disk to free up space in physical memory. A high rate of pages output might indicate a memory shortage. The Windows Server 2003 family writes more pages back to disk to free up space when physical memory is in short supply. This counter shows numbers of pages, and can be compared to other counts of pages without conversion. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Pages/sec | Shows the rate, in incidents per second, at which pages were read from or written to disk to resolve hard page faults. This counter is a primary indicator for the kinds of faults that cause system-wide delays. It is the sum of Pages Input/sec and Pages Output/sec. It is counted in numbers of pages, so it can be directly compared to other counts of pages such as Page Faults/sec. It includes pages retrieved to satisfy faults in the file system cache (usually requested by applications) and noncached mapped memory files. | PERF_COUNTER_COUNTER |
| Pool Nonpaged Allocs | Shows the number of calls to allocate space in the nonpaged pool. This counter is measured in numbers of calls to allocate space, regardless of the amount of space allocated in each call. | PERF_COUNTER_RAWCOUNT |
| Pool Nonpaged Bytes | Shows the size, in bytes, of the nonpaged pool. Pool Nonpaged Bytes is calculated differently than Process\Pool Nonpaged Bytes, so it might not equal Process(_Total )\Pool Nonpaged Bytes. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Allocs | Shows the number of calls to allocate space in the paged pool. This counter is measured in numbers of calls to allocate space, regardless of the amount of space allocated in each call. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Bytes | Shows the size, in bytes, of the paged pool. Pool Paged Bytes is calculated differently than Process\Pool Paged Bytes, so it might not equal Process(_Total )\Pool Paged Bytes. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Resident Bytes | Shows the size, in bytes, of the paged pool. Space used by the paged and nonpaged pools is taken from physical memory, so a pool that is too large denies memory space to processes. | PERF_COUNTER_RAWCOUNT |
| System Cache Resident Bytes | Shows the size, in bytes, of pageable operating system code in the file system cache. This value includes only current physical pages and does not include any virtual memory pages that are not currently resident. It does not equal the System Cache value shown in Task Manager. As a result, this value may be smaller than the actual amount of virtual memory in use by the file system cache. This value is a component of System Code Resident Bytes that represents all pageable operating system code that is currently in physical memory. | PERF_COUNTER_RAWCOUNT |
| System Code Resident Bytes | Shows the size, in bytes, of operating system code currently in physical memory that can be written to disk when not in use. This value is a component of System Code Total Bytes, which also includes operating system code on disk. System Code Resident Bytes (and System Code Total Bytes) does not include code that must remain in physical memory. | PERF_COUNTER_RAWCOUNT |
| System Code Total Bytes | Shows the size, in bytes, of pageable operating system code currently in virtual memory. It is a measure of the amount of physical memory being used by the operating system that can be written to disk when not in use. This value is calculated by adding the bytes in Ntoskrnl.exe, Hal.dll, the boot drivers, and file systems loaded by Ntldr/osloader. This counter does not include code that must remain in physical memory. | PERF_COUNTER_RAWCOUNT |
| System Driver Resident Bytes | Shows the size, in bytes, of pageable physical memory being used by device drivers. The counter is the working set (physical memory area) of the drivers. This value is a component of System Driver Total Bytes, which also includes driver memory that has been written to disk. Neither System Driver Resident Bytes nor System Driver Total Bytes includes memory that cannot be written to disk. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| System Driver Total Bytes | Shows the size, in bytes, of pageable virtual memory currently being used by device drivers. Pageable memory can be written to disk when it is not being used. It includes physical memory (System Driver Resident Bytes) and code and data written to disk. This counter is a component of System Code Total Bytes. | PERF_COUNTER_RAWCOUNT |
| Transition Faults/sec | Shows the rate, in incidents per second, at which page faults were resolved by recovering pages without additional disk activity, including pages that were being used by another process sharing the page, or that were on the modified page list or the standby list, or that were being written to disk at the time of the page fault. This counter is also equal to the number of pages faulted because only one page is faulted in each operation. | PERF_COUNTER_COUNTER |
| Write Copies/sec | Shows the rate, in incidents per second, at which page faults were caused by attempts to write that were satisfied by copying the page from elsewhere in physical memory. This is an economical way of sharing data since pages are only copied when they are written to; otherwise, the page is shared. This counter shows the number of copies, without regard to the number of pages copied in each operation. | PERF_COUNTER_COUNTER |

# MSMQ Queue Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The MSMQ Queue performance object monitors message statistics for a specified queue. There are instances for each queue on the computer. In addition, if a Message Queuing–based application has a private queue open on another computer, an instance for that queue is also available. The computer queue instance represents the computer's source journal and dead letter queues.

| Counter Name | Description | Counter Type |
|---|---|---|
| MSMQ Queue | Shows the Message Queuing queues in this computer. | PERF_COUNTER_RAWCOUNT |
| Bytes in Journal Queue | Shows the total number of bytes that reside in the journal queue. For the computer queue instance, this represents the computer journal queue. | PERF_COUNTER_RAWCOUNT |
| Bytes in Queue | Shows the total number of bytes that currently reside in the queue. For the computer queue instance, this represents the dead letter queue. | PERF_COUNTER_RAWCOUNT |
| Messages in Journal Queue | Shows the total number of messages that currently reside in the journal queue. For the computer queue instance, this represents the computer journal queue. | PERF_COUNTER_RAWCOUNT |
| Messages in Queue | Shows the total number of messages that currently reside in the queue. For the computer queue instance, this represents the dead letter queue. For queues residing on the local computer, this counter shows how many messages are waiting to be read. For queues residing on a remote computer, the counter shows the number of messages waiting to be sent. This counter is useful in determining if message handling is stalled. | PERF_COUNTER_RAWCOUNT |

# MSMQ Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The MSMQ Service performance object monitors session and message statistics for a specified computer that is running Message Queuing.

| Counter Name | Description | Counter Type |
|---|---|---|
| Incoming Messages/sec | Shows the rate, in incidents per second, at which Message Queuing messages were received by the Message Queuing service. This counter is useful for determining if the local Message Queuing service has received messages. | PERF_COUNTER_COUNTER |
| IP Sessions | Shows the number of open IP sessions. | PERF_COUNTER_RAWCOUNT |
| MSMQ Incoming Messages | Shows the number of Message Queuing messages that were received by the Message Queuing service. | PERF_COUNTER_RAWCOUNT |
| MSMQ Outgoing Messages | Shows the number of Message Queuing messages that were sent by the Message Queuing service. | PERF_COUNTER_RAWCOUNT |
| Outgoing Messages/sec | Shows the rate, in incidents per second, at which Message Queuing messages were sent by the Message Queuing service. This counter is useful for determining if the local Message Queuing service has sent messages. | PERF_COUNTER_COUNTER |
| Sessions | Shows the total number of open network sessions. A session is opened whenever a message is sent or received, and the session is closed automatically after two to five minutes of inactivity. The Windows Server 2003 family closes a session after two minutes; Windows XP Professional and most other Windows operating systems close a session after five minutes. This counter indicates if messaging activity has occurred recently. | PERF_COUNTER_RAWCOUNT |
| Total Bytes in All Queues | Shows the total number of bytes in all active queues under the Message Queuing service. | PERF_COUNTER_RAWCOUNT |
| Total Messages in All Queues | Shows the total number of messages in all active queues under the Message Queuing service. | PERF_COUNTER_RAWCOUNT |

# MSMQ Session Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The MSMQ Session performance object monitors statistics about active sessions between computers running Message Queuing. You can choose to have an instance for each session.

| Counter Name | Description | Counter Type |
|---|---|---|
| Incoming Bytes | Shows the total number of bytes that were received through the selected session. | PERF_COUNTER_RAWCOUNT |
| Incoming Bytes/sec | Shows the rate, in incidents per second, at which bytes were received through the selected session. | PERF_COUNTER_RAWCOUNT |
| Incoming Messages | Shows the total number of messages that were received through the selected session. | PERF_COUNTER_RAWCOUNT |
| Incoming Messages/sec | Shows the rate, in incidents per second, at which Message Queuing messages were received through the selected session. | PERF_COUNTER_RAWCOUNT |
| Outgoing Bytes | Shows the total number of bytes that were sent through the selected session. | PERF_COUNTER_RAWCOUNT |
| Outgoing Bytes/sec | Shows the rate, in incidents per second, at which Message Queuing messages were sent through the selected session. | PERF_COUNTER_RAWCOUNT |
| Outgoing Messages | Shows the total number of Message Queuing messages that were sent through the selected session. | PERF_COUNTER_RAWCOUNT |
| Outgoing Messages/sec | Shows the rate, in incidents per second, at which Message Queuing messages were sent through the selected session. | PERF_COUNTER_RAWCOUNT |

# NBT Connection Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NBT Connection performance object consists of counters that measure the rates at which bytes are sent and received over the NetBIOS over a TCP/IP (NetBT or NBT) connection between the local computer and a remote computer. The NetBT or NBT protocol provides NetBIOS support for the TCP/IP protocol. The NBT connection is identified by the name of the remote computer.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Received/sec | Shows the rate at which bytes are received by the local computer over an NBT connection to a remote computer. All bytes received by the local computer over the connection are counted. | PERF_COUNTER_BULK_COUNT |
| Bytes Sent/sec | Shows the rate at which bytes are sent by the local computer over an NBT connection to a remote computer. All bytes sent by the local computer over the connection are counted. | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the rate at which bytes are transmitted by the local computer over an NBT connection to a remote computer. All bytes transmitted by the local computer over the connection are counted. | PERF_COUNTER_BULK_COUNT |

# DUPTILE1_Network Interface Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Network Interface performance object consists of counters that measure the rates at which bytes and packets are sent and received over a TCP/IP connection. It includes counters that monitor connection errors.

The Network Interface counters display data about the network adapters on the server computer. The first instance of the Network Interface object (Instance 1) that you see in System Monitor represents the *loopback*. The *loopback* is a local path through the protocol driver and the network adapter. All other instances represent installed network adapters.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Received/sec | Shows the rate, in incidents per second, at which bytes were received over each network adapter. The counted bytes include framing characters. Bytes Received/sec is a subset of Bytes Total/sec. | PERF_COUNTER_COUNTER |
| Bytes Sent/sec | Shows the rate, in incidents per second, at which bytes were sent over each network adapter. The counted bytes include framing characters. Bytes Sent/sec is a subset of Bytes Total/sec. | PERF_COUNTER_COUNTER |
| Bytes Total/sec | Shows the rate, in incidents per second, at which bytes were sent and received on the network interface, including framing characters. Bytes Total/sec is the sum of the values of Bytes Received/sec and Bytes Sent/sec. | PERF_COUNTER_COUNTER |
| Current Bandwidth | Shows an estimate of the current bandwidth of the network interface in bits per second (bps). For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this value is the nominal bandwidth. | PERF_COUNTER_RAWCOUNT |
| Output Queue Length | Shows the length, in number of packets, of the output packet queue. If this is longer than two packets, it indicates that there are delays, and if possible the bottleneck should be found and eliminated. Since the requests are queued by Network Driver Interface Specification (NDIS) in this implementation, this value is always 0. | PERF_COUNTER_RAWCOUNT |
| Packets Outbound Discarded | Shows the number of outbound packets to be discarded, even though no errors were detected to prevent transmission. One possible reason for discarding such a packet could be to free up buffer space. | PERF_COUNTER_RAWCOUNT |
| Packets Outbound Errors | Shows the number of outbound packets that could not be transmitted because of errors. | PERF_COUNTER_RAWCOUNT |
| Packets Received Discarded | Shows the number of inbound packets that were discarded, even though no errors were detected to prevent their being delivered to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. | PERF_COUNTER_RAWCOUNT |
| Packets Received Errors | Shows the number of inbound packets that contained errors that prevented them from being delivered to a higher-layer protocol. | PERF_COUNTER_RAWCOUNT |
| Packets Received Non-Unicast/sec | Shows the rate, in incidents per second, at which non-unicast (subnet broadcast or subnet multicast) packets were delivered to a higher-layer protocol. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Packets Received Unicast/sec | Shows the rate, in incidents per second, at which subnet-unicast packets were delivered to a higher-layer protocol. | PERF_COUNTER_COUNTER |
| Packets Received Unknown | Shows the number of packets received through the interface that were discarded because of an unknown or unsupported protocol. | PERF_COUNTER_RAWCOUNT |
| Packets Received/sec | Shows the rate, in incidents per second, at which packets were received on the network interface. | PERF_COUNTER_COUNTER |
| Packets Sent/sec | Shows the rate, in incidents per second, at which packets were sent on the network interface. | PERF_COUNTER_COUNTER |
| Packets Sent Non-Unicast/sec | Shows the rate, in incidents per second, at which packets were requested to be transmitted to non-unicast (subnet broadcast or subnet multicast) addresses by higher-level protocols. This counter includes packets that were discarded or not sent. | PERF_COUNTER_COUNTER |
| Packets Sent Unicast/sec | Shows the rate, in incidents per second, at which packets were requested to be transmitted to subnet-unicast addresses by higher-level protocols. This counter includes the packets that were discarded or not sent. | PERF_COUNTER_COUNTER |

# NNTP Commands Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NNTP Commands performance object includes counters for all Network News Transport Protocol (NNTP) commands processed by the NNTP service, which is installed as an optional component of Internet Information Services.

NNTP counters are started for each virtual server instance and are reset to zero when the virtual server is started. A single NNTP service can have many virtual servers (also called sites).

| Counter Name | Description | Counter Type |
|---|---|---|
| Article Commands | Shows the number of ARTICLE commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Article Commands/sec | Shows the rate, in incidents per second, at which ARTICLE commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Check Commands | Shows the number of CHECK commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Check Commands/sec | Shows the rate, in incidents per second, at which CHECK commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Group Commands | Shows the number of GROUP commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Group Commands/sec | Shows the rate, in incidents per second, at which GROUP commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Help Commands | Shows the number of HELP commands that were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Help Commands/sec | Shows the rate, in incidents per second, at which HELP commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| IHave Commands | Shows the number of IHAVE commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| IHave Commands/sec | Shows the rate, in incidents per second, at which IHAVE commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Last Commands | Shows the number of LAST commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Last Commands/sec | Shows the rate, in incidents per second, at which LAST commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| List Commands | Shows the number of LIST commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| List Commands/sec | Shows the rate, in incidents per second, at which LIST commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Logon Attempts | Shows the number of logon attempts that have been made to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Logon Attempts/sec | Shows the rate, in incidents per second, at which logon attempts have been made to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Logon Failures | Shows the number of logons that failed on the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Logon Failures/sec | Shows the rate, in incidents per second, at which logons failed on the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Mode Commands | Shows the number of MODE commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Mode Commands/sec | Shows the rate, in incidents per second, at which MODE commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Newgroups Commands | Shows the number of NEWGROUPS commands that were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Newgroups Commands/sec | Shows the rate, in incidents per second, at which NEWSGROUPS commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Newnews Commands | Shows the number of NEWNEWS commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Newnews Commands/sec | Shows the rate, in incidents per second, at which NEWNEWS commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Next Commands | Shows the number of NEXT commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Next Commands/sec | Shows the rate, in incidents per second, at which NEXT commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Post Commands | Shows the number of POST commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Post Commands/sec | Shows the rate, in incidents per second, at which POST commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Quit Commands | Shows the number of QUIT commands that were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Quit Commands/sec | Shows the rate, in incidents per second, at which QUIT commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Search Commands | Shows the number of SEARCH commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Search Commands/sec | Shows the rate, in incidents per second, at which SEARCH commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Stat Commands | Shows the number of STAT commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Stat Commands/sec | Shows the rate, in incidents per second, at which STAT commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Takethis Commands | Shows the number of TAKETHIS commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Takethis Commands/sec | Shows the rate, in incidents per second, at which TAKETHIS commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| XHdr Commands | Shows the number of XHDR commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| XHdr Commands/sec | Shows the rate, in incidents per second, at which XHDR commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| XOver Commands | Shows the number of XOVER commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| XOver Commands/sec | Shows the rate, in incidents per second, at which XOVER commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| XPat Commands | Shows the number of XPAT commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| XPat Commands/sec | Shows the rate, in incidents per second, at which XPAT commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| XReplic Commands | Shows the number of XREPLIC commands received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| XReplic Commands/sec | Shows the rate, in incidents per second, at which XREPLIC commands were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |

NNTP Server Object

# NNTP Server Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NNTP Server performance object monitors posting, authentication, and connection activity on a Network News Transport Protocol (NNTP) Server. The NNTP service is an optional component of Internet Information Services (IIS).

NNTP counters are started for each virtual server instance and are reset to zero when the virtual server is started. A single NNTP service can have many virtual servers (also called sites).

In addition to monitoring these counters, it is recommended that you also monitor the system counters Physical Disk Object, Physical Disk Object, Physical Disk Object, and Processor Object.

| Counter Name | Description | Counter Type |
|---|---|---|
| Article Map Entries | Shows the entries inserted into the article mapping table of the NNTP Server. | PERF_COUNTER_RAWCOUNT |
| Article Map Entries/sec | Shows the rate, in incidents per second, at which entries were inserted into the article mapping table of the NNTP Server. | PERF_COUNTER_COUNTER |
| Articles Deleted | Shows the number of articles deleted on the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Articles Deleted/sec | Shows the rate, in incidents per second, at which articles were deleted from the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Articles Posted | Shows the number of articles posted (committed) to the NNTP Server since the NNTP service was last started. This can be used to determine if the server is accepting posts. If this value is smaller than that of Articles Received, it indicates that the server is rejecting articles and you need to investigate the cause. | PERF_COUNTER_RAWCOUNT |
| Articles Posted/sec | Shows the rate, in incidents per second, at which articles were posted to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Articles Received | Shows the total number of files received by the NNTP Server since the NNTP service was last started. Files received can include rejected articles. If this value is greater than that of Articles Posted, this indicates that the server is rejecting articles and you need to investigate the cause. | PERF_COUNTER_RAWCOUNT |
| Articles Received/sec | Shows the rate, in incidents per second, at which files were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Articles Sent | Shows the total number of files sent by the NNTP Server to other servers since the NNTP service was last started. Files sent can include rejected articles. | PERF_COUNTER_RAWCOUNT |
| Articles Sent/sec | Shows the rate, in incidents per second, at which files were sent by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Articles Total | Shows the sum of NNTP Server\Articles Sent and NNTP Server\Articles Received. This is the total number of files transferred by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Bytes Received/sec | Shows the rate, in incidents per second, at which that data bytes were received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_BULK_COUNT |
| Bytes Sent/sec | Shows the rate, in incidents per second, at which data bytes were sent by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the sum of NNTP Server\Bytes Sent/sec and NNTP Server\Bytes Received/sec. This is the total rate, in incidents per second, at which bytes were transferred by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_BULK_COUNT |
| Control Messages Failed | Shows the total number of control messages failed or not applied by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Control Messages Received | Shows the total number of control messages received by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Current Anonymous Users | Shows the number of anonymous users who are currently connected to the NNTP Server. | PERF_COUNTER_RAWCOUNT |
| Current Connections | Shows the current number of connections to the NNTP Server. | PERF_COUNTER_RAWCOUNT |
| Current NonAnonymous Users | Shows the number of nonanonymous users currently connected to the NNTP Server. | PERF_COUNTER_RAWCOUNT |
| Current Outbound Connections | Shows the number of current outbound connections being made by the NNTP Server. | PERF_COUNTER_RAWCOUNT |
| Failed Outbound Logons | Shows the number of failed outbound logons made by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| History Map Entries | Shows the number of entries inserted into the history mapping table of the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| History Map Entries/sec | Shows the rate, in incidents per second, at which entries were inserted into the history mapping table of the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |
| Maximum Anonymous Users | Shows the maximum number of anonymous users that were simultaneously connected to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Maximum Connections | Shows the maximum number of simultaneous connections to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Maximum NonAnonymous Users | Shows the maximum number of nonanonymous users that were simultaneously connected to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Moderated Postings Failed | Shows the total number of moderated postings that the NNTP Server failed to send to a Simple Mail Transfer Protocol (SMTP) Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Moderated Postings Sent | Shows the total number of moderated postings that the NNTP Server attempted to send to an SMTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Sessions Flow Controlled | Shows the number of client sessions that were currently in a flow controlled state in the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Anonymous Users | Shows the total number of anonymous users that have connected to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Connections | Shows the number of connections that have been made to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total NonAnonymous Users | Shows the total number of nonanonymous users that have connected to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Outbound Connections | Shows the number of outbound connections that have been made by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Outbound Connections Failed | Shows the number of unsuccessful outbound connections that have been made by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Passive Feeds | Shows the number of passive feeds that were accepted by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Pull Feeds | Shows the number of pull feeds that were made by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total Push Feeds | Shows the number of push feeds that were made by the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Total SSL Connections | Shows the number of Secure Sockets Layer (SSL) connections that have been made to the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Xover Entries | Shows the number of XOVER entries in the XOVER table of the NNTP Server since the NNTP service was last started. | PERF_COUNTER_RAWCOUNT |
| Xover Entries/sec | Shows the rate, in incidents per second, at which XOVER entries were inserted in the XOVER table of the NNTP Server since the NNTP service was last started. | PERF_COUNTER_COUNTER |

NNTP Commands Object

# NTDS Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NTDS object consists of counters that provide statistics about the activity of the Active Directory directory service. The object provides information about the following:

- The Name Service Provider Interface (NSPI), used to facilitate communication between Active Directory and Exchange Directory Service (XDS)
- The Local Security Authority (LSA), a protected subsystem that maintains security for the local computer
- The Security Accounts Manager (SAM) interface, which provides compatibility between Windows Server 2003, Windows 2000, and Windows NT 4.0 domains
- The Lightweight Directory Access Protocol (LDAP) interface, which provides the application programming interface (API) for LDAP clients and exposes the Active Directory Services Interface (ADSI) so additional applications may be written that can talk to Active Directory
- The Directory System Agent (DSA), the Active Directory process that runs on each domain controller and manages all the directory service functions
- The Knowledge Consistency Checker (KCC), an Active Directory component that is responsible for generating the replication topology between domain controllers

| Counter Name | Description | Counter Type |
|---|---|---|
| AB ANR/sec | Shows the rate at which Address Book clients perform Ambiguous Name Resolutions (ANR) operations. | PERF_COUNTER_COUNTER |
| AB Browses/sec | Shows the rate at which Address Book clients perform browse operations. | PERF_COUNTER_COUNTER |
| AB Client Sessions | Shows the number of connected Address Book client sessions. | PERF_COUNTER_RAWCOUNT |
| AB Matches/sec | Shows the rate at which Address Book clients perform find operations. | PERF_COUNTER_COUNTER |
| AB Property Reads/sec | Shows the rate at which Address Book clients perform property read operations. | PERF_COUNTER_COUNTER |
| AB Proxy Lookups/sec | Shows the rate at which proxy clients perform search operations. | PERF_COUNTER_COUNTER |
| AB Searches/sec | Shows the rate at which Address Book clients perform key search operations. | PERF_COUNTER_COUNTER |
| DRA Highest USN Committed (High part) | Shows the high-order 32 bits of the highest update sequence number (USN) committed on the DSA. | PERF_COUNTER_RAWCOUNT |
| DRA Highest USN Committed (Low part) | Shows the low-order 32 bits of the highest USN committed on the DSA. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| DRA Highest USN Issued (High part) | Shows the high-order 32 bits of the highest USN issued on the DSA. | PERF_COUNTER_RAWCOUNT |
| DRA Highest USN Issued (Low part) | Shows the low-order 32 bits of the highest USN issued on the DSA. | PERF_COUNTER_RAWCOUNT |
| DRA Inbound Bytes Compressed (Between Sites, After Compression)/sec | Shows the compressed size of inbound compressed replication data (size after compression, from DSAs in other sites). | PERF_COUNTER_COUNTER |
| DRA Inbound Bytes Compressed (Between Sites, Before Compression)/sec | Shows the original size of inbound compressed replication data (size before compression, from DSAs in other sites). | PERF_COUNTER_COUNTER |
| DRA Inbound Bytes Not Compressed (Within Site)/sec | Shows the number of incoming bytes replicated that were not compressed at the source (that is, from DSAs in the same site). | PERF_COUNTER_COUNTER |
| DRA Inbound Bytes Total/sec | Shows the total number of bytes replicated in. This counter is the sum of the number of uncompressed bytes (never compressed) and the number of compressed bytes (after compression). | PERF_COUNTER_COUNTER |
| DRA Inbound Full Sync Objects Remaining | Shows the number of objects remaining until the full synchronization is completed (when set). | PERF_COUNTER_RAWCOUNT |
| DRA Inbound Object Updates Remaining in Packet | Shows the number of object updates received in the current directory replication update packet that have not yet been applied to the local server. | PERF_COUNTER_RAWCOUNT |
| DRA Inbound Objects Applied/sec | Shows the rate at which replication updates received from replication partners are applied by the local directory service. This counter excludes changes that are received but not applied (because, for example, the change has already been made). This indicates how much replication update activity is occurring on the server as a result of changes generated on other servers. | PERF_COUNTER_COUNTER |
| DRA Inbound Objects Filtered/sec | Shows the number of objects received from inbound replication partners that contained no updates that needed to be applied. | PERF_COUNTER_COUNTER |
| DRA Inbound Objects/sec | Shows the number of objects received from neighbors through inbound replication. A *neighbor* is a domain controller from which the local domain controller replicates locally. | PERF_COUNTER_COUNTER |
| DRA Inbound Properties Applied/sec | Shows the number of properties that are updated due to the incoming property's winning the reconciliation logic that determines the final value to be replicated. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| DRA Inbound Properties Filtered/sec | Shows the number of property changes that are received during the replication that we have already seen. | PERF_COUNTER_COUNTER |
| DRA Inbound Properties Total/sec | Shows the total number of object properties received from inbound replication partners. | PERF_COUNTER_COUNTER |
| DRA Inbound Values (DNs only)/sec | Shows the number of object property values received from inbound replication partners that are distinguished names (DNs) that reference other objects. DN values, such as group or distribution list memberships, are generally more expensive to apply than other kinds of values. | PERF_COUNTER_COUNTER |
| DRA Inbound Values Total/sec | Shows the total number of object property values received from inbound replication partners. Each inbound object has one or more properties, and each property has zero or more values. Zero values indicate property removal. | PERF_COUNTER_COUNTER |
| DRA Outbound Bytes Compressed (Between Sites, After Compression)/sec | Shows the compressed size of outbound compressed replication data (size after compression, from DSAs in other sites). | PERF_COUNTER_COUNTER |
| DRA Outbound Bytes Compressed (Between Sites, Before Compression)/sec | Shows the original size of outbound compressed replication data (size before compression, from DSAs in other sites). | PERF_COUNTER_COUNTER |
| DRA Outbound Bytes Not Compressed (Within Site)/sec | Shows the number of bytes replicated out that were not compressed (that is, from DSAs in the same site). | PERF_COUNTER_COUNTER |
| DRA Outbound Bytes Total/sec | Shows the total number of bytes replicated out. This counter is the sum of the number of uncompressed bytes (never compressed) and the number of compressed bytes (after compression). | PERF_COUNTER_COUNTER |
| DRA Outbound Objects Filtered/sec | Shows the number of objects that were determined by outbound replication to have no updates that the outbound partner did not already have. | PERF_COUNTER_COUNTER |
| DRA Outbound Objects/sec | Shows the number of objects replicated out. | PERF_COUNTER_COUNTER |
| DRA Outbound Properties/sec | Shows the number of properties replicated out. | PERF_COUNTER_COUNTER |
| DRA Outbound Values (DNs only)/sec | Shows the number of object property values containing DNs sent to outbound replication partners. DN values, such as group or distribution list memberships, are generally more expensive to read than other kinds of values. | PERF_COUNTER_COUNTER |
| DRA Outbound Values Total/sec | Shows the number of object property values sent to outbound replication partners. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| DRA Pending Replication Synchronizations | Shows the number of directory synchronizations that are queued for this server but not yet processed. | PERF_COUNTER_RAWCOUNT |
| DRA Reads | Shows the percentage of directory reads coming from the directory replication agent (DRA). | PERF_RAW_FRACTION |
| DRA Searches | Shows the percentage of directory searches coming from the DRA. | PERF_RAW_FRACTION |
| DRA Sync Failures on Schema Mismatch | Shows the number of synchronization requests made to neighbors that failed because their schema are not synchronized. | PERF_COUNTER_RAWCOUNT |
| DRA Sync Requests Made | Shows the number of synchronization requests made to neighbors. | PERF_COUNTER_RAWCOUNT |
| DRA Sync Requests Successful | Shows the number of synchronization requests made to neighbors that were successfully returned. | PERF_COUNTER_RAWCOUNT |
| DRA Writes | Shows the percentage of directory writes coming from the DRA. | PERF_RAW_FRACTION |
| DS Client Binds/sec | Shows the number of Ntdsapi.dll binds per second serviced by this domain controller. | PERF_COUNTER_COUNTER |
| DS Client Name Translations/sec | Shows the number of Ntdsapi.dll name translations per second serviced by this domain controller. | PERF_COUNTER_COUNTER |
| DS Directory Reads/sec | Shows the number of directory reads per second. | PERF_COUNTER_COUNTER |
| DS Directory Searches/sec | Shows the number of directory searches per second. | PERF_COUNTER_COUNTER |
| DS Directory Writes/sec | Shows the number of directory writes per second. | PERF_COUNTER_COUNTER |
| DS Monitor List Size | Shows the number of requests to be notified when objects are updated that are currently registered with this DSA. | PERF_COUNTER_RAWCOUNT |
| DS Name Cache hit rate | Shows the percentage of directory object name component lookups that are satisfied out of the DSA's name cache. | PERF_RAW_FRACTION |
| DS Notify Queue Size | Shows the number of pending update notifications that have been queued but not yet transmitted to clients. | PERF_COUNTER_RAWCOUNT |
| DS Other Reads | Shows the percentage of directory reads that do not come from SAM, DRA, LDAP, LSA, XDS, KCC, or NSPI. | PERF_RAW_FRACTION |
| DS Other Searches | Shows the percentage of directory searches that do not come from SAM, DRA, LDAP, LSA, XDS, KCC, or NSPI. | PERF_RAW_FRACTION |
| DS Other Writes | Shows the percentage of directory writes that do not come from SAM, DRA, LDAP, LSA, XDS, KCC, or NSPI. | PERF_RAW_FRACTION |

| | | |
|---|---|---|
| DS Search sub-operations/sec | Shows the number of search suboperations per second. One search operation is made up of many suboperations. Each suboperation roughly corresponds to an object that the search causes the directory service to consider. | PERF_COUNTER_COUNTER |
| DS Security Descriptor Propagations Events | Shows the number of security descriptor propagation events that are queued but not yet processed. | PERF_COUNTER_RAWCOUNT |
| DS Security Descriptor Propagator Average Exclusion Time | Shows the average length of time that the security descriptor propagator spends waiting for exclusive access to database elements during a security descriptor propagation suboperation. | PERF_COUNTER_RAWCOUNT |
| DS Security Descriptor Propagator Runtime Queue | Shows the number of objects that remain to be examined while the current directory service security descriptor propagator event is being processed. | PERF_COUNTER_RAWCOUNT |
| DS Security Descriptor sub-operations/sec | Shows the number of security descriptor propagation suboperations per second. One security descriptor propagation operation is made up of many suboperations. | PERF_COUNTER_COUNTER |
| DS Server Binds/sec | Shows the number of domain controller–to–domain controller binds per second that are serviced by this domain controller. | PERF_COUNTER_COUNTER |
| DS Server Name Translations/sec | Shows the number of domain controller–to–domain controller name translations per second that are serviced by this domain controller. | PERF_COUNTER_COUNTER |
| DS Threads in Use | Shows the current number of threads in use by the directory service (which is different from the number of threads in the directory service process). This is the number of threads currently servicing client API calls; it can be used to indicate whether additional processors should be used. | PERF_COUNTER_RAWCOUNT |
| KCC Reads | Shows the percentage of directory reads that come from KCC. | PERF_RAW_FRACTION |
| KCC Searches | Shows the percentage of directory searches that come from KCC. | PERF_RAW_FRACTION |
| KCC Writes | Shows the percentage of directory writes that come from KCC. | PERF_RAW_FRACTION |
| KDC AS Requests | Shows the number of Authentication Server (AS) requests serviced by the Kerberos Key Distribution Center (KDC) per second. AS requests are used by the client to obtain a ticket-granting ticket. | PERF_COUNTER_COUNTER |
| KDC TGS Requests | Shows the number of Ticket Granting Server (TGS) requests serviced by the KDC per second. TGS requests are used by the client to obtain a ticket to a resource. | PERF_COUNTER_COUNTER |
| Kerberos Authentications | Shows the number of times per second that clients use a ticket to this domain controller to authenticate to this domain controller. | PERF_COUNTER_COUNTER |
| LDAP Active Threads | Shows the current number of threads in use by the LDAP subsystem of the local directory service. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| LDAP Bind Time | Shows the time, in milliseconds, taken for the last successful LDAP bind. | PERF_COUNTER_RAWCOUNT |
| LDAP Client Sessions | Shows the number of currently connected LDAP client sessions. | PERF_COUNTER_RAWCOUNT |
| LDAP Searches | Shows the percentage of directory searches coming from LDAP. | PERF_RAW_FRACTION |
| LDAP Searches/sec | Shows the rate at which LDAP clients perform search operations. | PERF_COUNTER_COUNTER |
| LDAP Successful Binds | Shows the percentage of LDAP bind attempts that are successful. | PERF_RAW_FRACTION |
| LDAP Successful Binds/sec | Shows the number of LDAP binds per second. | PERF_COUNTER_COUNTER |
| LDAP UDP operations/sec | Shows the number of User Datagram Protocol (UDP) operations that the LDAP server is processing per second. | PERF_COUNTER_COUNTER |
| LDAP Writes | Shows the percentage of directory writes coming from LDAP. | PERF_RAW_FRACTION |
| LDAP Writes/sec | Shows the rate at which LDAP clients perform write operations. | PERF_COUNTER_COUNTER |
| LSA Reads | Shows the percentage of directory reads that come from LSA. | PERF_RAW_FRACTION |
| LSA Searches | Shows the percentage of directory searches that come from LSA. | PERF_RAW_FRACTION |
| LSA Writes | Shows the percentage of directory writes that come from LSA. | PERF_RAW_FRACTION |
| NSPI Reads | Shows the percentage of directory reads that come from NSPI. | PERF_RAW_FRACTION |
| NSPI Searches | Shows the percentage of directory searches that come from NSPI. | PERF_RAW_FRACTION |
| NSPI Writes | Shows the percentage of directory writes that come from NSPI. | PERF_RAW_FRACTION |
| NTLM Authentications | Shows the number of NTLM authentications per second serviced by this domain controller. | PERF_COUNTER_COUNTER |
| SAM Account Group Membership Evaluations/sec | Shows the number of SAM Account Group Membership Evaluations per second. | PERF_COUNTER_COUNTER |
| SAM Create Machine Attempts/sec | Shows the number of SAM create machine attempts per second. | PERF_COUNTER_COUNTER |
| SAM Create User Attempts/sec | Shows the number of SAM create-user attempts per second. | PERF_COUNTER_COUNTER |
| SAM Enumerations/sec | Shows the number of SAM enumerations per second. | PERF_COUNTER_COUNTER |
| SAM GC Evaluations/sec | Shows the number of SAM global catalog evaluations per second. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| SAM Membership Changes/sec | Shows the number of SAM membership changes. | PERF_COUNTER_COUNTER |
| SAM Non-Transitive Membership Evaluations/sec | Shows the number of SAM nontransitive membership evaluations per second. | PERF_COUNTER_COUNTER |
| SAM Password Changes/sec | Shows the number of SAM password changes per second. | PERF_COUNTER_COUNTER |
| SAM Query Displays/sec | Shows the number of SAM query displays per second. | PERF_COUNTER_COUNTER |
| SAM Reads | Shows the percentage of directory reads that come from SAM. | PERF_RAW_FRACTION |
| SAM Resource Group Membership Evaluations/sec | Shows the number of SAM resource group membership evaluations per second. | PERF_COUNTER_COUNTER |
| SAM Searches | Shows the percentage of directory searches that come from SAM. | PERF_RAW_FRACTION |
| SAM Successful Create Machines/sec | Shows the number of machines that were successfully created per second. | PERF_COUNTER_COUNTER |
| SAM Successful Create Users/sec | Shows the number of users that were successfully created per second. | PERF_COUNTER_COUNTER |
| SAM Transitive Membership Evaluations/sec | Shows the number of SAM transitive membership evaluations per second. | PERF_COUNTER_COUNTER |
| SAM Universal Group Membership Evaluations/sec | Shows the number of SAM universal group membership evaluations per second. | PERF_COUNTER_COUNTER |
| SAM Writes | Shows the percentage of directory writes that come from SAM. | PERF_RAW_FRACTION |
| XDS Client Sessions | Shows the number of connected XDS client sessions. This indicates the number of connections from other Windows Server 2003 services and the Exchange Administrator program. | PERF_COUNTER_RAWCOUNT |
| XDS Reads | Shows the percentage of directory reads that come from XDS. | PERF_RAW_FRACTION |
| XDS Searches | Shows the percentage of directory searches that come from XDS. | PERF_RAW_FRACTION |
| XDS Writes | Shows the percentage of directory writes that come from XDS. | PERF_RAW_FRACTION |

# NWLink IPX Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NWLink IPX performance object consists of counters that measure data transmission to and from computers that use the Internetwork Packet Exchange (IPX) protocol. This object reports valid data only for counters that monitor datagrams and packets; for frame-related counters, the object tends to report zero values. In addition, connection-related data is not likely to be useful, because IPX is a connectionless protocol.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Total/sec | Shows the total rate at which bytes are sent to or received from the network by the protocol, but shows only the bytes in frames that carry data. This is the sum of the values of NWLink IPX\Frame Bytes/sec and NWLink IPX\Datagram Bytes/sec. | PERF_COUNTER_BULK_COUNT |
| Connection Session Timeouts | Shows the number of connections that are dropped because a session times out. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Connections Canceled | Shows the number of connections that are canceled. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Connections No Retries | Shows the number of connections that are successfully made on the first try. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Connections Open | Shows the number of connections currently open for this protocol. This counter shows the current count only and is not cumulative. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Connections With Retries | Shows the number of connections that are made after attempting to reconnect. A retry occurs when the first connection attempt fails. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Datagram Bytes Received/sec | Shows the rate at which datagram bytes are received by the computer. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes Sent/sec | Shows the rate at which datagram bytes are sent from the computer. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes/sec | Shows the rate at which datagram bytes are processed by the computer. This counter is the sum of the values of NWLink IPX\Datagram Bytes Received/sec and NWLink IPX\Datagram Bytes Sent/sec. | PERF_COUNTER_BULK_COUNT |
| Datagrams Received/sec | Shows the rate at which datagrams are received by the computer. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Datagrams Sent/sec | Shows the rate at which datagrams are sent from the computer. | PERF_COUNTER_COUNTER |
| Datagrams/sec | Shows the rate at which datagrams are processed by the computer. This counter shows the sum of the values of NWLink IPX\Datagrams Received/sec and NWLink IPX\Datagrams Sent/sec. | PERF_COUNTER_COUNTER |
| Disconnects Local | Shows the number of session disconnections that are initiated by the local computer. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Disconnects Remote | Shows the number of session disconnections that are initiated by the remote computer. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Expirations Ack | Shows the number of T2 timer expirations. | PERF_COUNTER_RAWCOUNT |
| Expirations Response | Shows the number of T1 timer expirations. | PERF_COUNTER_RAWCOUNT |
| Failures Adapter | Shows the number of times a connection is dropped because an adapter fails. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Failures Link | Shows the number of connections that are dropped due to a link failure. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Failures No Listen | Shows the number of connections that are rejected because the remote computer is not listening for connection requests. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Failures Not Found | Shows the number of connection attempts that fail because the remote computer cannot be found. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Local | Shows the number of connections that fail because of resource problems or shortages on the local computer. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Remote | Shows the number of connections that fail because of resource problems or shortages on the remote computer. This number is cumulative and shows a running total. Note that connection-related data is not likely to be useful, because IPX is a connectionless protocol. | PERF_COUNTER_RAWCOUNT |
| Frame Bytes Received/sec | Shows the rate at which data bytes are received by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Rejected/sec | Shows the rate at which data bytes are rejected by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |

| | | |
|---|---|---|
| Frame Bytes Re-Sent/sec | Shows the rate at which data bytes are re-sent by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Sent/sec | Shows the rate at which data bytes are sent by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes/sec | Shows the rate at which data bytes are processed by the computer. This counter is the sum of Frame Bytes Sent/sec and Frame Bytes Received/sec. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frames Received/sec | Shows the rate at which data frames are received by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Rejected/sec | Shows the rate at which data frames are rejected by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Re-Sent/sec | Shows the rate at which data frames are re-sent by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Sent/sec | Shows the rate at which data frames are sent by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames/sec | Shows the rate at which data frames are processed by the computer. This counter is the sum of the values of NWLink IPX\Frames Received/sec and NWLink IPX\Frames Sent/sec. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate at which packets are received by the computer. This counter shows all packets processed (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets Sent/sec | Shows the rate at which packets are sent by the computer. This counter shows all packets sent by the computer (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets/sec | Shows the rate at which packets are processed by the computer. This count is the sum of the values of NWLink IPX\Packets Sent/sec and NWLink IPX\Packets Received/sec. This counter includes all packets processed (control as well as data packets). | PERF_COUNTER_COUNTER |
| Piggyback Ack Queued/sec | Shows the rate at which "piggybacked" acknowledgments, acknowledgements that are added by the receiver onto the next outgoing data frame, are queued. | PERF_COUNTER_COUNTER |
| Piggyback Ack Timeouts | Shows the number of times that a "piggybacked" acknowledgment, an acknowledgement that is added by the receiver onto the next outgoing data frame, cannot be sent because there is no outgoing frame. If no outgoing frame is sent within the time-out period, an acknowledgment frame is sent, and this counter is incremented. | PERF_COUNTER_RAWCOUNT |
| Window Send Average | Shows the average number of data bytes that are sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |
| Window Send Maximum | Shows the maximum number of data bytes that are sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |

# NWLink NetBIOS Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NWLink NetBIOS performance object consists of counters that monitor Internetwork Packet Exchange (IPX) transport rates and connections. This object reports valid data only for counters that monitor datagrams and packets; for frame-related counters, the object tends to report zero values.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Total/sec | Shows the total rate of bytes sent to or received from the network by the protocol, but shows only the bytes in frames that carry data. This is the sum of the values of NWLink NetBIOS\Frame Bytes/sec and NWLink NetBIOS\Datagram Bytes/sec. | PERF_COUNTER_BULK_COUNT |
| Connection Session Timeouts | Shows the number of connections that are dropped because a session times out. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections Canceled | Shows the number of connections that are canceled. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections No Retries | Shows the number of connections that are successfully made on the first try. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections Open | Shows the number of connections currently open for this protocol. This counter shows the current count only and does not accumulate over time. | PERF_COUNTER_RAWCOUNT |
| Connections With Retries | Shows the number of connections that are made after attempting to reconnect. A retry occurs when the first connection attempt fails. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Datagram Bytes Received/sec | Shows the rate at which datagram bytes are received by the computer. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes Sent/sec | Shows the rate at which datagram bytes are sent from the computer. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes/sec | Shows the rate at which datagram bytes are processed by the computer. This counter is the sum of the values of NWLink NetBIOS\Datagram Bytes Received/sec and NWLink NetBIOS\Datagram Bytes Sent/sec. | PERF_COUNTER_BULK_COUNT |
| Datagrams Received/sec | Shows the rate at which datagrams are received by the computer. | PERF_COUNTER_COUNTER |
| Datagrams Sent/sec | Shows the rate at which datagrams are sent from the computer. | PERF_COUNTER_COUNTER |
| Datagrams/sec | Shows the rate at which datagrams are processed by the computer. This counter shows the sum of the values of NWLink NetBIOS\Datagrams Received/sec and NWLink NetBIOS\Datagrams Sent/sec. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Disconnects Local | Shows the number of session disconnections that are initiated by the local computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Disconnects Remote | Shows the number of session disconnections that are initiated by the remote computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Expirations Ack | Shows the number of T2 timer expirations. | PERF_COUNTER_RAWCOUNT |
| Expirations Response | Shows the number of T1 timer expirations. | PERF_COUNTER_RAWCOUNT |
| Failures Adapter | Shows the number of connections that are dropped because an adapter fails. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Link | Shows the number of connections that are dropped due to a link failure. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures No Listen | Shows the number of connections that are rejected because the remote computer is not listening for connection requests. | PERF_COUNTER_RAWCOUNT |
| Failures Not Found | Shows the number of connection attempts that fail because the remote computer cannot be found. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Local | Shows the number of connections that fail because of resource problems or shortages on the local computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Remote | Shows the number of connections that fail because of resource problems or shortages on the remote computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Frame Bytes Received/sec | Shows the rate at which data bytes are received by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Rejected/sec | Shows the rate at which data bytes are rejected by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Re-Sent/sec | Shows the rate at which data bytes are re-sent by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Sent/sec | Shows the rate at which data bytes are sent by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes/sec | Shows the rate at which data bytes are processed by the computer. This counter is the sum of the values of NWLink NetBIOS\Frame Bytes Received/sec and NWLink NetBIOS\Frame Bytes Sent/sec. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frames Received/sec | Shows the rate at which data frames are received by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Rejected/sec | Shows the rate at which data frames are rejected by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Frames Re-Sent/sec | Shows the rate at which data frames are re-sent by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Sent/sec | Shows the rate at which data frames are sent by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames/sec | Shows the rate at which data frames are processed by the computer. This counter is the sum of the values of NWLink NetBIOS\Frames Received/sec and NWLink NetBIOS\Frames Sent/sec. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate at which packets are received by the computer. This counter shows all packets processed (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets Sent/sec | Shows the rate at which packets are sent by the computer. This counter shows all packets sent by the computer (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets/sec | Shows the rate at which packets are processed by the computer. This counter is the sum of the values of NWLink NetBIOS\Packets Received/sec and NWLink NetBIOS\Packets Sent/sec. This counter includes all packets processed (control as well as data packets). | PERF_COUNTER_COUNTER |
| Piggyback Ack Queued/sec | Shows the rate at which "piggybacked" acknowledgments, acknowledgements that are added by the receiver onto the next outgoing data frame, are queued. | PERF_COUNTER_COUNTER |
| Piggyback Ack Timeouts | Shows the number of times that a "piggybacked" acknowledgment, an acknowledgement that is added by the receiver onto the next outgoing data frame, cannot be sent because there is no outgoing frame. If no outgoing frame is sent within the time-out period, an acknowledgment frame is sent, and this counter is incremented. | PERF_COUNTER_RAWCOUNT |
| Window Send Average | Shows the average number of data bytes that are sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |
| Window Send Maximum | Shows the maximum number of data bytes that are sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |

# NWLink SPX Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NWLink SPX performance object consists of counters that measure data transmission and session connections for computers that use the Sequenced Packet Exchange (SPX) protocol. This object reports valid data only for counters that monitor datagrams and packets; for frame-related counters, the object tends to report zero values.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Total/sec | Shows the total rate of bytes sent to or received from the network by the protocol, but shows only the bytes in frames that carry data. This is the sum of the values of Frame Bytes/sec and Datagram Bytes/sec. | PERF_COUNTER_BULK_COUNT |
| Connection Session Timeouts | Shows the number of connections that are dropped because a session times out. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections Canceled | Shows the number of connections that are canceled. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections No Retries | Shows the number of connections that are successfully made on the first try. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections Open | Shows the number of connections currently open for this protocol. This counter shows the current count only and is not cumulative. | PERF_COUNTER_RAWCOUNT |
| Connections With Retries | Shows the number of connections that are made after attempting to reconnect. A retry occurs when the first connection attempt fails. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Datagram Bytes Received/sec | Shows the rate at which datagram bytes are received by the computer. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes Sent/sec | Shows the rate at which datagram bytes are sent from the computer. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes/sec | Shows the rate at which datagram bytes are processed by the computer. This counter is the sum of the values of Datagram Bytes Received/sec and Datagram Bytes Sent/sec. | PERF_COUNTER_BULK_COUNT |
| Datagrams Received/sec | Shows the rate at which datagrams are received by the computer. | PERF_COUNTER_COUNTER |
| Datagrams Sent/sec | Shows the rate at which datagrams are sent from the computer. | PERF_COUNTER_COUNTER |
| Datagrams/sec | Shows the rate at which datagrams are processed by the computer. This counter is the sum of the values of Datagrams Received/sec and Datagrams Sent/sec. | PERF_COUNTER_COUNTER |
| Disconnects Local | Shows the number of session disconnections that are initiated by the local computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Disconnects Remote | Shows the number of session disconnections that are initiated by the remote computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Expirations Ack | Shows the number of T2 timer expirations | PERF_COUNTER_RAWCOUNT |
| Expirations Response | Shows the number of T1 timer expirations. | PERF_COUNTER_RAWCOUNT |
| Failures Adapter | Shows the number of connections that are dropped because an adapter fails. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Link | Shows the number of connections that are dropped due to a link failure. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures No Listen | Shows the number of connections that are rejected because the remote computer is not listening for connection requests. | PERF_COUNTER_RAWCOUNT |
| Failures Not Found | Shows the number of connection attempts that fail because the remote computer cannot be found. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Local | Shows the number of connections that fail because of resource problems or shortages on the local computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Remote | Shows the number of connections that fail because of resource problems or shortages on the remote computer. This number is cumulative and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Frame Bytes Received/sec | Shows the rate at which data bytes are received by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Rejected/sec | Shows the rate at which data bytes are rejected by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Re-Sent/sec | Shows the rate at which data bytes are re-sent by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Sent/sec | Shows the rate at which data bytes are sent by the computer. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes/sec | Shows the rate at which data bytes are processed by the computer. This counter is the sum of the values of Frame Bytes Received/sec and Frame Bytes Sent/sec. This counter shows only the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frames Received/sec | Shows the rate at which data frames are received by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Rejected/sec | Shows the rate at which data frames are rejected by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Re-Sent/sec | Shows the rate at which data frames are re-sent by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Frames Sent/sec | Shows the rate at which data frames are sent by the computer. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames/sec | Shows the rate at which data frames are processed by the computer. This counter is the sum of the values of Frames Received/sec and Frames Sent/sec. This counter shows only the frames that carry data. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate at which packets are received by the computer. This counter shows all packets processed (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets Sent/sec | Shows the rate at which packets are sent by the computer. This counter shows all packets sent by the computer (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets/sec | Shows the rate at which packets are processed by the computer. This counter is the sum of the values of Packets Sent/Sec and Packets Received/Sec. This counter includes all packets processed (control as well as data packets). NWLink SPX\Packets/sec is visible in IPX and NetBIOS. | PERF_COUNTER_COUNTER |
| Piggyback Ack Queued/sec | Shows the rate at which "piggybacked" acknowledgments, acknowledgements that are added by the receiver onto the next outgoing data frame, are queued. | PERF_COUNTER_COUNTER |
| Piggyback Ack Timeouts | Shows the number of times that a "piggybacked" acknowledgment, an acknowledgement that is added by the receiver onto the next outgoing data frame, cannot be sent because there is no outgoing frame. If no outgoing frame is sent within the time-out period, an acknowledgment frame is sent, and this counter is incremented. | PERF_COUNTER_RAWCOUNT |
| Window Send Average | Shows the running average number of data bytes that are sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |
| Window Send Maximum | Shows the maximum number of data bytes that are sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |

# Objects Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Objects performance object consists of counters that monitor logical objects in the system, such as processes, threads, mutexes, and semaphores. This information can be used to detect the unnecessary consumption of computer resources. Each object requires memory to store basic information about the object.

| Counter Name | Description | Counter Type |
|---|---|---|
| Events | Shows the number of events in the computer at the time of data collection. An event occurs when two or more threads try to synchronize execution. This is an instantaneous count, not an average over time. | PERF_COUNTER_RAWCOUNT |
| Mutexes | Shows the number of mutexes in the computer at the time of data collection. Mutexes are executive dispatcher objects that ensure threads are synchronized. Mutexes are used by threads to assure that only one thread is executing a particular section of code. This is an instantaneous count, not an average over time. | PERF_COUNTER_RAWCOUNT |
| Processes | Shows the number of processes in the computer at the time of data collection. Each process represents the running of a program. This is an instantaneous count, not an average over time. | PERF_COUNTER_RAWCOUNT |
| Sections | Shows the number of sections in the computer at the time of data collection. A section is a portion of virtual memory created by a process for storing data. A process can share sections with other processes. This is an instantaneous count, not an average over time. | PERF_COUNTER_RAWCOUNT |
| Semaphores | Shows the number of semaphores in the computer at the time of data collection. Threads use semaphores to obtain exclusive access to data structures that they share with other threads. This is an instantaneous count, not an average over time. | PERF_COUNTER_RAWCOUNT |
| Threads | Shows the number of threads in the computer at the time of data collection. A thread is the basic executable entity that can execute instructions in a processor. This is an instantaneous count, not an average over time. | PERF_COUNTER_RAWCOUNT |

# Paging File Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Paging File performance object consists of counters that monitor the paging file(s) on the computer. The paging file is a reserved space on disk that backs up committed physical memory on the computer.

| Counter Name | Description | Counter Type |
|---|---|---|
| Usage Peak | Shows the amount of the page file instance in use. | PERF_RAW_FRACTION |
| % Usage Peak | Shows the greatest percentage of the paging file that was in use during the sample interval. | PERF_100NSEC_TIMER |

# PBServer Monitor Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The PBServer Monitor performance object monitors activity on the phone book server. Phone Book Service is a comprehensive phone book management system, and is a component of Connection Point Services. Phone Book Service provides a central location for uploading and distributing access numbers for both public and private networks. A few of the counters, such as Error Hits, can be used to detect errors.

These counter objects do not show up in System Monitor until the service has been started. The service starts when a phone book is requested.

| Counter Name | Description | Counter Type |
|---|---|---|
| Delta Upgrade Hits | Shows the total number of updated (delta) phone book files that have been successfully downloaded to the Connection Manager client. | PERF_COUNTER_RAWCOUNT |
| Delta Upgrade Hits/sec | Shows the rate, in incidents per second, at which updated (delta) phone book files were successfully downloaded to the Connection Manager client. | PERF_COUNTER_COUNTER |
| Error Hits | Shows the total number of requests that could not be satisfied by the Phone Book Service. This could be due to a problem with the client or due to corruption in the service database. For example, the client is looking for the wrong phone book. To investigate the cause, review the Web Service log for Windows Server 2003 family verbose logging. Connection Manager requests appear in the log as Get requests to the Pbserver.dll. Also check for the PB= value in the log; this will be name of phone book. Research this name; try to find the name in the database (Pbserver.mdb). It may be necessary to repost the phone book using administrative tools. | PERF_COUNTER_RAWCOUNT |
| Error Hits/sec | Shows the rate, in incidents per second, at which requests could not be satisfied by the Phone Book Service. | PERF_COUNTER_COUNTER |
| Full Upgrade Hits | Shows the total number of full phone book files that have been successfully downloaded. | PERF_COUNTER_RAWCOUNT |
| Full Upgrade Hits/sec | Shows the rate, in incidents per second, at which full phone book files were successfully downloaded. | PERF_COUNTER_COUNTER |
| No Upgrade Hits | Shows the total number of requests for phone book files that did not require an update to the phone book file on the user's computer. | PERF_COUNTER_RAWCOUNT |
| No Upgrade Hits/sec | Shows the rate, in incidents per second, at which requests for phone book files did not require an update to the phone book file on the user's computer. | PERF_COUNTER_COUNTER |
| Total Hits | Shows the total number of requests for phone book files since Web services were last started. If this value seems low in comparison with the amount of user traffic you expect, this could indicate a problem. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Total Hits/sec | Shows the rate, in incidents per second, of all requests for phone book files. This counter is useful for determining the load on the Phone Book Service. | PERF_COUNTER_COUNTER |

# Physical Disk Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The PhysicalDisk performance object consists of counters that monitor hard or fixed disk drives. Disks are used to store file, program, and paging data. They are read to retrieve these items, and are written to record changes to them. The values of physical disk counters are sums of the values of the logical disks (or partitions) into which they are divided.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Disk Read Time | Shows the percentage of time that the selected disk drive was busy servicing read requests. | PERF_PRECISION_100NS_TIMER |
| % Disk Time | Shows the percentage of elapsed time that the selected disk drive was busy servicing read or write requests. | PERF_PRECISION_100NS_TIMER |
| % Disk Write Time | Shows the percentage of elapsed time that the selected disk drive was busy servicing write requests. | PERF_PRECISION_100NS_TIMER |
| % Idle Time | Shows the percentage of elapsed time during the sample interval that the selected disk drive was idle. | PERF_PRECISION_100NS_TIMER |
| Avg. Disk Bytes/Read | Shows the average number of bytes that were transferred from the disk during read operations. | PERF_AVERAGE_BULK |
| Avg. Disk Bytes/Transfer | Shows the average number of bytes that were transferred to or from the disk during write or read operations. | PERF_AVERAGE_BULK |
| Avg. Disk Bytes/Write | Shows the average number of bytes that were transferred to the disk during write operations. | PERF_AVERAGE_BULK |
| Avg. Disk Queue Length | Shows the average number of both read and write requests that were queued for the selected disk during the sample interval. | PERF_COUNTER_LARGE_QUEUELEN_TYPE |
| Avg. Disk Read Queue Length | Shows the average number of read requests that were queued for the selected disk during the sample interval. | PERF_COUNTER_LARGE_QUEUELEN_TYPE |
| Avg. Disk sec/Read | Shows the average time, in seconds, of a read of data from the disk. | PERF_AVERAGE_TIMER |
| Avg. Disk sec/Transfer | Shows the average time, in seconds, of a disk transfer. | PERF_AVERAGE_TIMER |
| Avg. Disk sec/Write | Shows the average time, in seconds, of a write of data to the disk. | PERF_AVERAGE_TIMER |
| Avg. Disk Write Queue Length | Shows the average number of write requests that were queued for the selected disk during the sample interval. | PERF_COUNTER_LARGE_QUEUELEN_TYPE |

| | | |
|---|---|---|
| Current Disk Queue Length | Shows the number of requests that were outstanding on the disk at the time that the performance data was collected. This is a snapshot, not an average over the time interval. It includes requests in service at the time of the collection. Multispindle disk devices can have multiple requests active at one time, but other concurrent requests are awaiting service. This counter might reflect a transitory high or low queue length, but if this counter is consistently high, then it is likely that there is a sustained load on the disk drive. Requests experience delays proportional to the length of this queue, minus the number of spindles on the disks. This difference should average less than two. | PERF_COUNTER_RAWCOUNT |
| Disk Bytes/sec | Shows the rate, in incidents per second, at which bytes were transferred to or from the disk during write or read operations. | PERF_COUNTER_BULK_COUNT |
| Disk Read Bytes/sec | Shows the rate, in incidents per second, at which bytes were transferred from the disk during read operations. | PERF_COUNTER_BULK_COUNT |
| Disk Reads/sec | Shows the rate, in incidents per second, at which read operations were performed on the disk. | PERF_COUNTER_COUNTER |
| Disk Transfers/sec | Shows the rate, in incidents per second, at which read and write operations were performed on the disk. | PERF_COUNTER_COUNTER |
| Disk Write Bytes/sec | Shows the rate, in incidents per second, at which bytes were transferred to the disk during write operations. | PERF_COUNTER_BULK_COUNT |
| Disk Writes/sec | Shows the rate, in incidents per second, at which write operations were performed on the disk. | PERF_COUNTER_COUNTER |
| Split IO/sec | Shows the rate, in incidents per second, at which input/output (I/O) requests to the disk were split into multiple requests. A split I/O might result from requesting data in a size that is too large to fit into a single I/O, or from a fragmented disk subsystem. | PERF_COUNTER_COUNTER |

# Print Queue Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Print Queue performance object is provided by Windows Server 2003 family printing features to track activity in the server print queue. The Print Queue counters are reset when either the print server or the spooler service is restarted.

| Counter Name | Description | Counter Type |
|---|---|---|
| Add Network Printer Calls | Shows the total number of calls from other print servers to add shared network printers to this print server since it was last started. | PERF_COUNTER_RAWCOUNT |
| Bytes Printed/sec | Shows the rate, in incidents per second, at which bytes were printed in a print queue. This is a rough indication of how busy a printer is. This counter can be used for bottleneck detection. | PERF_COUNTER_BULK_COUNT |
| Enumerate Network Printer Calls | Shows the total number of calls from browse clients to this print server to request network browse lists since the print server was last started. | PERF_COUNTER_RAWCOUNT |
| Job Errors | Shows the total number of job errors in a print queue since the print server was last started. Job errors can indicate network or connectivity problems with the print device. | PERF_COUNTER_RAWCOUNT |
| Jobs | Shows the current number of jobs in a print queue. This counter can be used to identify excessive use. | PERF_COUNTER_RAWCOUNT |
| Jobs Spooling | Shows the current number of spooling jobs in a print queue. | PERF_COUNTER_RAWCOUNT |
| Max Jobs Spooling | Shows the maximum number of spooling jobs in a print queue since the print server was last started. | PERF_COUNTER_RAWCOUNT |
| Max References | Shows the peak number of references (open handles) to this printer. | PERF_COUNTER_RAWCOUNT |
| Not Ready Errors | Shows the total number of printer not ready errors in a print queue since the print server was last started. | PERF_COUNTER_RAWCOUNT |
| Out of Paper Errors | Shows the total number of out of paper errors in a print queue since the print server was last started. | PERF_COUNTER_RAWCOUNT |
| References | Shows the current number of references (open handles) to a print queue. A reference can be a user or a program that is connecting to a printer and opening a print queue. | PERF_COUNTER_RAWCOUNT |
| Total Jobs Printed | Shows the total number of jobs printed on a print queue since the print server was last started. | PERF_COUNTER_RAWCOUNT |
| Total Pages Printed | Shows the total number of pages printed through Graphics Device Interface (GDI) on a print queue since the print server was last started. | PERF_COUNTER_RAWCOUNT |

# Process Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Process performance object consists of counters that monitor running application program and system processes. All the threads in a process share the same address space and have access to the same data.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Privileged Time | Shows the percentage of non-idle processor time spent executing code in privileged mode. Privileged mode is a processing mode designed for operating system components and hardware-manipulating drivers. It allows direct access to hardware and memory. The alternative, user mode, is a restricted processing mode designed for applications, environmental subsystems, and integral subsystems. The operating system switches application threads to privileged mode to access operating system services.<br><br>% Privileged Time includes time servicing interrupts and DPCs. A high rate of privileged time might be attributed to a large number of interrupts generated by a failing device. When a Windows system service is called, the service often runs in privileged mode to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults or interrupts.<br><br>Unlike some earlier Windows operating systems, Windows 2000 and the Windows Server 2003 family use process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. These subsystem processes provide additional protection. Therefore, some work done by Windows 2000 and Windows Server 2003 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |
| % Processor Time | Shows the percentage of time that the processor spent executing a non-idle thread. It is calculated by measuring the duration that the idle thread is active during the sample interval, and subtracting that time from 100 %. (Each processor has an idle thread that consumes cycles when no other threads are ready to run.) This counter is the primary indicator of processor activity, and displays the average percentage of busy time observed during the sample interval. Code executed to handle some hardware interrupts and trap conditions are included in this count. | PERF_100NSEC_TIMER |
| % User Time | Shows the percentage of time that the processor spent executing code in user mode. Applications, environment subsystems, and integral subsystems execute in user mode. Code executing in user mode cannot damage the integrity of the Windows Executive, kernel, and/or device drivers. Unlike some earlier Windows operating systems, Windows 2000 and Windows Server 2003 use process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. These subsystem processes provide additional protection. Therefore, some work done by Windows 2000 and Windows Server 2003 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |

| | | |
|---|---|---|
| Page Faults/sec | Shows the rate, in incidents per second, at which page faults were handled by the processor. A page fault occurs when a process requires code or data that is not in its working set. This counter includes both hard faults (those that require disk access) and soft faults (those where the faulted page is found elsewhere in physical memory). Most processors can handle large numbers of soft faults without consequence. However, hard faults can cause significant delays. | PERF_COUNTER_COUNTER |
| Page File Bytes | Shows the the current amount of virtual memory, in bytes, that a process has reserved for use in the paging file(s). Paging files are used to store pages of memory used by the process. Paging files are shared by all processes, and the lack of space in paging files can prevent other processes from allocating memory. If there is no paging file, this counter reflects the current amount of virtual memory that the process has reserved for use in physical memory. | PERF_COUNTER_RAWCOUNT |
| Page File Bytes Peak | Shows the maximum amount of virtual memory, in bytes, that a process has reserved for use in the paging file(s). Paging files are used to store pages of memory used by the process. Paging files are shared by all processes, and the lack of space in paging files can prevent other processes from allocating memory. If there is no paging file, this counter reflects the maximum amount of virtual memory that the process has reserved for use in physical memory. | PERF_COUNTER_RAWCOUNT |
| Priority Base | Shows the current base priority of this process. Threads within a process can raise and lower their own base priority relative to the process's base priority. | PERF_COUNTER_RAWCOUNT |
| Private Bytes | Shows the size, in bytes, that this process has allocated that cannot be shared with other processes. | PERF_COUNTER_RAWCOUNT |
| Working Set | Shows the size, in bytes, in the working set of this process. The working set is the set of memory pages that were touched recently by the threads in the process. If free memory in the computer is above a threshold, pages are left in the working set of a process, even if they are not in use. When free memory falls below a threshold, pages are trimmed from working sets. If the pages are needed, they will be soft-faulted back into the working set before leaving main memory. | PERF_COUNTER_RAWCOUNT |
| Creating Process ID | Shows the identifier of the process that created the current process. Note that the creating process might have terminated since the current process was created, and so the current Creating Process ID counter may no longer identify a running process. | PERF_COUNTER_RAWCOUNT |
| Elapsed Time | Shows the time, in seconds, that this process has been running. | PERF_ELAPSED_TIME |
| Handle Count | Shows the total number of handles currently open by this process. This number is the equal to the sum of the handles currently open by each thread in this process. | PERF_COUNTER_RAWCOUNT |
| ID Process | Shows the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process. | PERF_COUNTER_RAWCOUNT |
| IO Data Bytes/sec | Shows the rate, in incidents per second, at which the process was reading and writing bytes in I/O operations. It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Data Operations/sec | Shows the rate, in incidents per second, at which the process was issuing read and write I/O operations. It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |

| | | |
|---|---|---|
| IO Other Bytes/sec | Shows the rate, in incidents per second, at which the process was issuing bytes to I/O operations that do not involve data such as control operations. It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Other Operations/sec | Shows the rate, in incidents per second, at which the process was issuing I/O operations that were neither read nor write operations (for example, a control function). It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Read Bytes/sec | Shows the rate, in incidents per second, at which the process was reading bytes from I/O operations. It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Read Operations/sec | Shows the rate, in incidents per second, at which the process was issuing read I/O operations. It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Write Bytes/sec | Shows the rate, in incidents per second, at which the process was writing bytes to I/O operations. It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| IO Write Operations/sec | Shows the rate, in incidents per second, at which the process was issuing write I/O operations. It counts all I/O activity generated by the process including file, network, and device I/Os. | PERF_COUNTER_BULK_COUNT |
| Pool Nonpaged Bytes | Shows the number of bytes in the nonpaged pool, an area of system memory (physical memory used by the operating system) for objects that cannot be written to disk. Nonpaged pool pages cannot be paged out to the paging file, but instead remain in main memory as long as they are allocated. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Bytes | Shows the number of bytes in the paged pool, an area of system memory (physical memory used by the operating system) for objects that can be written to disk. Paged pool pages can be paged out to the paging file when not accessed by the system for sustained periods of time. Memory\Pool Paged Bytes and Process\Pool Paged Bytes are calculated differently than this counter, so the counters might not display the same amounts. | PERF_COUNTER_RAWCOUNT |
| Thread Count | Shows the number of threads that were active in this process. A thread is the object that executes instructions, which are the basic unit of execution in a processor. Every running process has at least one thread. | PERF_COUNTER_RAWCOUNT |
| Virtual Bytes | Shows the size, in bytes, of the virtual address space that the process is using. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. Virtual space is finite, and by using too much, the process can limit its ability to load libraries. | PERF_COUNTER_RAWCOUNT |
| Virtual Bytes Peak | Shows the maximum size, in bytes, of virtual address space that the process has used at any one time. Use of virtual address space does not necessarily imply corresponding use of either disk or main memory pages. However, virtual space is finite, and the process might limit its ability to load libraries by using too much. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Working Set Peak | Shows the maximum size, in bytes, in the working set of this process. The working set is the set of memory pages that were touched recently by the threads in the process. If free memory in the computer is above a certain threshold, pages are left in the working set of a process, even if they are not in use. When free memory falls below a certain threshold, pages are trimmed from working sets. If the pages are needed, they will be soft-faulted back into the working set before leaving main memory. | PERF_COUNTER_RAWCOUNT |

# Process Address Space Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Process Address Space performance object consists of counters that monitor memory allocation and use for a selected process.

This object contains "costly" counters for which data collection is typically either processor-intensive or memory-intensive. Costly counters cannot be selected with System Monitor but can be accessed by using Showperf.exe and other tools included in the Windows Resource Kit Tools Help for Windows Server 2003.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Free | Shows the total unused virtual address space of this process. | PERF_COUNTER_RAWCOUNT |
| Bytes Image Free | Shows the amount of virtual address space that is not in use and is not reserved by images that run within this process. | PERF_COUNTER_RAWCOUNT |
| Bytes Image Reserved | Shows the sum of all virtual memory reserved by images that run within this process. | PERF_COUNTER_RAWCOUNT |
| Bytes Reserved | Shows the total amount of virtual memory reserved for future use by this process. | PERF_COUNTER_RAWCOUNT |
| ID Process | Shows the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process. | PERF_COUNTER_RAWCOUNT |
| Image Space Exec Read Only | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *Execute read-only* memory can be executed by programs, in addition to being read. | PERF_COUNTER_RAWCOUNT |
| Image Space Exec Read/Write | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *Execute read/write* memory can be executed by programs, in addition to being read and written and modified. | PERF_COUNTER_RAWCOUNT |
| Image Space Exec Write Copy | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *Execute write copy* memory can be executed by programs, in addition to being read and written. This type of protection is used when memory needs to be shared between processes. If the sharing processes only read the memory, they all use the same memory. If a sharing process wants to have write access to this shared memory, a copy of this memory is made for that process. | PERF_COUNTER_RAWCOUNT |
| Image Space Executable | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *Executable* memory can be executed by programs, but cannot be read or written. This type of protection is not supported by all processor types. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Image Space No Access | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *No access* protection prevents a process from writing to or reading from these pages, and an access violation is generated if either is attempted. | PERF_COUNTER_RAWCOUNT |
| Image Space Read Only | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *Read-only* protection prevents the contents of these pages from being modified. Any attempt to write or modify these pages generates an access violation. | PERF_COUNTER_RAWCOUNT |
| Image Space Read/Write | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *Read/write* protection allows a process to read, modify, and write to these pages. | PERF_COUNTER_RAWCOUNT |
| Image Space Write Copy | Shows the virtual address space in use by the images that are being executed by the process. This counter is the sum of all the address space with this protection allocated by images that run within the selected process. *Write copy* protection is used when memory is shared for reading but not for writing. If the sharing processes only read the memory, they all use the same memory. If a sharing process wants to have read/write access to this shared memory, a copy of this memory is made for that process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space Exec Read Only | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space Exec Read/Write | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space Exec Write Copy | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space Executable | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space No Access | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space Read Only | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space Read/Write | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |
| Mapped Space Write Copy | Shows virtual memory that has been mapped to a specific virtual address (or range of virtual addresses) in the virtual address space of the process. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Reserved Space Exec Read Only | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Reserved Space Exec Read/Write | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Reserved Space Exec Write Copy | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Reserved Space Executable | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Reserved Space No Access | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Reserved Space Read Only | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Reserved Space Read/Write | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Reserved Space Write Copy | Shows virtual memory that has been reserved for future use by a process, but has not been mapped or committed. | PERF_COUNTER_RAWCOUNT |
| Unassigned Space Exec Read Only | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |
| Unassigned Space Exec Read/Write | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |
| Unassigned Space Exec Write Copy | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |
| Unassigned Space Executable | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |
| Unassigned Space No Access | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |
| Unassigned Space Read Only | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Unassigned Space Read/Write | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |
| Unassigned Space Write Copy | Shows mapped and committed virtual memory in use by the process that is not attributable to any particular image being executed by the process. | PERF_COUNTER_RAWCOUNT |

# Processor Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Processor performance object consists of counters that measure aspects of processor activity. The processor is the part of the computer that performs arithmetic and logical computations, initiates operations on peripherals, and runs the threads of processes. A computer can have multiple processors. The Processor object represents each processor as an instance of the object.

| Counter Name | Description | Counter Type |
|---|---|---|
| % C1 Time | Shows the percentage of time that the processor spent in the C1 low-power idle state. % C1 Time is a subset of the total processor idle time. C1 low-power idle state enables the processor to maintain its entire context and quickly return to the running state. Not all systems support the C1 state. | PERF_100NSEC_TIMER |
| % C2 Time | Shows the percentage of time that the processor spent in the C2 low-power idle state. % C2 Time is a subset of the total processor idle time. C2 low-power idle state enables the processor to maintain the context of the system caches. The C2 power state is a lower power and higher exit latency state than C1. Not all systems support the C2 state. | PERF_100NSEC_TIMER |
| % C3 Time | Shows the percentage of time that the processor spent in the C3 low-power idle state. % C3 Time is a subset of the total processor idle time. When the processor is in the C3 low-power idle state it is unable to maintain the coherency of its caches. The C3 power state is a lower power and higher exit latency state than C2. Not all systems support the C3 state. | PERF_100NSEC_TIMER |
| % DPC Time | Shows the percentage of time that the processor spent receiving and servicing deferred procedure calls (DPCs) during the sample interval. DPCs are interrupts that run at a lower priority than standard interrupts. % DPC Time is a component of % Privileged Time because DPCs are executed in privileged mode. They are counted separately and are not a component of the interrupt counters. This counter displays the average busy time as a percentage of the sample time. | PERF_100NSEC_TIMER |
| % Idle Time | Shows the time that the processor was idle during the sample interval. | PERF_100NSEC_TIMER |
| % Interrupt Time | Shows the percentage of time that the processor spent receiving and servicing hardware interrupts during the sample interval. This value is an indirect indicator of the activity of devices that generate interrupts, such as the system clock, the mouse, disk drivers, data communication lines, network interface cards and other peripheral devices. These devices normally interrupt the processor when they have completed a task or require attention. Normal thread execution is suspended during interrupts. Most system clocks interrupt the processor every 10 milliseconds, creating a background of interrupt activity. This counter displays the average busy time as a percentage of the sample time. | PERF_100NSEC_TIMER |

| | | |
|---|---|---|
| % Privileged Time | Shows the percentage of elapsed time that this thread spent executing code in privileged mode. When a Windows Server 2003 family operating system service is called, the service often runs in privileged mode in order to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults and interrupts. Unlike some early operating systems, Windows Server 2003 uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. These subsystem processes provide additional protection. Therefore, some work done by Windows Server 2003 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |
| % Processor Time | Shows the percentage of elapsed time that this thread used the processor to execute instructions. An instruction is the basic unit of execution in a processor, and a thread is the object that executes instructions. Code executed to handle some hardware interrupts and trap conditions is included in this count. | PERF_100NSEC_TIMER_INV |
| % User Time | Shows the percentage of elapsed time that this thread spent executing code in user mode. Applications, environment subsystems, and integral subsystems execute in user mode. Code executing in user mode cannot damage the integrity of the Windows Server 2003 Executive, Kernel, and device drivers. Unlike some early operating systems, Windows Server 2003 uses process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. These subsystem processes provide additional protection. Therefore, some work done by Windows Server 2003 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |
| C1 Transitions/sec | Shows the rate, in incidents per second, at which the CPU entered the C1 low-power idle state. The CPU enters the C1 state when it is sufficiently idle, and exits this state on any interrupt. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. | PERF_COUNTER_BULK_COUNT |
| C2 Transitions/sec | Shows the rate, in incidents per second, at which the CPU entered the C2 low-power idle state. The CPU enters the C2 state when it is sufficiently idle, and exits this state on any interrupt. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. | PERF_COUNTER_BULK_COUNT |
| C3 Transitions/sec | Shows the rate, in incidents per second, at which the CPU entered the C3 low-power idle state. The CPU enters the C3 state when it is sufficiently idle, and exits this state on any interrupt. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. | PERF_COUNTER_BULK_COUNT |
| DPC Rate | Shows the rate at which deferred procedure calls (DPCs) were added to the processor's DPC queue between the timer ticks of the processor clock. DPCs are interrupts that run at a lower priority than standard interrupts. Each processor has its own DPC queue. This counter measures the rate at which DPCs were added to the queue, not the number of DPCs in the queue. This counter displays the last observed value only; it is not an average. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| DPCs Queued/sec | Shows the average rate, in incidents per second, at which deferred procedure calls (DPCs) were added to the processor's DPC queue. DPCs are interrupts that run at a lower priority than standard interrupts. Each processor has its own DPC queue. This counter measures the rate at which DPCs were added to the queue, not the number of DPCs in the queue. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. | PERF_COUNTER_COUNTER |
| Interrupts/sec | Shows the rate, in incidents per second, at which the processor received and serviced hardware interrupts. It does not include deferred procedure calls (DPCs), which are counted separately. This value is an indirect indicator of the activity of devices that generate interrupts, such as the system clock, the mouse, disk drivers, data communication lines, network interface cards, and other peripheral devices. These devices normally interrupt the processor when they have completed a task or require attention. Normal thread execution is suspended during interrupts. Most system clocks interrupt the processor every 10 milliseconds, creating a background of interrupt activity. This counter displays the difference between the values observed in the last two samples, divided by the duration of the sample interval. | PERF_COUNTER_COUNTER |

# PSched Flow Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The PSched Flow Object shows statistics from the packet scheduler, a feature of Counters by Feature

| Counter Name | Description | Counter Type |
|---|---|---|
| Packets dropped | Shows the number of packets dropped by the packet scheduler. | PERF_COUNTER_RAWCOUNT |
| Packets scheduled | Shows the number of packets that were scheduled in some way (rather than just being directly sent to the underlying miniport). | PERF_COUNTER_RAWCOUNT |
| Packets transmitted | Shows the number of packets from this flow that have been sent. | PERF_COUNTER_RAWCOUNT |
| Average packets in shaper | Shows the average number of packets in the scheduler over the last sampling period. | PERF_COUNTER_RAWCOUNT |
| Max packets in shaper | Shows the maximum number of packets that have ever simultaneously been in the scheduler. | PERF_COUNTER_RAWCOUNT |
| Average packets in sequencer | Shows the average number of packets in the sequencer over the last sampling period. | PERF_COUNTER_RAWCOUNT |
| Max packets in sequencer | Shows the maximum number of packets that have ever simultaneously been in the sequencer. | PERF_COUNTER_RAWCOUNT |
| Bytes scheduled | Shows the number of bytes that were scheduled in some way (rather than just being directly sent to the underlying miniport). | PERF_COUNTER_RAWCOUNT |
| Bytes transmitted | Shows the number of bytes from this flow that have been sent. | PERF_COUNTER_RAWCOUNT |
| Bytes transmitted/sec | Shows the number of bytes per second from this flow that have been sent. | PERF_COUNTER_COUNTER |
| Bytes scheduled/sec | Shows the number of bytes per second from this flow that have been scheduled. | PERF_COUNTER_COUNTER |
| Packets transmitted/sec | Shows the number of packets per second from this flow that have been sent. | PERF_COUNTER_COUNTER |
| Packets scheduled/sec | Shows the number of packets per second from this flow that have been scheduled. | PERF_COUNTER_COUNTER |
| Packets dropped/sec | Shows the number of packets that were dropped by the packet scheduler from this flow per second. | PERF_COUNTER_COUNTER |
| Nonconforming packets scheduled | Shows the number of packets that have entered the packet scheduler at a rate which exceeded the flow parameters. | PERF_COUNTER_RAWCOUNT |
| Nonconforming packets scheduled/sec | Shows the rate at which nonconforming packets have entered the packet scheduler. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Nonconforming packets transmitted | Shows the number of packets that have been sent by the packet scheduler at a rate which exceeded the flow parameters. | PERF_COUNTER_RAWCOUNT |
| Nonconforming packets transmitted/sec | Shows the rate at which nonconforming packets have been sent by the packet scheduler. | PERF_COUNTER_COUNTER |
| Maximum Packets in netcard | Shows the maximum number of packets that have been queued in the network adapter by this flow. | PERF_COUNTER_RAWCOUNT |
| Average Packets in netcard | Shows the average number of packets that have been queued in the network adapter by this flow. | PERF_COUNTER_RAWCOUNT |

PSched Pipe Object

# PSched Pipe Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The PSched Pipe performance object reports statistics from the packet scheduler pipe. On a local area network (LAN) adapter, the pipe represents the network interface card, and on a wide area network (WAN) adapter, the pipe represents each WAN line.

| Counter Name | Description | Counter Type |
|---|---|---|
| Average Packets in Netcard | Shows the average number of packets in the pipe over the last sampling period. | PERF_COUNTER_RAWCOUNT |
| Average Packets in Sequencer | Shows the average number of packets in the sequencer over the last sampling period. | PERF_COUNTER_RAWCOUNT |
| Average Packets in Shaper | Shows the average number of packets in the scheduler shaper over the last sampling period. | PERF_COUNTER_RAWCOUNT |
| Flow Mods Rejected | Shows the number of times that a flow modification has been rejected. | PERF_COUNTER_RAWCOUNT |
| Flows Closed | Shows the number of flows that have been closed. | PERF_COUNTER_RAWCOUNT |
| Flows Modified | Shows the number of times that a flow has been modified succesfully. | PERF_COUNTER_RAWCOUNT |
| Flows Opened | Shows the number of flows that were opened on this pipe (some of which may now be closed). | PERF_COUNTER_RAWCOUNT |
| Flows Rejected | Shows the number of flow creations that were rejected. | PERF_COUNTER_RAWCOUNT |
| Max Packets in Netcard | Shows the maximum number of packets that were ever simultaneously in the network card. | PERF_COUNTER_RAWCOUNT |
| Max Packets in Sequencer | Shows the maximum number of packets that were ever simultaneously in the sequencer. | PERF_COUNTER_RAWCOUNT |
| Max Packets in Shaper | Shows the maximum number of packets that were ever simultaneously in the scheduler. | PERF_COUNTER_RAWCOUNT |
| Max Simultaneous Flows | Shows the maximum number of flows that were simultaneously open on this pipe. | PERF_COUNTER_RAWCOUNT |
| Nonconforming Packets Scheduled | Shows the number of packets that entered the packet scheduler at a rate that exceeded the packet's flow parameters. | PERF_COUNTER_RAWCOUNT |
| Nonconforming Packets Scheduled/sec | Shows the rate, in incidents per second, at which nonconforming packets entered the packet scheduler. | PERF_COUNTER_COUNTER |
| Nonconforming Packets Transmitted | Shows the number of packets that were sent by the packet scheduler at a rate that exceeded the packet's flow parameters. | PERF_COUNTER_RAWCOUNT |
| Nonconforming Packets Transmitted/sec | Shows the rate, in incidents per second, at which nonconforming packets were sent by the packet scheduler. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Out of Packets | Shows the number of times that the packet scheduler has been unable to allocate memory to send or receive a packet. | PERF_COUNTER_RAWCOUNT |

PSched Flow Object

# RAS Port Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The RAS Port performance object consists of counters that monitor individual remote access service (RAS) ports of the RAS device on the system.

| Counter Name | Description | Counter Type |
|---|---|---|
| Alignment Errors | Shows the total number of alignment errors on this connection. Alignment errors occur when a received byte is different from the expected byte. | PERF_COUNTER_RAWCOUNT |
| Buffer Overrun Errors | Shows the total number of buffer overrun errors on this connection. Buffer overrun errors occur when the software cannot handle the rate at which data is received. | PERF_COUNTER_RAWCOUNT |
| Bytes Received | Shows the total number of bytes that were received on this connection. | PERF_COUNTER_RAWCOUNT |
| Bytes Received/sec | Shows the rate, in incidents per second, at which bytes were received. | PERF_COUNTER_COUNTER |
| Bytes Transmitted | Shows the total number of bytes that were transmitted on this connection. | PERF_COUNTER_RAWCOUNT |
| Bytes Transmitted/sec | Shows the rate, in incidents per second, at which bytes were transmitted. | PERF_COUNTER_COUNTER |
| CRC Errors | Shows the total number of cyclic redundancy check (CRC) errors on this connection. CRC errors occur when the frame received contains erroneous data. | PERF_COUNTER_RAWCOUNT |
| Frames Received | Shows the total number of data frames received on this connection. | PERF_COUNTER_RAWCOUNT |
| Frames Received/sec | Shows the rate, in incidents per second, at which frames were received. | PERF_COUNTER_COUNTER |
| Frames Transmitted | Shows the total number of data frames transmitted on this connection. | PERF_COUNTER_RAWCOUNT |
| Frames Transmitted/sec | Shows the rate, in incidents per second, at which frames were transmitted. | PERF_COUNTER_COUNTER |
| Percent Compression In | Shows the compression ratio for bytes that were received. | PERF_COUNTER_RAWCOUNT |
| Percent Compression Out | Shows the compression ratio for bytes that were transmitted. | PERF_COUNTER_RAWCOUNT |
| Serial Overrun Errors | Shows the total number of serial overrun errors on this connection. Serial overrun errors occur when the hardware cannot handle the rate at which data is received. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Timeout Errors | Shows the total number of timeout errors on this connection. Timeout errors occur when an expected packet is not received in time. | PERF_COUNTER_RAWCOUNT |
| Total Errors | Shows the total number of CRC, timeout, serial overrun, alignment, and buffer overrun errors on this connection. | PERF_COUNTER_RAWCOUNT |
| Total Errors/sec | Shows the total rate, in incidents per second, of CRC, timeout, serial overrun, alignment, and buffer overrun errors. | PERF_COUNTER_COUNTER |

RAS Total Object

# RAS Total Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The RAS Total performance object consists of counters that combine values for all ports of the remote access service (RAS) device on the computer.

| Counter Name | Description | Counter Type |
|---|---|---|
| Alignment Errors | Shows the total number of alignment errors for this connection. Alignment errors occur when a received byte is different from the expected byte. | PERF_COUNTER_RAWCOUNT |
| Buffer Overrun Errors | Shows the total number of buffer overrun errors for this connection. Buffer overrun errors occur when the software cannot handle the rate at which data is received. | PERF_COUNTER_RAWCOUNT |
| Bytes Received | Shows the total number of bytes that were received for this connection. | PERF_COUNTER_RAWCOUNT |
| Bytes Received/sec | Shows the rate, in incidents per second, at which bytes were received. | PERF_COUNTER_COUNTER |
| Bytes Transmitted | Shows the total number of bytes that were transmitted for this connection. | PERF_COUNTER_RAWCOUNT |
| Bytes Transmitted/sec | Shows the rate, in incidents per second, at which bytes were transmitted. | PERF_COUNTER_COUNTER |
| CRC Errors | Shows the total number of cyclic redundancy check (CRC) errors for this connection. CRC errors occur when the frame that is received contains erroneous data. | PERF_COUNTER_RAWCOUNT |
| Frames Received | Shows the total number of data frames that were received for this connection. | PERF_COUNTER_RAWCOUNT |
| Frames Received/sec | Shows the rate, in incidents per second, at which frames were received. | PERF_COUNTER_COUNTER |
| Frames Transmitted | Shows the total number of data frames that were transmitted for this connection. | PERF_COUNTER_RAWCOUNT |
| Frames Transmitted/sec | Shows the rate, in incidents per second, at which frames were transmitted. | PERF_COUNTER_COUNTER |
| Percent Compression In | Shows the compression ratio for bytes that were received. | PERF_COUNTER_RAWCOUNT |
| Percent Compression Out | Shows the compression ratio for bytes that were transmitted. | PERF_COUNTER_RAWCOUNT |
| Serial Overrun Errors | Shows the total number of serial overrun errors for this connection. Serial overrun errors occur when the hardware cannot handle the rate at which data is received. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Timeout Errors | Shows the total number of timeout errors for this connection. Timeout errors occur when an expected packet is not received within the time expected. | PERF_COUNTER_RAWCOUNT |
| Total Connections | Shows the total number of remote access connections. | PERF_COUNTER_RAWCOUNT |
| Total Errors | Shows the total number of CRC, timeout, serial overrun, alignment, and buffer overrun errors for this connection. | PERF_COUNTER_RAWCOUNT |
| Total Errors/sec | Shows the total rate, in incidents per second, of CRC, timeout, serial overrun, alignment, and buffer overrun errors. | PERF_COUNTER_COUNTER |

RAS Port Object

# Redirector Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Redirector performance object consists of counters that monitor network connections originating at the local computer.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Received/sec | Shows the rate, in incidents per second, of bytes that were received by the redirector from the network. It includes all application data and network protocol information, such as packet headers. | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the rate, in incidents per second, at which the redirector processed data bytes. This includes all application and file data as well as protocol information, such as packet headers. | PERF_COUNTER_BULK_COUNT |
| Bytes Transmitted/sec | Shows the rate, in incidents per second, at which bytes left the redirector to the network. It includes all application data and network protocol information, such as packet headers. | PERF_COUNTER_BULK_COUNT |
| Connects Core | Shows the number of connections to servers running the original MS-Net SMB protocol, including MS-Net itself, Xenix, and VAXs. | PERF_COUNTER_RAWCOUNT |
| Connects LAN Manager 2.0 | Shows the number of connections to LAN Manager 2.0 servers, including LMX servers. | PERF_COUNTER_RAWCOUNT |
| Connects LAN Manager 2.1 | Shows the number of connections to LAN Manager 2.1 servers, including LMX servers. | PERF_COUNTER_RAWCOUNT |
| Connects Windows NT | Shows the total number of connections to computers that are running Windows NT, Windows 2000, Windows XP, and the Windows Server 2003 family. | PERF_COUNTER_RAWCOUNT |
| Current Commands | Shows the number of requests to the redirector that were queued for service. If this number is much larger than the number of network adapter cards installed in the computer, then the network(s) and/or the server(s) being accessed are seriously bottlenecked. | PERF_COUNTER_RAWCOUNT |
| File Data Operations/sec | Shows the rate, in incidents per second, at which the redirector processed data operations. To determine the efficiency of this path, calculate the average number of bytes transferred per operation by dividing the value of Bytes/sec by the value of this counter | PERF_COUNTER_COUNTER |
| File Read Operations/sec | Shows the rate, in incidents per second, at which applications asked the redirector for data. Each call to a file system, or similar application program interface (API) call, is counted as one operation. | PERF_COUNTER_COUNTER |
| File Write Operations/sec | Shows the rate, in incidents per second, at which applications sent data to the redirector. Each call to a file system, or similar API call, counts as one operation. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Network Errors/sec | Shows the rate, in incidents per second, at which serious unexpected errors occurred. Such errors generally indicate that the redirector and one or more servers are having serious communication difficulties. For example, a Server Manager Block protocol error generates a network error. An entry is written in the system event log, and can provide details. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate, in incidents per second, at which the redirector received packets (also called server message blocks or SMBs). Network transmissions are divided into packets. To calculate the average number of bytes received in a packet, divide the value of Bytes Received/sec by the value of this counter. Some packets received might not contain incoming data (for example, an acknowledgment of a write operation made by the redirector is counted as an incoming packet). | PERF_COUNTER_BULK_COUNT |
| Packets Transmitted/sec | Shows the rate, in incidents per second, at which the redirector sent packets (also called server message blocks or SMBs). Network transmissions are divided into packets. To calculate the average number of bytes transmitted in a packet, divide the value of Bytes Transmitted/sec by the value of this counter. | PERF_COUNTER_BULK_COUNT |
| Packets/sec | Shows the rate, in incidents per second, at which the redirector processed data packets. To determine the efficiency of this path, calculate the average number of bytes transferred per packet by dividing the value of Bytes Transmitted/sec by the value of this counter. For another measure of efficiency, calculate the average number of packets transferred per operation by dividing the value of this counter by the value of Operations/sec. | PERF_COUNTER_BULK_COUNT |
| Read Bytes Cache/sec | Shows the rate, in incidents per second, at which applications used the redirector to access the file system. Some data requests are satisfied by retrieving the data from the cache. Requests that miss the cache cause a page fault. | PERF_COUNTER_BULK_COUNT |
| Read Bytes Network/sec | Shows the rate, in incidents per second, at which applications read data across the network. This occurs when data sought in the file system cache is not found there and must be retrieved from the network. Dividing this value by the value of Bytes Received/sec indicates the proportion of application data that is traveling across the network. | PERF_COUNTER_BULK_COUNT |
| Read Bytes Non-Paging/sec | Shows the number of bytes, in incidents per second, read by the redirector in response to normal file requests by an application when they were redirected to come from another computer. In addition to file requests, this counter includes other methods of reading across the network, such as Named Pipes and Transactions. This counter counts only application data, not network protocol information. | PERF_COUNTER_BULK_COUNT |
| Read Bytes Paging/sec | Shows the rate, in incidents per second, at which the redirector attempted to read bytes in response to page faults. Page faults are caused by loading modules (such as programs and libraries), by a miss in the file system cache, or by files directly mapped into the address space of applications. | PERF_COUNTER_BULK_COUNT |
| Read Operations Random/sec | Shows the rate, in incidents per second, at which, on a file-by-file basis, non-sequential read operations are made. If a read operation is made using a particular file handle, and then is followed by another read operation that is not the next contiguous byte, this counter is incremented by one. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Read Packets Small/sec | Shows the rate, in incidents per second, at which read operations of less than one-fourth of the server's negotiated buffer size were made by applications. A high rate of small packet read operations indicates the possibility that buffers are being used inefficiently. This counter is incremented once for each small read operation. It does not count packets. | PERF_COUNTER_COUNTER |
| Read Packets/sec | Shows the rate, in incidents per second, at which read packets were placed on the network. Each time a single packet is sent with a request to read data remotely, this counter is incremented by one. | PERF_COUNTER_COUNTER |
| Reads Denied/sec | Shows the rate, in incidents per second, at which the server was unable to accommodate requests for raw read operations. When a read operation is much larger than the server's negotiated buffer size, the redirector requests a raw read operation. If granted, a raw read operation permits the transfer of the data without much protocol overhead on each packet. However, to accomplish a raw read operation, the server must lock out other requests; if the server is too busy, the request is denied. | PERF_COUNTER_COUNTER |
| Reads Large/sec | Shows the rate, in incidents per second, at which read operations that were more than double the server's negotiated buffer size were made by applications. Too many large read operations could place a strain on server resources. This counter is incremented once for each large read operation. It does not count packets. | PERF_COUNTER_COUNTER |
| Server Disconnects | Shows the number of times that a server has disconnected the redirector. | PERF_COUNTER_RAWCOUNT |
| Server Reconnects | Shows the number of times that the redirector had to reconnect to a server to complete a new active request. Users can be disconnected by the server if they remain inactive for too long. Even if all remote files are closed, the redirector keeps connections intact locally for about ten minutes. Such inactive connections are called dormant connections. Reconnecting is expensive in time. | PERF_COUNTER_RAWCOUNT |
| Server Sessions | Shows the total number of security objects that are managed by the redirector. For example, logging on to a server followed by a network access to the same server establishes one connection, but two sessions. | PERF_COUNTER_RAWCOUNT |
| Server Sessions Hung | Shows the number of active sessions that were timed out and were unable to proceed due to a lack of response from the remote server. | PERF_COUNTER_RAWCOUNT |
| Write Bytes Cache/sec | Shows the rate, in incidents per second, at which applications on a computer used the redirector to write to the file system cache. The data might not leave the computer immediately; it can be retained in the cache for further modification before being written to the network, reducing network traffic. Every byte that is written to the cache is counted here. | PERF_COUNTER_BULK_COUNT |
| Write Bytes Network/sec | Shows the rate, in incidents per second, at which applications wrote data across the network. This occurs when the file system cache is bypassed, such as for named pipes or transactions, or else when the cache writes the bytes to disk to make room for other data. To calculate what proportion of application data is being written to the network, divide the value of this counter by the value of Bytes Transmitted/sec. | PERF_COUNTER_BULK_COUNT |

| | | |
|---|---|---|
| Write Bytes Non-Paging/sec | Shows the rate, in incidents per second, at which bytes were written by the redirector. This is in response to normal file outputs by an application, when the bytes were redirected to another computer. In addition to file requests, this counter includes other methods of writing across the network such as Named Pipes and Transactions. This counter only counts application data, and does not count network protocol information. | PERF_COUNTER_BULK_COUNT |
| Write Bytes Paging/sec | Shows the rate, in incidents per second, at which the redirector attempted to write bytes that were changed in the pages being used by applications. The program data changed by modules (such as programs and libraries) that were loaded over the network are paged out when no longer needed. Other output pages come from the cache. | PERF_COUNTER_BULK_COUNT |
| Write Operations Random/sec | Shows the rate, in incidents per second, at which, on a file-by-file basis, non-sequential write operations were made. If a write operation is made using a particular file handle and then is followed by another write operation that is not the next contiguous byte, this counter is incremented by one. | PERF_COUNTER_COUNTER |
| Write Packets Small/sec | Shows the rate, in incidents per second, at which write operations were made by applications that are less than one-fourth of the server's negotiated buffer size. Too many write operations can indicate a waste of buffers on the server. This counter shows write operations, not packets, and is incremented once for each write operation. | PERF_COUNTER_COUNTER |
| Write Packets/sec | Shows the rate, in incidents per second, at which write operations were sent to the network. Each time a single packet is sent with a request to write remote data, this counter is incremented by one. | PERF_COUNTER_COUNTER |
| Writes Denied/sec | Shows the rate, in incidents per second, at which the server was unable to accommodate requests for raw write operations. When a write operation is much larger than the server's negotiated buffer size, the redirector requests a raw write operation. If granted, a raw write operation permits the transfer of the data without much protocol overhead on each packet. However, to accomplish a raw write operation, the server must lock out other requests; if the server is too busy, the request is denied. | PERF_COUNTER_COUNTER |
| Writes Large/sec | Shows the rate, in incidents per second, at which write operations that were more than double the server's negotiated buffer size were made by applications. Too many large write operations could place a strain on server resources. This counter is incremented once for each large write operation. It does not count packets. | PERF_COUNTER_COUNTER |

Server Object
Server Work Queues Object

# Server Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Server performance object consists of counters that measure communication between the local computer and the network.

| Counter Name | Description | Counter Type |
|---|---|---|
| Blocking Requests Rejected | Shows the number of times that the server rejected blocking server message block (SMB) requests due to insufficient count of free work items. This counter indicates whether the MaxWorkItem or MinFreeWorkItems server registry parameters might need tuning. | PERF_COUNTER_COUNTER |
| Bytes Received/sec | Shows the rate, in incidents per second, at which the server received bytes from the network. This counter indicates how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the rate, in incidents per second, at which the server transmitted bytes through the network. This value provides an overall indication of how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Bytes Transmitted/sec | Shows the rate, in incidents per second, at which the server sent bytes on the network. This counter indicates how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Context Blocks Queued/sec | Shows the rate, in incidents per second, at which work context blocks were placed on the server's file system process queue to await server action. | PERF_COUNTER_COUNTER |
| Errors Access Permissions | Shows the number of times that attempts to open files on behalf of clients have failed with the message STATUS_ACCESS_DENIED. If this counter is high, it can indicate that someone is attempting to access random files without proper authorization. | PERF_COUNTER_RAWCOUNT |
| Errors Granted Access | Shows the number of times that attempts to access files successfully opened were denied. This counter can indicate attempts to access files without proper authorization. | PERF_COUNTER_RAWCOUNT |
| Errors Logon | Shows the number of failed logon attempts to the server. If this counter is high, it can indicate that password guessing programs are attempting to compromise the server's security. | PERF_COUNTER_RAWCOUNT |
| Errors System | Shows the number of times that an internal server error was detected. Errors can reflect problems with logon, security, memory allocation, disk operations, transport driver interface operations, communication (such as receipt of unimplemented or unrecognized SMBs), or I/O Request Packet stack size for the server.<br><br>Many of these errors are also written to the System log and Security log in Event Viewer. The server can recover from most the errors displayed by this counter, but they are unexpected and should be reported to Microsoft Product Support Services. | PERF_COUNTER_RAWCOUNT |
| File Directory Searches | Shows the number of searches for files currently active in the server. This counter indicates current server activity. | PERF_COUNTER_RAWCOUNT |
| Files Open | Shows the number of files currently opened on the server. This counter indicates current server activity. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Files Opened Total | Shows the number of successful attempts to open a file, performed by the server on behalf of clients. This counter is useful in determining the amounts of file I/O and overhead for path-based operations, and for determining the effectiveness of open locks. | PERF_COUNTER_RAWCOUNT |
| Logon Total | Shows all interactive logon attempts, network logon attempts, service logon attempts, successful logon attempts, and failed logon attempts since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| Logon/sec | Shows the rate, in incidents per second, of all interactive logon attempts, network logon attempts, service logon attempts, successful logon attempts, and failed logon attempts since the computer was last started. | PERF_COUNTER_COUNTER |
| Pool Nonpaged Bytes | Shows the size, in bytes, of nonpageable computer memory that the server was using. This value is useful for determining the values of the MaxNonpagedMemoryUsage entry in the Windows Server 2003 family registry. | PERF_COUNTER_RAWCOUNT |
| Pool Nonpaged Failures | Shows the number of times that allocations from the nonpaged pool have failed. If this counter is high, it indicates that the computer's physical memory is too small. | PERF_COUNTER_COUNTER |
| Pool Nonpaged Peak | Shows the maximum size, in bytes, of the nonpaged pool that the server had in use at any one point. This counter indicates how much physical memory the computer should have. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Bytes | Shows the size, in bytes, of pageable computer memory that the server was using. This counter can help to determine good values for the MaxPagedMemoryUsage registry entry. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Failures | Shows the number of times that allocations from the paged pool have failed. If this counter is high, it indicates that the computer's physical memory or page file are too small. | PERF_COUNTER_RAWCOUNT |
| Pool Paged Peak | Shows the maximum size, in bytes, of the paged pool that the server has allocated. This counter indicates the proper sizes of the page file(s) and physical memory. | PERF_COUNTER_RAWCOUNT |
| Server Sessions | Shows the number of sessions currently active in the server. This counter indicates current server activity. | PERF_COUNTER_RAWCOUNT |
| Sessions Errored Out | Shows the number of sessions that have been closed due to unexpected error conditions. This counter indicates how frequently network problems caused dropped sessions on the server. This counter reports auto-disconnects as well as errored-out sessions. For a more accurate value for errored-out sessions, subtract the value of Sessions Timed Out from Sessions Errored Out. | PERF_COUNTER_RAWCOUNT |
| Sessions Forced Off | Shows the number of sessions that have been forced to log off. This counter can indicate how many sessions were forced to log off due to logon time constraints. | PERF_COUNTER_RAWCOUNT |
| Sessions Logged Off | Shows the number of sessions that have terminated normally. This counter is useful in interpreting the statistics from Sessions Timed Out and Sessions Errored Out. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Sessions Timed Out | Shows the number of sessions that have been closed because idle time exceeded the AutoDisconnect parameter for the server. This counter shows whether the AutoDisconnect setting is helping to conserve resources. | PERF_COUNTER_RAWCOUNT |
| Work Item Shortages | Shows the number of times that STATUS_DATA_NOT_ACCEPTED was returned at receive indication time. This occurs when a work item is not available or cannot be allocated to service the incoming request. This counter indicates whether the InitWorkItems or MaxWorkItems registry entries might need to be adjusted. | PERF_COUNTER_COUNTER |

# Server Work Queues Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Server Work Queues performance object consists of counters that monitor the length of queues and objects in the queues.

| Counter Name | Description | Counter Type |
|---|---|---|
| Active Threads | Shows the number of threads working on a request from the server client for this CPU. The system keeps this number as low as possible to minimize unnecessary context switching. This is an instantaneous count for the CPU, not an average over time. | PERF_COUNTER_RAWCOUNT |
| Available Threads | Shows the number of server threads on this processor that are not currently working on requests from a client. The server dynamically adjusts the number of threads to maximize server performance. | PERF_COUNTER_RAWCOUNT |
| Available Work Items | Shows the instantaneous number of available work items for this CPU. A work item is typically a request from a client to the server; the server maintains a pool of available work items per CPU to speed processing. A sustained near-zero value indicates the need to increase the MinFreeWorkItems registry value for the server service. This value is always zero in the Blocking Queue instance. | PERF_COUNTER_RAWCOUNT |
| Borrowed Work Items | Shows the number of free work items borrowed from another CPU because a CPU ran out of available work items in its pool. An increasing value of this running counter might indicate the need to increase the MaxWorkItems or MinFreeWorkItems registry values for the server service. This value is always zero in the Blocking Queue instance. | PERF_COUNTER_RAWCOUNT |
| Bytes Received/sec | Shows the rate, in incidents per second, at which the server received bytes from the network clients on this CPU. This value is a measure of how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Bytes Sent/sec | Shows the rate, in incidents per second, at which the server sent bytes to the network clients on this CPU. This value is a measure of how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Bytes Transferred/sec | Shows the rate, in incidents per second, at which the server exchanged bytes with the network clients on this CPU. This value is a measure of how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Context Blocks Queued/sec | Shows the rate, in incidents per second, at which work context blocks have to be placed on the server's file system process queue to await server action. | PERF_COUNTER_COUNTER |
| Current Clients | Shows the current count of the clients being processed by this CPU. The server actively balances the client load across all of the CPUs in the system. If a single work queue can easily and quickly handle all the requests from clients, the clients might not be spread across multiple queues until a higher load is encountered. This value is always zero in the Blocking Queue instance. | PERF_COUNTER_RAWCOUNT |
| Queue Length | Shows the current length of the server work queue for this CPU. A sustained queue length greater than four might indicate processor congestion. This is an instantaneous count, not an average over time. | PERF_COUNTER_RAWCOUNT |
| Read Bytes/sec | Shows the rate, in incidents per second, at which the server read data from files for the clients on this CPU. This value is a measure of how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Read Operations/sec | Shows the rate, in incidents per second, at which the server performed file read operations for the clients on this CPU. This value is a measure of how busy the server is. This value is always zero in the Blocking Queue instance. | PERF_COUNTER_BULK_COUNT |
| Total Bytes/sec | Shows the rate, in incidents per second, at which the server read and wrote data to and from the files for the clients on this CPU. This value is a measure of how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Total Operations/sec | Shows the rate, in incidents per second, at which the server performed file read and write operations for the clients on this CPU. This value is a measure of how busy the server is. This value is always zero in the Blocking Queue instance. | PERF_COUNTER_BULK_COUNT |

| | | |
|---|---|---|
| Work Item Shortages | Shows the number of times that a work item was not available or could not be allocated to service the incoming request. A work item is the location where the server stores a server message block (SMB). The amount of work items available fluctuates between a minimum and maximum value configured, based on how the server is configured and the amount of memory on the computer. If work item shortages are occurring, it might be caused by an overloaded server. If the Work Item Shortages counter value is increasing, consider changing the value of the registry entry HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters\Maxworkitems. Allowing this value to be achieved consistently initiates flow control, which hurts performance. This value is always zero in the Blocking Queue instance. | PERF_COUNTER_RAWCOUNT |
| Write Bytes/sec | Shows the rate, in incidents per second, at which the server wrote data to files for the clients on this CPU. This value is a measure of how busy the server is. | PERF_COUNTER_BULK_COUNT |
| Write Operations/sec | Shows the rate, in incidents per second, at which the server performed file write operations for the clients on this CPU. This value is a measure of how busy the server is. This value is always zero in the Blocking Queue instance. | PERF_COUNTER_BULK_COUNT |

# SMTP Server Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The SMTP Server performance object consists of counters that describe the activity of the Exchange NTFS store driver, which is responsible for storing queued messages that are being processed by the Simple Mail Transfer Protocol (SMTP) service.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Recipients Local | Shows the percentage of recipients that were delivered locally. | PERF_RAW_FRACTION |
| % Recipients Remote | Shows the percentage of recipients that were delivered remotely. | PERF_RAW_FRACTION |
| Avg Recipients/msg Received | Shows the average number of recipients per inbound message received. | PERF_RAW_FRACTION |
| Avg Recipients/msg Sent | Shows the average number of recipients per outbound message sent. | PERF_RAW_FRACTION |
| Avg Retries/msg Delivered | Shows the average number of retries per local delivery. | PERF_RAW_FRACTION |
| Avg Retries/msg Sent | Shows the average number of retries per outbound message sent. | PERF_RAW_FRACTION |
| Badmailed Messages (Bad Pickup File) | Shows the number of malformed pickup messages sent to the badmail directory, which is a directory used to save messages that cannot be handled. These are usually non-delivery reports (NDRs) generated in response to NDRs. | PERF_COUNTER_RAWCOUNT |
| Badmailed Messages (General Failure) | Shows the number of messages sent to badmail for reasons not associated with a specific counter. | PERF_COUNTER_RAWCOUNT |
| Badmailed Messages (Hop Count Exceeded) | Shows the number of messages sent to badmail because they exceeded the maximum hop count. | PERF_COUNTER_RAWCOUNT |
| Badmailed Messages (NDR of DSN) | Shows the number of Delivery Status Notifications (DSN) sent to badmail because a message could not be delivered. If a message is undeliverable, it is returned to the sender with an NDR. | PERF_COUNTER_RAWCOUNT |
| Badmailed Messages (No Recipients) | Shows the number of messages sent to badmail because they had no recipients. | PERF_COUNTER_RAWCOUNT |
| Badmailed Messages (Triggered via Event) | Shows the number of messages sent to badmail at the request of a server event sink. The server events mechanism is used by SMTP to notify event sinks when specific events occur. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Bytes Received Total | Shows the total number of bytes received by the server. | PERF_COUNTER_LARGE_RAWCOUNT |
| Bytes Received/sec | Shows the rate, in incidents per second, at which bytes were received by the server. | PERF_COUNTER_BULK_COUNT |
| Bytes Sent Total | Shows the total number of bytes sent by the server. | PERF_COUNTER_LARGE_RAWCOUNT |
| Bytes Sent/sec | Shows the rate, in incidents per second, at which bytes were sent by the server. | PERF_COUNTER_BULK_COUNT |
| Bytes Total | Shows the total number of bytes sent and received by the server. | PERF_COUNTER_LARGE_RAWCOUNT |
| Bytes Total/sec | Shows the rate, in incidents per second, at which bytes were sent and received by the server. | PERF_COUNTER_BULK_COUNT |
| Cat: Address Lookup Completions | Shows the number of address lookup completions processed by the server. | PERF_COUNTER_RAWCOUNT |
| Cat: Address Lookup Completions/sec | Shows the rate, in incidents per second, at which address lookup completions were processed by the server. | PERF_COUNTER_COUNTER |
| Cat: Address Lookups | Shows the number of Lightweight Directory Access Protocol (LDAP) Directory lookups for individual addresses by the server. | PERF_COUNTER_RAWCOUNT |
| Cat: Address Lookups Not Found | Shows the number of address lookups that did not find any LDAP Directory object. | PERF_COUNTER_RAWCOUNT |
| Cat: Address Lookups/sec | Shows the rate, in incidents per second, at which address lookups were dispatched to the LDAP Directory. | PERF_COUNTER_COUNTER |
| Cat: Categorizations Completed | Shows the total number of messages to the categorizer that have completed categorization. Categorizing means looking up sender and recipient properties in the directory service, including doing distribution list expansion. | PERF_COUNTER_RAWCOUNT |
| Cat: Categorizations Completed Successfully | Shows the number of categorizations that were completed without any errors. | PERF_COUNTER_RAWCOUNT |
| Cat: Categorizations Completed/sec | Shows the rate, in incidents per second, at which messages submitted to categorizer were completed. | PERF_COUNTER_COUNTER |
| Cat: Categorizations Failed (DS Connection Failure) | Shows the number of categorizations that failed due to an LDAP Directory connection failure. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Cat: Categorizations Failed (DS Logon Failure) | Shows the number of categorizations that failed due to an LDAP Directory logon failure. | PERF_COUNTER_RAWCOUNT |
| Cat: Categorizations Failed (Non-Retryable Error) | Shows the number of categorizations that failed with a hard error (one which doesn't allow attempts to retry the operation). | PERF_COUNTER_RAWCOUNT |
| Cat: Categorizations Failed (Out Of Memory) | Shows the number of categorizations that failed due to lack of available memory. | PERF_COUNTER_RAWCOUNT |
| Cat: Categorizations Failed (Retryable Error) | Shows the number of categorizations that failed with a error that allowed an attempt to retry the operation. | PERF_COUNTER_RAWCOUNT |
| Cat: Categorizations Failed (Sink Retryable Error) | Shows the number of categorizations that failed with a generic error that allowed an attempt to retry the operation. | PERF_COUNTER_RAWCOUNT |
| Cat: Categorizations In Progress | Shows the number of categorizations in progress. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Bind Failures | Shows the total number of LDAP bind failures. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Binds | Shows the total number of successful LDAP binds, also known as bind authentications, that were performed. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Connection Failures | Shows the total number of connection failures encountered for LDAP servers. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Connections | Shows the total number of LDAP connections opened since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Connections Currently Open | Shows the number of LDAP connections currently open. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP General Completion Failures | Shows the number of LDAP completions with a generic failure. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Paged Search Completion Failures | Shows the number of LDAP paged searches that completed with a failure. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Paged Search Failures | Shows the number of failures to dispatch an asynchronous paged LDAP search. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Cat: LDAP Paged Searches | Shows the number of LDAP paged searches that were successfully dispatched. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Paged Searches Completed | Shows the number of paged LDAP completions processed. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Search Completion Failures | Shows the number of LDAP searches that completed with a failure. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Search Failures | Shows the number of failures to dispatch an asynchronous LDAP search. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Searches | Shows the number of LDAP searches that were successfully dispatched. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Searches Abandoned | Shows the umber of LDAP searches that were abandoned. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Searches Completed | Shows the number of LDAP search completions that were processed. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Searches Completed/sec | Shows the rate, in incidents per second, at which LDAP search completions were processed. | PERF_COUNTER_COUNTER |
| Cat: LDAP Searches Pending Completion | Shows the number of LDAP searches that were pending asynchronous completion. | PERF_COUNTER_RAWCOUNT |
| Cat: LDAP Searches/sec | Shows the rate, in incidents per second, at which number LDAP searches were successfully dispatched. | PERF_COUNTER_COUNTER |
| Cat: Mailmsg Duplicate Collisions | Shows the number of times that a duplicate recipient address was detected by either mailmsg or the categorizer. | PERF_COUNTER_RAWCOUNT |
| Cat: Messages Aborted | Shows the number of messages that were marked to be aborted by the categorizer. | PERF_COUNTER_RAWCOUNT |
| Cat: Messages Bifurcated | Shows the number of new messages that were created by the categorizer (bifurcation). | PERF_COUNTER_RAWCOUNT |
| Cat: Messages Categorized | Shows the number of messages that the categorizer has submitted to queuing. | PERF_COUNTER_RAWCOUNT |
| Cat: Messages Submitted | Shows the total number of messages that were submitted to the categorizer. | PERF_COUNTER_RAWCOUNT |
| Cat: Messages Submitted/sec | Shows the rate, in incidents per second, at which messages were submitted to the categorizer. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Cat: Recipients After Categorization | Shows the number of mail message recipients that were submitted from the categorizer to queuing. | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients Before Categorization | Shows the number of mail message recipients that were submitted to the categorizer. | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients In Categorization | Shows the number of recipients that the categorizer was currently processing. | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients NDRd (Ambiguous Address) | Shows the number of recipients with addresses that match multiple LDAP Directory objects. | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients NDRd (Forwarding Loop) | Shows the number of recipients that received an NDR from the categorizer due to forwarding loop detection. | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients NDRd (Illegal Address) | Shows the number of recipients that received an NDR from the categorizer due to illegal addresses. | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients NDRd (Sink Recip Errors) | Shows the number of recipients that received an NDR from the categorizer due to generic recipient failure. | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients NDRd (Unresolved) | Shows the number of unresolved recipients (local addresses not found). | PERF_COUNTER_RAWCOUNT |
| Cat: Recipients NDRd by Categorizer | Shows the number of recipients set to receive an NDR from the categorizer. | PERF_COUNTER_RAWCOUNT |
| Cat: Senders Unresolved | Shows the number of senders that were not found in the LDAP Directory. | PERF_COUNTER_RAWCOUNT |
| Cat: Senders With Ambiguous Addresses | Shows the number of senders with addresses that match multiple LDAP Directory objects. | PERF_COUNTER_RAWCOUNT |
| Categorizer Queue Length | Shows the number of messages in the categorizer queue waiting to be categorized. | PERF_COUNTER_RAWCOUNT |
| Connection Errors/sec | Shows the rate, in incidents per second, at which connection errors occurred. | PERF_COUNTER_COUNTER |
| Current Messages In Local Delivery | Shows the number of messages that were currently being processed by a server event sink for local delivery. | PERF_COUNTER_RAWCOUNT |
| Directory Drops Total | Shows the total number of messages placed in a drop directory. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Directory Drops/sec | Shows the rate, in incidents per second, at which messages were placed in a drop directory. | PERF_COUNTER_COUNTER |
| DNS Queries Total | Shows the total number of DNS lookups. | PERF_COUNTER_RAWCOUNT |
| DNS Queries/sec | Shows the rate, in incidents per second, of DNS lookups. | PERF_COUNTER_COUNTER |
| ETRN Messages Total | Shows the total number of extended turn (ETRN) messages received by the server. | PERF_COUNTER_RAWCOUNT |
| ETRN Messages/sec | Shows the rate, in incidents per second, of ETRN messages. | PERF_COUNTER_COUNTER |
| Inbound Connections Current | Shows the total number of connections that were currently inbound. | PERF_COUNTER_RAWCOUNT |
| Inbound Connections Total | Shows the total number of inbound connections received. | PERF_COUNTER_RAWCOUNT |
| Local Queue Length | Shows the number of messages in the local queue. | PERF_COUNTER_RAWCOUNT |
| Local Retry Queue Length | Shows the number of messages in the local retry queue. | PERF_COUNTER_RAWCOUNT |
| Message Bytes Received Total | Shows the total number of bytes received in messages. | PERF_COUNTER_LARGE_RAWCOUNT |
| Message Bytes Received/sec | Shows the rate, in incidents per second, at which bytes were received in messages. | PERF_COUNTER_BULK_COUNT |
| Message Bytes Sent Total | Shows the total number of bytes sent in messages. | PERF_COUNTER_LARGE_RAWCOUNT |
| Message Bytes Sent/sec | Shows the rate, in incidents per second, at which bytes were sent in messages. | PERF_COUNTER_BULK_COUNT |
| Message Bytes Total | Shows the total number of bytes sent and received in messages. | PERF_COUNTER_LARGE_RAWCOUNT |
| Message Bytes Total/sec | Shows the rate, in incidents per second, at which bytes were sent and received in messages. | PERF_COUNTER_BULK_COUNT |
| Message Delivery Retries | Shows the total number of local deliveries that were retried. | PERF_COUNTER_RAWCOUNT |
| Message Received/sec | Shows the rate, in incidents per second, at which inbound messages were being received. | PERF_COUNTER_COUNTER |
| Message Send Retries | Shows the total number of outbound message sends that were retried. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Messages Currently Undeliverable | Shows the number of messages that were reported as currently undeliverable by routing. | PERF_COUNTER_RAWCOUNT |
| Messages Delivered Total | Shows the total number of messages that were delivered to local mailboxes. | PERF_COUNTER_RAWCOUNT |
| Messages Delivered/sec | Shows the rate, in incidents per second, at which messages were delivered to local mailboxes. | PERF_COUNTER_COUNTER |
| Messages Pending Routing | Shows the number of messages that were categorized but not routed. | PERF_COUNTER_RAWCOUNT |
| Messages Received Total | Shows the total number of inbound messages that were accepted. | PERF_COUNTER_RAWCOUNT |
| Messages Refused for Address Objects | Shows the total number of messages that were refused due to no address objects. | PERF_COUNTER_RAWCOUNT |
| Messages Refused for Mail Objects | Shows the total number of messages that were refused due to no mail objects. | PERF_COUNTER_RAWCOUNT |
| Messages Refused for Size | Shows the total number of messages that were rejected because they were too big. | PERF_COUNTER_RAWCOUNT |
| Messages Sent Total | Shows the total number of outbound messages that were sent. | PERF_COUNTER_RAWCOUNT |
| Messages Sent/sec | Shows the rate, in incidents per second, at which outbound messages were sent. | PERF_COUNTER_COUNTER |
| NDRs Generated | Shows the number of NDRs that were generated. | PERF_COUNTER_RAWCOUNT |
| Number of MailFiles Open | Shows the number of handles to open mail files. | PERF_COUNTER_RAWCOUNT |
| Number of QueueFiles Open | Shows the number of handles to open queue files. | PERF_COUNTER_RAWCOUNT |
| Outbound Connections Current | Shows the number of connections that were currently outbound. | PERF_COUNTER_RAWCOUNT |
| Outbound Connections Refused | Shows the number of outbound connection attempts that were refused by remote sites. | PERF_COUNTER_RAWCOUNT |
| Outbound Connections Total | Shows the total number of outbound connections that were attempted. | PERF_COUNTER_RAWCOUNT |
| Pickup Directory Messages Retrieved Total | Shows the total number of messages that were retrieved from the mail pick-up directory. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Pickup Directory Messages Retrieved/sec | Shows the rate, in incidents per second, at which messages were retrieved from the mail pick-up directory. | PERF_COUNTER_COUNTER |
| Remote Queue Length | Shows the number of messages that were in the remote queue. | PERF_COUNTER_RAWCOUNT |
| Remote Retry Queue Length | Shows the number of messages that were in the retry queue for remote delivery. | PERF_COUNTER_RAWCOUNT |
| Routing Table Lookups Total | Shows the total number of routing table lookups. | PERF_COUNTER_RAWCOUNT |
| Routing Table Lookups/sec | Shows the rate, in incidents per second, of routing table lookups. | PERF_COUNTER_COUNTER |
| Total Connection Errors | Shows the total number of connection errors. | PERF_COUNTER_RAWCOUNT |
| Total DSN Failures | Shows the total number of failed DSN generation attempts. | PERF_COUNTER_RAWCOUNT |
| Total messages submitted | Shows the total number of messages submitted to queuing for delivery. | PERF_COUNTER_RAWCOUNT |

SMTP NTFS Store Driver Object

# SMTP NTFS Store Driver Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The SMTP NTFS Store Driver performance object consists of counters that describe the activity of the Exchange NTFS store driver, which is responsible for message transport to and from the message store. The Simple Mail Transport Protocol (SMTP) is the protocol in the TCP/IP suite that directs the exchange of electronic mail.

| Counter Name | Description | Counter Type |
|---|---|---|
| Messages Allocated | Shows the total number of messages allocated since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| Messages Deleted | Shows the total number of messages deleted since the computer was last started. | PERF_COUNTER_RAWCOUNT |
| Messages Enumerated | Shows the total number of messages enumerated during startup. | PERF_COUNTER_RAWCOUNT |
| Messages in the Queue Directory | Shows the current number of messages in the queue directory. | PERF_COUNTER_RAWCOUNT |
| Open Message Bodies | Shows the current number of open message bodies. | PERF_COUNTER_RAWCOUNT |
| Open Message Streams | Shows the current number of open message streams. | PERF_COUNTER_RAWCOUNT |

SMTP Server Object

# System Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The System performance object consists of counters that apply to more than one component of the computer. The data collected by the system counters is derived from activity in the processor, memory, or disk subsystems.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Registry Quota In Use | Shows the percentage of the Total Registry Quota Allowed that was being used by the system. | PERF_RAW_FRACTION |
| Alignment Fixups/sec | Shows the rate, in incidents per second, at which alignment faults were fixed by the system. | PERF_COUNTER_COUNTER |
| Context Switches/sec | Shows the combined rate, in incidents per second, at which all processors on the computer were switched from one thread to another. It is the sum of the values of Thread\Context Switches/sec for each thread running on all processors on the computer, and is measured in numbers of switches. Context switches occur when a running thread voluntarily relinquishes the processor, or is preempted by a higher priority, ready thread. | PERF_COUNTER_COUNTER |
| Exception Dispatches/sec | Shows the rate, in incidents per second, at which exceptions were dispatched by the system. | PERF_COUNTER_COUNTER |
| File Control Bytes/sec | Shows the overall rate, in incidents per second, at which bytes were transferred for all file system operations that were neither read nor write operations, such as file system control requests and requests for information about device characteristics or status. | PERF_COUNTER_BULK_COUNT |
| File Control Operations/sec | Shows the combined rate, in incidents per second, of file system operations that were neither read nor write operations, such as file system control requests and requests for information about device characteristics or status. This is the inverse of File Data Operations/sec. | PERF_COUNTER_COUNTER |
| File Data Operations/sec | Shows the combined rate, in incidents per second, of read and write operations on disks, serial, or parallel devices. This is the inverse of File Control Operations/sec. | PERF_COUNTER_COUNTER |
| File Read Bytes/sec | Shows the overall rate, in incidents per second, at which bytes were read to satisfy file system read requests to all devices on the computer, including read operations from the file system cache. | PERF_COUNTER_BULK_COUNT |
| File Read Operations/sec | Shows the combined rate, in incidents per second, of file system read requests to all devices on the computer, including requests to read from the file system cache. | PERF_COUNTER_COUNTER |
| File Write Bytes/sec | Shows the overall rate, in incidents per second, at which bytes were written to satisfy file system write requests to all devices on the computer, including write operations to the file system cache. | PERF_COUNTER_BULK_COUNT |
| File Write Operations/sec | Shows the combined rate, in incidents per second, of file system write requests to all devices on the computer, including requests to write to data in the file system cache. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Floating Emulations/sec | Shows the rate, in incidents per second, of floating emulations performed by the system. | PERF_COUNTER_COUNTER |
| Processes | Shows the number of processes in the computer at the time of data collection. This is an instantaneous count, not an average over the time interval. Each process represents a program that is running. | PERF_COUNTER_RAWCOUNT |
| Processor Queue Length | Shows the number of threads in the processor queue. Unlike the disk counters, this counter shows ready threads only, not threads that are running. There is a single queue for processor time, even on computers with multiple processors. Therefore, if a computer has multiple processors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of greater than two threads generally indicates processor congestion. | PERF_COUNTER_RAWCOUNT |
| System Calls/sec | Shows the combined rate, in incidents per second, of calls to operating system service routines by all processes running on the computer. These routines perform all of the basic scheduling and synchronization of activities on the computer, and provide access to nongraphic devices, memory management, and name space management. | PERF_COUNTER_COUNTER |
| System Up Time | Shows the total time, in seconds, that the computer has been operational since it was last started. | PERF_ELAPSED_TIME |
| Threads | Shows the number of threads in the computer at the time of data collection. This is an instantaneous count, not an average over the time interval. A thread is the basic executable entity that can execute instructions in a processor. | PERF_COUNTER_COUNTER |

# Telephony Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Telephony performance object provides counters for monitoring telephone-communication activity on a computer that is running a Windows Server 2003 family operating system.

| Counter Name | Description | Counter Type |
|---|---|---|
| Active Lines | Shows the number of telephone or integrated services digital network (ISDN) lines that were serviced by the computer and that were in use by applications during the sample period. | PERF_COUNTER_RAWCOUNT |
| Active Telephones | Shows the number of telephone devices (telephones or speaker phones) that were in use by applications during the sample period. | PERF_COUNTER_RAWCOUNT |
| Client Apps | Shows the number of applications that that were using telephony services. | PERF_COUNTER_RAWCOUNT |
| Current Incoming Calls | Shows the number of incoming calls that that were being serviced by the computer during the sample period. | PERF_COUNTER_RAWCOUNT |
| Current Outgoing Calls | Shows the number of outgoing calls that that were being serviced by the computer during the sample period. | PERF_COUNTER_RAWCOUNT |
| Incoming Calls/sec | Shows the rate, in incidents per second, at which incoming calls were answered by this computer. | PERF_COUNTER_COUNTER |
| Lines | Shows the number of telephone lines that were serviced by the computer. | PERF_COUNTER_RAWCOUNT |
| Outgoing Calls/sec | Shows the rate, in incidents per second, at which outgoing calls were made by the computer. | PERF_COUNTER_COUNTER |
| Telephone Devices | Shows the number of telephone devices (telephones or speaker phones) that were serviced by the computer. | PERF_COUNTER_RAWCOUNT |

# TCP Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The TCP performance object consists of counters that measure the rates at which Transmission Control Protocol (TCP) segments are sent and received using TCP. It includes counters that monitor the number of TCP connections in each TCP connection state.

| Counter Name | Description | Counter Type |
|---|---|---|
| Connection Failures | Shows the number of times that TCP connections have made a direct transition to the CLOSED state from the SYN-SENT or SYN-RCVD state, plus the number of times TCP connections have made a direct transition to the LISTEN state from the SYN-RCVD state, since the server was last started. | PERF_COUNTER_RAWCOUNT |
| Connections Active | Shows the number of times TCP connections have made a direct transition to the SYN-SENT state from the CLOSED state, since the server was last started. | PERF_COUNTER_RAWCOUNT |
| Connections Established | Shows the number of TCP connections for which the state was either ESTABLISHED or CLOSE-WAIT, since the server was last started. | PERF_COUNTER_RAWCOUNT |
| Connections Passive | Shows the number of times that TCP connections have made a direct transition to the SYN-RCVD state from the LISTEN state, since the server was last started. | PERF_COUNTER_RAWCOUNT |
| Connections Reset | Shows the number of times that TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED or CLOSE-WAIT state, since the server was last started. | PERF_COUNTER_RAWCOUNT |
| Segments Received/sec | Shows the rate, in incidents per second, at which segments were received, including those received in error. This count includes segments received on currently established connections. Segments Received/sec is a subset of Segments/sec. | PERF_COUNTER_COUNTER |
| Segments Retransmitted/sec | Shows the rate, in incidents per second, at which segments containing one or more previously transmitted bytes were retransmitted. | PERF_COUNTER_COUNTER |
| Segments Sent/sec | Shows the rate, in incidents per second, at which segments were sent. This value includes those on current connections, but excludes those containing only retransmitted bytes. Segments Sent/sec is a subset of Segments/sec. | PERF_COUNTER_COUNTER |
| Segments/sec | Shows the rate, in incidents per second, at which TCP segments were sent or received using the TCP protocol. Segments/sec is the sum of the values of Segments Received/sec and Segments Sent/sec. | PERF_COUNTER_COUNTER |

# Terminal Services Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Terminal Services object provides per-session resource statistics such as packet and frame transmission data, errors, and cache activity for Terminal Services.

In addition, the Terminal Services object reports session-specific activity using the following Process object counters:

| Counter Name | Description | Counter Type |
|---|---|---|
| Input Async Frame Error | Shows the number of input async framing errors. These can be caused by a noisy transmission line. Using a smaller packet size may help in some cases. | PERF_COUNTER_RAWCOUNT |
| Input Bytes | Shows the number of bytes input on this session that includes all protocol overhead. | PERF_COUNTER_COUNTER |

# Terminal Services Session Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Terminal Services Session performance object provides per-session resource statistics, such as packet and frame transmission data, errors, and cache activity for Terminal Services.

In addition, the Terminal Services Session performance object reports session-specific activity using the following Process object counters:

| | |
|---|---|
| Process Object | Process Object |
| Process Object | Process Object |
| Process Object | Process Object |
| Process Object | Process Object |
| Process Object | Process Object |
| Process Object | Process Object |
| Process Object | Process Object |
| Process Object | |

| Counter Name | Description | Counter Type |
|---|---|---|
| Input Async Frame Error | Shows the number of input async framing errors. These can be caused by a noisy transmission line. Using a smaller packet size can help in some cases. | PERF_COUNTER_RAWCOUNT |
| Input Async Overflow | Shows the number of input async overflow errors. These can be caused by a lack of buffer space available on the host. | PERF_COUNTER_RAWCOUNT |
| Input Async Overrun | Shows the number of input async overrun errors. These can be caused by the baud rate being faster than the computer can handle, or by a serial line that does not use a 16550 universal asynchronous receiver-transmitter (UART). Overruns can also occur if too many high speed serial lines are active at one time for the processor's power. | PERF_COUNTER_RAWCOUNT |
| Input Async Parity Error | Shows the number of input async parity errors. These can be caused by a noisy transmission line. | PERF_COUNTER_RAWCOUNT |
| Input Bytes | Shows the number of bytes input on this session, which includes all protocol overhead. | PERF_COUNTER_COUNTER |
| Input Compress Flushes | Shows the number of input compression dictionary flushes. When the data cannot be compressed, the compression dictionary is flushed so that newer data has a better chance of being compressed. One possible cause of data not compressing is transferring compressed files using client drive mapping. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Input Compressed Bytes | Shows the number of bytes that were input after compression. This number compared with the Total Bytes input is the compression ratio. | PERF_COUNTER_COUNTER |
| Input Compression Ratio | Shows the compression ratio of the server input data stream. This is Input Compressed Bytes compared with the Total Bytes input. | PERF_COUNTER_RAWCOUNT |
| Input Errors | Shows the number of input errors of all types. Some examples of input errors are lost acknowledgments (ACKs) or badly formed packets. | PERF_COUNTER_RAWCOUNT |
| Input Frames | Shows the number of frames input on this session. | PERF_COUNTER_COUNTER |
| Input Timeouts | Shows the total number of timeouts on the communication line, as seen from the client side of the connection. These are typically the result of a noisy line. On some high-latency networks, this could be the result of the protocol timeout being too short. Increasing the protocol timeout on these types of lines will improve performance by reducing the need for retransmissions. | PERF_COUNTER_RAWCOUNT |
| Input Transport Errors | Shows the number of Terminal Services transport-level errors on input. | PERF_COUNTER_RAWCOUNT |
| Input WaitForOutBuf | Shows the number of times that a "wait for an available send buffer" was done by the protocols on the client side of the connection. | PERF_COUNTER_RAWCOUNT |
| Input WdBytes | Shows the number of bytes input on this session after all protocol overhead has been removed. | PERF_COUNTER_COUNTER |
| Input WdFrames | Shows the number of frames input after any additional protocol added frames have been removed. | PERF_COUNTER_COUNTER |
| Output Async Frame Error | Shows the number of output async framing errors. These could be caused by a hardware or line problem. | PERF_COUNTER_RAWCOUNT |
| Output Async Overflow | Shows the number of output async overflow errors. | PERF_COUNTER_RAWCOUNT |
| Output Async Overrun | Shows the number of output async overrun errors. | PERF_COUNTER_RAWCOUNT |
| Output Async Parity Error | Shows the number of output async parity errors. These can be caused by a hardware or line problem. | PERF_COUNTER_RAWCOUNT |
| Output Bytes | Shows the number of bytes output on this session, which includes all protocol overhead. | PERF_COUNTER_COUNTER |
| Output Compress Flushes | Shows the number of output compression dictionary flushes. When the data cannot be compressed, the compression dictionary is flushed so that newer data has a better chance of being compressed. One possible cause of data not compressing is transferring compressed files using client drive mapping. | PERF_COUNTER_RAWCOUNT |
| Output Compressed Bytes | Shows the number of bytes output after compression. This number compared with the Total Bytes output is the compression ratio. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Output Compression Ratio | Shows the compression ratio of the server output data stream. Output Compressed Bytes compared with the Total Bytes output is the compression ratio. | PERF_COUNTER_RAWCOUNT |
| Output Errors | Shows the number of output errors of all types. Some examples of output errors are lost ACKs or badly formed packets. | PERF_COUNTER_RAWCOUNT |
| Output Frames | Shows the number of frames that were output on this session. | PERF_COUNTER_COUNTER |
| Output Timeouts | Shows the total number of timeouts on the communication line, from the host side of the connection. These are typically the result of a noisy line. | PERF_COUNTER_RAWCOUNT |
| Output Transport Errors | Shows the number of Terminal Services transport-level errors on output. | PERF_COUNTER_RAWCOUNT |
| Output WaitForOutBuf | Shows the number of times that a "wait for an available send buffer" was done by the protocol on the server side of the connection. | PERF_COUNTER_COUNTER |
| Output WdBytes | Shows the number of bytes output on this session after all protocol overhead has been removed. | PERF_COUNTER_COUNTER |
| Output WdFrames | Shows the number of frames output before any additional protocol frames have been added. | PERF_COUNTER_COUNTER |
| Protocol Bitmap Cache Hit Ratio | Shows the hit ratio in the protocol bitmap cache. A higher hit ratio means better performance, since data transmissions are reduced. Low hit ratios are due to the screen updating with new information that is either not re-used, or is flushed out of the client cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Bitmap Cache Hits | Shows the number of hits in the protocol bitmap cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Bitmap Cache Reads | Shows the number of references to the protocol bitmap cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Brush Cache Hit Ratio | Shows the hit ratio in the protocol brush cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Brush Cache Hits | Shows the number of hits in the protocol brush cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Brush Cache Reads | Shows the number of references to the protocol brush cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Glyph Cache Hit Ratio | Shows the hit ratio in the protocol glyph cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Glyph Cache Hits | Shows the number of hits in the protocol glyph cache. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Protocol Glyph Cache Reads | Shows the number of references to the protocol glyph cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Save Screen Bitmap Cache Hit Ratio | Shows the hit ratio in the protocol save screen bitmap cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Save Screen Bitmap Cache Hits | Shows the number of hits in the protocol save screen bitmap cache. | PERF_COUNTER_RAWCOUNT |
| Protocol Save Screen Bitmap Cache Reads | Shows the number of references to the protocol save screen bitmap cache. | PERF_COUNTER_RAWCOUNT |
| Total Async Frame Error | Shows the total number of async framing errors. | PERF_COUNTER_RAWCOUNT |
| Total Async Overflow | Shows the total number of async overflow errors. | PERF_COUNTER_RAWCOUNT |
| Total Async Overrun | Shows the total number of async overrun errors. | PERF_COUNTER_RAWCOUNT |
| Total Async Parity Error | Shows the total number of async parity errors. | PERF_COUNTER_RAWCOUNT |
| Total Bytes | Shows the total number of bytes on this session, which includes all protocol overhead. | PERF_COUNTER_COUNTER |
| Total Compress Flushes | Shows the total number of compression dictionary flushes. | PERF_COUNTER_RAWCOUNT |
| Total Compressed Bytes | Shows the total number of bytes after compression. This number compared with the Total Bytes output is the compression ratio. | PERF_COUNTER_COUNTER |
| Total Compression Ratio | Shows the total compression ratio of the server data stream. This is the Total Compressed Bytes compared with the Total Bytes output. | PERF_COUNTER_RAWCOUNT |
| Total Errors | Shows the total number of errors of all types. | PERF_COUNTER_RAWCOUNT |
| Total Frames | Shows the total number of frames on this session. | PERF_COUNTER_COUNTER |
| Total Protocol Cache Hit Ratio | Shows the overall hit ratio for all protocol caches. | PERF_COUNTER_RAWCOUNT |
| Total Protocol Cache Hits | Shows the total hits in all protocol caches. The protocol caches Windows objects that are likely to be re-used, to avoid having to resend them on the transmission line. Examples of objects are Windows icons and brushes. Hits in the cache represent objects that did not need to be resent. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Total Protocol Cache Reads | Shows the total references to all protocol caches. | PERF_COUNTER_RAWCOUNT |
| Total Timeouts | Shows the total number of timeouts on the communication line, from both the host and client sides of the connection. | PERF_COUNTER_RAWCOUNT |
| Total Transport Errors | Shows the total number of Terminal Services transport-level errors. | PERF_COUNTER_RAWCOUNT |
| Total WaitForOutBuf | Shows the number of times that a "wait for an available send buffer" was done by the protocols on both the server and client sides of the connection. | PERF_COUNTER_COUNTER |
| Total WdBytes | Shows the total number of bytes on this session after all protocol overhead has been removed. | PERF_COUNTER_COUNTER |
| Total WdFrames | Shows the total number of frames input and output before any additional protocol frames have been added. | PERF_COUNTER_COUNTER |

Terminal Services Object

# Thread Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Thread performance object consists of counters that measure aspects of thread behavior. A thread is the basic object that executes instructions on a processor. All running processes have at least one thread.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Privileged Time | Shows the percentage of non-idle processor time spent executing code in privileged mode. Privileged mode is a processing mode designed for operating system components and hardware-manipulating drivers. It allows direct access to hardware and memory. The alternative, user mode, is a restricted processing mode designed for applications, environmental subsystems, and integral subsystems. The operating system switches application threads to privileged mode to access operating system services.<br><br>% Privileged Time includes time servicing interrupts and DPCs. A high rate of privileged time might be attributed to a large number of interrupts generated by a failing device. When a Windows system service is called, the service often runs in privileged mode to gain access to system-private data. Such data is protected from access by threads executing in user mode. Calls to the system can be explicit or implicit, such as page faults or interrupts.<br><br>Unlike some earlier Windows operating systems, Windows 2000 and the Windows Server 2003 family use process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. These subsystem processes provide additional protection. Therefore, some work done by Windows 2000 and Windows Server 2003 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |
| % Processor Time | Shows the percentage of time that the processor spent executing a non-idle thread. It is calculated by measuring the duration that the idle thread is active during the sample interval, and subtracting that time from 100 %. (Each processor has an idle thread that consumes cycles when no other threads are ready to run.) This counter is the primary indicator of processor activity, and displays the average percentage of busy time observed during the sample interval. Code executed to handle some hardware interrupts and trap conditions are included in this count. | PERF_100NSEC_TIMER |
| % User Time | Shows the percentage of time that the processor spent executing code in user mode. Applications, environment subsystems, and integral subsystems execute in user mode. Code executing in user mode cannot damage the integrity of the Windows Executive, kernel, and/or device drivers. Unlike some earlier Windows operating systems, Windows 2000 and Windows Server 2003 use process boundaries for subsystem protection in addition to the traditional protection of user and privileged modes. These subsystem processes provide additional protection. Therefore, some work done by Windows 2000 and Windows Server 2003 on behalf of your application might appear in other subsystem processes in addition to the privileged time in your process. | PERF_100NSEC_TIMER |
| Context Switches/sec | Shows the combined rate, in incidents per second, at which all processors on the computer were switched from one thread to another Context switches occur when a running thread voluntarily relinquishes the processor, or is preempted by a higher priority, ready thread. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Elapsed Time | Shows the time, in seconds, that this process has been running. | PERF_ELAPSED_TIME |
| ID Process | Shows the unique identifier of this process. ID Process numbers are reused, so they only identify a process for the lifetime of that process. | PERF_COUNTER_RAWCOUNT |
| ID Thread | Shows the unique identifier of this thread. ID Thread numbers are reused, so they only identify a thread for the lifetime of that thread. | PERF_COUNTER_RAWCOUNT |
| Priority Base | Shows the current base priority of this process. Threads within a process can raise and lower their own base priority relative to the process's base priority. | PERF_COUNTER_RAWCOUNT |
| Priority Current | Shows the current dynamic priority of this thread. The system can raise the dynamic priority of the thread above the base priority if the thread is handling user input, or lower it toward the base priority if the thread becomes compute bound. | PERF_COUNTER_RAWCOUNT |
| Start Address | Shows the starting virtual address for this thread. | PERF_COUNTER_RAWCOUNT |
| Thread State | Shows the current state of the thread. Valid values are: 0 Initialized 1 Ready 2 Running 3 Standby 4 Terminated 5 Waiting 6 Transition 7 Unknown | PERF_COUNTER_RAWCOUNT |
| Thread Wait Reason | Shows the reason that a thread was in the Wait state. This counter is only applicable when the thread is in the Wait state, which is indicated by a Thread State value of 5. Values for this counter are as follows: 0 Waiting for a component of the Windows NT Executive 1 Waiting for a page to be freed 2 Waiting for a page to be mapped or copied 3 Waiting for space to be allocated in the paged or nonpaged pool 4 Waiting for an Execution Delay to be resolved 5 Suspended 6 Waiting for a user request 7 Waiting for a component of the Windows NT Executive 8 Waiting for a page to be freed 9 Waiting for a page to be mapped or copied 10 Waiting for space to be allocated in the paged or nonpaged pool 11 Waiting for an Execution Delay to be resolved 12 Suspended 13 Waiting for a user request 14 Waiting for an event pair high 15 Waiting for an event pair low 16 Waiting for an LPC Receive notice 17 Waiting for an LPC Reply notice 18 Waiting for virtual memory to be allocated 19 Waiting for a page to be written to disk 20+ (Reserved for future use) | PERF_COUNTER_RAWCOUNT |

# Thread Details Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Thread Details performance object consists of counters that measure aspects of thread behavior that are difficult or time-consuming to collect. These counters are distinguished from those in the Thread performance object by their high overhead.

This object contains *costly* counters, for which data collection is typically either processor-intensive or memory-intensive. Costly counters cannot be selected with System Monitor but can be accessed using another parsing tool.

| Counter Name | Description | Counter Type |
|---|---|---|
| User PC | Shows the current user program counter for this thread. This is also known as an instruction pointer in CPU registers. | PERF_COUNTER_LARGE_RAWCOUNT_HEX |

# UDP Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The UDP performance object consists of counters that measure the rates at which User Data Protocol (UDP) datagrams are sent and received using the UDP. It includes counters that monitor UDP errors.

| Counter Name | Description | Counter Type |
|---|---|---|
| Datagrams No Port/sec | Shows the rate, in incidents per second, at which UDP datagrams were received for which there was no application at the destination port. | PERF_COUNTER_COUNTER |
| Datagrams Received Errors | Shows the number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. | PERF_COUNTER_RAWCOUNT |
| Datagrams Received/sec | Shows the rate, in incidents per second, at which UDP datagrams were delivered to UDP users. | PERF_COUNTER_COUNTER |
| Datagrams Sent/sec | Shows the rate, in incidents per second, at which UDP datagrams were sent from the computer. | PERF_COUNTER_COUNTER |
| Datagrams/sec | Shows the rate, in incidents per second, at which UDP datagrams were transferred by the computer. | PERF_COUNTER_COUNTER |

# Web Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Web Service performance object counters (installed with Internet Information Services) monitor file transfer rates, bandwidth usage, connection rates, errors, and numbers and types of users.

You can view performance data for all instances of this object (using the _Total instance) or for specific instances, such as the Default Web Site or Administration Web Site instances.

| Counter Name | Description | Counter Type |
|---|---|---|
| Anonymous Users/sec | Shows the rate, in incidents per second, at which users made anonymous connections using the Web service. | PERF_COUNTER_COUNTER |
| Bytes Received/sec | Shows the rate, in incidents per second, at which data bytes were received by the Web service. | PERF_COUNTER_BULK_COUNT |
| Bytes Sent/sec | Shows the rate, in incidents per second, at which data bytes were sent by the Web service. | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the sum of Web Service\Bytes Sent/sec and Web Service\Bytes Received/sec. This is the total rate, in incidents per second, at which bytes were transferred by the Web service. | PERF_COUNTER_BULK_COUNT |
| CGI Requests/sec | Shows the rate, in incidents per second, at which Common Gateway Interface (CGI) requests were simultaneously being processed by the Web service. | PERF_COUNTER_COUNTER |
| Connection Attempts/sec | Shows the rate, in incidents per second, at which connections using the Web service were being attempted. | PERF_COUNTER_COUNTER |
| Copy Requests/sec | Shows the rate, in incidents per second, at which Hypertext Transfer Protocol (HTTP) requests using the COPY method were made. COPY requests are used for copying files and directories. | PERF_COUNTER_COUNTER |
| Current Anonymous Users | Shows the number of users who had an anonymous connection using the Web service. | PERF_COUNTER_RAWCOUNT |
| Current Blocked Bandwidth Bytes | Shows the current total of bytes that were temporarily blocked due to bandwidth throttling settings. | PERF_COUNTER_RAWCOUNT |
| Current CAL count for authenticated users | Shows the current count of licenses used simultaneously by the Web service for authenticated connections. | PERF_COUNTER_RAWCOUNT |
| Current CAL count for SSL connections | Shows the current count of licenses used simultaneously by the Web service for Secure Socket Layer (SSL) connections. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Current CGI Requests | Shows the current number of CGI requests that were simultaneously being processed by the Web service. | PERF_COUNTER_RAWCOUNT |
| Current Connections | Shows the current number of connections established with the Web service. | PERF_COUNTER_RAWCOUNT |
| Current ISAPI Extension Requests | Shows the current number of Internet Server Application Programming Interface (ISAPI) Extension requests that were simultaneously being processed by the Web service. | PERF_COUNTER_RAWCOUNT |
| Current Non-Anonymous Users | Shows the number of users who currently have a non-anonymous connection using the Web service. | PERF_COUNTER_RAWCOUNT |
| Delete Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the DELETE method were made. Delete requests are generally used for file removals. | PERF_COUNTER_COUNTER |
| Files Received/sec | Shows the rate, in incidents per second, at which files were received by the Web service. | PERF_COUNTER_COUNTER |
| Files Sent/sec | Shows the rate, in incidents per second, at which files were sent by the Web service. | PERF_COUNTER_COUNTER |
| Files/sec | Shows the rate, in incidents per second, at which files were transferred, that is, sent and received by the Web service. | PERF_COUNTER_COUNTER |
| Get Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the GET method were made. GET requests are generally used for basic file retrievals or image maps, though they can be used with forms. | PERF_COUNTER_COUNTER |
| Head Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the HEAD method are made. HEAD requests generally indicate a client is querying the state of a document they already have to see if it needs to be refreshed. | PERF_COUNTER_COUNTER |
| ISAPI Extension Requests/sec | Shows the rate, in incidents per second, at which ISAPI Extension Requests were simultaneously being processed by the Web service. | PERF_COUNTER_COUNTER |
| Lock Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the LOCK method were made. LOCK requests are used to lock a file for one user so only that user can modify the file. | PERF_COUNTER_COUNTER |
| Locked Errors/sec | Shows the rate, in incidents per second, of errors due to requests that could not be satisfied by the server because the requested document was locked. These are generally reported as an HTTP 423 error code to the client. | PERF_COUNTER_COUNTER |
| Logon Attempts/sec | Shows the rate, in incidents per second, at which logons using the Web service were being attempted. | PERF_COUNTER_COUNTER |
| Maximum Anonymous Users | Shows the maximum number of users who established concurrent anonymous connections using the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Maximum CAL Count for Authenticated Users | Shows the maximum count of licenses used simultaneously by the Web service for authenticated connections. | PERF_COUNTER_RAWCOUNT |
| Maximum CAL Count for SSL Connections | Shows the maximum count of licenses used simultaneously by the Web service for SSL connections. | PERF_COUNTER_RAWCOUNT |
| Maximum CGI Requests | Shows the maximum number of CGI requests simultaneously processed by the Web service. | PERF_COUNTER_RAWCOUNT |
| Maximum Connections | Shows the maximum number of simultaneous connections established with the Web service. | PERF_COUNTER_RAWCOUNT |
| Maximum ISAPI Extension Requests | Shows the maximum number of extension requests simultaneously processed by the Web service. | PERF_COUNTER_RAWCOUNT |
| Maximum Non-Anonymous Users | Shows the maximum number of users who established concurrent non-anonymous connections using the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Measured Async I/O Bandwidth Usage | Shows the measured bandwidth of asynchronous I/O, averaged over one minute. | PERF_COUNTER_RAWCOUNT |
| Mkcol Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the MKCOL method were made. MKCOL requests are used to create directories on the server. | PERF_COUNTER_COUNTER |
| Move Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the MOVE method were made. MOVE requests are used for moving files and directories. | PERF_COUNTER_COUNTER |
| Non-Anonymous Users/sec | Shows the rate, in incidents per second, at which users were making non-anonymous connections using the Web service. | PERF_COUNTER_COUNTER |
| Not Found Errors/sec | Shows the rate, in incidents per second, of errors due to requests that could not be satisfied by the server because the requested document could not be found. These are generally reported as an HTTP 404 error code to the client. | PERF_COUNTER_COUNTER |
| Options Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the OPTIONS method were made. | PERF_COUNTER_COUNTER |
| Other Request Methods/sec | Shows the rate, in incidents per second, at which HTTP requests were made that do not use the OPTIONS, GET, HEAD, POST, PUT, DELETE, TRACE, MOVE, COPY, MKCOL, PROPFIND, PROPPATCH, MS-SEARCH, LOCK, or UNLOCK methods. These may include LINK or other methods supported by gateway applications. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Post Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the POST method were made. POST requests are generally used for forms or gateway requests. | PERF_COUNTER_COUNTER |
| Propfind Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the PROPFIND method were made. PROPFIND requests retrieve property values on files and directories. | PERF_COUNTER_COUNTER |
| Proppatch Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the PROPPATCH method were made. PROPPATCH requests set property values on files and directories. | PERF_COUNTER_COUNTER |
| Put Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the PUT method were made. The PUT method requests that the document sent to the server be stored under the supplied Internet address. | PERF_COUNTER_COUNTER |
| Search Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the MS-SEARCH method were made. SEARCH requests are used to query the server to find resources that match a set of conditions provided by the client. | PERF_COUNTER_COUNTER |
| Service Uptime | Shows the uptime for the Web service since it was last start started. | PERF_COUNTER_RAWCOUNT |
| Total Anonymous Users | Shows the total number of users who established an anonymous connection with the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Blocked Bandwidth Bytes | Shows the total number of bytes that were temporarily blocked due to bandwidth throttling settings (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Bytes Received | Shows the number of data bytes that were received by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Bytes Sent | Shows the number of data bytes that were sent by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Bytes Transferred | Shows the total bytes that were either received or sent by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total CGI Requests | Shows the total number of CGI requests. CGI requests are custom gateway executable files (.exe) that the administrator can install to add forms processing or other dynamic data sources. CGI requests initiate a process on the server that can be a large drain on server resources. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Connection Attempts (all instances) | Shows the number of connections that were attempted using the Web service (counted since service startup). This counter is for all instances listed. | PERF_COUNTER_RAWCOUNT |
| Total Copy Requests | Shows the number of HTTP requests using the COPY method (counted since service startup). COPY requests are used for copying files and directories. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Total Count of Failed CAL Requests for Authenticated Users | Shows the number of HTTP requests that failed due to a license being unavailable for an authenticated user. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total count of failed CAL requests for SSL connections | Shows the total count of HTTP requests that failed due to a license being unavailable for SSL connections. | PERF_COUNTER_RAWCOUNT |
| Total Delete Requests | Shows the number of HTTP requests using the DELETE method (counted since service startup). DELETE requests are generally used for file removals. | PERF_COUNTER_RAWCOUNT |
| Total Files Received | Shows the total number of files received by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Files Sent | Shows the total number of files sent by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Files Transferred | Shows the sum of Files Sent and Files Received. This is the total number of files transferred by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Get Requests | Shows the total number of HTTP requests using the GET method (counted since service startup). GET requests are generally used for basic file retrievals or image maps, though they can be used with forms. | PERF_COUNTER_RAWCOUNT |
| Total Head Requests | Shows the total number of HTTP requests using the HEAD method (counted since service startup). HEAD requests generally indicate that a client is querying the state of a document they already have to see if it needs to be refreshed. | PERF_COUNTER_RAWCOUNT |
| Total ISAPI Extension Requests | Shows the total number of ISAPI Extension Requests. ISAPI Extension Requests are custom gateway dynamic-link libraries (DLLs) that the administrator can install to add forms processing or other dynamic data sources. Unlike CGI requests, ISAPI requests are simple calls to a DLL routine, thus they are better suited to high performance gateway applications. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Lock Requests | Shows the total number of HTTP requests using the LOCK method (counted since service startup). LOCK requests are used to lock a file for one user so that only that user can modify the file. | PERF_COUNTER_RAWCOUNT |
| Total Locked Errors | Shows the total number of requests that could not be satisfied by the server because the requested was locked. These are generally reported as an HTTP 423 error code to the client. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Logon Attempts | Shows the total number of logons that have been attempted using the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Method Requests | Shows the total number of all HTTP requests (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Method Requests/sec | Shows the rate, in incidents per second, at which all HTTP requests were made. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Total Mkcol Requests | Shows the total number of HTTP requests using the MKCOL method (counted since service startup). MKCOL requests are used to create directories on the server. | PERF_COUNTER_RAWCOUNT |
| Total Move Requests | Shows the total number of HTTP requests using the MOVE method (counted since service startup). MOVE requests are used for moving files and directories. | PERF_COUNTER_RAWCOUNT |
| Total Non-Anonymous Users | Shows the total number of users who established a non-anonymous connection with the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Not Found Errors | Shows the total number of requests that could not be satisfied by the server because the requested document could not be found. These are generally reported as an HTTP 404 error code to the client. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Options Requests | Shows the total number of HTTP requests using the OPTIONS method (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Other Request Methods | Shows the total number of HTTP requests that are not OPTIONS, GET, HEAD, POST, PUT, DELETE, TRACE, MOVE, COPY, MKCOL, PROPFIND, PROPPATCH, MS-SEARCH, LOCK, or UNLOCK methods (counted since service startup). These may include LINK or other methods supported by gateway applications. | PERF_COUNTER_RAWCOUNT |
| Total Post Requests | Shows the total number of HTTP requests using the POST method (counted since service startup). POST requests are generally used for forms or gateway requests. | PERF_COUNTER_RAWCOUNT |
| Total Propfind Requests | Shows the total number of HTTP requests using the PROPFIND method (counted since service startup). PROPFIND requests retrieve property values on files and directories. | PERF_COUNTER_RAWCOUNT |
| Total Proppatch Requests | Shows the total number of HTTP requests using the PROPPATCH method (counted since service startup). PROPPATCH requests set property values on files and directories. | PERF_COUNTER_RAWCOUNT |
| Total Put Requests | Shows the total number of HTTP requests using the PUT method (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Search Requests | Shows the total number of HTTP requests using the MS-SEARCH method (counted since service startup). SEARCH requests are used to query the server to find resources that match a set of conditions provided by the client. | PERF_COUNTER_RAWCOUNT |
| Total Trace Requests | Shows the total number of HTTP requests using the TRACE method (counted since service startup). TRACE requests allow the client to see what is being received at the end of the request chain and to use the information for diagnostic purposes. | PERF_COUNTER_RAWCOUNT |
| Total Unlock Requests | Shows the total number of HTTP requests using the UNLOCK method (counted since service startup). UNLOCK requests are used to remove locks from files. | PERF_COUNTER_RAWCOUNT |
| Trace Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the TRACE method were made. TRACE requests allow the client to see what is being received at the end of the request chain and to use the information for diagnostic purposes. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Unlock Requests/sec | Shows the rate, in incidents per second, at which HTTP requests using the UNLOCK method were made. UNLOCK requests are used to remove locks from files. | PERF_COUNTER_COUNTER |

Web Service Cache Object

# Web Service Cache Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Web Service Cache object counters installed with Internet Information Services monitor file transfer rates, bandwidth usage, and connection rates.

You can view performance data for all instances of this object (using the _Total instance) or for specific instances, such as the Default Web Site or Administration Web Site instances.

In addition to these counters, counters supplied by the Internet Information Services Global performance object combine data for the Web service with the performance data they report for IIS as a whole. For more information, see the Internet Information Services Global Object.

| Counter Name | Description | Counter Type |
|---|---|---|
| Anonymous Users/sec | Shows the rate at which users are making anonymous connections using the Web service. | PERF_COUNTER_COUNTER |
| Bytes Received/sec | Showsthe rate that data bytes are received by the Web service. | PERF_COUNTER_BULK_COUNT |
| Bytes Sent/sec | Shows the rate that data bytes are sent by the Web service. | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the sum of Web Service\Bytes Sent/sec and Web Service\Bytes Received/sec. This is the total rate of bytes transferred by the Web service. | PERF_COUNTER_BULK_COUNT |
| CGI Requests/sec | Shows the rate at which Common Gateway Interface (CGI) requests are simultaneously being processed by the Web service. | PERF_COUNTER_COUNTER |
| Connection Attempts/sec | Shows the rate at which connections using the Web service are being attempted. | PERF_COUNTER_COUNTER |
| Copy Requests/sec | Shows the rate at which HTTP requests using the COPY method are made. Copy requests are used for copying files and directories | PERF_COUNTER_COUNTER |
| Current Anonymous Users | Shows the number of users who currently have an anonymous connection using the Web service. | PERF_COUNTER_RAWCOUNT |
| Current Blocked Async I/O Requests | Shows current requests that are temporarily blocked due to bandwidth throttling settings. | PERF_COUNTER_RAWCOUNT |
| Current CAL count for authenticated users | Shows the current count of licenses used simultaneously by the Web service for authenticated connections. | PERF_COUNTER_RAWCOUNT |
| Current CAL count for SSL connections | Shows the current count of licenses used simultaneously by the Web service for SSL connections. | PERF_COUNTER_RAWCOUNT |
| Current CGI Requests | Shows the current number of CGI requests that are simultaneously being processed by the Web service. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Current Connections | Shows the current number of connections established with the Web service. | PERF_COUNTER_RAWCOUNT |
| Current ISAPI Extension Requests | Shows the current number of Extension requests that are simultaneously being processed by the Web service. | PERF_COUNTER_RAWCOUNT |
| Current NonAnonymous Users | Shows the number of users who currently have a non-anonymous connection using the Web service. | PERF_COUNTER_RAWCOUNT |
| Delete Requests/sec | Shows the rate at which HTTP requests using the DELETE method are made. Delete requests are generally used for file removals. | PERF_COUNTER_COUNTER |
| Files Received/sec | Shows the rate at which files are received by the Web service. | PERF_COUNTER_COUNTER |
| Files Sent/sec | Shows the rate at which files are sent by the Web service. | PERF_COUNTER_COUNTER |
| Files/sec | Shows the rate at which files are transferred, that is, sent and received by the Web service. | PERF_COUNTER_COUNTER |
| Get Requests/sec | Shows the rate at which HTTP requests using the GET method are made. Get requests are generally used for basic file retrievals or image maps, though they can be used with forms. | PERF_COUNTER_COUNTER |
| Head Requests/sec | Shows the rate at which HTTP requests using the HEAD method are made. Head requests generally indicate a client is querying the state of a document they already have to see if it needs to be refreshed. | PERF_COUNTER_COUNTER |
| ISAPI Extension Requests/sec | Shows the rate at which ISAPI Extension requests are simultaneously being processed by the Web service. | PERF_COUNTER_COUNTER |
| Lock Requests/sec | Shows the rate at which HTTP requests using the LOCK method are made. Lock requests are used to lock a file for one user so that only that user can modify the file. | PERF_COUNTER_COUNTER |
| Locked Errors/sec | Shows the rate of errors due to requests that couldn't be satisfied by the server because the requested document was locked. These are generally reported as an HTTP 423 error code to the client. | PERF_COUNTER_COUNTER |
| Logon Attempts/sec | Shows the rate at which logons using the Web service are being attempted. | PERF_COUNTER_COUNTER |
| Maximum Anonymous Users | Shows the maximum number of users who established concurrent anonymous connections using the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Maximum CAL count for authenticated users | Shows the maximum count of licenses used simultaneously by the Web service for authenticated connections. | PERF_COUNTER_RAWCOUNT |
| Maximum CAL count for SSL connections | Shows the maximum count of licenses used simultaneously by the Web service for SSL connections. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Maximum CGI Requests | Shows the maximum number of CGI requests simultaneously processed by the Web service. | PERF_COUNTER_RAWCOUNT |
| Maximum Connections | Shows the maximum number of simultaneous connections established with the Web service. | PERF_COUNTER_RAWCOUNT |
| Maximum ISAPI Extension Requests | Shows the maximum number of Extension requests simultaneously processed by the Web service. | PERF_COUNTER_RAWCOUNT |
| Maximum NonAnonymous Users | Shows the maximum number of users who established concurrent non-anonymous connections using the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Measured Async I/O Bandwidth Usage | Shows the measured bandwidth of asynchronous I/O averaged over a minute. | PERF_COUNTER_RAWCOUNT |
| Mkcol Requests/sec | Shows the rate at which HTTP requests using the MKCOL method are made. MKCOL requests are used to create directories on the server. | PERF_COUNTER_COUNTER |
| Move Requests/sec | Shows the rate at which HTTP requests using the MOVE method are made. MOVE requests are used for moving files and directories. | PERF_COUNTER_COUNTER |
| NonAnonymous Users/sec | Shows the rate at which users are making nonanonymous connections using the Web service. | PERF_COUNTER_COUNTER |
| Not Found Errors/sec | Shows the rate of errors due to requests that couldn't be satisfied by the server because the requested document could not be found. These are generally reported as an HTTP 404 error code to the client. | PERF_COUNTER_COUNTER |
| Options Requests/sec | Shows the rate at which HTTP requests using the OPTIONS method are made. | PERF_COUNTER_COUNTER |
| Other Request Methods/sec | Shows the rate at which HTTP requests are made that do not use the OPTIONS, GET, HEAD, POST, PUT, DELETE, TRACE, MOVE, COPY, MKCOL, PROPFIND, PROPPATCH, MS-SEARCH, LOCK or UNLOCK methods. These may include LINK or other methods supported by gateway applications. | PERF_COUNTER_COUNTER |
| Post Requests/sec | Shows the rate at which HTTP requests using the POST method are made. POST requests are generally used for forms or gateway requests. | PERF_COUNTER_COUNTER |
| Propfind Requests/sec | Shows the rate at which HTTP requests using the PROPFIND method are made. PROPFIND requests retrieve property values on files and directories. | PERF_COUNTER_COUNTER |
| Proppatch Requests/sec | Shows the rate at which HTTP requests using the PROPPATCH method are made. PROPPATCH requests set property values on files and directories. | PERF_COUNTER_COUNTER |
| Put Requests/sec | Shows the rate at which HTTP requests using the PUT method are made. The PUT method requests that the document sent to the server be stored under the supplied Internet address. | PERF_COUNTER_COUNTER |
| Search Requests/sec | Shows the rate at which HTTP requests using the MS-SEARCH method are made. Search requests are used to query the server to find resources that match a set of conditions provided by the client. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Total Allowed Async I/O Requests | Shows the total number of requests allowed by bandwidth throttling settings (counted since service startup). When bandwidth throttling is defined, the number of allowed user requests is restricted. | PERF_COUNTER_RAWCOUNT |
| Total Anonymous Users | Shows the total number of users who established an anonymous connection with the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Blocked Async I/O Requests | Shows the number of total requests temporarily blocked due to bandwidth throttling settings (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total CGI Requests | Shows the total number of CGI requests. CGI requests are custom gateway executables (.exe) the administrator can install to add forms processing or other dynamic data sources. CGI requests initiate a process on the server which can be a large drain on server resources. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Connection Attempts (all instances) | Shows the number of connections that have been attempted using the Web service (counted since service startup). This counter is for all instances listed. | PERF_COUNTER_RAWCOUNT |
| Total Copy Requests | Shows the number of HTTP requests using the COPY method (counted since service startup). COPY requests are used for copying files and directories | PERF_COUNTER_RAWCOUNT |
| Total count of failed CAL requests for authenticated users | Shows the number of HTTP requests that failed due to a license being unavailable for an authenticated user. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total count of failed CAL requests for SSL connections | Shows the total count of HTTP requests that failed due to a license being unavailable for SSL connections. | PERF_COUNTER_RAWCOUNT |
| Total Delete Requests | Shows the number of HTTP requests using the DELETE method (counted since service startup). Delete requests are generally used for file removals. | PERF_COUNTER_RAWCOUNT |
| Total Files Received | Shows the total number of files received by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Files Sent | Shows the total number of files sent by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Files Transferred | Shows the sum of Files Sent and Files Received. This is the total number of files transferred by the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Get Requests | Shows the number of HTTP requests using the GET method (counted since service startup). GET requests are generally used for basic file retrievals or image maps, though they can be used with forms. | PERF_COUNTER_RAWCOUNT |
| Total Head Requests | Shows the number of HTTP requests using the HEAD method (counted since service startup). Head requests generally indicate a client is querying the state of a document they already have to see if it needs to be refreshed. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Total ISAPI Extension Requests | Shows the total number of ISAPI Extension Requests. ISAPI Extension Requests are custom gateway Dynamic Link Libraries (.dll) the administrator can install to add forms processing or other dynamic data sources. Unlike CGI requests, ISAPI requests are simple calls to a DLL library routine, thus they are better suited to high performance gateway applications. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Lock Requests | Shows the number of HTTP requests using the LOCK method (counted since service startup). LOCK requests are used to lock a file for one user so that only that user can modify the file. | PERF_COUNTER_RAWCOUNT |
| Total Locked Errors | Shows the number of requests that couldn't be satisfied by the server because the requested was locked. These are generally reported as an HTTP 423 error code to the client. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Logon Attempts | Shows the number of logons that have been attempted using the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Method Requests | Shows the number of all HTTP requests (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Method Requests/sec | Shows the rate at which all HTTP requests are made. | PERF_COUNTER_COUNTER |
| Total Mkcol Requests | Shows the number of HTTP requests using the MKCOL method (counted since service startup). MKCOL requests are used to create directories on the server. | PERF_COUNTER_RAWCOUNT |
| Total Move Requests | Shows the number of HTTP requests using the MOVE method (counted since service startup). MOVE requests are used for moving files and directories. | PERF_COUNTER_RAWCOUNT |
| Total NonAnonymous Users | Shows the total number of users who established a non-anonymous connection with the Web service (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Not Found Errors | Shows the number of requests that couldn't be satisfied by the server because the requested document could not be found. These are generally reported as an HTTP 404 error code to the client. The count is the total since service startup. | PERF_COUNTER_RAWCOUNT |
| Total Options Requests | Shows the number of HTTP requests using the OPTIONS method (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Other Request Methods | Shows the number of HTTP requests that are not OPTIONS, GET, HEAD, POST, PUT, DELETE, TRACE, MOVE, COPY, MKCOL, PROPFIND, PROPPATCH, MS-SEARCH, LOCK or UNLOCK methods (counted since service startup). These may include LINK or other methods supported by gateway applications. | PERF_COUNTER_RAWCOUNT |
| Total Post Requests | Shows the number of HTTP requests using the POST method (counted since service startup). POST requests are generally used for forms or gateway requests. | PERF_COUNTER_RAWCOUNT |
| Total Propfind Requests | Shows the number of HTTP requests using the PROPFIND method (counted since service startup). PROPFIND requests retrieve property values on files and directories. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Total Proppatch Requests | Shows the number of HTTP requests using the PROPPATCH method (counted since service startup). PROPPATCH requests set property values on files and directories. | PERF_COUNTER_RAWCOUNT |
| Total Put Requests | Shows the number of HTTP requests using the PUT method (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Rejected Async I/O Requests | Shows the total number of requests rejected due to bandwidth throttling settings (counted since service startup). | PERF_COUNTER_RAWCOUNT |
| Total Search Requests | Shows the number of HTTP requests using the MS-SEARCH method (counted since service startup). Search requests are used to query the server to find resources that match a set of conditions provided by the client. | PERF_COUNTER_RAWCOUNT |
| Total Trace Requests | Shows the number of HTTP requests using the TRACE method (counted since service startup). TRACE requests allow the client to see what is being received at the end of the request chain and use the information for diagnostic purposes. | PERF_COUNTER_RAWCOUNT |
| Total Unlock Requests | Shows the number of HTTP requests using the UNLOCK method (counted since service startup). UNLOCK requests are used to remove locks from files. | PERF_COUNTER_RAWCOUNT |
| Trace Requests/sec | Shows the rate at which HTTP requests using the TRACE method are made. TRACE requests allow the client to see what is being received at the end of the request chain and use the information for diagnostic purposes. | PERF_COUNTER_COUNTER |
| Unlock Requests/sec | Shows the rate at which HTTP requests using the UNLOCK method are made. UNLOCK requests are used to remove locks from files. | PERF_COUNTER_COUNTER |

# Windows Media Station Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Windows Media Station Service performance object consists of counters that provide statistics about the Windows Media Station service, which provides multicasting, distribution, and storage functions for Advanced Systems Format (ASF) streams.

| Counter Name | Description | Counter Type |
|---|---|---|
| Stations | Shows the number of station objects that currently exist on the server. | PERF_COUNTER_RAWCOUNT |
| Controllers | Shows the number of controllers that are currently connected to the server. | PERF_COUNTER_RAWCOUNT |
| Streams | Shows the number of stream objects that currently exist on the server. | PERF_COUNTER_RAWCOUNT |

Windows Media Unicast Service Object

# Windows Media Unicast Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Windows Media Unicast Service performance object consists of counters that provide statistics about the Windows Media Unicast service, which provides unicasting functions for Advanced Systems Format (ASF) streams.

| Counter Name | Description | Counter Type |
|---|---|---|
| Active Live Unicast Streams | Shows the number of live unicast streams that are being streamed. | PERF_COUNTER_RAWCOUNT |
| Active Streams | Shows the number of active files, or streams, currently being sent to the instances of Windows Media Player. This counter provides an overall indicator of system activity. A client is still connected once it has stopped playing a file, because the Windows Media Unicast service maintains the bandwidth allocation to that client for 60 seconds after the client stops playing (this is called the Client Inactivity Time-out period). After the Client Inactivity Time-out period has elapsed, the server actively checks the client's status by periodically sending a message to each client. The server keeps a client connection open as long as the client responds to a message within three minutes (this is called the Client Terminal Time-out). | PERF_COUNTER_RAWCOUNT |
| Active TCP Streams | Shows the number of active Transmission Control Protocol (TCP) streams that are currently being sent to the instances of Windows Media Player. | PERF_COUNTER_RAWCOUNT |
| Active UDP Streams | Shows the number of active User Datagram Protocol (UDP) streams currently being sent to the instances of Windows Media Player. | PERF_COUNTER_RAWCOUNT |
| Aggregate Read Rate | Shows the sum, in bytes per second, of the read rates for all files being sent to the instances of Windows Media Player. This counter indicates the speed at which the server is reading data from the disk. The graph usually appears jagged because the block read time is shorter than the block sends. | PERF_COUNTER_BULK_COUNT |
| Aggregate Send Rate | Shows the sum, in bytes per second, of the send rates for all files being sent to the instances of Windows Media Player. This counter indicates the speed at which the server is sending data to the players. The graph must appear relatively smooth; a jagged graph can indicate that streams are battling for bandwidth. | PERF_COUNTER_BULK_COUNT |
| Allocated Bandwidth | Shows the amount of bandwidth that the server allocates, based on the number of instances of Windows Media Player that are currently connected. Generally, clients connected to Windows Media Services that are not receiving streams are still allocated bandwidth. If a Windows Media Player has had bandwidth allocated to it, but does not send a command during the Client Inactivity Time-out period, its bandwidth is deallocated. The Client Inactivity Time-out period is 60 seconds. | PERF_COUNTER_RAWCOUNT |
| Authentication Requests | Shows the number of times an authentication plug-in is called to authenticate a client. Depending on the protocol in use — either HTTP or Microsoft Media Server (MMS) — a single client may be authenticated once or several times as it accesses each piece of unicast content. This is a general indicator of how often the server uses authentication plug-ins. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Authentications Denied | Shows the number of times that clients are denied access to unicast content by authentication plug-ins. Clients are denied access by an authentication plug-in when their IDs cannot be verified, no user accounts exist, or the authentication plug-in is not working. | PERF_COUNTER_COUNTER |
| Authorization Requests | Shows the number of times that an authorization plug-in is called to authorize a client. Each client action—such as opening or playing unicast content—is separately authorized, so the total number of authorization requests is greater than the number of connected clients. This is a general indicator of how often the server uses authorization plug-ins. | PERF_COUNTER_COUNTER |
| Authorizations Refused | Shows the number of times that clients are denied access to unicast content by authorization plug-ins. Plug-ins deny access to clients based on their function (for example, a billing plug-in may deny client access to unicast content if the user account contains insufficient funds). | PERF_COUNTER_COUNTER |
| Connected Clients | Shows the number of client programs that are currently connected. This indicates all instances of Windows Media Player that are connected to the system. This counter includes clients that are playing streamed content, clients in paused and connected states, and clients that the server has not yet detected as being disconnected. The latter can occur if a client has lost power, or has been disconnected from the network and has not been able to notify the server that it has been disconnected. | PERF_COUNTER_RAWCOUNT |
| Connection Rate | Shows the rate at which clients are connecting to the server. This is used to determine the number of instantaneous connections being serviced by the server. The default is 10 connections per second. This counter is useful for correlating client connections with the utilization of system resources. | PERF_COUNTER_COUNTER |
| HTTP Streams | Shows the number of active HTTP streams that are currently being sent to instances of Windows Media Player. This counter reports the sum of the values of HTTP Streams Reading Body and HTTP Streams Reading Header. | PERF_COUNTER_RAWCOUNT |
| HTTP Streams Reading Body | Shows the number of connected clients that have read the file header and are actively streaming unicast content via HTTP. | PERF_COUNTER_RAWCOUNT |
| HTTP Streams Reading Header | Shows the number of clients that are connected to the server via HTTP and are reading a file header, but are not yet streaming the unicast content. | PERF_COUNTER_RAWCOUNT |
| Late Reads | Shows the number of late read completions per second. A *late read* is a disk read operation that takes significantly longer than expected to complete. Typically, this counter is nonzero only when the server is under a very heavy load. If this counter is often nonzero, the system might not be properly configured (for example, you might need additional hard disk drives or a lower setting for the maximum number of clients), or other applications might be competing with Windows Media Services for use of the disk. | PERF_COUNTER_COUNTER |
| Pending Connections | Shows the number of clients that are attempting to connect to the server but are not yet connected. This number may be high if the server is running near maximum capacity and cannot process a large number of connection requests in a timely manner. | PERF_COUNTER_RAWCOUNT |
| Plugin Errors | Shows the number of times that the plug-ins failed to perform their function (for example, a plug-in could not reach its user database, or the plug-in crashed). | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Plugin Events | Shows the number of events reported to plug-ins. This is an indicator of how often the server uses external plug-ins. | PERF_COUNTER_COUNTER |
| Scheduling Rate | Shows the rate, in seconds, at which requests are being made for tasks to be scheduled. Scheduled tasks include reading data from the disk and writing data to the network. The scheduling rate is roughly proportional to the rate at which packets are being sent by the server; it does not represent a one-to-one correspondence. | PERF_COUNTER_COUNTER |
| Stream Errors | Shows the number of errors that occur per second. Stream errors represent the number of stream data packets that are discarded by the server. They are introduced by the server when it cannot meet the demand for data and must throw packets away to avoid running behind schedule indefinitely. Stream errors show up most often after late reads occur. They indicate that the system is not configured properly, or other applications are competing for system resources. Heavy network traffic can also contribute to stream errors. | PERF_COUNTER_COUNTER |
| Stream Terminations | Shows the rate at which streams are terminated due to errors. Stream terminations indicate that the system is not configured properly, or the file being streamed is corrupted. The server unilaterally terminates a stream under certain circumstances — most commonly, when the server is running significantly behind schedule. If the server must throw away several packets in a row from a given stream to remain on schedule, it terminates the stream. Streams can also be terminated if invalid data is encountered during file streaming. | PERF_COUNTER_COUNTER |
| UDP Resend Requests | Shows the number of times clients ask the Windows Media Services server to re-send data packets that were not received. This value may be high when the server cannot reliably send packets via UDP. This is a good indicator of server or network overload. | PERF_COUNTER_COUNTER |
| UDP Resends Sent | Shows the number of UDP re-send requests that are processed by the Windows Media Services server. If the server is under a heavy load, not all UDP re-send requests are processed. | PERF_COUNTER_COUNTER |

Windows Media Station Service Object

# WINS Server Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The WINS Server performance object reports the activity of a computer that is running Windows Internet Name Service (WINS). This object's counters are cleared each time you start and stop the service. WINS provides a dynamic database service that can register and resolve NetBIOS names to the IP addresses that are used on your network. The Windows Server 2003 family provides WINS, which enables the server computer to act as a NetBIOS name server and to register and resolve names for WINS-enabled client computers on your network, as described in the NetBIOS over TCP/IP standards.

| Counter Name | Description | Counter Type |
|---|---|---|
| Unique Registrations/sec | Shows the rate, in incidents per second, at which unique registrations were received by the server. | PERF_COUNTER_COUNTER |
| Group Registrations/sec | Shows the rate, in incidents per second, at which group registrations were received by the server. | PERF_COUNTER_COUNTER |
| Total Number of Registrations/sec | Shows the total rate, in incidents per second, at which registrations were received by the server. This rate is the sum of the unique and group registration rates. | PERF_COUNTER_COUNTER |
| Unique Renewals/sec | Shows the rate, in incidents per second, at which unique renewals were received by the server. | PERF_COUNTER_COUNTER |
| Group Renewals/sec | Shows the rate, in incidents per second, at which group renewals were received by the server. | PERF_COUNTER_COUNTER |
| Total Number of Renewals/sec | Shows the total rate, in incidents per second, at which renewals were received by the server. This rate is the sum of the unique and group renewal rates. | PERF_COUNTER_COUNTER |
| Releases/sec | Shows the rate, in incidents per second, at which releases were received by the server. | PERF_COUNTER_COUNTER |
| Queries/sec | Shows the rate, in incidents per second, at which queries were received by the server. | PERF_COUNTER_COUNTER |
| Unique Conflicts/sec | Shows the rate, in incidents per second, at which unique registrations or renewals that were received by the server resulted in conflicts with records in the database. | PERF_COUNTER_COUNTER |
| Group Conflicts/sec | Shows the rate, in incidents per second, at which group registrations that were received by the server resulted in conflicts with records in the database. | PERF_COUNTER_COUNTER |
| Total Number of Conflicts/sec | Shows the total rate, in incidents per second, at which conflicts were received by the server. This rate is the sum of the unique and group conflict rates. | PERF_COUNTER_COUNTER |
| Successful Releases/sec | Shows the rate, in incidents per second, of successful releases. | PERF_COUNTER_COUNTER |
| Failed Releases/sec | Shows the rate, in incidents per second, of failed releases. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Successful Queries/sec | Shows the rate, in incidents per second, of successful queries. | PERF_COUNTER_COUNTER |
| Failed Queries/sec | Shows the rate, in incidents per second, of failed queries. | PERF_COUNTER_COUNTER |

# WMI Objects Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The WMI Objects performance object consists of counters that describe the activity of Windows Management Instrumentation (WMI) objects. WMI has a reverse adapter that makes WMI performance data visible in System Monitor. WMI performance data only appears when the reverse adapter for WMI is installed.

| **Counter Name** | **Description** | **Counter Type** |
|---|---|---|
| HiPerfClasses | Shows the number of whole classes that the reverse adapter obtained from WMI. | PERF_COUNTER_LARGE_RAWCOUNT |
| HiPerfValidity | Shows the validity of shared memory held in the performance structure. A value of 1 indicates that data is valid and a value of 0 indicates that data is invalid. | PERF_COUNTER_RAWCOUNT |

# WSRM Policy Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The WSRM Policy performance object, installed with Windows System Resource Manager (WSRM), consists of a counter that provides the percentage of CPU cycles of the entire system that are used by the current resource-allocation policy, since the time the policy was set to manage the behavior of WSRM. (The resource-allocation policy is an ordered list of resource allocations that specifies the management behavior of WSRM at a given time.) Each WSRM Policy object will have one instance whose name is the same as the current active policy.

| Counter Name | Description | Counter Type |
|---|---|---|
| System Managed CPU % | The percentage of CPU cycles managed by WSRM that are used by the combined process-matching criteria. A process-matching criterion is the mechanism in WSRM that matches running processes to a resource-allocation policy. | PERF_SAMPLE_FRACTION |

# WSRM Process Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The WSRM Process performance object, installed with Windows System Resource Manager (WSRM), consists of a counter that provides the percentage of total managed CPU cycles used by a particular process, since the time that the resource-allocation policy was set to manage the behavior of WSRM. (The resource-allocation policy is an ordered list of resource allocations that specifies the management behavior of WSRM at a given time.) One instance of this object exists for every managed process. Note that Total Managed CPU cycles is the sum of the CPU cycles for all the managed processes.

| Counter Name | Description | Counter Type |
|---|---|---|
| Actual Managed CPU % | The percentage of total managed CPU cycles that have been used by this process-matching criterion. A process-matching criterion is the mechanism in WSRM that matches running processes to a resource-allocation policy. | PERF_RAW_FRACTION |

# WSRM Process Matching Criteria Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The WSRM process-matching criteria performance object, installed with Windows System Resource Manager (WSRM), consists of counters that monitor the CPU usage and memory usage of the processes matched by the process-matching criteria. The criteria are included in the managing resource-allocation policy. Each object will have as many instances as the number of process-matching criteria within the current active policy.

| Counter Name | Description | Counter Type |
|---|---|---|
| Actual Managed CPU % | The percentage of total managed CPU cycles that have been used by this process-matching criterion. A process-matching criterion is the mechanism in WSRM that matches running processes to a resource-allocation policy. | PERF_RAW_FRACTION |
| Managed CPU % | The percentage of managed CPU cycles used by this process-matching criterion between the last process samplings. | PERF_SAMPLE_FRACTION |
| Page File (MB) | The total size of page files used by this process. | PERF_COUNTER_RAWCOUNT |
| Process Count | The number of processes associated with this process-matching criterion. | PERF_COUNTER_RAWCOUNT |
| Target Managed CPU % | The percentage of total managed CPU cycles allocated to this process-matching criterion. | PERF_RAW_FRACTION |
| Working Set (MB) | The total size of the set of memory pages used by the threads of this process. | PERF_COUNTER_RAWCOUNT |

# ACS/RSVP Interfaces Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

ACS/RSVP Interfaces performance object counters report statistics about Resource Reservation Protocol (RSVP) activity, flow, bandwidth, RSVP messages sent, and so on for a specific interface or IP address. The ACS/RSVP Interfaces object is available if QoS Admission Control Service (QoS ACS) or RSVP is running and there is one object for each IP address on the system.

| Counter Name | Description | Counter Type |
|---|---|---|
| Admitted Bandwidth | Shows the total admitted bandwidth on this interface, in bits per second. | PERF_COUNTER_RAWCOUNT |
| Blocked RESVs | Shows the number of blockaded reservations that failed due to failed reservations that have not been removed from this node. For more information about blockade states, see RFC 2205. | PERF_COUNTER_RAWCOUNT |
| General Failures | Shows the total number of non-admission control errors that have occurred on this interface. For more information about other traffic control failures, see RFC 2205. | PERF_COUNTER_RAWCOUNT |
| Maximum Admitted Bandwidth | Shows the highest amount of allocated bandwidth admitted on the interface during the period in which QoS ACS or RSVP has been running. | PERF_COUNTER_RAWCOUNT |
| Number of Active Flows | Shows the number of reserved flows that were installed and maintained by RSVP on this interface. | PERF_COUNTER_RAWCOUNT |
| Number of Incoming Messages Dropped | Shows the number of incoming or received messages that were dropped due to syntax errors, protocol violations, and other errors. | PERF_COUNTER_RAWCOUNT |
| Number of Outgoing Messages Dropped | Shows the number of outgoing messages that were dropped due to errors while sending. | PERF_COUNTER_RAWCOUNT |
| PATH ERR Messages Received | Shows the total number of PATH ERR messages that were received on this interface. This number indicates the number of times that a PATH has been rejected by a remote host. | PERF_COUNTER_RAWCOUNT |
| PATH ERR Messages Sent | Shows the total number of PATH ERR rejection messages that were sent by the QoS ACS or RSVP service. The PATH error messages indicate an error in response to the PATH message. | PERF_COUNTER_RAWCOUNT |
| PATH Messages Received | Shows the total number of PATH messages that have been received on this interface. | PERF_COUNTER_RAWCOUNT |
| PATH Messages Sent | Shows the total number of PATH messages that were sent by the QoS ACS or RSVP service on this the interface. | PERF_COUNTER_RAWCOUNT |
| PATH State Block Timeouts | Shows the total number of times that the RSVP PATH state timed out. This happens when no PATH messages were received within the designated timeout period. This error message can be caused by a route change. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| PATH TEAR Messages Received | Shows the total number of PATH TEAR messages that have been received on the interface. A PATH TEAR message removes the PATH state along the route and in this host. | PERF_COUNTER_RAWCOUNT |
| PATH TEAR Messages Sent | Shows the total number of PATH TEAR messages that were sent on the interface to tear down an RSVP PATH state in the network. | PERF_COUNTER_RAWCOUNT |
| Policy Control Failures | Shows the total number of RSVP requests that were not admitted on this interface due to a conflict with policy settings. | PERF_COUNTER_RAWCOUNT |
| Receive Messages Errors - Big Messages | Shows the total number of incoming RSVP messages that were dropped because they were bigger than the maximum configured RSVP message size. | PERF_COUNTER_RAWCOUNT |
| Receive Messages Errors - No Memory | Shows the total number of incoming RSVP messages that were dropped due to insufficient memory. | PERF_COUNTER_RAWCOUNT |
| Resource Control Failures | Shows the number of reservations that failed due to the lack of resources. | PERF_COUNTER_RAWCOUNT |
| RESV CONFIRM Messages Received | Shows the total number of RESV CONFIRM messages that have been received on this interface. | PERF_COUNTER_RAWCOUNT |
| RESV CONFIRM Messages Sent | Shows the total number of RESV CONFIRM messages that were sent on this interface in response to RESV messages that were sent by remote hosts. | PERF_COUNTER_RAWCOUNT |
| RESV ERR Messages Received | Shows the total number of RESV ERR messages that were received on this interface by the QoS ACS or RSVP service, rejecting incoming RESV messages. An RESV ERR message indicates an error in response to the RESV. | PERF_COUNTER_RAWCOUNT |
| RESV ERR Messages Sent | Shows the total number of RESV errors that were sent on this interface. This number indicates how many reservations have been rejected by the network. | PERF_COUNTER_RAWCOUNT |
| RESV Messages Received | Shows the total number of RESV messages that have been received on this interface. | PERF_COUNTER_RAWCOUNT |
| RESV Messages Sent | Shows the total number of RESV messages that were sent by the ACS/RSVP service on this the interface. | PERF_COUNTER_RAWCOUNT |
| RESV State Block Timeouts | Shows the total number of times that the RSVP RESV state timed out. This happens when no RESV messages are received within the designated timeout period. This error message can be caused by a route change. | PERF_COUNTER_RAWCOUNT |
| RESV TEAR Messages Received | Shows the total number of RESV TEAR messages that have been received on the interface. An RESV TEAR message removes the reservation along the route and in this host. | PERF_COUNTER_RAWCOUNT |
| RESV TEAR Messages Sent | Shows the total number of RESV TEAR messages that were sent on the interface to tear down an RESV state in the network. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Send Messages Errors - Big Messages | Shows the total number of outgoing RSVP messages that were dropped because they were bigger than the maximum configured RSVP message size. | PERF_COUNTER_RAWCOUNT |
| Send Messages Errors - No Memory | Shows the total number of outgoing RSVP messages that were dropped due to insufficient memory. | PERF_COUNTER_RAWCOUNT |
| Signaling Bytes Received | Shows the total, in bytes, of the RSVP signaling traffic that has been received by the ACS/RSVP service on this interface. | PERF_COUNTER_RAWCOUNT |
| Signaling Bytes Sent | Shows the total, in bytes, of RSVP signaling traffic that was sent by the ACS/RSVP service on this interface. | PERF_COUNTER_RAWCOUNT |

# ACS/RSVP Service Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The ACS/RSVP Service performance object reports statistics about the Resource Reservation Protocol (RSVP) service and about local applications that use Quality of Service (QoS). The ACS/RSVP Service object is available even if the RSVP service is not running.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes in QoS Notifications | Shows a running total of the number of bytes that were delivered in QoS notifications to applications that use QoS. | PERF_COUNTER_RAWCOUNT |
| Failed QoS Requests | Shows the number of QoS requests that were generated by applications that use QoS and that were rejected by the ACS/RSVP service. Failed QoS requests can be caused by invalid QoS requests. | PERF_COUNTER_RAWCOUNT |
| Failed QoS Sends | Shows the number of QoS notifications from the ACS/RSVP service that could not be sent to the QoS applications. Failed QoS sends can be caused by terminated applications. | PERF_COUNTER_RAWCOUNT |
| Network Interfaces | Shows the number of local network interfaces (IP addresses) that are visible to, and used by, the RSVP service. | PERF_COUNTER_RAWCOUNT |
| Network Sockets | Shows the total number of raw sockets that were opened for the purpose of RSVP signaling. | PERF_COUNTER_RAWCOUNT |
| QoS notifications | Shows the number of QoS notifications that were delivered to applications that use QoS by the QoS RSVP service. | PERF_COUNTER_RAWCOUNT |
| QoS Sockets | Shows the number of sockets that use QoS. | PERF_COUNTER_RAWCOUNT |
| QoS-Enabled Receivers | Shows the number of RESV messages sent for receivers that use QoS. | PERF_COUNTER_RAWCOUNT |
| QoS-Enabled Senders | Shows the number of PATH messages sent for senders that use QoS. | PERF_COUNTER_RAWCOUNT |
| RSVP Sessions | Shows the current number of active RSVP sessions on the ACS/RSVP service. | PERF_COUNTER_RAWCOUNT |
| Timers | Shows the number of timer events that are scheduled to take place. This counter shows the activity level of the ACS/RSVP service. | PERF_COUNTER_RAWCOUNT |

Counters by Feature

# Gateway Service for NetWare Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Gateway Service for NetWare performance object consists of counters that measure packet transmission rates and activity of the Gateway for NetWare service.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Received/sec | Shows the rate of bytes coming in to the Redirector from the network. It includes all application data in addition to network protocol information (such as packet headers.) | PERF_COUNTER_BULK_COUNT |
| Bytes Total/sec | Shows the rate the Redirector is processing data bytes. It includes all application and file data in addition to protocol information. | PERF_COUNTER_BULK_COUNT |
| Bytes Transmitted/sec | Shows the rate at which bytes are leaving the Redirector to the network. It includes all application in addition to network protocol information. | PERF_COUNTER_BULK_COUNT |
| Connect NetWare 2.x | Shows the number of connections to NetWare 2.x servers. | PERF_COUNTER_RAWCOUNT |
| Connect NetWare 3.x | Shows the number of connections to NetWare 3.x servers. | PERF_COUNTER_RAWCOUNT |
| Connect NetWare 4.x | Shows the number of connections to NetWare 4.x servers. | PERF_COUNTER_RAWCOUNT |
| File Data Operations/sec | Shows the rate at which the Redirector is processing data operations. One operation includes many bytes but can be reduced because each packet has protocol overhead. You can determine the efficiency of this path by dividing the value of Bytes/sec by this counter to determine the average number of bytes transferred per operation. | PERF_COUNTER_COUNTER |
| File Read Operations/sec | Shows the rate at which applications are asking the Redirector for data. Each call to a file system or similar API call counts as one operation. | PERF_COUNTER_COUNTER |
| File Write Operations/sec | Shows the rate at which applications are sending data to the Redirector. Each call to a file system or similar API call counts as one operation. | PERF_COUNTER_COUNTER |
| Packet Burst IO/sec | Shows the sum of the values of Gateway Services for NetWare\Packet Burst Read NCPs/sec and Gateway Services for NetWare\Packet Burst Write NCPs/sec. | PERF_COUNTER_COUNTER |
| Packet Burst Read NCP Count/sec | Shows the rate of NetWare Core Protocol requests for Packet Burst Read. Packet Burst is a windowing protocol that improves performance. | PERF_COUNTER_COUNTER |
| Packet Burst Read Timeouts/sec | Shows the rate the NetWare Service needs to retransmit a Burst Read Request because the NetWare server took too long to respond. | PERF_COUNTER_COUNTER |
| Packet Burst Write NCP Count/sec | Shows the rate of NetWare Core Protocol requests for Packet Burst Write. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Packet Burst Write Timeouts/sec | Shows the rate at which the NetWare Service needs to retransmit a Burst Write Request because the NetWare server took too long to respond. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate at which the Redirector is receiving packets (SMBs). Network transmissions are divided into packets. The average number of bytes received in a packet can be obtained by dividing the value of Gateway Services for NetWare\Bytes Received/sec by this counter. Some packets received might not contain incoming data, for example an acknowledgment to a write made by the Redirector would count as an incoming packet. | PERF_COUNTER_BULK_COUNT |
| Packets Transmitted/sec | Shows the rate at which the Redirector is sending packets. Network transmissions are divided into packets. The average number of bytes transmitted in a packet can be obtained by dividing the value of Bytes Transmitted/sec by this counter. | PERF_COUNTER_BULK_COUNT |
| Packets/sec | Shows the rate the Redirector is processing data packets. One packet typically includes many bytes but can be reduced because each packet has protocol overhead. You can determine the efficiency of this path by dividing the value of Gateway Services for NetWare\Bytes Total/sec by this counter to determine the average number of bytes transferred/packet. You can also divide this counter by the value of Operations/sec to determine the average number of packets per operation. | PERF_COUNTER_BULK_COUNT |
| Read Operations Random/sec | Shows the rate at which, on a file-by-file basis, nonsequential reads are made. If a read is made using a particular file handle, and then is followed by another read that is not the contiguous next byte, this counter is incremented by one. | PERF_COUNTER_COUNTER |
| Read Packets/sec | Shows the rate at which read packets are being placed on the network. Each time a single packet is sent with a request to read data remotely, this counter is incremented by one. | PERF_COUNTER_COUNTER |
| Server Disconnects | Shows the number of times that a server has disconnected your Redirector. See also Server Reconnects. | PERF_COUNTER_RAWCOUNT |
| Server Reconnects | Shows the number of times the Redirector has had to reconnect to a server to complete a new active request. You can be disconnected by the Server if you remain inactive for too long. Locally even if all your remote files are closed, the Redirector will keep your connections intact for ten minutes. Such inactive connections are called Dormant Connections. Reconnecting is expensive in time. | PERF_COUNTER_RAWCOUNT |
| Server Sessions | Shows the total number of security objects that the Redirector has managed. For example, a logon to a server followed by a network access to the same server will establish one connection, but two sessions. | PERF_COUNTER_RAWCOUNT |
| Write Operations Random/sec | Shows the rate at which, on a file-by-file basis, nonsequential writes are made. | PERF_COUNTER_COUNTER |
| Write Packets/sec | Shows the rate at which writes are being sent to the network. Each time a single packet is sent with a request to write remote data, this counter is incremented by one. | PERF_COUNTER_COUNTER |

# NetBEUI Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NetBEUI performance object consists of counters that measure data transmission for network activity which conforms to the NetBIOS End User Interface (NetBEUI) standard.

| Counter Name | Description | Counter Type |
|---|---|---|
| Bytes Total/sec | Shows the total rate of bytes sent to or received from the network by the protocol, but only counts the bytes in frames (packets) which carry data. This is the sum of the values of Frame Bytes/sec and Datagram Bytes/sec. | PERF_COUNTER_BULK_COUNT |
| Connection Session Timeouts | Shows the number of connections that were dropped due to a session time out. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| | Shows the number of connections that were canceled. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections No Retries | Shows the total count of connections that were successfully made on the first try. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Connections Open | Shows the number of connections currently open for this protocol. This counter shows the current count only and does not accumulate over time. | PERF_COUNTER_RAWCOUNT |
| Connections With Retries | Shows the total count of connections that were made after retrying the attempt. A retry occurs when the first connection attempt failed. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Datagram Bytes Received/sec | Shows the rate at which datagram bytes are received by the computer. A datagram is a connectionless packet whose delivery to a remote computer is not guaranteed. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes Sent/sec | Shows the rate at which datagram bytes are sent from the computer. | PERF_COUNTER_BULK_COUNT |
| Datagram Bytes/sec | Shows the rate at which datagram bytes are processed by the computer. This counter measures datagram bytes that are both received and sent. | PERF_COUNTER_BULK_COUNT |
| Datagrams Received/sec | Shows the rate at which datagrams are received by the computer. | PERF_COUNTER_COUNTER |
| Datagrams Sent/sec | Shows the rate at which datagrams are sent from the computer. | PERF_COUNTER_COUNTER |
| Datagrams/sec | Shows the rate at which datagrams are processed by the computer. This counter measures datagrams that are both received and sent. | PERF_COUNTER_COUNTER |
| Disconnects Local | Shows the number of session disconnections that were initiated by the local computer. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |

| | | |
|---|---|---|
| Disconnects Remote | Shows the number of session disconnections that were initiated by the remote computer. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Expirations Ack | Shows the count of T2 timer expirations. | PERF_COUNTER_RAWCOUNT |
| Expirations Response | Shows the count of T1 timer expirations. | PERF_COUNTER_RAWCOUNT |
| Failures Adapter | Shows the number of connections that were dropped due to an adapter failure. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Link | Shows the number of connections that were dropped due to a link failure. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures No Listen | Shows the number of connections that were rejected because the remote computer was not listening for connection requests. | PERF_COUNTER_RAWCOUNT |
| Failures Not Found | Shows the number of connection attempts that failed because the remote computer could not be found. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Local | Shows the number of connections that failed because of resource problems or shortages on the local computer. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Failures Resource Remote | Shows the number of connections that failed because of resource problems or shortages on the remote computer. This counter is an accumulator and shows a running total. | PERF_COUNTER_RAWCOUNT |
| Frame Bytes Received/sec | Shows the rate at which data bytes are received by the computer. This counter only shows the frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Rejected/sec | Shows the rate at which data bytes are rejected. This counter only shows the bytes in data frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Re-Sent/sec | Shows the rate at which data bytes are re-sent by the computer. This counter only shows the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes Sent/sec | Shows the rate at which data bytes are sent by the computer. This counter only shows the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frame Bytes/sec | Shows the rate at which data bytes are processed by the computer. This counter is the sum of the values of Frame Bytes Received/sec and Frame Bytes Sent/sec. This counter only shows the bytes in frames that carry data. | PERF_COUNTER_BULK_COUNT |
| Frames Received/sec | Shows the rate at which data frames are received by the computer. This counter only shows the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Rejected/sec | Shows the rate at which data frames are rejected. This counter only shows the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames Re-Sent/sec | Shows the rate at which data frames are re-sent by the computer. This counter only shows the frames that carry data. | PERF_COUNTER_COUNTER |

| | | |
|---|---|---|
| Frames Sent/sec | Shows the rate at which data frames are sent by the computer. This counter only shows the frames that carry data. | PERF_COUNTER_COUNTER |
| Frames/sec | Shows the rate at which data frames are processed by the computer. This counter is the sum of the values of Frames Received/sec and Frames Sent/sec and only shows the frames that carry data. | PERF_COUNTER_COUNTER |
| Packets Received/sec | Shows the rate at which packets are received by the computer. This counter shows all packets processed (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets Sent/sec | Shows the rate at which packets are sent by the computer. This counter shows all packets sent by the computer (control as well as data packets). | PERF_COUNTER_COUNTER |
| Packets/sec | Shows the rate at which packets are processed by the computer. This count is the sum of the values of Packets Sent/sec and Packets Received/sec and includes all packets processed (control as well as data packets). | PERF_COUNTER_COUNTER |
| Piggyback Ack Queued/sec | Shows the rate at which piggyback acknowledgments are queued. Piggyback acknowledgments are acknowledgments of received packets that are to be included in the next outgoing packet to the remote computer. | PERF_COUNTER_COUNTER |
| Piggyback Ack Timeouts | Shows the number of times that a piggyback acknowledgment could not be sent because there was no outgoing packet to the remote computer on which to piggyback. If no outgoing packet is sent within the time-out period, then an acknowledgment packet is sent and this counter is incremented. | PERF_COUNTER_RAWCOUNT |
| Window Send Average | Shows the average number of data bytes that were sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |
| Window Send Maximum | Shows the maximum number of data bytes that are sent before waiting for an acknowledgment from the remote computer. | PERF_COUNTER_RAWCOUNT |

NetBEUI Resource Object

# NetBEUI Resource Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The NetBEUI Resource performance object consists of counters that track the use of buffers by the NetBEUI protocol.

| Counter Name | Description | Counter Type |
|---|---|---|
| Times Exhausted | Shows the number of times that all resources (buffers) were in use. The number in parentheses following the resource name is used to identify the resource in Event Log messages. | PERF_COUNTER_RAWCOUNT |
| Used Average | Shows the current number of resources (buffers) in use. The number in parentheses following the resource name is used to identify the resource in Event Log messages. | PERF_COUNTER_RAWCOUNT |
| Used Maximum | Shows the maximum number of NetBEUI resources (buffers) in use at any point in time. This value is useful in sizing the maximum resources provided. The number in parentheses following the resource name is used to identify the resource in Event Log messages. | PERF_COUNTER_RAWCOUNT |

# Network Segment Object

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Network Segment performance object provides network statistics for the local network segment; it is installed by the Network Monitor driver protocol on Windows 2000 Professional and by Network Monitor Tools on Windows 2000 Server.

| Counter Name | Description | Counter Type |
|---|---|---|
| % Broadcast Frames | Shows the percentage of network bandwidth that is made up of broadcast traffic on this network segment. | PERF_AVERAGE_BULK |
| % Multicast Frames | Shows the percentage of network bandwidth that is made up of multicast traffic on this network segment. | PERF_AVERAGE_BULK |
| % Network Utilization | %Shows the percentage of network bandwidth in use on this network segment. | PERF_COUNTER_MULTI_TIMER |
| Broadcast Frames Received/sec | Shows the number of broadcast frames received per second on this network segment. | PERF_COUNTER_COUNTER |
| Multicast Frames Received/sec | Shows the number of multicast frames received per second on this network segment. | PERF_COUNTER_COUNTER |
| Total Bytes Received/sec | Shows the number of bytes received per second on this network segment. | PERF_COUNTER_COUNTER |
| Total Frames Received/sec | Shows the total number of frames received per second on this network segment. | PERF_COUNTER_COUNTER |

# Windows Server 2003 System Performance Counters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following counters are standard in the Windows Server 2003 operating system, are installed by Setup by default. Note that some may only be visible if you install or start the associated service.

- ACS/RSVP Service Object
- Browser Object
- Cache Object
- Distributed Transaction Coordinator Object
- Http Indexing Service Object
- IAS Accounting Clients Object
- IAS Accounting Server Object
- IAS Authentication Clients Object
- IAS Authentication Server Object
- ICMP Object
- Indexing Service Object
- Indexing Service Filter Object
- IP Object
- Job Object Object
- Job Object Details
- LogicalDisk Object
- Memory Object
- NBT Connection Object
- DUPTILE1_Network Interface Object
- Objects Object
- Paging File Object
- Physical Disk Object
- Print Queue Object
- Process Object

- Processor Object
- Redirector Object
- Server Object
- Server Work Queues Object
- System Object
- TCP Object
- Telephony Object
- Thread Object
- UDP Object

In addition, some counters are considered "costly," meaning that it takes a long time to collect data from them. These counters do not appear in System Monitor and can only be viewed using Showperf.exe or other performance-related tools in the Windows Server 2003 Technical Reference. The following are examples of costly counters:

Image Object

Process Address Space Object

Thread Details Object

For information about bottlenecks in some of these subsystem components, see the following topics:

Find memory bottlenecks

Find processor bottlenecks

Finding Cache Bottlenecks

Find disk bottlenecks

When monitoring multiprocessor systems, see the following topic:

Finding Bottlenecks on Multiprocessor Computers

# Bottleneck-Detection Counters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Some counters are useful for identifying bottlenecks, performance problems that affect the operating system or installed applications. A bottleneck exists when a single component is adversely affecting the performance of the whole system. This section lists counters to watch when trying to diagnose or prevent performance problems.

- Find memory bottlenecks
- Find processor bottlenecks
- Find disk bottlenecks
- Finding Cache Bottlenecks
- Finding Bottlenecks on Multiprocessor Computers

# Counters for Finding Network Bottlenecks

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the following counters to identify bottlenecked network resources:

- DUPTILE1_Network Interface Object
- DUPTILE1_Network Interface Object
- DUPTILE1_Network Interface Object
- *Protocol_layer_object*\Segments Received/sec
- *Protocol_layer_object*\Segments Sent/sec
- *Protocol_layer_object*\Frames Sent/sec
- *Protocol_layer_object*\Frames Received/sec

  *Protocol_layer_object* can be TCP Object, UDP Object, NetBEUI Object, NWLink IPX Object, NWLink NetBIOS Object, NWLink SPX Object, or other protocol layer performance objects. For NWLink performance objects, frame-related counters report only zeroes. Use datagram-based counters for these objects.

# Windows Server 2003 Resource Kit Registry Reference

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Welcome to the Resource Kit Registry Reference for Windows Server 2003.

The Registry Reference is a searchable technical reference that provides detailed descriptions of selected Windows Server 2003 registry content. It describes the subtrees, keys, subkeys, and entries that advanced users want to know about, including many entries that cannot be changed by using Windows tools or programming interfaces. It also contains essential background information about the Windows registry, as well as methods of backing up and restoring the registry, and tips on how to edit the registry safely.

**Caution**

- Directly editing the registry bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you are certain that you must edit the registry, first back it up by using one of the methods described in Backing Up and Restoring the Registry. After you make changes, be sure to test them before returning your computer to normal operation.

For more information, see one of the following:

- HKEY_CURRENT_CONFIG
- HKEY_CLASSES_ROOT
- HKEY_CURRENT_USER
- HKEY_LOCAL_MACHINE
- SYSTEM
- About the Registry Reference

# Glossary of Registry Terms

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z

**A**

**Active Window Tracking**
A window is activated (and optionally brought to the foreground) when the user moves the mouse over it.

**asynchronous transfer mode (ATM)**
A high-speed, connection-oriented, virtual circuit-based packet switching protocol used to transport many different types of network traffic. ATM packages data in 53-byte, fixed-length cells that can be switched quickly between logical connections on a network.

**authentication package**
Dynamic-link libraries (DLLs) loaded by the Local Security Authority (LSA) and used for local logon and network authentication. MSV1_0, the default authentication package for Windows 2000, Windows XP, and the Windows Server 2003 family, identifies users by their user names and validates them by their passwords.

**B**

**black hole router (TCP/IP)**
A router that does not return ICMP Destination Unreachable messages when it needs to fragment a TCP packet on which the Don't-Fragment bit is set. TCP must receive Destination Unreachable messages to perform Path MTU Discovery.

**browse list**
Any list of items that can be browsed, such as a list of servers on a network, or a list of printers displayed in the Add Printer wizard.

**C**

**code page**
A means of providing support for character sets and keyboard layouts for different countries or regions. A code page is a table that relates the binary character codes used by a program to keys on the keyboard or to characters on the display.

**context-sensitive**
Menus, buttons, and help text are those that are associated with a particular point (or context) in a window or dialog box. In Windows, when you right-click a context-senstive point, a menu appears displaying options for that context, or a "What's this" button appears which, when pressed, displays information about the context you clicked. In many dialog boxes, you can display context-sensitive help, that is, information about the context point, by clicking the question mark button on the caption bar and then clicking the context point.

**control set**
A complete set of the configuration data required to start devices and system services. The system always maintains at least two control sets in the registry. It identifies one as CurrentControlSet and the other as the LastKnownGood control set. The current control set is the one that was most recently used to start the system. The system stores its control set designations in the Select subkey.

**cryptographic key cache**
A reserved memory space where Message Queuing saves recently used encrypted symmetric keys so that the keys can be used again. Reusing keys makes encrypting and decrypting messages much faster. The cryptographic key cache has two sections, one for keys found in incoming messages and another for keys that are generated for outgoing messages. The size of each section can be adjusted by using the CryptSendKeyCacheSize and CryptReceiveKeyCacheSize entries.

**current control set**
The control set that was used to start the system this time. Only a successfully started system has a current control set. At startup, the system selects from among the numbered control sets stored in the registry. The number of the control set selected to be the current one appears in the **Current** entry in the HKLM\SYSTEM\Select subkey. The current control set is stored in the HKLM\SYSTEM\CurrentControlSet subkey.

See also: control set

**D**

**deadlock**
A situation in which a thread will not relinquish its exclusive access to a critical section.

**E**

**enumerator**
The means by which Windows learns about a device. Enumerator is a concept is used in Windows Plug and Play. It is a property of a device.

**F**

**failover time**
The amount of time it takes a resource, either individually or in a group, to complete the failover process.

**file name completion**
A quick search feature of the Windows command processor, Cmd.exe.

- When you type a path and file name and then press the file name completion character, the command processor searches for all files whose path and file name match your entry.

- When you type a path and then press the directory name completion character, the command processor searches for all files whose path (but not necessarily the file name) matches your entry.

The command processor displays one of the matching file names each time you type a completion character. To go backward through the list of file names, press SHIFT + *completion character*.

**file system cache**
An area of physical memory that holds frequently used pages. It allows applications and services to locate pages rapidly and reduces disk activity.

**foreground process / background process**
A process moves to the foreground when a user interacts with it; otherwise, it is a background process. This distinction lets the operating system optimize the performance of processes that are most important to the user. The system often assigns higher a processor time priority to foreground processes. As a result, the threads of foreground processes can preempt (interrupt) a running thread of a lower priority process. The threads of foreground processes often receive more processor time each time they run.

**G**

**global catalog**
A directory database that applications and clients can query to locate any object in a forest. The global catalog is hosted on one or more domain controllers in the forest. It contains a partial replica of every domain directory partition in the forest. These partial replicas include replicas of every object in the forest, as follows: the attributes most frequently used in search operations and the attributes required to locate a full replica of the object.

In Microsoft Provisioning System, the Exchange server maintains a list of global catalogs, and it maintains a load balance across global catalogs.

**globally unique identifier (GUID)**
A 16-byte value generated from the unique identifier on a device, the current date and time, and a sequence number. A GUID is used to identify a particular device or component.

**H**

**hardware profile**
Data that describes the configuration and characteristics of specific computer equipment. This information can be used to configure computers for using peripheral devices.

**hot keys**
A Windows feature that allows quick activation of specified accessibility features through a combination of keys pressed in unison.

**hot tracking**
When the cursor moves over an item, highlighting it but not selecting it.

**hubbed mode**
A mode in which the Address Resolution Protocol/multicast address resolution service (ARP/MARS) provides asynchronous transfer mode (ATM) addresses to requesting clients in the form of a multicast server (MCS) list value. In this mode, ARP/MARS acts as a multicast server, providing active forwarding of all multicast and broadcast traffic destined for IP addresses contained within the ranges specified in the list.

See also: asynchronous transfer mode (ATM); multicast address resolution service (MARS); nonhubbed mode

**I**

**ILMI**
See definition for: integrated local management interface (ILMI)

**Input Method Editor (IME)**
A program used to enter the thousands of different characters in written Asian languages with a standard 101-key keyboard. An IME consists of both an engine that converts keystrokes into phonetic and ideographic characters and a dictionary of commonly used ideographic words. As the user enters keystrokes, the IME engine attempts to identify which character or characters that the keystrokes should be converted into.

**integrated local management interface (ILMI)**
A limited set of Simple Network Management Protocol (SNMP) functions included in the asynchronous transfer mode (ATM) specification for the ATM user network interface (UNI).

See also: asynchronous transfer mode (ATM); Simple Network Management Protocol (SNMP)

**interface (TCP/IP)**
In TCP/IP, a set of communications functions that permit core elements of the TCP/IP protocol suite to communicate with TCP/IP services. The most commonly known interfaces, the Transport Driver Interface (TDI) and the Network Device Interface (NDIS) are public, and their specifications are available from Microsoft. In addition, there are a number of higher level interfaces available to user-mode applications. The most commonly used are Windows Sockets, RPC, and NetBIOS.

**IPX/SPX**

**iteration**
See definition for: iterative query

**iterative query**
A query made to a DNS server for the best answer the server can provide without seeking further help from other DNS servers. Also called a *nonrecursive query*.

**J**
There are no glossary terms that begin with this letter.

**K**

**key**
In Registry Editor, a folder that appears in the left pane of the Registry Editor window. A key can contain subkeys and entries. For example, Environment is a key of **HKEY_CURRENT_USER**.

In IP security (IPSec), a value used in combination with an algorithm to encrypt or decrypt data. Key settings for IPSec are configurable to provide greater security.

See also: registry

**L**

**Language ID**
A 16-bit value which consists of a primary and a secondary language ID. Bits 0-9 make up the primary language ID and bits 10-15 comprise the sub-language ID.

**LastKnownGood control set**
The control set used most recently to start the system successfully. When the system identifies the LastKnownGood control set, such as ControlSet001, it stores the number of the control set in the **LastKnownGood** entry in the HKLM\SYSTEM\Select subkey.

See also: control set

**Layer Two Tunneling Protocol (L2TP)**
An industry-standard Internet tunneling protocol that provides encapsulation for sending Point-to-Point Protocol (PPP) frames across packet-oriented media. For IP networks, L2TP traffic is sent as User Datagram Protocol (UDP) messages. In Microsoft operating systems, L2TP is used in conjunction with Internet Protocol security (IPSec) as a virtual private network (VPN) technology to provide remote access or router-to-router VPN connections. L2TP is described in RFC 2661.

**Locale**
A group of user preference information, such as date and time formatting, represented as a list of values related to the user's language and sublanguage.

**Locale ID**
A 32-bit value which consists of the language ID in the low word (bits 0-15) and the sorting ID (bits 16-19) and a reserved value (bits 20-31) in the high word.

See also: Language ID

**M**

**multicast address resolution service (MARS)**
A service for resolving multicast IP addresses to the asynchronous transfer mode (ATM) addresses of the clients that have joined that multicast group. MARS can work in conjunction with the multicast server (MCS) and clients to distribute multicast data through point-to-multipoint connections.

See also: asynchronous transfer mode (ATM)

**N**

**NDIS**
See definition for: Network Driver Interface Specification (NDIS)

**Network Driver Interface Specification (NDIS)**
A Microsoft/3Com specification establishing a common shared interface for Microsoft operating systems to support protocol-independent transport of multiple network transport protocols (such as TCP/IP, NetBEUI, IPX/SPX, and AppleTalk). NDIS allows more than one transport protocol to be bound and to operate simultaneously over a single network adapter.

**nonhubbed mode**
A mode in which asynchronous transfer mode (ATM) Address Resolution Protocol/multicast address resolution service (ARP/MARS) does not forward multicast and broadcast traffic for multicast group clients. In this mode, the service returns a dynamic listing of ATM hosts currently registered for the multicast group address to requesting clients. Clients then use this list to initiate and establish their own point-to-multipoint virtual connections with each of the members in the multicast list.

See also: asynchronous transfer mode (ATM); hubbed mode; multicast address resolution service (MARS)

**nonpaged pool**
Operating system memory that is never paged to disk. Paging is the moving of infrequently used parts of a program's working memory from RAM to another storage medium, usually the hard disk. In Task Manager, the amount of memory used by a process, in kilobytes.

See also: Task Manager

**O**
There are no glossary terms that begin with this letter.

**P**

**paged pool**
The system-allocated virtual memory that has been charged to a process and that can be paged. Paging is the moving of infrequently used parts of a program's working memory from random access memory (RAM) to another storage medium, usually the hard disk.

In Task Manager, the amount of system-allocated virtual memory, in kilobytes, used by a process.

See also: Task Manager

**pipe**

A section of shared memory used for interprocess communication. A program can write to a pipe and a program in another process can read the entry and reply. Processes that create pipes are commonly known as pipe servers and processes that read from the pipe are known as pipe clients.

**pod**
A group of UNIX computers that are designated to receive password synchronization updates from a Windows-based server. When a password changes, the change is sent to one UNIX host in each pod. The UNIX computers that comprise the pod are listed in the value of Hosts.

**pool leaks**
Application errors that occur when an application allocates, but does not free, pool space.

**published printer**
A printer that appears in Active Directory. The list of published printers is accessible by using the Add Printer Wizard.

**Q**
There are no glossary terms that begin with this letter.

**R**

**raster fonts**
Fonts that are stored as bitmaps. Raster fonts are designed with a specific size and resolution for a specific printer and cannot be scaled or rotated. If a printer does not support raster fonts, it will not print them. The five raster fonts are Courier, MS Sans Serif, MS Serif, Small, and Symbol. Also called *bit-mapped fonts*.

**recursive resolution**
One of the two process types (iterative and recursive) for DNS name resolution. In this process, a resolver (a DNS client) will request that a DNS server provide a complete answer to a query that does not include pointers to other DNS servers. When a client makes a query and requests that the server use recursive resolution to answer, it effectively shifts the workload of resolving the query from the client to the DNS server. If the DNS server supports and uses recursive resolution, it contacts other DNS servers as necessary (using iterative queries on behalf of the client) until it obtains a definitive answer to the query. This type of resolution allows the client resolver to be small and simple.

See also: iteration; iterative query

**referenced entry (TCP/IP ARP cache table)**
An ARP cache table entry is considered to be referenced when an outbound IP packet is sent to the address described by the entry.

**registry**
A database repository for information about a computer's configuration. The registry contains information that Windows continually references during operation, such as:

- Profiles for each user
- The programs installed on the computer and the types of documents that each can create
- Property settings for folders and program icons
- What hardware exists on the system
- Which ports are being used

The registry is organized hierarchically as a tree, and it is made up of keys and their subkeys, hives, and entries.

See also: key

**S**

**scan code**
A code number transmitted to an IBM or compatible computer when a key is pressed or released. Each key on the keyboard has a unique scan code.

**service group**

A group of similar services that are loaded together at startup. Most services that appear in the HKLM\SYSTEM\CurrentControlSet\Services subkey are part of a service group. The system loads one service group at a time. Services that are not in a group are loaded after all service groups are loaded.

**Simple Network Management Protocol (SNMP)**
A network protocol used to manage TCP/IP networks. In Windows, the SNMP service is used to provide status information about a host on a TCP/IP network.

**site**
One or more well-connected (highly reliable and fast) TCP/IP subnets. A site allows administrators to configure Active Directory access and replication topology to take advantage of the physical network.

**SNMP**
See definition for: Simple Network Management Protocol (SNMP)

**sorting ID**
A code which dictates the correct order for sorting the characters of a language. The sorting ID is used in conjunction with a locale ID to distinguish between default sorts and alternate sorts for locales which have more than one sorting order.

**subtree**
Any node within a tree, along with any selection of connected descendant nodes.

The highest level of the registry (for example, **HKEY_LOCAL_MACHINE**).

See also: key; registry

**SYN flooding**
A malicious attempt to impair a server that occurs when a computer sends the server numerous Transmission Control Protocol (TCP) connection requests that contain fictitious IP addresses. As a result, the resources of the server are occupied by futile attempts to send acknowledgments to the fictitious IP addresses. The term *SYN* refers to the *synchronize sequence number* message that is used to initialize a TCP connection. Also known as a *SYN attack*.

See also: SYN flooding attack protection

**SYN flooding attack protection**
A Transmission Control Protocol (TCP) feature that detects symptoms of SYN flooding and responds by reducing the resources (memory and time) a server spends on connection requests that it cannot acknowledge.

See also: SYN flooding

**T**

**Task Manager**
A tool that provides information about programs and processes running on the computer. Using Task Manager, you can end or run programs, end processes, and display a dynamic overview of your computer's performance.

**twip**
A unit of measure used in typesetting and desktop publishing, equal to one-twentieth of a printer's point (1/1440 inch). The twip notation begins with a dash (-), which, in this context, indicates a twip unit, not a negative value.

**U**

**UNC**
See definition for: Universal Naming Convention (UNC)

**UNC provider**
Interprets names in Universal Naming Convention format.

**UNI**
See definition for: user-to-network interface

**Universal Naming Convention (UNC)**
A convention for naming files and other resources beginning with two backslashes (\), indicating that the resource exists on a network computer. UNC names conform to the *servername**sharename* syntax, where *servername* is the server's name and *sharename* is the name of the shared resource. The UNC name of a directory or file can also include the directory path after the share name, by using the following syntax: *servername**sharename**directory**filename*.

**user-to-network interface**
The interface and signaling protocol used to establish connections between ATM users or end stations and an ATM switch or network. The ATM Call Manager component of Windows ATM Services support UNI.

**V**

**virtual machine**
A program that provides an independent operating system environment within another operating system. A virtual machine permits the user to run programs that are native to a different operating system.

**W**
There are no glossary terms that begin with this letter.

**X**
There are no glossary terms that begin with this letter.

**Y**
There are no glossary terms that begin with this letter.

**Z**
There are no glossary terms that begin with this letter.

# About the Registry Reference

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Registry Reference describes registry content that is useful to administrators and support personnel. It is not a complete listing of all registry contents. The reference documents many registry entries that you can only change by editing the registry, and also documents many entries that should be changed by using standard user interfaces. The reference also describes entries that you can view, but that you should not change for any reason.

**For more information, see the following topics:**

- How to Use the Registry Reference
- Registry Reference Document Conventions

# How to Use the Registry Reference

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Registry Reference describes selected elements of the registry that is installed by default with Windows Server 2003, and to a limited extent, Windows XP Professional. In addition to the default content, this reference also describes subkeys and entries that you can add to your registry, and ones that the system adds when you install optional services (such as hardware drivers, software drivers, or network services). This reference is not a complete listing of all registry contents. It does not document subkeys or entries for applications (such as Microsoft Word), nor does it describe the registry editor itself, Regedit.exe.

**How to Find Registry Elements**

The Registry Reference is designed to mimic the structure of Regedit.exe, the registry editor included in Windows Server 2003. Registry elements appear in the Registry Reference in their registry path, just as they do in Regedit.exe.

To find the description of a registry element, use the **Search** tab or click the books and pages in the table of contents in the left pane. A description of each element appears in the right pane. For example, to find a description of the DNS service subkey, in the left pane click **HKEY_LOCAL_MACHINE**, click **SYSTEM**, click **CurrentControlSet**, click **Services**, and click **DNS**, just as you do in Regedit.exe. Or, on the **Search** tab, type **DNS** in the Search box, select **Search titles only**, and press ENTER.

**Generic Subkeys**

This reference includes generic subkeys that do not appear in the registry, but that represent a group of subkeys with common characteristics. You can identify these generic subkeys by the brackets surrounding their names. For example, the entries that are common to most service subkeys appear in the <Service-name> subkey. If you are looking for a common entry and do not find it in the subkey in which it appears in your registry, look for a generic subkey.

**Limitations of this Reference**

If you cannot find a registry element, it might be because it is not included in this reference. The Registry Reference does not describe all elements that might appear in the registry. Some registry elements are specific to your registry. Others are part of the Windows internal code and are not meaningful to users. Many entries just store values you have set in Windows. The Registry Reference primarily documents entries that advanced users might need to change but that cannot be changed by using the Windows interface or the administrative tools provided with Windows.

Although we make every effort to be timely and accurate, the registry is part of the Windows internal program code and is therefore subject to change at any time. Possible discrepancies include changes in the locations of the entries, the default values, the range of possible values, the use of the data, and the content of entries. For updates and corrections, see the Windows Deployment and Resource Kits Web Site link below.

# Registry Reference Document Conventions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Document Conventions**
Each registry element documented in the Registry Reference has a page that includes following details: the name of the registry element, its registry path, and a description of the element. Optionally, the page might also include a change method, activation method, notes, tips, cautions, or cross-references to related entries.

**Element name and Registry path**
Element names are not unique within the registry, but are unique within their path. The *registry path* shows the location of the element in the registry. You can use the path to navigate to the element.

**Data Type, Range, and Default Value**
For registry entries only, the page includes a table with the data type, range, and default value.

| Data type | Range | Default |
|---|---|---|
| Defines the length and type of data that can be stored in the entry. See Data Types in the Registry. | Demonstrates the syntax or format of the data in the entry and provides the range of valid values. For example, **0 \| 4** means that "0" and "4" are the only values permitted. Words that describe a range, but that are not part of the range, appear in italics. For example, *IP address*. Italics are also used to show the data units. For example, 1–60 *seconds*. | The default is the value of an entry that has not been changed. If the entry does not necessarily appear in the registry, the default shows the value that describes how the system behaves without the registry entry. For example, if the system behaves as though the value is 0 if the entry is not in the registry, then the default value of an entry is 0. |

**Description**
For registry folders (DfOfSubtree, DfOfKey, and DfOfSubkey), the description explains what kinds of data are stored in the folder. It also explains which programs or services create or use the data in the folder.

For DfOfEntry, the description explains how the program or service interprets the value of the entry. If the entry has a range of values, then the description includes a table describing the effect of each value on the program or service.

**Change Method**
The change method describes the graphical user interface (GUI) or command-line method you should use to modify the element. Use these recommended methods whenever possible. If there is no change method described, then the element can be changed only by editing the registry directly.

**Activation Method**
The activation method describes additional steps that you must take to make changes to the element effective. Many changes are effective immediately if you make them by using the standard interfaces, rather than by editing the registry. However, to make some changes effective, you must restart a service, restart Windows, or log off and log on again.

**Note**
Notes provide additional information about the element. Typically, notes explain when the system adds an entry to the registry, qualifies the use of an entry, or describes the order of precedence of related entries.

**Tip**
Tips provide suggestions for using or learning more about the element.

**Caution**
Cautions describe the harm that might result if you add, change, or delete a registry element. Please take the cautions seriously. They are intended to protect your system.

**Related Entries**
Related entries are entries that configure the same component, or configure the same features on a different component. Related entries help you find the entry that meets your needs.

# About the Windows Registry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows operating systems cannot function without a registry. Nearly every action the computer performs requires the operating system to examine data stored in the registry to determine details like what resource to use, where to write a result, or how to display activity for the user. A registry with erroneous data can cause the computer to perform poorly, incorrectly, or not at all. Erroneous data in the registry can be caused by something as simple as a typing error made while editing the registry, or as serious as a physical disk error. Because of the central role played by the registry, it is essential that you back it up regularly and before making any modifications.

**For more information, see the following topics:**

- Overview of the Windows Registry
- Editing the Registry
- Data Types in the Registry
- Backing Up and Restoring the Registry

# Overview of the Windows Registry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The registry is a hierarchical database that stores the values of variables in Windows and the applications and services that run on Windows. The operating system and other programs also use the registry to store data about users and about the current configuration of the system and its components. Because the registry is available whenever the system is running, programs that start and stop can keep persistent data in the registry.

**Structure of the Registry**
Much of the registry consists of nested containers known as subtrees, keys, and subkeys, which are like folders. The actual data is stored in the registry entries, the lowest level element in the registry. The entries are like files. The series of nested containers make up a path to each entry. Because entry names are unique only within a path, entries are referenced by their full registry path and name.

The following figure shows the registry of a typical computer, as viewed with the registry editor Regedit.exe. The figure shows the terminology that this reference uses to refer to different parts of the registry.

**Subtree**
Subtrees are the *root*, or primary divisions, of the registry.

The Windows Server 2003 registry is divided into five subtrees. Subtrees themselves do not contain configuration data; they contain the keys, subkeys, and entries in which the data is stored.

Click the name of a subtree to see its description:

- HKEY_CLASSES_ROOT
- HKEY_CURRENT_USER
- HKEY_LOCAL_MACHINE
- HKEY_USERS
- HKEY_CURRENT_CONFIG

**Key**
Keys are the next level down from subtree, which contain at least one subkey (for example, Hardware Key). Some subtrees do not have keys.

**Subkey**
Subkeys are the next level down from keys or subtrees (if the subtree has no keys). Subkeys store entries and other subkeys.

**Entry**
Entries are the lowest-level element in the registry. They appear in the right pane of the registry editor window. Each entry consists of the entry name, its Data Types in the Registry (which defines the length and format of data that the entry can store), and a field known as the *value* of the registry entry. Data is stored in the value. Entries are referenced by their registry path and name.

Entries store the actual configuration data for the operating system and the programs that run on the system. As such, they are different from subtrees, keys, and subkeys, which are merely containers.

**Hive Files**
The permanent parts of the registry are stored as a set of files called the hive files. You can find a list of locations for these files in the hivelist subkey in HKLM\SYSTEM\CurrentControlSet\Control. These files are saved in systemroot\System32\Config and updated with each login. They consist of the following files, which store four of the five keys in HKEY_LOCAL_MACHINE and one key in HKEY_USERS:

- **SAM** Contains information stored in the key HKLM\SAM about the Security Accounts Manager (SAM) service.

- **SECURITY** Contains the security information stored in the key HKLM\SECURITY.
- **SOFTWARE** Contains information stored in the key HKLM\SOFTWARE about the computer's software configuration.
- **SYSTEM** Contains information stored in the HKLM\SYSTEM about the computer's system configuration.
- **DEFAULT** Contains the default system information that is stored in the key HKEY_USERS\.DEFAULT.

HKEY_LOCAL_MACHINE\HARDWARE is not stored as a file, because it is recreated each time the system starts.

**Variability of the Registry**
No two registries are exactly alike. Because the registry stores data about the hardware and software that is installed on and available to your computer, the values of many registry entries are specific to the computer and its current configuration. In addition, some of the registry content is created anew each time you start the operating system or log on. As a result, many changes to the registry are lost when you restart the computer, or when you log off and log on again.

The location of registry entries can change. Entries for programs sometimes move when the program is updated. Some programs move entire sections of the registry to a new location when a service or feature is enabled.

Because of the variability of the registry, it is not prudent to refer directly to a registry entry in any program or script. If you do, the program or script might not operate correctly with future versions of the operating system. To retrieve, add, delete, or change a registry entry, use the standard Win32 application programming interfaces (APIs). The APIs are updated with each version of the system to find the data you need.

**How Registry Data is Used**
Programs store many types of data in registry entries. Typically, programs use standard Win32 APIs to retrieve data from the registry. The program specifies an entry by its path and name, and the API returns the value of the entry. Programs also use standard APIs to add and delete registry content, and to change the values of registry entries.

After it retrieves and reads the data in the value of an entry, each program interprets the data and implements its result independently, depending on how the program is written. For example, a value of 1 might indicate to a program that an optional feature is enabled or disabled, or it might force the program to wait for one millisecond or one day before taking action. A file location stored in a registry entry might tell the program where to find a file, or it might instruct the program to move the file to the specified location.

Windows Server 2003 operating system components and programs use the registry in the following ways:

- **Setup** Both the Windows Server 2003 Setup program and other setup programs (for programs or hardware) add configuration data to the registry. For example, new information is added when you install a new SCSI adapter or change the settings for your display. Setup also reads information from the registry to determine if the prerequisite components are installed.
- **Recognizer** Each time you start the computer, the recognizer places hardware configuration data in the registry. This data includes a list of hardware detected in your system. Hardware detection is done by the hardware recognizer (Ntdetect.com) and the Windows Server 2003 kernel (Ntoskrnl.exe) programs.
- **Kernel** During system startup, the kernel extracts information from the registry, such as which device drivers to load and their load order. The kernel also passes information about itself (such as its version number) to the registry.
- **Device drivers** Device drivers send and receive load parameters and configuration data from the registry. A device driver must report the system resources that it uses, such as hardware interrupts and DMA channels, so that the system can add this information to the registry. Programs and device drivers can access this registry information to provide users with smart installation and configuration programs.

Because programs are so variable, it is very difficult to predict how a specific program will interpret the registry data. It is important to remember that the registry belongs to programs, not to users. Therefore, unless you are very familiar with the program or the registry entry, do not attempt to modify the registry.

**Users and the Registry**
Most users never need to view or edit the registry. The administrative tools and Windows interface enable users to safely

change their preferences and the services and features of the operating system. However, in rare instances, the only way to change an operating system variable is by editing the registry. For more information, see Editing the Registry.

**For More Information About the Registry**

The registry topics in Help and Support Center for Windows Server 2003 provide essential background information, including procedures for viewing and editing the registry. Also see the Windows Deployment and Resource Kits Web site link below.

# Editing the Registry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Most users never need to edit the registry. You can configure most system services by using the programs provided with Windows (such as Computer Management, Control Panel, and Group Policy), or by using the administrative tools that install with optional services (such as WINS Manager and Internet Service Manager).

**Using the Registry Editor**
If you need to view the registry or to change a value that can be changed only in the registry directly, use Regedit.exe, the registry editor installed with Windows Server 2003. An alternative registry editor, Regedt32.exe, which is included in Windows 2000 and earlier, is not included in Windows Server 2003, although many of its functions appear in the Windows Server 2003 version of Regedit.exe.

**Caution**

- Do not experiment with the registry or change any settings if you do not understand them completely. The vast majority of registry settings are maintained automatically, and many can only be maintained correctly by the operating system itself. Changing these settings can produce unexpected, contradictory, or uninterpretable instructions in operating system and application programs. Editing registry settings can also degrade the performance of your system, obscure the location of essential files, or invalidate your Windows licensing agreement. Before making any changes, be sure to back up the registry by using one of the methods described in Backing Up and Restoring the Registry. After you make changes, be sure to test them before returning your computer to normal operation.

To start Regedit.exe, click **Start**, click **Run**, and then type **Regedit**.

Regedit.exe does not display the registry directly. Instead, it constructs a virtual database from several sources of data. These sources include some of the files in %systemroot%\System32\config. Regedit.exe does not display some portions of the registry that are particularly sensitive and that should never be edited, such as a subtree related to performance counters. For more information about Regedit.exe, see Registry Editor in Help and Support Center for Windows Server 2003, or see Help in Regedit.exe.

**Making Registry Changes Effective**
When you use an administrative tool to change the configuration of a system feature or service, the change usually takes effect either immediately or soon.

However, if you make the same change by editing the registry, for the change to take effect you might need to log off and log on again, restart the service, or restart Windows.

In general, if you change the value of any entry in the CurrentControlSet subkey, you must restart the computer for the changes to take effect. Also, if you use the registry editor Regedit.exe to change values for most entries in HKEY_CURRENT_USER, you must log off and log on again for the changes to take effect.

When a change to the value of an entry is not immediate, the description of the entry contains an **Activation Method**, which describes what you need to do to make the change effective.

# Data Types in the Registry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Data types define what kind of data a registry entry can store. The Windows Server 2003 registry uses the following data types:

**REG_SZ**
A fixed-length text string. Boolean ("True" or "False") values and other short text values usually have this data type. For an example, see the Pattern Entry entry.

**REG_EXPAND_SZ**
A variable-length text string. REG_EXPAND_SZ data can include variables that are resolved when an application or service uses the data. For example, the value of the File entry includes the variable %systemroot%. When the Event Log service references this entry, the variable is replaced by the name of the directory containing the Windows Server 2003 system files.

**REG_MULTI_SZ**
Multiple text strings formatted as an array of null-terminated strings, and terminated by two null characters. Entries that contain lists or multiple data in a readable form are usually this data type. The values in a REG_MULTI_SZ entry can be separated by spaces, commas, or other marks. For an example, see the value of the Machine entry, which is a list of paths accessible by all remote users.

**REG_BINARY**
Raw binary data. Most hardware component information is stored as binary data. It can be displayed in an easy-to-read format by using Windows Server 2003 Diagnostics. For an example, see theCustomColors entry.

**REG_DWORD**
A 32-bit (4-byte) number. Boolean ("True" or "False") values and many entries for device drivers and services use this data type. REG_DWORD data can be displayed and entered in hexadecimal or decimal format in the registry editor Regedit.exe. For an example, see the ActivityLogFlag entry.

**REG_DWORD_BIG_ENDIAN**
Same as REG_DWORD. A 32-bit number in which the most significant byte is displayed as the leftmost (or high-order) byte. This is the most common format for storing numbers in computers that are running Windows Server 2003.

**REG_DWORD_LITTLE_ENDIAN**
A 32-bit number in which the most significant byte is displayed as the rightmost (or low-order) byte. This is opposite of the order in which bytes are stored in the REG_DWORD and REG_DWORD_BIG_ENDIAN data types.

**REG_LINK**
Indicates a symbolic link between system or application data and a registry value. You can use Unicode characters in a REG_LINK entry.

**REG_FULL_RESOURCE_DESCRIPTOR**
A series of nested arrays designed to store a resource list for a hardware component or driver.

# Backing Up and Restoring the Registry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

It is important to back up your registry regularly, and it is also important to back up your current, working registry before you edit it. The greatest challenge to using a backup to restore a severely damaged registry is that Windows requires the registry to operate. The system constantly reads and writes to the registry, so without a functional registry to run Windows, you cannot easily start the registry restore tools. Saving a backup of the registry on removable media, a compatible disk partition, or a secure network share, can make it much easier to restore a computer to operation if an error prevents you from accessing files on your hard disk.

**Security Considerations**

Maintain the highest possible security for the backup copy of your registry, especially if you are backing up the registry for a server. The registry contains sensitive security and user information that an attacker can use to circumvent your network security or to damage your system. Use the same physical security that you use on your servers to make sure that no one can access this information. If you are saving a backup to of the registry a network share, make sure that the share is secure. Also, make sure that the backup cannot be infected by a virus, so that you can restore your system if the entire network becomes infected.

**Improve Security by Using Runas**

Running your computer as a member of the Administrators group makes the system more vulnerable to security threats. It is a best practice to log on by using an account in the Users group and then to provide administrative credentials only to use administrative tools that require them. When backing up or editing the registry, consider using Runas, a command-line tool that allows you to issue commands as if they were issued by an account that is different from that of your current logon session.

For Runas syntax and examples, see Runas in Help and Support Center for Windows Server 2003.

**Test Your Backup Methods**

Before relying on any method for backing up or restoring the registry, be sure to test the method thoroughly on a non-critical system. It is important to verify that your restoration method will work with your particular system configuration. Practicing backing up and restoring the registry will allow you to identify any problems or limitations of your backup methods before you need to repair a non-working registry. For example, network policy settings might prevent you from using registry backup and restore tools on the affected system.

**When to Back up Your Registry**

**Back up your registry regularly.** It is a best practice to back up your system on a regular schedule. Make sure that you back up the entire registry as a part of this regular system backup.

**Back up your registry before you edit it.** Using the registry editors bypasses standard safeguards, and it is possible for you to make changes to the registry that degrade performance or cause system failure. Before you edit the registry, save a copy of each of the subkeys in which you plan to make changes. Backing up only a portion of the registry is typically faster than backing up the entire registry, and uses less storage space. However, backing up the entire registry can provide more complete recovery in the event of system failure. If you chose to create a partial backup, it should be in addition to the complete backup that you make on a regular schedule.

**Back up your registry before you install or remove hardware or software.** To avoid losing configuration information, back up the registry immediately before you intend to make hardware or software changes. This way, you can restore the system to its previous configuration if the changes conflict or degrade performance. Back up the registry again after you have made the changes and determined that they are successful.

**How to Back Up Your Registry**

Before restoring the registry from a backup of the working registry, be sure to create a second backup of the current non-working registry. In the event that you find that the settings of the registry files that you are about to restore are less functional than the current non-working registry settings, you might want to restore from the second backup.

The following are descriptions of several methods for backing up and restoring your registry. Choose the method or methods that best meet your backup requirements.

**Backup Utility**

*Backup* is a utility included with Windows Server 2003 that you can use to back up and restore the entire registry. If you already use Backup to regularly back up your hard disk, you can easily include the registry in these backups.

Backup can create backup files on many kinds of media, including local and networked disk resources. Backup can create backups of files that are open and in use, in addition to closed files, so it is your best choice for creating a complete backup copy without disturbing active users or processes.

To back up the registry by using Backup, when you select the drives, files, and folders that you want to include in a backup set, also select **System State**. System State is a collection of system-specific data maintained by the operating system, which includes the registry. When you choose to back up or restore System State data, all of the data that is relevant to your system configuration is backed up or restored. Because it must be backed up and restored as a unit, the file size of this backup can be hundreds of megabytes. To restore the registry by using Backup, restore System State.

For more information about using the Backup utility and System State to backup and restore your registry, see Backup overview and System State data in Help and Support Center for Windows Server 2003.

**Ntbackup.exe**

*Ntbackup.exe* is a command-line tool that allows you to create backup files of your registry. Ntbackup.exe cannot be used to restore your registry, but Ntbackup.exe files can be used with Backup to perform the restoration.

For more information about using Ntbackup.exe to backup your registry, see Ntbackup in Help and Support Center for Windows Server 2003.

**Manually Copying Files**

You can back up the registry by manually copying the registry files from their storage location in the file system to another location. However, to make use of these files in the event of registry failure, you need to be able to start the computer by using an operating system that can read both the file system of the backup media and of the partition in which the non-working operating system is installed. Because you cannot copy files while they are open and in use, and the files that constitute the registry are always open and in use while the operating system is running, you cannot simply copy them as you would a typical file. To copy these files, you must shutdown the operating system and use another installed operating system or utility that can access and read the file system.

To back up the registry by manually copying files, copy all files in Systemroot\System32\Config to removable media, a network share, or a compatible partition. Be sure to note the actual path to these files, because Systemroot resolves differently when your computer is running a different operating system.

To restore the registry by manually copying files, copy the backed up registry files from their backup location to their original location (the location indicated by Systemroot\System32\Config when the associated operating system was running). This overwrites all registry settings with those in the backed up registry files. Restart the computer by using the repaired operating system.

**Regedit.exe and Reg.exe**

The registry editor Regedit.exe and the command-line tool Reg.exe allow you to back up and restore individual subkeys, keys, or whole subtrees by saving parts of your registry as files on your computer, removable media, or network shares.

Reg.exe can only be used to modify local registries, but Regedit.exe can be used to modify both local and remote registries. If a problem prevents users from logging in but does not stop the system from starting up, you might be able to connect to that system remotely from another computer by using Regedit.exe.

For more information about using Regedit.exe to backup and restore your registry, see Registry Editor overview in Help and Support Center for Windows Server 2003, or see Help in Regedit.exe. For more information about using Reg.exe to backup and restore your registry, see Reg in Help and Support Center for Windows Server 2003.

**RegBack.exe, RegRest.exe, and Regedt32.exe**

The functionality of the Windows 2000 Resource Kit Tools RegBack.exe and RegRest.exe is now integrated into Reg.exe. The functionality of the Windows 2000 registry editor Regedt32.exe is now integrated into Regedit.exe.

**Other Recovery Methods**

If your system cannot be restored from an available backup, consider the following recovery methods.

**Last Known Good Configuration**

Do not rely on Last Known Good Configuration as your only method of restoring the registry. It is a limited restoration that only restores information in HKLM\SYSTEM\CurrentControlSet. For this reason, Last Known Good Configuration is a convenient way to restore your hardware configuration, but is only effective when your problem is the result of hardware-related registry settings.

**Disaster Recovery**

For more information about recovering a system that does not start, including startup options, Recovery Console, and

Automated System Recovery (ASR), see "Disaster Recovery" in Help and Support Center for Windows Server 2003.

# HKEY_CURRENT_CONFIG

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCC

**Description**
The HKEY_CURRENT_CONFIG (HKCC) subtree stores configuration data for the current hardware profile.

This subtree does not contain any data. It just stores a pointer to the content of the Hardware Profiles\Current subkey in the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\CurrentControlSet\Hardware Profiles subkey. The content of the Current subkey appears in HKEY_CURRENT_CONFIG, and it can be viewed and changed in either location. This subtree provides easier access to the data.

### Note

- For information about the content of HKEY_CURRENT_CONFIG, see the description of the CurrentControlSet\Hardware Profiles subkey and its Hardware Profiles\Current subkey.

**See Also**
**Concepts**
Hardware Profiles\Current
CurrentControlSet\Hardware Profiles

# HKEY_CLASSES_ROOT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCR

**Description**
The HKEY_CLASSES_ROOT subtree contains two types of data:

1. Data that associates file types with programs. The file type subkeys in HKEY_CLASSES_ROOT have the same name as the file name extension for the file type, such as .exe. File type associations are stored in the registry, but you should use Windows Explorer to change them. In Windows Explorer, from the **Tools** menu, click **Folder Options**, and then click the **File Types** tab.

2. Configuration data for COM objects, Visual Basic programs, or other automation. The configuration subkeys use either the program IDs (such as for COM, Visual Basic, automation, and scripting) or parent keys for other classes of information (such as for CLSID, Interface, TypeLib, AppId, and so on).

The content of HKEY_CLASSES_ROOT comes from two sources: HKEY_LOCAL_MACHINE\SOFTWARE\Classes and HKEY_CURRENT_USER\SOFTWARE\Classes. If a subkey or entry appears in either location, then it also appears in HKEY_CLASSES_ROOT. If the values of entries in the two Classes subkeys conflict, then only the value in HKEY_CURRENT_USER\SOFTWARE\Classes appears in HKEY_CLASSES_ROOT.

In Windows NT 4.0 and earlier, HKEY_CLASSES_ROOT displayed the data only in HKEY_LOCAL_MACHINE\SOFTWARE\Classes. The current, merged configuration lets the system independently register program classes for each user. This feature is known as *per-user class registration*.

Per-user class registration has several benefits:

- Multiple users can customize a single computer. For example, one user can install an application that uses a particular file type, and another user can install a different application that uses the same file type without affecting the first user.

- Roaming class registration. Because class registrations are stored in the user profile, the class registrations are loaded on each computer through the application management extension after the profile is loaded. When the user logs on to a different computer, the registration travels with the user through the directory and is written to a local portion of the user profile.

  Note: Roaming class registration is only available when using Intellimirror Software Management.

- Increased registry security. Previously, users could change or delete registry keys in HKLM\SOFTWARE\Classes, thus breaking an application or changing its behavior. However, with class information now written to the user profile, a system administrator can limit access to HKLM\SOFTWARE\Classes.

**Notes**

- This is a change in functionality from Windows NT 4.0, where HKEY_CLASSES_ROOT was an alias of HKEY_LOCAL_MACHINE\SOFTWARE\Classes.

- If an entry exists in both HKEY_LOCAL_MACHINE\SOFTWARE\Classes and HKEY_CURRENT_USER\SOFTWARE\Classes, then the value of the entry in HKEY_CURRENT_USER\SOFTWARE\Classes takes precedence.

- If you create a new key or subkey in HKEY_CLASSES_ROOT, then it will also be created in HKEY_LOCAL_MACHINE\SOFTWARE\Classes. If you create a new entry in this same key or subkey, then that entry will also appear in that key or subkey in HKEY_LOCAL_MACHINE\SOFTWARE\Classes.

- If you create a new entry in an existing subkey, where that entry will appear depends on whether the subkey already exists in HKEY_LOCAL_MACHINE\SOFTWARE\Classes or HKEY_CURRENT_USER\SOFTWARE\Classes:

- If the subkey exists in both HKEY_CURRENT_USER\SOFTWARE\Classes and HKEY_LOCAL_MACHINE\SOFTWARE\Classes, then the entry will appear in that subkey in HKEY_CURRENT_USER\SOFTWARE\Classes only.

- If the subkey already exists only in HKEY_CURRENT_USER\SOFTWARE\Classes, then the entry will appear in that subkey in HKEY_CURRENT_USER\SOFTWARE\Classes.

- If the subkey already exists only in HKEY_LOCAL_MACHINE\SOFTWARE\Classes, then the entry will appear in that subkey in HKEY_LOCAL_MACHINE\SOFTWARE\Classes.

# HKEY_CURRENT_USER

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU

**Description**
The HKEY_CURRENT_USER subtree contains the user profile for the user who is currently logged on to the computer. The user profile includes environment variables, personal program groups, desktop settings, network connections, printers, and application preferences. The data in the user profile is similar to the data stored in the Win.ini file in Windows 3.*x*.

The HKEY_CURRENT_USER subtree does not contain any data. It just stores a pointer to the content of the HKEY_USERS*Security ID (SID) of current user* subkey. Therefore, the content of that subkey also appears in HKEY_CURRENT_USER, and it can be viewed and changed in either location. The HKEY_CURRENT_USER subtree just provides easier access to the data.

A new HKEY_CURRENT_USER subtree is created each time a user logs on. The data for the subtree comes from the profile of the current user. If no profile is available, then the subtree is built from the user profile settings established for a default user, which are stored in *System drive*\Documents and Settings\Default User (WINNT)\Ntuser.dat.

# Console

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Console**
HKCU

**Description**
The Console key stores data for the console subsystem, which hosts all character-mode applications, such as Command Processor. In addition, the Console key can contain subkeys for custom command windows.

**Change Method**
To change the console window settings, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Notes

- The values of the entries in this key reflect the default window settings.

- The entries in this key, or the ability to change them, might be affected by Group Policy. For detailed information about particular Group Policy settings, see the *Windows Server 2003 Technical Reference* Group Policy Reference. For general information about Group Policy, see Windows Server 2003 Help or Windows XP Professional Help.

# ColorTable#

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *RGB value* | (Depends on color.) |

**Description**
Defines the colors in the color well on the **Colors** tab of the console **Properties** or **Defaults** dialog box. Each of the 16 ColorTable*x* entries corresponds to one of the registry entries **ColorTable00–ColorTable15.**

**Change Method**
To change the available colors, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Colors** tab, and then select a color well. Use the RGB boxes in the **Selected Color Values** group box to change that color.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.
- The ColorTable# entry is a variable representing the entries **ColorTable00–ColorTable15** in the HKCU\Console key. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the Console key.

# CursorSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Percentage* | 0x19 (25%) |

**Description**
Specifies the percentage of a character cell that the cursor occupies. This setting affects the default window.

| Value | Meaning |
|---|---|
| 0x19 | Small (25%) |
| 0x32 | Medium (50%) |
| 0x64 | Large (100%) |

**Change Method**
To change the size of the cursor, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Options** tab, and then use the **Cursor Size** group box to change the cursor size.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

# FaceName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Font name* | (None) |

**Description**
Specifies the name of an alternate command window font. If there is no font name in the value of this entry, the system usesraster fonts.

**Change Method**
To change the alternate font, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Font** tab, and then select a font from the **Fonts** list box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

# FontFamily

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Number* | 0 |

**Description**
Specifies the font family of the font used in the command window.

| Value | Meaning |
|---|---|
| 0 | Raster fonts |
| 48 | TrueType fonts |

**Change Method**
To change the font type, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Font** tab, and then select a font from the **Fonts** single selection list box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

# FontSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Height by width* (in pixels) | 0x0 |

**Description**
Specifies the size of the font used in the command window.

The value of this entry is an 8-byte hexadecimal value. The first four digits specify the height of characters in pixels. The last four digits specify the width of characters in pixels.

For example, if the value of this entry is 0xC0005, characters in the command window are 12 (0xC) pixels high and 5 pixels wide. A value of 0x0 indicates the default character size, which is 8 pixels high and 12 pixels wide.

**Change Method**
To change the font size, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Font** tab, and then select a size from the **Size** single selection list box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- A value of 0x0 is not a null value, but reflects the default window settings.

# FontWeight

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies the weight or thickness of the command window font.

| Value | Meaning |
|---|---|
| 0 | Normal weight |
| 1 | Bold text |

**Change Method**
To change the font weight, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Font** tab and either select or clear the **Bold fonts** check box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

# FullScreen

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the command window opens in full-screen mode.

| Value | Meaning |
|---|---|
| 0 | Window mode |
| 1 | Full-screen mode |

**Change Method**
To change the screen mode, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Options** tab, and then select either **Window** or **Full Screen** in the **Display Options** group box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.
- This entry is supported only by computers with CPUs that are of x86 architecture.

# HistoryBufferSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Number of commands* | 50 |

**Description**
Specifies the number of commands that can be stored in each command history buffer.

**Change Method**
To change the size of the history buffer, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Options** tab, and then change the **Buffer Size** in the **Command History** group box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

**See Also**
**Concepts**
NumberOfHistoryBuffers

# InsertMode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies how the system responds when the user types over existing characters.

| Value | Meaning |
|---|---|
| 0 | Overtype mode. Typed characters replace highlighted characters. |
| 1 | Insert mode. Typed characters are inserted before the highlighted characters. |

**Change Method**
To change the typing mode, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Options** tab, and then select **Insert Mode** in the **Edit Options** group box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

# LoadConIme

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the IME proxy process for the Windows Server 2003 console (Conime.exe) loads automatically when you log on to Windows Server 2003.

| Value | Meaning |
|---|---|
| 0 | Do not load Conime.exe automatically. |
| 1 | Load Conime.exe automatically when Windows Server 2003 starts. |

**Activation Method**
To make changes to this entry effective, you must log off of Windows Server 2003, and then log on again.

### Note

- This entry is used only when the locale of the computer is set to 932 (Japanese), 936 (Chinese), 949 (Korean Unified Hangul), or 950 (Chinese Big5 Extended).

# NumberOfHistoryBuffers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Number of buffers* | 4 |

**Description**
Specifies the number of history buffers allocated to store commands.

**Change Method**
To change the number of history buffers, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Options** tab, and then change the **Number of Buffers** in the **Command History** group box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

**See Also**
**Concepts**
HistoryBufferSize

# PopupColors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Background color number, text number* | 0xF5 (Bright White, Purple) |

**Description**

Specifies the colors used in popup windows, by color number.

The value of this entry is a hexadecimal value. The first significant number (seventh digit) represents the background color. The second significant number (eighth digit) represents the text color.

| Hexadecimal value | Color |
|---|---|
| 0 | Black |
| 1 | Blue |
| 2 | Green |
| 3 | Aqua |
| 4 | Red |
| 5 | Purple |
| 6 | Yellow |
| 7 | White |
| 8 | Gray |
| 9 | Light Blue |
| A | Light Green |
| B | Light Aqua |
| C | Light Red |
| D | Light Purple |
| E | Light Yellow |
| F | Bright White |

**Change Method**

To change the colors of the popup windows, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Colors** tab, and then use the color well control options to change the colors.

**Activation Method**

Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

**Note**

- The value of this entry reflects the default window settings.

# QuickEdit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether QuickEdit mode is enabled. In QuickEdit mode, users can cut and paste text by using the mouse.

| Value | Meaning |
|---|---|
| 0 | QuickEdit mode is disabled. Users must use commands on the **Edit** menu to cut and paste. |
| 1 | QuickEdit mode is enabled. Users can use either the mouse or commands on the **Edit** menu to cut and paste. |

**Change Method**
To change the editing options, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Options** tab, and then select **Quick Edit Mode** in the **Edit Options** group box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

# ScreenBufferSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Lines by columns* (in pixels) Maximum: 0x7FFF7FFF | 0x190050 (25 lines by 80 columns) |

**Description**
Specifies the size of the screen buffer (the screen that is retained in memory). If the size of the screen displayed on the monitor is smaller than the screen buffer, you can scroll to see the entire screen. You cannot display a console screen that is larger than the screen buffer.

The value of this entry is an 4-byte hexadecimal value. The first 2 bytes (high word) represent the number of lines that appear on the screen. The last 2 bytes (low word) represent the number of columns on the screen.

For example, the default value, 0x190050, indicates that the screen buffer is 25 (0x19) lines high and 80 (0x50) columns wide.

**Change Method**
To change the screen buffer size, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Layout** tab, and then use the **Screen Buffer Size** group box to set the width and height.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

**See Also**
**Concepts**
WindowSize

# ScreenColors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0–F (*Color number*) | 0x7 |

**Description**
Specifies the colors of console windows.

The value of this entry is an 4-byte hexadecimal value. The first 2 bytes (high word) represent the background color. The last 2 bytes (low word) represent the text color.

| Hexadecimal value | Color |
|---|---|
| 0 | Black |
| 1 | Blue |
| 2 | Green |
| 3 | Aqua |
| 4 | Red |
| 5 | Purple |
| 6 | Yellow |
| 7 | White |
| 8 | Gray |
| 9 | Light Blue |
| A | Light Green |
| B | Light Aqua |
| C | Light Red |
| D | Light Purple |
| E | Light Yellow |
| F | Bright White |

**Change Method**
To change the screen colors, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Colors** tab, and then use the color well options to change the values.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

**Note**

- The value of this entry reflects the default window settings.
- For Command Processor windows, the value of DefaultColor Entry takes precedence over the value of **ScreenColors.**

# WindowPosition

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Position* Maximum: 0x7FFF7FFF | |

**Description**
Specifies the position of the command window on the user's screen.

The value of this entry is an 4-byte hexadecimal value. The first 2 bytes (high word) represent the position of the window on the X (horizontal) axis. The last 2 bytes (low word) represent the position of the window on the Y (vertical) axis.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To change the window position, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Layout** tab, and then use the **Window Position** group box.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Notes

- Setting the value of this entry greater than the maximum will result in serious Command-console display problems.
- If this entry does not appear in the registry, the system selects a position for the window. This is equivalent to the **Let system position window** option on the **Layout** tab in the **Console Properties** box.

# WindowSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Size (number of characters)* Maximum: 0x7FFF7FFF | 0x190050 |

**Description**
Specifies the size of the command window.

The value of this entry is an 4-byte hexadecimal value. The first 2 bytes (high word) represent the number of lines that appear on the screen. The last 2 bytes (low word) represent the number of lines of columns on the screen.

For example, the default value, 0x190050, indicates that the screen buffer is 25 (0x19) lines high and 80 (0x50) columns wide.

If the screen buffer (the size of the screen retained in memory) is larger than the window size, you can scroll to see the entire screen. You cannot make the window size larger than the screen buffer size.

**Change Method**
To change the window size, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only. Click the **Layout** tab, and then use the **Window Size** box to set the width and height of the window.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The value of this entry reflects the default window settings.

**See Also**
**Concepts**
ScreenBufferSize

# console-window-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console

**Description**
Represents a particular console window.

When you save the configuration of a character-based window, such as when you create a shortcut to a screen, the system adds a subkey to the Console key, in which it saves the configuration of the window. These subkeys are named for the command windows. When you open the window, the system uses the values of the entries in this subkey rather than the values of the entries in the root of the Console key.

The entries in the *console-window-name* subkey are the same as the entries in the Console key.

**Change Method**
To change the console window settings, click the system menu icon in the title bar, and then select either **Defaults** to change the settings for all instances of that window, or **Properties** to change the current window only.

**Activation Method**
Changes made in the **Properties** dialog box are effective immediately. Changes made either in the **Defaults** dialog box or in the registry are effective the next time you open a console window.

### Note

- The *console-window-name* subkey does not appear unless the current user has changed the properties of the command window.

- The *console-window-name* subkey is a variable representing the subkeys in the Console key. It does not actually appear in the registry. This variable subkey displays information that is common to the subkeys in the Console key.

# element-name Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKCU\Console*console-window-name*

**Description**
The entries in the *console-window-name* subkey are used instead of those in the Console key for that console window. The meanings of these entries are the same as those of the entries in the Console key.

### Notes

- The *element-name* entry does not appear unless the current user has changed the properties of the command window.
- *element-name* is a variable representing the entries in the *console-window-name* subkey. It does not actually appear in the registry. This variable entry displays information that is common to the entries in the *console-window-name* subkey.

# Control Panel Key

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Control Panel**
HKCU

**Description**
The Control Panel key and its subkeys contain entries that specify the accessibility, regional, and desktop appearance settings.

**Change Method**
To change the values of these entries, use Control Panel.

### Note

- The entries in this key can be overriden by entries of the same name in the Microsoft\Control Panel and HKCU\Software\Policies\Microsoft\Windows\Control Panel subkeys.

# Accessibility Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessibility**
HKCU\Control Panel

**Description**
The Accessibility subkey contains subkeys and entries that specify the accessibility settings.

**Change Method**
To change the values of these entries, either double-click **Accessibility Options** in **Control Panel** or use the Accessibility hot keys.

# Accessibility-option

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessibility-option**
HKCU\Control Panel\Accessibility

**Description**
Represents an accessibility option.

**Change Method**
To change the values of these entries, either double-click **Accessibility Options** in **Control Panel** or use the Accessibility hot keys.

### Note

- The entry *Accessibility_option* is a placeholder representing the entries in the HKCU\Control Panel\Accessibility subkey. "Accessibility_option" does not actually appear in the registry. This type of entry stores information that is common to the entries in the Accessibility subkey.

# Appearance

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Appearance**
HKCU\Control Panel

**Description**
The Appearance subkey stores information about the appearance of the Windows elements.

### Note

- The entries in this subkey can be superseded by Group Policy settings included in Windows Server 2003.

# Current Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Current**
HKCU\Control Panel\Appearance

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Scheme name* | Windows Standard |

**Description**
Stores the name of the color scheme currently in use on the computer.

**Change Method**
To change the color scheme, in **Control Panel** double-click **Display**. Click the **Appearance** tab, and then select a scheme from the drop-down list.

### Note

- This entry appears in the registry only when the current scheme is not "Windows Standard."

# CustomColors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CustomColors**
HKCU\Control Panel\Appearance

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *RGB value* | 0xFFFFFF |

**Description**
Stores information about the custom colors that the user creates.

**Change Method**
To change the color scheme, in **Control Panel** double-click **Display**, click the **Appearance** tab, click the **Color** drop-down list, and then click **Other**. Select a color, and then click **Add to Custom Colors**.

# Schemes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Schemes**
HKCU\Control Panel\Appearance

**Description**
The Schemes subkey stores information about the schemes used on the computer.

# Scheme-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Scheme-name**
HKCU\Control Panel\Appearance\Schemes

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *RGB values* | (None) |

**Description**
Specifies the appearance of each element of the window scheme.

**Change Method**
To change the scheme, in **Control Panel** double-click **Display**, click the **Appearance** tab, and then select a scheme from the **Scheme** list. To change any of the individual elements of the scheme, select the element from the **Item** list.

### Note

- The *Scheme-name* subkey is a placeholder that represents the appearance schemes subkeys in the subkey HKCU\Control Panel\Appearance\Schemes*Scheme-name*. "Scheme-name" does not actually appear in the registry. This type of subkey stores information that is common to screen savers, and it is stored in the Schemes subkey.

# Colors Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Colors**
HKCU\Control Panel

**Description**
The Colors subkey contains entries that determine the color of each element of the Windows Server 2003 desktop. The values are shown as a series of three numbers, which refer to the RGB (red-green-blue) value of the color.

**Change Method**
To change the colors of the elements of the Windows Server 2003 desktop, in **Control Panel** double-click **Display**, then click the **Appearance** tab. Either change the complete color scheme, or change the colors of individual items.

**Activation Method**
Changes made using the **Display Properties** dialog box are effective immediately; changes made using the registry are not effective until the computer is restarted.

# Colors\element-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**element-name**
HKCU\Control Panel\Colors

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *RGB values* | *RGB value* |

**Description**
Represents a color and stores entries that apply only to that color.

**Change Method**
To change the colors of the elements of the Windows Server 2003 desktop, in **Control Panel** double-click **Display**. In the **Display Properties** dialog box, click the **Appearance** tab.

**Activation Method**
Changes made using the **Display Properties** box are effective immediately; changes made using the registry are not effective until the computer has been restarted.

### Notes

- The *element-name* entry is a placeholder representing the entries in the HKCU\Control Panel\Colors subkey. "Element-name" does not actually appear in the registry. This type of entry stores information that is common to the entries in the Colors subkey.

- The entries in the Colors subkey contain values that specify the color of each element of the Windows Server 2003 desktop. The values are shown as a series of three numbers, which refer to the RGB (red-green-blue) value of the color.

# Control Panel\Current

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Current**
HKCU\Control Panel

**Description**
The Current subkey appears in the registry, but it is not used in Windows Server 2003.

# Color Schemes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Color Schemes**
HKCU\Control Panel\Current

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Color scheme* | Windows Standard |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# Custom Colors

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Custom Colors**
HKCU\Control Panel

**Description**
The Custom Colors subkey defines the custom colors in the color palette. The entries in the Custom Colors subkey are named **ColorA** through **ColorP**, and they all have a default value of 0xFFFFFF.

**Change Method**
To change the custom colors, in **Control Panel** double-click **Display**, click the **Appearance** tab, click the **Colors** drop-down list, and then click **Other**.

# Color Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Color**
HKCU\Control Panel\Custom Colors

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *RGB value* | 0xFFFFFF |

**Description**
Represents a custom color.

**Change Method**
To change the custom colors, in **Control Panel** double-click **Display**, click the **Appearance** tab, click the **Colors** list, and then click **Other**.

### Note

- The *Color* entry is a placeholder that represents the entries in the HKCU\Control Panel\Custom Colors subkey. "Color" is not the name of an actual entry in this subkey. This type of entry stores information that is common to the entries in the Custom Colors subkey.

# Control Panel\Desktop Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Desktop**
HKCU\Control Panel

**Description**
The Desktop subkey contains entries that control the appearance of the screen background and the position of windows and icons on the screen.

# ActiveWndTrkTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ActiveWndTrkTimeout**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Milliseconds* | 0 |

**Description**
Specifies time (in milliseconds) that the mouse needs to remain over a window before the window is activated.

# AutoEndTasks

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AutoEndTasks**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**
Specifies whether user processes end automatically when the user either logs off or shuts down Windows Server 2003.

| Value | Meaning |
|---|---|
| 0 | Processes do not end automatically. The system waits until the process ends, and, if the process takes more time than the value of the HungAppTimeout entry, then the **End Task** dialog box appears, stating that the application cannot respond to the End Task request. |
| 1 | Processes end automatically. |

**See Also**
**Concepts**
HungAppTimeout
WaitToKillAppTimeout

# CoolSwitch

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CoolSwitch**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
This entry is not used by and has no effect on Windows Server 2003.

# CoolSwitchColumns

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CoolSwitchColumns**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Number of columns in decimal* | 7 |

**Description**
Specifies how many columns of icons can appear in the **Task Switcher** (ALT+TAB) box. If there are more tasks than columns, **Task Switcher** displays multiple rows.

**See Also**
**Concepts**
CoolSwitchRows

# CoolSwitchRows

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CoolSwitchRows**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Number of rows in decimal* | 3 |

**Description**
Specifies how many rows of icons can appear in the **Task Switcher** (ALT+TAB) box. If there are more tasks than can be displayed in the number of rows specified by this entry and the number of columns specified by the value of **CoolSwitchColumns**, CoolSwitchColumns scrolls the displayed icons.

**See Also**

CoolSwitchColumns

# CursorBlinkRate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CursorBlinkRate**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Milliseconds in decimal* | 530 |

**Description**
Specifies how much time elapses between each blink of the selection cursor.

**Change Method**
To change the time between cursor blinks, in **Control Panel** double-click **Keyboard**, click the **Speed** tab, and then use the slider in the **Cursor blink rate** box.

# DragFullWindows

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DragFullWindows**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
Specifies what appears on the screen while a user drags a window.

| Value | Meaning |
|---|---|
| 0 | Only the outline of the window moves. |
| 1 | The entire window and its contents move. |

**Change Method**
To change what appears on the screen while a user drags a window, in **Control Panel** double-click **Display**, click the **Effects** tab, and then click the **Show window contents while dragging** check box.

### Note

- When the system is first installed, the value of this entry is 2 until Win32k.sys is loaded during the very first login session and queries the video adapter for its capabilities. Depending on the answer, the value of this entry is then set to 0 or 1.

# DragHeight

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DragHeight**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Number of pixels in decimal* | 4 |

**Description**
Specifies the height of the rectangle used to detect the start of a drag operation.

**See Also**
**Concepts**
DragWidth

# DragWidth

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DragWidth**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Number of pixels in decimal* | 4 |

**Description**
Specifies the width of the rectangle used to detect the start of a drag operation.

**See Also**
**Concepts**
DragHeight

# FontSmoothing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**FontSmoothing**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 2 | 2 |

**Description**
Determines whether the edges of large fonts are painted in different shades of gray to make the font look smoother.

| Value | Meaning |
|---|---|
| 0 | Font smoothing is disabled. Edges are not painted different shades of gray. |
| 2 | Font smoothing is enabled. Edges are painted different shades of gray. |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Display**, click the **Effects** tab, and then click the **Smooth edges of screen fonts** check box.

# ForegroundFlashCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ForegroundFlashCount**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Number of flashes in decimal* | 3 |

**Description**
Specifies the number of times the taskbar button flashes to notify the user that the system has activated a background window. If the time elapsed since the last user input exceeds the value of the ForegroundLockTimeout entry, the window will automatically be brought to the foreground.

**See Also**
**Concepts**
ForegroundLockTimeout

# ForegroundLockTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ForegroundLockTimeout**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Milliseconds* | 200000 |

**Description**
Specifies the time, following user input, during which the system keeps applications from moving into the foreground automatically (without selection by the user).

**See Also**
**Concepts**
ForegroundFlashCount

# GridGranularity

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**GridGranularity**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0–49 (*8-pixel units*) | 0 |

**Description**
Windows Server 2003 does not use this entry, however, the entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

**Caution**

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# HungAppTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**HungAppTimeout**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Milliseconds in decimal* | 5000 |

**Description**
Specifies how long the system waits for user processes to end after the user clicks the **End Task** command button in Task Manager or after the user has selected to restart or shutdown the system. If this threshold is exceeded, the **End Task** dialog box appears, stating that the process did not respond.

**See Also**
**Concepts**
AutoEndTasks
WaitToKillAppTimeout

# MenuShowDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MenuShowDelay**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Milliseconds in decimal* | 400 |

**Description**
Specifies the interval from the time the cursor is pointed at a menu until the menu items are displayed.

# PaintDesktopVersion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PaintDesktopVersion**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the version and build number of Windows is visible on the desktop.

| Value | Meaning |
|---|---|
| 0 | Disabled. The version and build number of Windows does not appear on the desktop. |
| 1 | Enabled. The version and build number of Windows appears on the desktop. |

# Pattern Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Pattern**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | (None) \| b1 b2 b3 b4 b5 b6 b7 b8 (*in decimal*) | (None) |

**Description**
Specifies a pattern for the screen background.

The value of this entry (b1–b8) defines a two-color pattern bitmap that is 8 pixels wide and 8 pixels high. Each b-number value specifies the pattern for one row of the bitmap. The b-number values are 8-bit binary values, which are entered in decimal. The bits in each b-number value represent a row of 8 pixels. If a bit is set to 0, the pixel it defines is set to the background color. If a bit is set to 1, the pixel it defines is set to the foreground color.

For example, if you set the b1 value to the decimal value 128, the top row of pixels in the bitmap appears as the binary equivalent, 10000000. The system interprets this to mean that the first pixel has the foreground color and the seven remaining pixels have the background color.

The background color is determined by the value of the **Background** entry, and the foreground color is determined by the value of the **WindowText** entry, both of which appear in the Colors Subkey subkey.

**Concepts**
Colors Subkey

# ScreenSaveActive Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ScreenSaveActive**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**
Specifies whether a screen saver is selected. Windows Server 2003 has a default value of 0 for this entry (Windows XP has 1).

| Value | Meaning |
|---|---|
| 0 | No screen saver is selected. |
| 1 | A screen saver is selected. |

**Change Method**
To select a screen saver, in **Control Panel** double-click **Display**, then click the **Screen Saver** tab. You can then either select a screen saver from the list or select (None).

### Note

- This entry can be superseded by a Group Policy setting included in Windows Server 2003. While the **No screen saver** Group Policy setting is enabled, the system ignores this entry. The configuration of the **No screen saver** Group Policy setting is stored in the **ScreenSaveActive** entry, which is in the Policies subkey.

**Concepts**
SCRNSAVE.EXE
ScreenSaveTimeOut Entry

# ScreenSaveTimeOut Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ScreenSaveTimeOut**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Seconds in decimal* | 600 (10 minutes) |

**Description**
Specifies how long the system must remain idle before the screen saver starts.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Display**, click the **Screen Saver** tab, and then change the value in the **Wait** box.

**See Also**
**Concepts**
ScreenSaveActive Entry

# SCRNSAVE.EXE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SCRNSAVE.EXE**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File name* | (None) |

**Description**
Specifies the name of the screen saver executable file.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Display**, click the **Screen Saver** tab, and then select a screen saver from the **Screen saver** list.

You can also change this entry with the application programming interface (API) function **InstallScreenSaver**, which is exported by Desk.cpl. You can access this function with the command line **rundll32.exe desk.cpl,InstallScreenSaver *%1***, where *%1* is the name of a screen saver executable file.

**Activation Method**
Changes made to this entry become effective the next time the system starts a screen saver. Changes made to this entry while a screen saver is running have no effect on the running screen saver.

### Notes

- Windows operating systems add this entry to the registry when you use **Display** in Control Panel to select a screen saver. If you disable all screen savers by choosing **(None)** from the Screen Saver list, then the operating system deletes this entry from the registry and calls the **SystemParametersInfo** function with *uiAction* equal to SPI_SETSCREENSAVEACTIVE and *uiParam* equal to FALSE.

- On a computer that is running an operating system in the Windows NT, Windows 2000, Windows XP, or Windows Server 2003 family, this entry can be superseded by a Group Policy setting. While the **Screen saver executable name** Group Policy setting is enabled, the system ignores this entry. The configuration of the **Screen saver executable name** Group Policy setting is stored in the **SCRNSAVE.EXE** entry, which is in the Policies subkey.

# TileWallpaper

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TileWallpaper**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**
Specifies how the desktop wallpaper is positioned on the screen.

| Value | Meaning |
|---|---|
| 0 | Wallpaper is centered on the screen. |
| 1 | Wallpaper is tiled across the screen. |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Display**, click the **Desktop** tab, and then select **Center** or **Tile** from the **Position** box.

### Note

- In **Display Properties**, you can also select **Stretch**, in addition to **Center** and **Tile**. For both centering and stretching, the value of this entry is zero, and stretching is configured by the entry **WallpaperStyle**.

# WaitToKillAppTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WaitToKillAppTimeout**
HKCU\Control Panel\Desktop

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Milliseconds in decimal* | 20000 (20 seconds) |

**Description**
Specifies how long the system waits for user processes to end after the user attempts to log off or to shut down Windows Server 2003. When the time specified in this entry expires, the **End Task** dialog box appears, stating that the process did not respond. If the value of AutoEndTasks is 1, the system ends the process automatically.

**See Also**
**Concepts**
AutoEndTasks
HungAppTimeout

# WindowMetrics

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WindowMetrics**
HKCU\Control Panel\Desktop

**Description**
The WindowMetics subkey contains the current dimensions of window display elements. The units of some of the entries are in pixels, others are in X-Y coordinates, and some are in twips.

# BorderWidth

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**BorderWidth**
HKCU\Control Panel\Desktop\WindowMetrics

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 to -750 (twips) | -15 (15 twips) |

**Description**
Specifies the current setting for the width of the borders around all the windows that have borders that can be sized.

**Change Method**
To change the value of this entry, in **Control Panel**, double-click **Display**, and then click the **Appearance** tab. Click the **Advanced** button. Select **Active Window Border** from the **Item** list, and then set the value of **Size**. The numbers in the **Size** box correspond to pixels, where one pixel equals fifteen twips.

**Activation Method**
Changes made in Control Panel are effective immediately. Changes made by using the registry editor Regedit.exe are not effective until you log off and then log on again.

### Notes

- Values entered in twips (minus values) are rounded to the nearest pixel value. For instance, -17 converts to 1 pixel, and -28 converts to 2 pixels.

- The registry also accepts values in pixels (0 to 50); however, any values entered in Control Panel will be converted to twips in the registry.

# CaptionFont

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CaptionFont**
HKCU\Control Panel\Desktop\WindowMetrics

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *a data structure (in binary) that describes a font* | *data structure that describes the font Tahoma* |

**Description**
Stores a LOGFONT data structure that describes a font. The system uses the font described by this entry as the caption font.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Display**, and then click the **Appearance** tab. Next, click the **Advanced** button. Select **Active Title Bar** from the **Item** list, and then make selections from the **Font** and **Size** lists.

# Shell Icon BPP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shell Icon BPP**
HKCU\Control Panel\Desktop\WindowMetrics

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 4 \| 8 \| 16 \| 24 \| 32 | 4 |

**Description**
Specifies the color resolution of the icons on the Windows Server 2003 desktop.

The value of this entry specifies the number of bits used to describe each pixel.

| Value (number of bits) | Meaning |
|---|---|
| 4 | 16 colors |
| 8 | 256 colors |
| 16 | 65,536 colors |
| 24 | 16,777,216 colors |
| 32 | 16,777,216 colors |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Change Method**
To use the maximum number of colors as determined by your display hardware and drivers, in **Control Panel** double-click **Display**, click the **Effects** tab, and then click the **Show icons using all possible colors** check box .

# ShellIconSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ShellIconSize**
HKCU\Control Panel\Desktop\WindowMetrics

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 16–48 (*pixels, in decimal*) | 32 (*pixels*) |

**Description**
Specifies the size of icons that the Windows Explorer interface uses.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Size

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Size**
HKCU\Control Panel\Desktop\WindowMetrics

| Data type | Range | Default value |
|---|---|---|

# International Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**International**
HKCU\Control Panel

**Description**
The International subkey stores options that are selected in Regional and Language Options in Control Panel. These entries determine how the system and programs display dates, times, currency, and other locale-specific notation. The data for each user is stored separately.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# AddHijriDate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AddHijriDate**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *A valid adjustment value.* | (None) |

**Description**
Specifies adjustments to the date within the Hijri calendar.

The *Hijri calendar* is a lunar calendar used in the Islamic world. The months begin and end according to a decree that is based on the observation of the new moon. It is difficult to accurately predict the beginnings and endings of the months, and there are regional variations, so an adjustment of between zero and two days is made to the calendar.

The **AddHijriDate** entry stores this adjustment value as follows:

| Value | Meaning |
|---|---|
| AddHijriDate-2 | Subtract two days. |
| AddHijriDate | Subtract one day. |
| (blank) | No adjustment is necessary. (If the date has not been adjusted, this entry does not appear in the registry. If the date has been adjusted and then restored to its original value, this entry appears in the registry with no value.) |
| AddHijriDate+1 | Add one day. |
| AddHijriDate+2 | Add two days. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe or by using the **Change Method** described below.

**Change Method**
To change the value of this entry, or to add it to the registry, first install the files for complex script and right-to-left languages. In **Control Panel**, click **Regional and Language Options**, then click the **Languages** tab. Under **Supplemental language support**, select the checkbox to **Install files for complex script and right-to-left languages (including Thai)**. Click **OK**.

To change the value of this entry, or to add it to the registry, from **Control Panel**, click on **Regional and Language Options**. In the **Standards and Formats** box, select a locale that uses the Hijri calendar. Click on the **Customize** button, then click on the **Date** tab. In the **Adjust Hijri date to:** drop-down list, select the appropriate value. Click **OK**, then click **OK** again.

**Activation Method**
Changes to this entry made through **Control Panel** take effect immediately.

# iCalendarType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iCalendarType**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0–12 (*Calendar-ID*) | 1 |

**Description**
Specifies the type of calendar currently being used on the system, as represented by its calendar ID.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Date** tab, and then select a calendar from the **Calendar type** list. Click **OK**. Note that the **Calendar type** list only appears if the computer is configured for a locale that has more than one calendar. (You can change the locale on the **Regional Options** tab of **Regional and Language Options**.)

**Activation Method**
Changes you make in **Regional and Language Options** are effective immediately.

# iCountry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iCountry**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Country/region code* | 1 |

**Description**
Stores the country/region code. This number is the same as the country or region's international telephone code, except for Canada, which is 2.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, and then click the **Regional Options** tab. Next, select a country/region from the click the list under **Standards and formats** (not the list under **Location** on the same page). Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# iCurrDigits

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iCurrDigits**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0–9 (*in decimal*) | 2 |

**Description**
Specifies the number of digits displayed in the fractional portion of currency.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Currency** tab, and then select from the **No. of digits after decimal** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

iDigits

# iCurrency

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iCurrency**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 \| 2 \| 3 | 0 |

**Description**
Specifies the format for displaying positive numbers as currency.

| Value | Meaning |
|---|---|
| 0 | $1.1 |
| 1 | 1.1$ |
| 2 | $ 1.1 |
| 3 | 1.1 $ |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Currency** tab, and then select a format from the **Positive currency format** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# iFirstDayOfWeek

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iFirstDayOfWeek**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0–6 | 6 |

**Description**
Specifies which day is considered first in a week.

| Value | Meaning |
|---|---|
| 0 | Monday |
| 1 | Tuesday |
| 2 | Wednesday |
| 3 | Thursday |
| 4 | Friday |
| 5 | Saturday |
| 6 | Sunday |

# iFirstWeekOfYear

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iFirstWeekOfYear**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 \| 2 | 0 |

**Description**
Specifies which week of the year is considered first.

| Value | Meaning |
|---|---|
| 0 | Week containing January 1 is the first week of the year. |
| 1 | First full week following January 1 is the first week of the year. |
| 2 | First week containing at least four days is the first week of the year. |

# iLZero

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iLZero**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
Specifies whether a leading zero is used in decimal fractions.

| Value | Meaning | Example |
|---|---|---|
| 0 | Uses no leading zero. | .1 |
| 1 | Uses a leading zero. | 0.1 |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. Click the **Numbers** tab, and then select from the **Display leading zeroes** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# iMeasure

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iMeasure**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
Specifies which measurement system is used.

| Value | Meaning |
|---|---|
| 0 | Metric |
| 1 | U.S. |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. Click the **Numbers** tab, and then select from the **Measurement system** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# iNegCurr

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iNegCurr**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0–15 (*in decimal*) | 0 |

**Description**
Specifies the format of negative currency amounts.

| Value | Meaning | Example |
|---|---|---|
| 0 | ($1.1) | ($100.00) |
| 1 | -$1.1 | -$100.00 |
| 2 | $-1.1 | $-100.00 |
| 3 | $1.1- | $100.00- |
| 4 | (1.1$) | (100.00$) |
| 5 | -1.1$ | -100.00$ |
| 6 | 1.1-$ | 100.00-$ |
| 7 | 1.1$- | 100.00$- |
| 8 | -1.1 $ | -100.00 $ (space before $) |
| 9 | -$ 1.1 | -$ 100.00 (space after $) |
| 10 | 1.1 $- | 100.00 $- (space before $) |
| 11 | $ 1.1- | $ 100.00- (space after $) |
| 12 | $ -1.1 | $ -100.00 (space after $) |
| 13 | 1.1- $ | 100.00- $ (space before $) |
| 14 | ($ 1.1) | ($ 100.00) (space after $) |
| 15 | (1.1 $) | (100.00 $) (space before $) |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. Click the **Currency** tab, and then select from the **Negative currency format** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# iNegNumber

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iNegNumber**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0–4 | 1 |

**Description**
Specifies the format of negative numbers.

| Value | Meaning |
|---|---|
| 0 | (1.1) |
| 1 | -1.1 |
| 2 | - 1.1 |
| 3 | 1.1- |
| 4 | 1.1 - |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. Click the **Date** tab, and then select from the **Negative number format** list. Click **OK**.

**Activation Method**
Changes you make in **Regional and Language Options** are effective immediately.

# iTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iTime**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
Specifies whether time is displayed with a 12-hour or 24-hour clock format.

| Value | Meaning |
|---|---|
| 0 | 12-hour clock |
| 1 | 24-hour clock |

**Change Method**
The value of this entry is set when you select a time format. To select a time format, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. Click the **Time** tab, and then select a format from the **Time format** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# iTimePrefix

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iTimePrefix**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**
Specifies whether the time marker (that is, AM or PM) appears before or after the time.

| Value | Meaning | Example |
|---|---|---|
| 0 | Suffix | 9:15 AM |
| 1 | Prefix | AM 9:15 |

# iTLZero

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**iTLZero**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**
Specifies whether leading zeros are inserted before single-digit hours in time displays.

| Value | Meaning | Example |
|---|---|---|
| 0 | A leading zero is not inserted before a single-digit hour. | 6:04 PM |
| 1 | A leading zero is inserted before a single-digit hour. | 06:04 PM |

**Change Method**
The value of this entry is set when you select a time format. To select a time format, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. Click the **Time** tab, and then select a format from the **Time format** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# International\Locale

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Locale**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | 00000409 (*U.S. English*) |

**Description**
Specifies the locale that the current user has selected. The locale identifies the geographic variation of the spoken language that the user has chosen. The chosen locale determines the default values for all other regional preferences, such as how dates and times are formatted and the symbols that are used in currency. It also determines which options appear in the drop-down lists on the tabs within the **Regional and Language Options** box.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **General** tab, and then select a locale from the **Your locale (location)** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# NumShape

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NumShape**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 \| 2 | 1 |

**Description**
Specifies the shape of digits in Unicode languages. By default, the digits 0–9 are displayed with the appropriate digit shape for the default locale (presuming that the appropriate font is available). The value of this entry determines whether the digits 0–9 are forced to display as European digits.

| Value | Meaning |
|---|---|
| 0 | The shape of the digits depends on the context. |
| 1 | Digits are diplayed according to the default locale. |
| 2 | Digit shapes are determined by the sNativeDigits entry. |

When the value of this entry is 0, European digits follow Latin text, Arabic-Indic digits follow Arabic text, and Thai digits follow Thai text. When there is no preceding text, the system takes both the locale and the displayed reading order into consideration, as shown in the following table.

| Locale | Reading order | Digits |
|---|---|---|
| Arabic | right-to-left | Arabic-Indic |
| Thai | left-to-right | Thai |
| All others | any | Locale default |

**See Also**
**Concepts**

# s1159

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**s1159**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* | AM |

**Description**
Specifies the text or symbols used in 12-hour time formats to indicate that the time displayed is before noon.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Time** tab, and then select a symbol from the **AM symbol** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# s2359

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**s2359**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* | PM |

**Description**
Specifies the text or symbols used to indicate that the time displayed is at or after noon in 12-hour time formats.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Time** tab, and then select a symbol from the **PM symbol** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# sCountry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sCountry**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Name of country or region* | United States |

**Description**
Specifies the fully localized name of the country or region. This name is based on the localized version of the product.

### Caution

- Do not change the value of this entry. This value must comply with ISO standards and correspond to ISO values for functionality and language selection.

# sCurrency

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sCurrency**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol or character* | $ |

**Description**
Specifies the currency symbol used to display monetary values.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Currency** tab, and then select a symbol from the **Currency symbol** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

### Note

- Regional Options in Control Panel restricts this entry from accepting the numeric digits 0–9. Using the registry editor Regedit.exe to set the value of this entry to a numeric digit could have one of two effects:
    - If an application calls the GetCurrencyFormat API, then the system will use the default symbol for the locale.
    - If an application does not use the GetCurrencyFormat API and the application does not check the format itself, then the numeric value will be used. This could cause errors if the value is used in calculations.

**See Also**
**Concepts**
iCurrency

# sDate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sDate**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol or character* | / |

**Description**
Specifies the symbol separating numbers when the date is displayed in short date (numeric) format, such as 6/5/69.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Date** tab, and then select a symbol from the **Date separator** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

**Note**

- Regional Options in Control Panel links the **sDate** and sShortDate values. This ensures that the date separator and the date format are synchronized. For example:

| sDate | sShortDate | Meaning |
|---|---|---|
| / | m/d/yy | 6/5/69 |

- Setting **sTime** and **sTimeFormat** independently in the registry can result in conflicting values. To repair these settings, use Regional Options in Control Panel.

- Setting only one value in the registry might not change the date as it appears in applications, because an application might read either **sDate** or **sShortDate.**

# sDecimal

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sDecimal**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol or character* | . (period) |

**Description**
Specifies the punctuation used to separate the fractional part of a decimal number from the whole-number part.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Currency** tab, and then select a symbol from the **Decimal symbol** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

### Note

- Regional Options in Control Panel restricts this entry from accepting the numeric digits 0–9. Using the registry editor Regedit.exe to set this value to a numeric digit could have one of two effects:
    - If an application calls the GetNumberFormat API, then the system will use the default symbol for the locale.
    - If an application does not use the GetNumberFormat API and the application does not check the format itself, then the numeric value will be used. This could cause errors if the value is used in calculations.

# sGrouping

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sGrouping**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *number of digits*[;*number of digits*...] | 3;0 |

**Description**
Describes how digits in a whole number are grouped.

Each numeric value in this entry determines how many digits will be grouped together. The first number in this value determines the number of digits immediately preceding the decimal point, and each subsequent value determines the number of digits between thousands separators. If the last value is 0, then the preceding value is repeated.

| Value | Example |
|---|---|
| 3;2;0 | 12,34,56,789 |
| 3;0 | 123,456,789 |
| 0;0 | 123456789 |

The symbol used to separate the groups is determined by the value ofsThousand.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize** button. Next, click the **Numbers** tab, and then select a grouping from the **Digit grouping** list. Click **OK**.

**Activation Method**
Changes you make in **Regional and Language Options** are effective immediately.

### Note

- **Regional and Language Options** in Control Panel limits this value to the three options in the table, but you can enter up to five groups of digits, such as 1;2;3;4;5, in the value of this entry.

HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol or character* | , (comma) |

**Description**
Specifies the symbol used to separate items in a list.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Numbers** tab, and then select a grouping from the **List Separator** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

# sLongDate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sLongDate**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Date format* | dddd, MMMM dd, yyyy |

**Description**
Specifies the format, including the abbreviations and separators, used to display dates in long date (text) format.

| Value | Example |
|---|---|
| dddd, MMMM dd, yyyy | Saturday, October 12, 1986 |
| MMMM dd, yyyy | October 12, 1986 |
| dddd, dd MMMM, yyyy | Saturday, 12 October, 1986 |
| dd MMMM, yyyy | 12 October, 1986 |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Date** tab, and then select a format from the **Long date format** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

### Note

- You can also create your own date format if you use the correct values. (For more information about these values, see *Day, Month, Year, and Time Format*.) Click in the **Short date format** box, rather than clicking on the arrow to the right of the box, and replace or insert the necessary characters.

# sMonDecimalSep

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sMonDecimalSep**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol* | "." (period) |

**Description**
Specifies the symbol used to separate the decimal values in currency.

For example, in the value **$1.20**, a period separates the decimal values.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Currency** tab, and then select a symbol from the **Decimal symbol** list. Click **OK**.

**Activation Method**
Changes you make in **Regional and Language Options** are effective immediately.

### Note

- **Regional and Language Options** in Control Panel restricts this entry from accepting the numeric digits 0–9. Editing the registry directly to set this entry to a numeric digit could have one of two effects:
    - If an application calls the GetCurrencyFormat API, the system will use the default symbol for the locale.
    - If an application does not use the GetCurrencyFormat API and the application does not check the format itself, the numeric value will be used. This could cause errors if the value is used in calculations.

# sMonGrouping

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sMonGrouping**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *number of digits*[;*number of digits*...] | 3;0 |

**Description**
Specifies how digits are grouped to the left of the decimal in currency.

Each numeric value in this entry determines how many digits are grouped together. The first number in this value determines the number of digits immediately preceeding the decimal point, and each subsequent value determines the number of digits between thousands separators. If the last value is 0, then the preceding value is repeated.

| Value | Example |
|---|---|
| 3;2;0 | 12,34,56,789 |
| 3;0 | 123,456,789 |
| 0;0 | 123456789 |

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click **Customize**. Next, click the **Currency** tab, and then select a grouping from the **Digit grouping** list.

**Activation Method**
Changes you make in **Regional and Language Options** are effective immediately.

### Note

- **Regional and Language Options** in Control Panel limits this value to the three options displayed in the table below. However, you can enter up to five groups of digits in this value in the registry. For example, you can enter 1;2;3;4;5.

# sMonThousandSep

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sMonThousandSep**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol* | "," (comma) |

**Description**
Specifies the symbol used to group digits in currency. Digits groupings are specified by the value of sMonGrouping.

For example, if **sMonGrouping** specifies grouping by thousands and the value of this entry stores a comma, then one thousand dollars is displayed numerically as **$1,000**.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Currency** tab, and then select a symbol from the **Digit grouping symbol** list.

**Activation Method**
Changes you make in **Regional and Language Options** are effective immediately.

### Note

- **Regional and Language Options** in Control Panel restricts this entry from accepting the numeric digits 0–9. Editing the registry directly to set this value to a numeric digit could have one of two effects:
    - If an application calls the GetCurrencyFormat API, the system will use the default symbol for the locale.
    - If an application does not use the GetCurrencyFormat API and the application does not check the format itself, the numeric value will be used. This could cause errors if the value is used in calculations.

# sNativeDigits

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sNativeDigits**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Number set* | 0123456789 |

**Description**
Describes the ten characters that are the native equivalent to the ASCII 0–9, as determined by the locale.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Numbers** tab, and then select substitution scheme from the **Standard digits** list. Click **OK**.

Note that **Standard digits** only appears when, on the **Languages** tab of **Regional and Language Options**, **Install files for complex script and right-to-left languages** is selected.

**Activation Method**
Changes you make in **Regional and Language Options** are effective immediately.

# sNegativeSign

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sNegativeSign**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol* | "-" (hyphen) |

**Description**
Specifies the symbol that is used to display negative numbers.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. On the **Numbers** tab, select a symbol from the **Negative sign symbol** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

### Note

- **Regional and Language Options** in Control Panel restricts this entry from accepting the numeric digits 0–9. Using the registry editor Regedit.exe to set this value to a numeric digit could have one of two effects:

    - If an application calls the GetNumberFormat or GetCurrencyFormat API, then the system will use the default symbol for the locale.

    - If an application does not use the GetNumberFormat or GetCurrencyFormat API and the application does not check the format itself, then the numeric value will be used. This could cause errors if the value is used in calculations.

# sPositiveSign

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sPositiveSign**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol* | (None) |

**Description**
Specifies the symbol used to display positive numbers.

### Note

- Currently, no locale uses a symbol for positive numbers.
- **Regional and Language Options** in Control Panel restricts this entry from accepting the numeric digits 0–9. Using the registry editor Regedit.exe to set this value to a numeric digit could have one of two effects:
    - If an application calls the GetNumberFormat or GetCurrencyFormat API, then the system will use the default symbol for the locale.
    - If an application does not use the GetNumberFormat or GetCurrencyFormat API and the application does not check the format itself, then the numeric value will be used. This could cause errors if the value is used in calculations.

# sShortDate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sShortDate**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Time format* | M/d/yy |

**Description**
Specifies the format used to display dates in short date (numeric) format, for example 6/5/69.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. Click the **Date** tab, and then select a format from the **Short date format** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

### Notes

- You can also create your own date format if you use the correct values. (For more information about these values, see *Day, Month, Year, and Time Format*.) Click in the **Short date format** box, rather than clicking on the arrow to the right of the box, and replace or insert the necessary characters.

- **Regional and Language Options** in Control Panel links the sDate and **sShortDate** entries. This ensures the date separator and the date format are synchronized. For example,

| sDate | sShortDate | Meaning |
|---|---|---|
| / | m/d/yy | 6/5/69 |

- Setting **sDate** and **sShortDate** independently in the registry can result in conflicting values. To repair these settings, use Regional Options in Control Panel.

- Setting only one value in the registry might not change the date as it appears in applications, because an application can read either **sDate** or **sShortDate.**

# sThousand

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sThousand**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol or character* | , (comma) |

**Description**
Specifies the symbol used to group the digits in a whole number.

For example, if the value of this entry is a comma, and the value of sGrouping is 3;0, then the system displays the number 3000 as 3,000.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**. On the **Regional Options** tab, click the **Customize** button. On the **Numbers** tab, select a symbol from the **Digit grouping symbol** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

### Note

- **Regional and Language Options** in Control Panel restricts this entry from accepting the numeric digits 0–9. Using the registry editor Regedit.exe to set this value to a numeric digit could have one of two effects:
    - If an application calls the GetNumberFormat API, then the system will use the default symbol for the locale.
    - If an application does not use the GetNumberFormat API and the application does not check the format itself, then the numeric value will be used. This could cause errors if the value is used in calculations.

# sTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**sTime**
HKCU\Control Panel\International

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Symbol or character* | : (colon) |

**Description**
Specifies the character used to separate the hours, minutes, and seconds when displaying time. For example, if the value is a colon, noon appears as 12:00:00.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **Regional and Language Options**, click the **Regional Options** tab, and then click the **Customize...** button. Next, click the **Time** tab, and then select a character from the **Time separator** list. Click **OK**.

**Activation Method**
Changes made in **Regional and Language Options** are effective immediately.

### Note

- **Regional and Language Options** in Control Panel links the **sTime** and sTimeFormat entries. This ensures that the time separator and the time format are synchronized. For example,

| sTime | sTimeFormat | Meaning |
|---|---|---|
| : | h:mm:ss tt | 8:20:00 AM |

- Setting **sTime** and **sTimeFormat** independently in the registry can result in conflicting values. To repair these settings, use Regional Options in Control Panel.

- Setting only one value in the registry might not change the time as it appears in applications, because an application can read either **sTime** or **sTimeFormat**.

# Patterns

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Patterns**
HKCU\Control Panel

**Description**
The Patterns subkey contains entries that specify the colors of desktop patterns.

**Change Method**
To change the values of the entries in this subkey, in **Control Panel** double-click **Display**, click the **Background** tab, click the **Pattern** button, and then select a pattern from the list. You can edit the pattern by clicking the **Edit Pattern** button.

# Patterns\Pattern

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**>Pattern**
HKCU\Control Panel\Patterns

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | (None) \| b1 b2 b3 b4 b5 b6 b7 b8 (*in decimal*) | 170 85 170 85 170 85 170 85 |

**Description**
Represents a pattern.

**Change Method**
To change the values of the entries in this subkey, in **Control Panel** double-click **Display**, click the **Background** tab, click the **Pattern** button, and then select a pattern from the list. You can edit the pattern by clicking the **Edit Pattern** button.

### Notes

- The *Pattern* entry is a variable representing the entries in the HKCU\Control Panel\Patterns subkey. It does not actually appear in the registry. This variable entry is used to display information that is common to the entries in the Patterns subkey.

- The values b1–b8 define a two-color pattern bitmap that is 8 pixels wide and 8 pixels high. Each b-number specifies the pattern for one row of the bitmap. The b-numbers are 8-bit binary values, which are entered in decimal. The bits in each b-number value represent a row of 8 pixels. If a bit is set to 0, then the pixel it defines is set to the background color. If a bit is set to 1, then the pixel it defines is set to the foreground color.

- For example, if you set the b1 value to the decimal value 128, then the top row of pixels in the bitmap appears as the binary equivalent, 10000000. The system interprets this to mean that the first pixel has the foreground color and the seven remaining pixels have the background color.

- The background color is determined by the value of **Background** and the foreground color is determined by the value of **WindowText**, both of which appear in the Colors Subkey subkey.

- Each entry in the Patterns subkey is named for and describes a pattern, and each has the REG_SZ data type.

# Screen Saver.Screensaver-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Screen Saver.Screensaver-name**
HKCU\Control Panel

**Description**
This subkey represents a screen saver, and it stores entries that apply only to that screen saver.

The Control Panel subkey can contain subkeys representing each screen saver installed on Windows Server 2003. The Screen Saver.*Screensaver-name* subkey is a variable representing these subkeys. Each Screen Saver.*Screensaver-name* subkey stores data that is specific to a screen saver.

**Change Method**
To change the screen saver, in **Control Panel** double-click **Display**, click the **Screen Saver** tab, and then select a screen saver from the **Screen Saver** list.

### Note

- The Screen Saver.*Screensaver-name* subkey is a placeholder representing the screen saver subkeys in HKCU\Control Panel subkey. "Screen Saver.Screensaver-name" does not actually appear in the registry. This is a type of subkey that stores information that is common to screen savers and that is stored in the Control Panel subkey.

# Screen Saver.Screensaver-name\element-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**element-name**
HKCU\Control Panel\Screen Saver.*Screensaver-name*

**Description**
Each *element-name* entry represents an element of the screen saver that the user can alter.

**Change Method**
To change the screen saver elements, in **Control Panel** double-click **Display**, click the **Screen Saver** tab, and then click **Settings**.

### Note

- The *element-name* entry is a placeholder that represents the entries in the subkey HKCU\Control Panel\Screen Saver.*Screensaver-name*. "Screen Saver.Screensaver-name" does not actually appear in the registry. This type of entry displays information that is common to the entries in the Screen Saver.*Screensaver-name* subkey.

# Environment Key

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Environment**
HKCU

**Description**
The Environment key stores the values of environment variables that users can set. Each entry in this key associates an environment variable with the path that is substituted for the variable. The user's profile defines the default values for these entries.

**Change Method**
To change the values of entries in this key, in **Control Panel** double-click **System**, click the **Advanced** tab, and then click **Environment Variables**. These entries appear in the **User variables for *user-name*** section.

**Activation Method**
To make changes to the entries in this key effective, you must log off and then log on again. Changes to these variables take effect when a non-Windows-based application is run or when the command prompt is used.

### Caution

- The data type of entries in this key must be REG_EXPAND_SZ. If a user or application changes the data type, the system will not replace the variable with its intended value.

**See Also**
**Concepts**
Environment Subkey

# TEMP Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TEMP**
HKCU\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\Temp |

**Description**
Specifies the path represented by the TEMP variable.

**Change Method**
To change the value of this entry, in **Control Panel** use **System**, click the **Advanced** tab, and then click **Environment Variables**. In the **User variables for *user-name*** dialog box, select **TEMP**, click **Edit**, and then enter the new data in the **Variable Value** dialog box.

**Activation Method**
To make changes to the entries in this subkey effective, you must log off and then log on again. Changes to these variables take effect either when a non-Windows-based application is run or when the command prompt is used.

### Caution

- The data type of entries in this subkey must be REG_EXPAND_SZ. If a user or application changes the data type, the system will not replace the variable with its intended value.

# TMP Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TMP**
HKCU\Environment

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\Temp |

**Description**
Specifies the path represented by the TMP variable.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **System**, click the **Advanced** tab, and then click **Environment Variables**. In the **User variables for *user-name*** dialog box, select **TMP**, click **Edit**, and then enter the new data in the **Variable Value** dialog box.

**Activation Method**
To make changes to the entries in this subkey effective, you must log off and then log on again. Changes to these variables take effect when a non-Windows-based application is run or when the command prompt is used.

### Caution

- The data type of entries in this subkey must be REG_EXPAND_SZ. If a user or application changes the data type, the system will not replace the variable with its intended value.

# Network Key

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network**
HKCU

**Description**
The Network key stores information about mapped network drives. Each subkey in Network represents a drive that is connected to the computer and that will be reconnected when the user logs on again. The subkeys are named for the drive letter to which the drive is mapped. The system adds a *Drive letter* subkey to the registry when a drive is mapped and **Reconnect at Logon** is selected. The entries in the *Drive letter* subkeys store data that is used to reconnect the drive.

**Change Method**
To map to a network drive, in **Control Panel**, select **Network and Dial-up Connections**. From the **Tools** menu, select **Map Network Drive**. In the **Folder** box, type the path to the drive, and then click **Finish**.

# Drive letter

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Drive letter**
HKCU\Network

**Description**
The *Drive letter* subkey represents a mapped network drive that the system recognizes.

**Change Method**
To map to a network drive, in Control Panel, from the **Tools** menu select **Map Network Drive**. In the **Folder** box, type the path to the drive, and then click **Finish**.

### Notes

- The *Drive letter* subkey is a variable representing the subkeys in the HKCU\Network key. It does not actually appear in the registry. This variable entry displays information that is common to the subkeys in the Network subkey.

- The subkeys are named for the drive letter to which the drive is mapped. The system adds a *Drive letter* subkey to the registry when a drive is mapped and **Reconnect at Logon** is selected. The entries in the *Drive letter* subkeys store data that is used to reconnect the drive.

# ConnectionType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ConnectionType**
HKCU\Network*Drive letter*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 1 \| 2 | 1 |

**Description**
Specifies how the drive is connected to the local computer.

| Value | Meaning |
|---|---|
| 1 | Drive redirection |
| 2 | Print redirection |

# ProviderName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ProviderName**
HKCU\Network*Drive letter*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Network name* | Microsoft Windows Network |

**Description**
Specifies the network provider used to map this particular network drive.

# ProviderType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ProviderType**
HKCU\Network*Drive letter*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *provider-number* | *provider-number* |

**Description**
Specifies a constant that identifies the provider used to map this network drive. The value for the Microsoft LanMan provider is 0x20000. Other values are assigned by Microsoft to third-party providers.

# SOFTWARE Subtree

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Software**
HKCU

**Description**
This subtree contains the user profile for the user who is currently logged on to the computer. The user profile includes environment variables, personal program groups, desktop settings, network connections, printers, and application preferences.

This subtree does not contain any data. It only stores a pointer to the content of the HKEY_USERS*Security ID (SID)* of the current user's subkey. Therefore, the content of that subkey also appears in this subtree, and it can be viewed and changed in either location. This subtree provides easier access to the data.

A new HKEY_CURRENT_USER subtree is created each time a user logs on. The data for the subtree comes from the profile of the current user. If no profile is available, then the subtree is built from the user profile settings established for a default user, which are stored in System drive\Documents and Settings\Default User (WINNT)\Ntuser.dat.

# Microsoft Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft**
HKCU\Software

**Description**
The Microsoft subkey stores configuration data for Microsoft programs running on the computer. Each subkey in the Microsoft subkey represents a different program. The entries in the program subkeys are specific to the current user.

The Microsoft subkey in HKEY_CURRENT_USER stores entries that apply only to the current user of the computer. The Software\Microsoft subkey in HKEY_LOCAL_MACHINE stores entries that apply to all users of the computer.

# Command Processor Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Command Processor**
HKCU\Software\Microsoft

**Description**
The Command Processor subkey stores user preferences for the command processor (Cmd.exe).

**Change Method**
You can change the values of the entries in this subkey by using Command Processor (Cmd.exe), but only for the duration of that Cmd.exe's execution. For all other changes, you must edit the registry directly.

**Activation Method**
If you make changes to the value of the entries in this subkey by editing the registry directly, you must restart Cmd.exe to make the changes effective.

## Notes

- Entries in the Command Processor subkey can also appear in HKLM. If both appear, in most cases the values in HKCU take precedence over the values in HKLM. However, the HKLM **Autorun** entry executes before the HKCU **Autorun** entry. Command-line settings entered in Cmd.exe take precedence over registry settings.

- For more information about Command Processor, see Windows Server 2003 Help or Windows XP Professional Help.

# AutoRun Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AutoRun**
HKCU\Software\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *command* | (None) |

**Description**
Contains commands that run each time you start Command Processor (Cmd.exe).

**Change Method**
You can change the value of this entry by using Command Processor (Cmd.exe) and typing **CMD /D**, but only for the duration of that instance of Cmd.exe. For all other changes, you must edit the registry directly.

**Activation Method**
To make changes to this entry effective, you must restart Cmd.exe.

### Notes

- **AutoRun** can appear in HKLM and HKCU. If both appear in the registry, the value of the entry in HKLM executes first, then the value in HKCU executes.
- The command-line parameters take precedence over the registry settings.

### Tip

- For more information about the AutoRun feature, at the command prompt, type **CMD /?**.

# CompletionChar Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CompletionChar**
HKCU\Software\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0x1F \| 0x20 | 0x9 (the **TAB** key) |

**Description**
Specifies a character that activates the filename completion feature in Command Processor (Cmd.exe).

To specify a character, enter the hexadecimal value of an ASCII control character other than 0x20 (space). For example, 0x4 represents Ctrl+D and 0x6 represents Ctrl+F.

| Value | Meaning |
|---|---|
| 0x0 | Disables completion. |
| 0x1–0x1F | Corresponding ASCII control character. |
| 0xD | Disables completion. |
| 0x20 | **SPACEBAR**. Disables completion. |

**Change Method**
You can change the value of this entry by using Command Processor (Cmd.exe), but only for the duration of that Cmd.exe's execution. For all other changes, you must edit the registry directly.

To enable or disable file name completion and directory name completion for one use of the command processor, at the command prompt, type **CMD /F:ON** (to enable) or **CMD /F:OFF** (to disable). This command sets the completion character to CTRL+F (0x6).

**Activation Method**
If you make changes to the value of this entry by editing the registry directly, you must restart Cmd.exe to make the changes effective.

### Notes

- **CompletionChar** can appear in HKLM and HKCU. If both appear in the registry, the value of the entry in HKCU takes precedence over the value in HKLM. The command-line switches take precedence over the registry settings while using Command Processor (Cmd.exe).
- Assigning the values 0x0, 0xD, or 0x20 to this entry disables file name completion rather than assigning a completion character.
- If you use the console Paste function to enter text into a CMD window, you might trigger completion if the characters you paste contain completion characters.

### Tip

- For more information about the file name completion feature, at the command prompt, type: **CMD /?**
- The datatype of this entry can be either REG_DWORD or REG_SZ.

Command Processor\CompletionChar

# DefaultColor Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DefaultColor**
HKCU\Software\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFE | 0x0 |

**Description**
Specifies a default background color and text color for the Command Processor (Cmd.exe) window. The value consists of two hexadecimal digits. The first digit specifies the background color; the second digit specifies the text color. The hexadecimal values correspond to colors in the following table.

| Hexadecimal value | Color |
|---|---|
| 0 | Black |
| 1 | Blue |
| 2 | Green |
| 3 | Aqua |
| 4 | Red |
| 5 | Purple |
| 6 | Yellow |
| 7 | White |
| 8 | Gray |
| 9 | Light Blue |
| A | Light Green |
| B | Light Aqua |
| C | Light Red |
| D | Light Purple |
| E | Light Yellow |
| F | Bright White |

This entry is used only when its value is valid and not 0x0, and when the user has not specified the window color by using the COLOR or /T commands. Values are not valid if the background color and the text color are identical, such as 0x55. If the value of this entry is not valid or is 0x0, and the user has not entered a command to change the color, then Cmd.exe uses the colors specified for the console window in which Cmd.exe runs.

**Activation Method**
If you make changes to the value of this entry by editing the registry directly, you must restart Cmd.exe to make the changes effective.

## Notes

- **DefaultColor** can appear in HKLM and HKCU. If both appear in the registry, then the value of the entry in HKCU takes precedence over the value in HKLM.

- The datatype of this entry can be either REG_DWORD or REG_SZ.

# DelayedExpansion Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DelayedExpansion**
HKCU\Software\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the command processor, Cmd.exe, supports delayed expansion of environment variables. If the value of this entry is 1, then the Cmd.exe interprets an exclamation point (!) as an environment variable that is expanded only when used.

By default, Cmd.exe expands variables when it reads a line of text. However, you can direct Cmd.exe to expand a variable only when it is used. If you do this, you can include variables in compound conditional statements and prevent them from being set before they are tested.

| Value | Meaning |
|---|---|
| 0 | Delayed expansion is not supported. Cmd.exe expands environment variables when it reads them, and it does not interpret exclamation points as delayed variables. |
| 1 | Delayed expansion is supported. The system expands environment variables surrounded by exclamation points, such as !VAR!, only when they are used. |

**Change Method**
You can change the value of this entry by using Cmd.exe and typing **cmd /v:on**, but only for the duration of that Cmd.exe's execution. For all other changes, you must use the registry editor Regedit.exe.

**Activation Method**
If you make changes to the value of this entry by using Regedit.exe, then you must restart Cmd.exe to make the changes effective.

## Notes

- **DelayedExpansion** can appear in HKLM and in HKCU. If both appear in the registry, the value of the entry in HKCU takes precedence over the value in HKLM.
- The datatype of this entry can be either REG_DWORD or REG_SZ.
- This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe. Even when this entry appears in the registry, the setting of the command-line parameter **/v** takes precedence over it.

## Tip

- For more details, run Cmd.exe and type **help set** or **cmd /?**, and read the entry on the **/v** command.

Command Processor\DelayedExpansion

# EnableExtensions Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**EnableExtensions**
HKCU\Software\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the extensions to the command processor (Cmd.exe), such as chdir and setlocal, are enabled. Because the extensions might be incompatible with a command-script language, Windows Server 2003 lets you disable the extensions. This entry affects all extensions. You cannot use this entry to selectively enable or disable extensions.

| Value | Meaning |
|---|---|
| 0 | Disabled |
| 1 | Enabled |

**Change Method**
You can change the value of this entry by using Command Processor (Cmd.exe) and typing **cmd /e:off**, but only for the duration of that Cmd.exe's execution. For all other changes, you must edit the registry directly.

**Activation Method**
If you make changes to the value of this entry by editing the registry directly, you must restart Cmd.exe to make the changes effective.

### Notes

- The datatype of this entry can be either REG_DWORD or REG_SZ.
- **EnableExtensions** can appear in HKLM and in HKCU. If both appear in the registry, the value of the entry in HKCU takes precedence over the value in HKLM.

**See Also**
**Concepts**

# PathCompletionChar Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PathCompletionChar**
HKCU\Software\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0x1F \| 0x20 | 0x9 (the **TAB** key) |

**Description**
Specifies a character that activates the directory name completion feature in Command Processor (Cmd.exe).

To specify a character, enter the hexadecimal value of an ASCII control character other than 0x20 (SPACEBAR). For example, 0x4 represents Ctrl+D, and 0x6 represents Ctrl+F.

| Value | Meaning |
|---|---|
| 0x0 | Disables completion. |
| 0x1–0x1F | Corresponding ASCII control character. |
| 0xD | Disables completion. |
| 0x9 | **TAB** key. |
| 0x20 | **SPACEBAR**. Disables completion. |

**Change Method**
You can change the value of this entry by using Cmd.exe, but only for the duration of that Cmd.exe's execution. For all other changes, you must use the registry editor Regedit.exe.

**Activation Method**
If you make changes to the value of this entry by using Regedit.exe, you must restart Cmd.exe to make the changes effective.

### Notes

- **PathCompletionChar** can appear in HKLM and HKCU. If both appear in the registry, then the value of the entry in HKCU takes precedence over the value in HKLM.
- Assigning the values of 0x0, 0xD, or 0x20 to this entry disables file name completion rather than assigning a completion character.
- The command-line perameters take precedence over the registry settings while using Cmd.exe.
- The datatype of this entry can be either REG_DWORD or REG_SZ.
- If you use the console Paste function to enter text into a CMD window, then you might trigger completion if the characters you paste contain completion characters.

### Tip

- To enable or disable directory name completion for one use of Cmd.exe, at the command prompt, type **CMD /F:ON** (to enable) or **CMD /F:OFF** (to disable). This command sets the completion character to CTRL+D (0x4).
- For more information about the path completion feature, at the command prompt, type **CMD /?**.

# Driver Signing Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Driver Signing**
HKCU\Software\Microsoft

**Description**
The Driver Signing subkey in HKCU stores entries for the driver signing feature for Windows Server 2003. The entries in this subkey apply only to the current user of the computer.

Microsoft digitally signs driver files to affirm that the driver software has been tested with Windows and has not been altered since it was tested.

### Note

- The entries in this subkey apply only to the current user of the computer. The entries in the Microsoft\Driver Signing subkey in HKLM apply to all users of the computer.
- The system adds this subkey to the registry when you change the default value of one of its entries.

### Tip

- For more information about driver signing, see Windows Server 2003 Help or Windows XP Professional Help.

**See Also**
**Concepts**
Microsoft\Driver Signing

# Policy Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policy**
HKCU\Software\Microsoft\Driver Signing

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 1 |

**Description**
Specifies how the system responds when a user tries to install device-driver files that are not digitally signed.

| Value | Meaning |
|---|---|
| 0 | Ignore. The system proceeds with the installation even if it includes unsigned files. |
| 1 | Warn. The system notifies the user that files are not digitally signed, and it lets the user decide whether to stop the installation or to proceed with it and permit unsigned files to be installed. |
| 2 | Block. The system does not install unsigned files. As a result, the installation stops, and none of the files in the driver package are installed. |

This entry applies only to the current user of the computer. However, if a stricter setting is configured for all users of the computer (in the Driver Signing\Policy entry in HKLM) or if a user Group Policy setting establishes a stricter configuration (in the entry **BehaviorOnFailedVerify** in HKLM), then this value is ignored for the current user.

This entry stores the option selected in the **File signature verification** section of the **Driver Signing Options** dialog box when the **Apply setting as system default** box is not selected. If the box is selected, the selection applies to all users of the computer, and it is stored in the Driver Signing\Policy entry in HKLM.

**Change Method**
To change the value of this entry, in **Control Panel** double-click **System**, click the **Hardware** tab, click **Driver Signing**, and then select an option in **File signature verification**. (Do not select the **Apply setting as a system default** check box.)

### Note

- The system adds this entry to the registry when you change the default value by using System in Control Panel.
- This entry applies to all users of the computer. The **Policy** entry also can appear in the HKCU\SOFTWARE\Microsoft\Driver Signing for a particular user. Also, you can use the **Code signing for device drivers** Group Policy setting to add the entry**BehaviorOnFailedVerify** to the registry.

### Tip

- For more information about driver signing and code signing, see Windows Server 2003 Help and Support Center or Windows XP Professional Help and Support Center.

# Microsoft\Fax Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Fax**
HKCU\Software\Microsoft\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# fxsclnt

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**fxsclnt**
HKCU\Software\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The fxsclnt subkey stores configuration data of the current user for the Fax Console.

# FaxConsoleView

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**FaxConsoleView**
HKCU\Software\Microsoft\Fax\fxsclnt

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The *FaxConsoleView* subkey is a type of subkey that stores configuration information for the way faxes are displayed in the Fax Console of the Fax service.

"*FaxConsoleView*" is a placeholder for actual subkeys with one of the following four names: InboxView, IncomingView, OutboxView, and SentItemsView.

# Archive

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Archive**
HKCU\Software\Microsoft\Fax\fxsclnt

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The Archive subkey stores user configuration data for the Fax Console.

**Change Method**
You can change this entry only by editing the registry.

# SortAscending

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SortAscending**
HKCU\Software\Microsoft\Fax\fxsclnt*FaxConsoleView*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies whether the sorting within the view is ascending or descending. *FaxConsoleView* is one of four views named InboxView, IncomingView, OutboxView or SentItemsView.

**Change Method**
This entry is maintained automatically by Fax Console.

### Note

- *FaxConsoleView* is a placeholder for the types of subkeys in the fxsclnt subkey; "FaxConsoleView" does not actually appear in the registry.

# SortColumn

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SortColumn**
HKCU\Software\Microsoft\Fax\fxsclnt*FaxConsoleView*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies the column by which Fax Console sorts. *FaxConsoleView* is one of four views named InboxView, IncomingView, OutboxView or SentItemsView.

**Change Method**
This entry is maintained automatically by Fax Console.

### Note

- *FaxConsoleView* is a placeholder for the types of subkeys in the fxsclnt subkey; "FaxConsoleView" does not actually appear in the registry.

# Columns

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Columns**
HKCU\Software\Microsoft\Fax\fxsclnt*FaxConsoleView*

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The Columns subkey stores current user configuration data for column order and appearance within the Fax Console folders.

# Order Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Order**
HKCU\Software\Microsoft\Fax\fxsclnt*FaxConsoleView*\Columns

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies the position of the column <Column ID> in Fax Console. *FaxConsoleView* is one of four views named InboxView, IncomingView, OutboxView or SentItemsView.

**Change Method**
This entry is maintained automatically by Fax Console.

### Note

- *FaxConsoleView* is a placeholder for the types of subkeys in the fxsclnt subkey; "FaxConsoleView" does not actually appear in the registry.

# MessagesPerCall

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MessagesPerCall**
HKCU\Software\Microsoft\Fax\fxsclnt\Archive

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies a number of fax messages within a single request during the Inbox or SentItems folder refresh. This entry can be used to optimize the refresh time of big archives.

**Change Method**
You can change this entry only by editing the registry.

# Confirm

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Confirm**
HKCU\Software\Microsoft\Fax\fxsclnt

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

# ItemDeletion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ItemDeletion**
HKCU\Software\Microsoft\Fax\fxsclnt\Confirm

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
The value of this entry determines whether or not deletion of a fax message or cover page should be confirmed.

| Value | Meaning |
|---|---|
| 0 | The deletion of fax message or cover page should not be confirmed. |
| 1 | The deletion of fax message or cover page should be confirmed |

**Change Method**
You can change this entry only by editing the registry.

# MainFrame

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MainFrame**
HKCU\Software\Microsoft\Fax\fxsclnt

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The MainFrame sub key stores current user configuration data for the Fax Console main window size and position. This data is used to place the Fax Console window at the same place it was opened last time.

# Maximized

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maximized**
HKCU\Software\Microsoft\Fax\fxsclnt\MainFrame

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies whether or not Fax Console window was maximized.

| Value | Meaning |
|---|---|
| 0 | Fax Console window was not maximized. |
| 1 | Fax Console window was maximized. |

**Change Method**
This entry is maintained automatically by Fax Console.

# NormalPosBottom

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NormalPosBottom**
HKCU\Software\Microsoft\Fax\fxsclnt\MainFrame

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores the last bottom Y (vertical) coordinate of the Fax Console window.

**Change Method**
This entry is maintained automatically by Fax Console.

# NormalPosLeft

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NormalPosLeft**
HKCU\Software\Microsoft\Fax\fxsclnt\MainFrame

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores the last left X (horizontal) coordinate of the Fax Console window.

**Change Method**
This entry is maintained automatically by Fax Console.

# NormalPosRight

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NormalPosRight**
HKCU\Software\Microsoft\Fax\fxsclnt\MainFrame

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores the last right X (horizontal) coordinate of the Fax Console window.

**Change Method**
This entry is maintained automatically by Fax Console.

# NormalPosTop

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NormalPosTop**
HKCU\Software\Microsoft\Fax\fxsclnt\MainFrame

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores the last upper Y (vertical) coordinate of the Fax Console window.

**Change Method**
This entry is maintained automatically by Fax Console.

# SplitterPos

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SplitterPos**
HKCU\Software\Microsoft\Fax\fxsclnt\MainFrame

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores the last X (horizontal) coordinate of the Fax Console splitter bar. The splitter bar is the vertical line that seperates the left tree view from the right list view.

**Change Method**
This entry is maintained automatically by Fax Console.

# Fax\Setup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setup**
HKCU\Software\Microsoft\Fax\

**Description**
The Setup subkey stores configuration information about the current user for the Fax Service.

# CfgWzdrUserInfo

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CfgWzdrUserInfo**
HKCU\Software\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies whether the Fax service shows the Sender Information page during invocation of the Fax Configuration Wizard.

**Change Method**
The value of this entry is set by the Fax Configuration Wizard upon first complete.

# WereCpesConverted

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WereCpesConverted**
HKCU\Software\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies whether or not Windows 95 CPE cover pages have been converted to the new COV format.

# UserInfo

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**UserInfo**
HKCU\Software\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The UserInfo subkey stores configuration information about the sender of a fax for the Fax Service. This information can be sent in a cover page to the recipient of a fax.

# FaxNumber

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**FaxNumber**
HKCU\Software\Microsoft\Fax\UserInfo

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores the telephone number of the local Fax device. The Fax Service prints this number in the banner of pages that it transmits when the registry entry Branding is equal to 1.

**Change Method**
To change the value of this entry, click on the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Console**. In **Fax Console**, on the **Tools** menu, select **Sender Information**. In **Sender Information**, type the telephone number for the fax device in the **Fax number** box.

**Activation Method**
Changes made to this entry though **Fax Console** or through the Fax API are effective immediately.

Branding

# File Manager

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File Manager**
HKCU\Software\Microsoft

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this subkey or its entries from the registry, and do not change the values in the entries. These changes can cause serious, unexpected results.

# FxsCover

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**FxsCover**
HKCU\Software\Microsoft

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The FxsCover subkey stores information for the Cover Page Editor, a component of the Fax Service.

# Ntbackup Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Ntbackup**
HKCU\Software\Microsoft

**Description**
The Ntbackup subkey contains entries that store configuration data for Windows Backup (Ntbackup.exe). Windows Backup enables you to back up files to tape, and to restore files from tape. You can use Windows Backup to back up the files in which the registry is stored.

### Note

- When you upgrade from a previous version of Windows on which you used Windows Backup, delete the subkeys and entries in the Ntbackup subkey before running the upgraded version of Windows Backup. This ensures that registry entries are appropriate to the most recent version of Windows Backup.

- To run Windows Backup, from the **Start** menu, point to **Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

### Caution

- When you configure Windows Backup, it adds its default subkeys and entries to the registry. Some of these entries are no longer used by Windows Backup. The other entries are maintained by the system, and you should never change any of them by editing the registry. Altering these values can prevent Windows Backup from successfully backing up and/or restoring data, and it can cause your system to behave unpredictably.

# Backup Engine

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backup Engine**
HKCU\Software\Microsoft\Ntbackup

**Description**
The Backup Engine subkey stores user preference information for the Backup utility.

### Caution

- Do not change the values of the entries in this subkey. These entries are maintained by the system, and modifying them might cause Backup to improperly save or restore data, resulting in data loss.

# Use fast file restore

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use fast file restore**
HKCU\Software\Microsoft\Ntbackup\Backup Engine

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 1 |

**Description**
Specifies whether the fast file restore feature is enabled.

| Value | Meaning |
|---|---|
| 0 | Disables fast file restore. |
| 1 | Enables fast file restore. |

**Tip**

- Fast file restore is desirable for most tasks. However, you should disable fast file restore if you encounter problems restoring a file that resides entirely on the last tape of a multiple tape restore operation. Change the value of this entry to 0 by using the registry editor Regedit.exe. Rerun Backup, then, by using Regedit.exe, change the value of this entry back to 1.

# User Interface

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User Interface**
HKCU\Software\Microsoft\Ntbackup

**Description**
The User Interface subkey stores user preference information for Backup.

**Caution**

- Do not change the values of the entries in this subkey. These entries are maintained by the system, and modifying them might cause Backup to improperly save or restore data, resulting in data loss.

# RAS Phonebook

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RAS Phonebook**
HKCU\Software\Microsoft

**Description**
The RAS Phonebook subkey is created and maintained by the Routing and Remote Access service. It stores entries that configure dial-up features for each user, such as the options on the **Dial-up Preferences** dialog box in Network and Dial-up Connections.

**Change Method**
To change the values of entries in this subkey, use Network and Dial-up Connections. Do not edit the registry.

**Tip**

- To open the **Dial-up Preferences** dialog box, start Network and Dial-up Connections, click the **Advanced** menu, and then select **Dial-up Preferences**.

# Microsoft\Windows

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows**
HKCU\Software\Microsoft

**Description**
The Windows subkey stores configuration data for the programs running on the Win32 subsystem. The subkeys of the Windows subkey represent versions of the Win32 subsystem, such as CurrentVersion, which refers to the version currently running on the computer. Each version subkey contains subkeys representing programs that run on that version of the subsystem.

The Windows subkey in HKEY_CURRENT_USER stores entries that apply only to the current user of the computer. The SOFTWARE\Microsoft\Windows subkey in HKEY_LOCAL_MACHINE stores entries that apply to all users of the computer.

**See Also**
**Concepts**
Microsoft\Windows Subkey

# CurrentVersion Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CurrentVersion**
HKCU\Software\Microsoft\Windows

**Description**
The CurrentVersion subkey stores configuration data for programs running on the Win32 subsystem. The subkeys of CurrentVersion represent programs that run on the current version of the Win32 subsystem and that store user-specific configuration data for those programs.

# CurrentVersion\Explorer Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Explorer**
HKCU\Software\Microsoft\Windows\CurrentVersion

**Description**
The Explorer subkey stores configuration data for Windows Explorer and the Windows interface, including the **Start** menu, the desktop, common folders, and Control Panel.

# Shutdown Setting

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shutdown Setting**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1 \| 0x2 \| 0x4 \| 0x8 \| 0x10 \| 0x20 \| 0x40 \| 0x80 | 0x2 |

**Description**
Specifies how the system interprets a command to shut down the system.

This entry stores the setting selected most recently from the list on the **Shut Down Windows** dialog box. This setting is displayed as the default the next time the dialog box appears.

| Value | Meaning |
|---|---|
| 0x1 | Log off. Ends the session, leaving the computer running on full power. |
| 0x2 | Shut down. Ends the session and shuts down Windows Server 2003 so that the power can be turned off safely. |
| 0x4 | Restart. Ends the session, shuts down Windows Server 2003, and starts Windows Server 2003 again. |
| 0x8 | Restart in MS-DOS mode. (Not available in Windows Server 2003.) |
| 0x10 | Stand by. Maintains the session, keeping the computer running on low power with data still in memory. (This setting requires power management hardware support.) |
| 0x20 | Stand by (with wakeup events disabled). Maintains the session, keeping the computer running on low power with data still in memory. (This setting requires power management hardware support.) |
| 0x40 | Hibernate. Saves the session to disk so that the power can be turned off safely. The session is restored the next time Windows Server 2003 is started. |
| 0x80 | Disconnect. Disconnects the session. The session can be reconnected the next time the user logs on. (Disconnect is available only in Terminal Server sessions.) |

**Change Method**
The value of this entry is changed whenever the user selects an option in the **Shut Down Windows** window and clicks **OK**.

### Note

- The list on the **Shut Down Windows** dialog box displays all of the shut-down options that the computer supports. If the value of this entry is changed to represent an unsupported option, then the system uses the default value of 0x2.

# Advanced Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Advanced**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer

**Description**
The Advanced subkey stores the settings of the options in the **Taskbar and Start Menu Properties** dialog box.

**Change Method**
To change the value of entries in this subkey, from the **Start** menu, point to **Settings**, click **Taskbar & Start Menu**, then make changes in the **Taskbar and Start Menu Properties** dialog box. Do not edit this entry directly in the registry.

# Intellimenus Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IntelliMenus**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\Advanced

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | YES \| No | YES |

**Description**
Enables or disables personalized menus.

This entry stores the setting of the **Use Personalized Menus** check box in the **Taskbar and Start Menu Properties** dialog box.

Windows Server 2003 personalizes a long menu by moving recently used items to the top of the menu and by hiding items that have not been used recently. Users can display the hidden items by clicking an arrow to extend the menu.

| Value | Meaning |
|---|---|
| YES | Enables personalized menus. |
| No | Disables personalized menus. |

**Change Method**
To change the value of this entry, from the **Start** menu, point to **Settings**, and then click **Taskbar & Start Menu**. On the **General** tab, select or clear the **Use Personalized Menus** check box.

### Note

- This entry can be superseded by a Group Policy setting included in Windows Server 2003. While the **Disable Personalized Menus** policy setting is in effect, the system removes the **Use Personalized Menus** check box from the **Start** menu and ignores this entry. The configuration of the **Disable Personalized Menus** policy setting is stored in the value of **Intellimenus** in the Policies subkey. If users cannot find the **Use Personalized Menus** option, then check the configuration of the **Disable Personalized Menus** policy setting.

- Personalized menus require user tracking. If the **Disable user tracking** policy setting is in effect, then Group Policy sets the value of **NoInstrumentation** to 1. As a result, the system disables user tracking and personalized menus, and ignores the value of this entry.

# Shell Folders Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shell Folders**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Note

- Paths to the Windows Explorer folders are stored in the User Shell Folders Subkey subkey.

### Caution

- Do not delete this subkey or its entries from the registry, and do not change the values in the entries. These changes can cause serious, unexpected results.

# User Shell Folders Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User Shell Folders**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer

**Description**
The User Shell Folders subkey stores the paths to Windows Explorer folders for the current user of the computer.

### Note

- The entries in this subkey can also appear in the subkey Shell Folders. Both the subkeys Shell Folders and User Shell Folders can appear in both the keys HKEY_LOCAL_MACHINE and HKEY_CURRENT_USER. The entries that appear in user User Shell Folders take precedence over those in Shell Folders. The entries that appear in HKEY_CURRENT_USER take precedence over those in HKEY_LOCAL_MACHINE.

# User Shell Folders\Desktop

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Desktop**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\Desktop |

**Description**
Stores the path to the folder containing the shortcuts and Internet addresses that appear on the user's desktop.

You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's profile folder. The default is *Systemroot*\Documents and Settings*username*.

Common Desktop

# Favorites

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Favorites**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\Favorites |

**Description**
Stores the path to the folder containing the Internet addresses that appear in the **Favorites** menu of the user's Internet browser.

You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's profile folder. The default is *Systemroot*\Documents and Settings*username*.

# NetHood

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NetHood**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\NetHood |

**Description**
Stores the path to the folder containing shortcuts to servers that the user has added to My Network Places.

You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's profile folder. The default is *Systemroot*\Documents and Settings*username*.

# User Shell Folders\Personal Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Personal**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\My Documents |

**Description**
Stores the path to the user's Personal folder.

The Personal folder is the default location for saving application files. You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's Profiles folder. The default is *Systemroot*\Documents and Settings*username*.

# PrintHood

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PrintHood**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\PrintHood |

**Description**
Stores the path to the folder containing shortcuts to printers that the user has added to the computer.

You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's Profiles folder. The default is *Systemroot*\Documents and Settings*username*.

# User Shell Folders\Programs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Programs**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\Start Menu\Programs |

**Description**
Stores the path to the folder that contains the items that appear in the **Programs** menu on the **Start** menu.

You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's Profiles folder. The default is *Systemroot*\Documents and Settings*username*.

# SendTo

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SendTo**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\SendTo |

**Description**
Stores the path to the folder containing links to drives, communication programs, and applications.

You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's Profiles folder. The default is *Systemroot*\Documents and Settings*username*.

# Start Menu

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Start Menu**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\Start Menu |

**Description**
Stores the path to the folder containing the items that appear in the **Start** menu.

You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's Profiles folder. The default is *Systemroot*\Documents and Settings*username*.

Common Startup

# Recent

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recent**
HKCU\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *Path* | %USERPROFILE%\Recent |

**Description**
Stores the path to the folder containing the names of the documents that the user opened most recently.

These items appear in the **Documents** menu on the user's **Start** menu. You can enter any valid Universal Naming Convention (UNC) name or mapped drive in the value of this entry.

### Note

- The %USERPROFILE% variable represents the path to the user's Profiles folder. The default is *Systemroot*\Documents and Settings*username*.

# CurrentVersion\Policies Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policies**
HKCU\Software\Microsoft\Windows\CurrentVersion

**Description**
The Policies subkey contains entries that store Group Policy settings.

Group Policy adds, deletes, and changes the values of entries in this subkey when you enable or disable a policy setting. When the policy settings affecting a particular user or computer change (such as when the user moves to a new user group) Group Policy deletes the entries for the old group and adds the entries for the new group.

Group Policy manages registry entries in four Policies subkeys:

- Policies Subkey
- CurrentVersion\Policies
- Software\Policies
- CurrentVersion\Policies Subkey

The Policies subkeys in HKCU store policy-related entries that are configured separately for each user. The system adds these entries when you enable (and, for some policies, when you disable) a policy setting in the User Configuration folder in Group Policy.

The Policies subkeys in HKLM store policy-related entries that apply to all users of the computer. The system adds these entries when you enable (and, for some policies, when you disable) a policy setting in the Computer Configuration folder in Group Policy.

Many policy-related entries can appear in both HKCU and HKLM. Typically, when both entries exist, the entries in HKLM take precedence over the entries in HKCU.

This subkey stores policy-related entries for Windows NT 4.0 and earlier. The SOFTWARE\Policies subkey was added for Windows 2000, and it remains in Windows Server 2003. Please note that the different versions of Windows support different policy settings.

**Change Method**
To add, remove, or change the value of entries in this subkey, use Group Policy.

### Note

- Many of the entries in the Policies subkeys have counterparts in other registry subkeys. These counterparts, known as *preferences*, have the same effect as entries in the Policies subkey. However, when an entry appears in the Policies subkey, the preference is almost always ignored. For details, see the individual entry descriptions.

### Caution

- Do not use the registry editor to change the values in this subkey. If you do, they will be overwritten the next time your policy settings are refreshed.

# Policies\ActiveDesktop

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ActiveDesktop**
HKCU\Software\Microsoft\Windows\CurrentVersion\Policies

**Description**
The ActiveDesktop subkey stores the entries created when you configure a Group Policy setting for Active Desktop in Windows Server 2003. Group Policy creates and maintains these entries, and Active Desktop reads and interprets them.

# AdminComponent Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AdminComponent**
HKCU\Software\Microsoft\Windows\CurrentVersion\Policies\ActiveDesktop

**Description**
The AdminComponent subkey stores entries that Group Policy settings add for Active Desktop. These entries specify items that an administrator has added to or deleted from Active Desktop by configuring a policy setting.

# Policies\Explorer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Explorer**
HKCU\Software\Microsoft\Windows\CurrentVersion\Policies

**Description**
The Explorer subkey contains entries that store the configurations of Group Policy settings for Windows Explorer and for the Windows interface. These include policy settings for the **Start** menu, taskbar, desktop, and Control Panel. Group Policy creates and maintains the entries in this subkey, and Windows Explorer reads and interprets them.

This subkey stores policy-related entries that are configured separately for each user. The Software\Microsoft\Windows\CurrentVersion\Policies\Explorer subkey in HKEY_LOCAL_MACHINE stores policy-related entries that apply to all users of the computer.

### Note

- Many of the entries in the Policies subkeys have counterparts in other registry subkeys. These counterparts, known as *preferences*, have the same effect as entries in the Policies subkey. However, when an entry appears in the Policies subkey, the preference is almost always ignored. For details, see the individual entry descriptions.

**Concepts**
Policies\Explorer Subkey

# Explorer\NoFileAssociate

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoFileAssociate**
HKCU\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 for servers running Terminal Services, 0 for all others |

**Description**
Disables the buttons on the **File Types** tab. As a result, users can view file type associations, but they cannot add, delete, or change the associations.

The **File Types** tab shows which programs open when a user double-clicks a type of file. The file types are represented by the file name extension.

| Value | Meaning |
|---|---|
| 0 | The user can add, delete, and change file type associations. |
| 1 | The user cannot add, delete, or change file type associations. |

By disabling this tab, you might prevent the current user from creating an association that starts a risky or destructive program. Also, the current user cannot create less-productive associations, such as associating the .doc file type with Microsoft Wordpad instead of Microsoft Word.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Notes

- Although this entry is located in the Policies\Explorer subkey, it is not associated with a Group Policy included in Windows Server 2003. You can create a policy by adding this entry to an Administrative Templates (.adm) file. For more information about creating custom .adm files, see Windows Server 2003 Help and Support Center or Windows XP Professional Help and Support Center.

- This entry applies only to the current user. To prevent any user of the computer from adding, deleting, or changing file type associations, use the NoFileAssociate Entry entry in the HKLM subtree. If the settings of the **NoFileAssociate** entries conflict, the setting in HKCU takes precedence over the setting in HKLM.

### Tip

- To see the **File Types** tab, in My Computer, from the **Tools** menu, click **Folder Options**, and then click the **File Types** tab.

### Caution

- This entry specifies only whether buttons on the **File Types** tab in **Folder Options** are available. Any other method of changing file type associations is unaffected by this entry.

**Concepts**
NoFileAssociate Entry

# Windows Help

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Help**
HKCU\Software\Microsoft

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this subkey or its entries from the registry, and do not change the values in the entries. These changes can cause serious, unexpected results.

# Microsoft\Windows NT

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows NT**
HKCU\Software\Microsoft

**Description**
The Windows NT subkey stores configuration data for components of Windows Server 2003. The subkeys of the Windows NT subkey represent versions of the operating system, such as CurrentVersion, which refers to the version currently running on the computer. Each version subkey contains subkeys representing components that run on that version of the system.

The Windows NT subkey in HKEY_CURRENT_USER stores entries that apply only to the current user of the computer. The SOFTWARE\Microsoft\Windows NT subkey in HKEY_LOCAL_MACHINE stores entries that apply to all users of the computer.

**Concepts**
Microsoft\Windows NT Subkey

# Windows NT\CurrentVersion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CurrentVersion**
HKCU\Software\Microsoft\Windows NT

**Description**
The CurrentVersion subkey stores configuration data for programs that are designed to run on the most current version of Windows Server 2003 installed on the computer. The subkeys of CurrentVersion correspond to programs that run on the current version of Windows Server 2003. Those subkeys store user-specific configuration data for those programs.

# Devices Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Devices**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
The Devices subkey lists the local printers and network-accessible printers to which the client computer has a connection.

Each of the entries in this subkey has the following format:

| Entry name | Data type | Value |
|---|---|---|
| *printer-name* | REG_SZ | *driver-name*,*port*: |

*Printer-name* is either the name of the local printer or *****server-name******printer-name*.

*Driver-name* for Windows clients is **winspool**.

When the printer is a local printer, *port* is the name of the port to which it is connected; for example, **LPT1**. Otherwise, *port* is **Ne***xx*, where *xx* is a numeric value, starting with 00. This latter format is used for printers that are access through the network, for local printers with ports that begin with ****, when the port name has a space in it, and when the name of the port has a length greater than five.

# Extensions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Extensions**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
The Extensions subkey stores entries that associate file name extensions with the programs that run them at the command line. These entries are used only when a file name extension is not already associated with a program.

Each of the entries in this subkey has the following format:

| Entry name | Data type | Value |
|---|---|---|
| *File name extension* | REG_SZ | *Command line to run* |

In the following example, the entry indicates that the default action for all files with the extension .txt is to open the file with Microsoft Notepad:

| Entry name | Data type | Value |
|---|---|---|
| txt | REG_SZ | Notepad.exe^.txt |

In the following example, the entry indicates that the default action for all files with the extension .txt is to open the file with notepad and print it to the default printer. At run time, the caret symbol (^) is replaced with the name of the selected file in the command line:

| Entry name | Data type | Value |
|---|---|---|
| txt | REG_SZ | Notepad.exe^.txt -openandprint |

**Change Method**
To associate a file type with a program, use Windows Explorer. From the **Tools** menu, click **Folder Options**, and then click the **File Types** tab.

### Note

- This subkey exists to provide backward compatibility with older versions of Windows. In Windows Server 2003, file associations are provided primarily by the information stored in HKEY_CLASSES_ROOT.

### Tip

- For more information about creating a file association, see the Microsoft Platform Software Development Kit (SDK).

HKEY_CLASSES_ROOT

# Network Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support administration tools designed for Windows NT 4.0 or earlier.

# Server Manager

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Server Manager**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Network

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 and earlier. Specifically, this subkey stores configuration data for Server Manager.

# User Manager

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User Manager**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Network

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 and earlier. Specifically, this subkey stores configuration data for User Manager.

### Note

- In Windows Server 2003 and Windows XP Professional, use the Users and Groups snap-in. For more information about new ways to do familiar tasks, see Windows Server 2003 Help and Support Center or Windows XP Professional Help and Support Center.

# User Manager for Domains

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User Manager for Domains**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Network

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 and earlier. Specifically, this subkey stores configuration data for User Manager for Domains.

### Notes

- In Windows Server 2003, use Active Directory Users and Computers. For more information about new ways to do familiar tasks, see Windows Server 2003 Help or Windows XP Professional Help.

- If you are administering an Active Directory domain, use Active Directory Users and Computers. If you are remotely administering a Windows NT 4.0 domain, you will need to use User Manager for Domains from a computer running Windows NT 4.0 or Windows 2000; User Manager for Domains is not supported on Windows Server 2003.

# Program Manager

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Program Manager**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
Program Manager is the primary desktop interface for Windows NT 3.51 and earlier. In Windows Server 2003, the default interface is Windows Explorer, but you can still use Program Manager (Progman.exe).

# Program Manager\Restrictions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restrictions**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager

**Description**
The Restrictions subkey remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this subkey.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# NoClose Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoClose**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Restrictions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# NoFileMenu Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoFileMenu**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Restrictions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# NoRun Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoRun**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Restrictions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# NoSaveSettings Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NoSaveSettings**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Restrictions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# Program Manager\Restrictions Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restrictions**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Restrictions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
The Restrictions subkey remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this subkey.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# ShowCommonGroups

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ShowCommonGroups**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Restrictions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# EditLevel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**EditLevel**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Restrictions

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 \| 3 \| 4 | 0 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# Program Manager\Settings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Settings**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager

**Description**
The Settings subkey remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this subkey.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# AutoArrange

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AutoArrange**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Settings

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# display.drv

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**display.drv**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Settings

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File name* | vga.drv |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# MinOnRun

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MinOnRun**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Settings

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# SaveSettings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SaveSettings**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager\Settings

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this entry.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# UNICODE Groups

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**UNICODE Groups**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Program Manager

**Description**
The UNICODE Groups subkey remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this subkey.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# TaskManager

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TaskManager**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
The TaskManager subkey stores preferences for Task Manager.

# TrueType

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TrueType**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
The TrueType subkey stores data that determines the use and display of TrueType fonts in Windows-based applications.

# TTEnable

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TTEnable**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\TrueType

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | 1 |

**Description**
Specifies whether **Add Fonts** in the Fonts folder displays TrueType fonts. When the value of this entry is 1, or if this value is absent from the registry, **Add Fonts** displays all font files. When the value of this entry is not 1, **Add Fonts** displays only fonts with the file name extensions .FON and .FO_.

**Change Method**
You should not change the value of this entry.

### Note

- Changing the value of this entry to a value other than 1 will not disable TrueType fonts. TrueType fonts are always enabled.

# TTonly

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TTonly**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\TrueType

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | 0 \| 1 | 0 |

**Description**
This entry is obsolete. It once determined whether fonts other than TrueType fonts can be used in Windows-based programs, and it can still be changed from the Fonts folder. However, its value is unused.

| Value | Meaning |
|---|---|
| 0 | All installed fonts can be used. |
| 1 | Only TrueType fonts can be used. |

**Change Method**
This entry is obsolete, though it can still be found in the Fonts folder. In **Control Panel** double-click **Fonts**. On the **Tools** menu, click **Folder Options**, and then click the **TrueType Fonts** tab. Select the **Show only TrueType Fonts in the programs on my computer** check box.

### Note

- For more information on Fonts, click the **Help** menu in the Fonts folder.

# CurrentVersion\Windows

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
The Windows subkey contains entries that store user preferences.

**See Also**
**Concepts**
Control\Windows Subkey
CurrentVersion\Windows Subkey

# Device Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Device**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Output-device-name*,winspool,*Port-connection* | *Output-device-name*,winspool,*Port-connection* |

**Description**
Specifies the default printer. An explicit port and driver must be assigned to the printer device. The *device-driver* is the file name (without the extension) of the device-driver file.

**Change Method**
To change the default printer, from the **Start** menu, point to **Settings**, and click **Printers**. Right-click the printer, and then click **Set as Default Printer**.

# Documents

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Documents**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File name extensions* | (None) |

**Description**
Defines files that Windows Server 2003 treats as documents. Enter the file name extensions without the preceding periods, and separate the extensions from each other with a space.

Use this entry only to define document file name extensions that are not associated with any application and that are not listed in the Extensions subkey.

# fPrintError

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**fPrintError**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether error messages generated during debugging are printed. Error messages usually indicate serious problems in the Window Manager code.

| Value | Meaning |
|---|---|
| 0 | Disabled. Error messages do not print. |
| 1 | Enabled. Error messages print. |

**Note**

- This entry appears only when running a debug build of the operating system.

# fPrintFileLine

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**fPrintFileLine**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether to print the file and line number that generated an error message during debugging.

| Value | Meaning |
|---|---|
| 0 | Disabled. File and line number do not print. |
| 1 | Enabled. File and line number do print. |

**Note**

- This entry appears only when running a debug build of the operating system.

# fPrintVerbose

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**fPrintVerbose**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies the level of detail printed when debugging generates warnings and error messages. Verbose data is intended only for Microsoft internal development purposes.

| Value | Meaning |
|---|---|
| 0 | Standard debugging data is displayed. |
| 1 | All data is displayed. |

**Note**

- This entry appears only when running a debug build of the operating system.

**See Also**

# fPromptOnWarning

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**fPromptOnWarning**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the debugger prompts the user when debugging generates warnings. Warnings usually indicate errors in an application's interaction with the Window Manager.

| Value | Meaning |
|---|---|
| 0 | Do not prompt. |
| 1 | Prompt. |

**Note**

- This entry appears only when running a debug build of the operating system.

# load

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**load**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | [*Path*]*File name(s)* | (This entry has no default value.) |

**Description**
Specifies the programs that run when Windows Server 2003 starts. The programs are minimized (they appear as taskbar icons) while they are running.

This entry stores a list of file names of programs or files associated with an application. Each file name must be separated from the others by a space. If the file is not located in the *Systemroot* directory, then you must specify the path to the file.

**Change Method**
To load a program at startup, add the application to *Systemroot*\Documents and Settings\All Users\Start Menu\Programs\Startup. Right-click the application icon, click **Properties**, click the **Shortcut** tab, then in the **Run** list, select **Minimized**. This will not actually change the value of the **load** registry entry, but it will emulate the behavior.

**See Also**
**Concepts**
run Entry

# NetMessage

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NetMessage**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | yes \| no | no |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Caution

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# NullPort

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NullPort**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* \| None | (None) |

**Description**
Windows Server 2003 does not use this entry. The entry remains in the registry to support programs designed for Windows NT 4.0 or earlier.

**Caution**

- Do not delete this entry from the registry or change its value. These changes can cause serious, unexpected results.

# Windows\Programs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Programs**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File name extensions* (no periods) | com exe bat pif cmd |

**Description**
Specifes the file types that Windows Server 2003 considers to be applications. Each file name extension must be separated from the others by a space.

**See Also**
**Concepts**
Documents

# run Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**run**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Windows

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | [*Path*]*File name(s)* | (This entry has no default value.) |

**Description**
Specifies the applications that the user sets Windows Server 2003 to run at startup.

This entry stores a list of file names of applications or documents associated with an application. Each file name must be separated from the others by a space. If the file is not located in the *Systemroot* directory, you must specify the path to the file.

# Winlogon Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Winlogon**
HKCU\Software\Microsoft\Windows NT\CurrentVersion

**Description**
The Winlogon subkey stores configuration data for the Winlogon component of Windows Server 2003. Winlogon authenticates an interactive user and enables the user to log on. Winlogon supports desktops, the **Ctrl+Alt+Del** secure attention sequence, screen saver control, network provider support, authentication, and password updates.

### Note

- Many of the entries in this subkey can be configured or overridden by the Security Configuration Editor in Group Policy.

# ReportDC

Updated: November 10, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ReportDC**
HKU\.DEFAULT\Software\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Stores the user setting for the domain controller message. (The computer setting is stored in the value of ReportControllerMissing.)

This entry determines, in part, whether the system displays the following message when it cannot contact the domain controller that stores a user's roaming user profile:

```
A domain controller for your domain could not be contacted. You have been logged on using cached account
information. Changes made to your profile since you last logged on might not be available.
```

This entry stores the setting of the **Do not display this message again** check box on the domain controller message dialog box. When the checkbox is selected, the system sets the value of this entry to 0.

| Value | Meaning |
|---|---|
| 0 | Do not display the domain controller message. (The check box is selected.) |
| 1 (or not in the registry) | Display the domain controller message. (The check box is cleared.) |

Two registry entries manage the display of the domain controller message: **ReportDC** and ReportControllerMissing. The message is displayed only when both entries are set to their display setting, that is, when **ReportDC** is either set to 1 or does not appear in the registry, and when **ReportDomainController** appears in the registry with a value of TRUE. By default, the message is not displayed.

**Change Method**
The value of this entry is changed when you check or clear **Do not display this message again** on the domain controller message box.

### Note

- While the domain controller message is displayed, other elements of the user interface are disabled, but all processes continue to run normally. If the **OK** button accompanying the message is not clicked after two minutes, the message box disappears.

NoPopUpsOnBoot
ReportControllerMissing

# Winlogon\RunLogonScriptSync

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RunLogonScriptSync**
HKCU\Software\Microsoft\Windows NT\CurrentVersion\Winlogon

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the system waits for the logon script to finish running before it starts Windows Explorer and creates the desktop.

| Value | Meaning |
|---|---|
| 0 | The logon script and Windows Explorer can run simultaneously. |
| 1 | Windows Explorer does not start until the logon script has finished running. |

- For detailed information about particular Group Policy settings, see the *Windows Server 2003 Technical Reference*.
- For general information about Group Policy, see Windows Server 2003 Help or Windows XP Professional Help.

**Change Method**
To change the value of this entry, use Group Policy. This entry corresponds to the **Run logon scripts synchronously** Group Policy setting (User Configuration\Administrative Templates\System\Logon/Logoff).

### Notes

- This entry also appears in the CurrentVersion\Winlogon subkey in HKEY_LOCAL_MACHINE (see Winlogon\RunLogonScriptSync Subkey). The value in HKEY_LOCAL_MACHINE applies to all users. The value in HKEY_CURRENT_USER is configured separately for each user.
- This entry can be superseded by Group Policy settings included in Windows Server 2003. While the **Run logon scripts synchronously** Group Policy setting is enabled (in the Computer Configuration or User Configuration policy folders), the system ignores this entry. The configuration of the **Run logon scripts synchronously** policy setting is stored in the values of **RunLogonScriptSync** in HKEY_LOCAL_MACHINE and of **RunLogonScriptSync** in HKEY_CURRENT_USER.

# Microsoft\Windows Script

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Script**
HKCU\Software\Microsoft\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Windows Script\Settings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Settings**
HKCU\Software\Microsoft\Windows Script\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Settings\Enabled

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabled**
HKCU\Software\Microsoft\Windows Script\Settings

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Windows Script Host (WSH) is disabled for the current user. This entry disables all scripts that rely on WSH, including VBScript and Jscript. If WSH is disabled and the user attempts to run a WSH script, then a message alerts the user that WSH is disabled. The message appears even if the user attempts to run the script from a bat ch file or a designated script host.

| Value | Meaning |
|---|---|
| 0 | WSH is disabled for the current user. |
| 1 | WSH is enabled for the current user. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Software\Policies

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policies**
HKCU\Software

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Policies\Microsoft

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft**
HKCU\Software\Policies

**Description**
The Microsoft subkey contains entries that store Group Policy settings for Microsoft products. Group Policy creates and maintains the entries in this subkey.

This subkey stores entries that are configured separately for each user. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the User Configuration folder in Group Policy.

The Policies\Microsoft Subkey subkey in HKEY_LOCAL_MACHINE stores entries for policy settings that apply to all users of the computer. The system adds these entries when you enable (and, for some policy settings, when you disable) a policy setting in the Computer Configuration folder in Group Policy.

**Change Method**
To add, remove, or change the entries in this subkey, use Group Policy.

# Microsoft\Control Panel

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Control Panel**
HKCU\Software\Policies\Microsoft

**Description**
The Control Panel subkey contains entries that store Group Policy settings for Control Panel programs. Group Policy creates and maintains the entries in this subkey, and the Control Panel programs read and interpret them.

**Change Method**
To add, remove, or change the entries in this subkey, use Group Policy.

### Note

- The entries in this subkey take precedence over entries of the same name in the HKCU\Control Panel Key and HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Control Panel subkeys.

# Control Panel\International

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**International**
HKCU\Software\Policies\Microsoft\Control Panel

**Description**
The International subkey contains entries that store Group Policy settings for calendar options in Regional Options in Control Panel. Group Policy reads and maintains the entries in this subkey, and Regional Options reads and interprets them.

There is also a Regional Options setting for the desktop in Group Policy, which is stored in the values of the entries in the Control Panel\Desktop subkey.

**Change Method**
To change the value of this entry, use Group Policy.

### Note

- The entries in this subkey, which all relate to Group Policy setting, take precedence over the entries in the International Subkey subkey in the HKCU\Control Panel subkey, which do not relate to Group Policy settings.

**See Also**
**Concepts**
International Subkey

# Calendars

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Calendars**
HKCU\Software\Policies\Microsoft\Control Panel\International

**Description**
The Calendars subkey contains entries that store Group Policy settings for calendar options in Regional Options in Control Panel. Group Policy reads and maintains the entries in this subkey, and Regional Options reads and interprets them.

There is also a Regional Options setting for the desktop in Group Policy, which is stored in the values of the entries in the Control Panel\Desktop subkey.

**Change Method**
To change the value of this entry, use Group Policy.

### Note

- The entries in this subkey, which all relate to Group Policy settings, take precedence over the entries in HKCU\Control Panel\International\Calendars subkey, which do not relate to Group Policy settings.

# Microsoft\MMC Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MMC**
HKCU\Software\Policies\Microsoft

**Description**
The MMC subkey contains entries that store Group Policy settings for the Microsoft Management Console (MMC). The entries in this subkey are written and maintained by Group Policy, and the MMC program reads and interprets them.

# Class-ID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Class-ID**
HKCU\Software\Policies\Microsoft\MMC

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Policies\Microsoft\Windows Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows**
HKCU\Software\Policies\Microsoft

**Description**
The Windows subkey contains entries that store Group Policy settings for components of Windows Server 2003. Group Policy creates and maintains the subkeys and entries in the Windows subkey, and those subkeys and entries are read and interpreted by the component that implements them.

This subkey stores entries that are configured separately for each user. There is also a Windows Subkey subkey in the HKEY_LOCAL_MACHINE subtree, which stores entries that apply to all users of the computer.

**See Also**
**Concepts**
Windows Subkey

# Installer Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installer**
HKCU\Software\Policies\Microsoft\Windows

**Description**
The Installer subkey stores the entries created when you configure a Group Policy setting for Windows Installer. Group Policy creates and maintains these entries, and Windows Installer reads and interprets them.

This subkey stores policy-related entries that are configured separately for each user. The system adds these entries to the registry when you enable (and, for some policies, when you disable) a policy in the User Configuration folder in Group Policy.

There is also an Windows\Installer Subkey subkey in the Policies subkey in the HKEY_LOCAL_MACHINE subtree, which stores entries for policies that apply to all users of the computer. The system adds these entries to the registry when you enable (and, for some policies, when you disable) a policy in the Computer Configuration folder in Group Policy.

**Change Method**
To add, remove, or change the value of entries in this subkey, use Group Policy.

**See Also**
**Concepts**
Windows\Installer Subkey

# UNICODE Program Groups

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**UNICODE Program Groups**
HKCU

**Description**
The UNICODE Program Groups key remains in the registry. However, Windows Server 2003 does not include Program Manager, the component that used this key.

### Note

- If a user or program attempts to start Program Manager, Windows Server 2003 starts Windows Explorer instead.

# HKEY_LOCAL_MACHINE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM

**Description**
The HKEY_LOCAL_MACHINE subtree contains information about the local computer system, including hardware and operating system data, such as bus type, system memory, device drivers, and startup control parameters.

# Hardware Key

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM

**Description**
The HARDWARE key stores data about the computer hardware that the system detects. This key is recreated each time the system starts. It includes information about devices, and about the software drivers and other resources associated with devices.

# HARDWARE\DESCRIPTION

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\HARDWARE

**Description**
The DESCRIPTION subkey is a repository for data collected by the Windows Server 2003 hardware recognizer. It includes information about the BIOS, processors, and bus architecture. The DESCRIPTION subkey is recreated each time the system starts.

# System Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\HARDWARE\DESCRIPTION

**Description**
The System subkey stores data collected by the Windows Server 2003 hardware recognizer. It includes information about the BIOS, processors, and bus architecture. The System subkey is recreated each time the system starts.

# DEVICEMAP

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\HARDWARE

**Description**
The DEVICEMAP subkey contains a set of subkeys representing the base classes of all devices on the computer. A driver that controls a device stores the base class name in an entry in the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services subkey.

# SAM Key

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM

**Description**
The SAM key contains information used by the Security Accounts Manager. Servers that are running Windows Server 2003 and are acting as domain controllers use this key to store user and group information pertaining to the directory service restore mode. Domain controllers maintain domain user and group information in Active Directory to manage user security. However, Windows NT 4.0 and earlier, as well as Windows Server 2003s that are not part of a Windows Server 2003 domain, use SAM. All the data in this key is in binary form.

The HKLM\SECURITY\SAM subkey stores a duplicate of the information in this key.

The information in the SAM key is not viewable by users of Windows XP Professional, and should not be edited directly in Windows Server 2003.

**Change Method**
To change the values of the entries in this key, use Active Directory.

### Caution

- Do not alter or add entries in the SAM key. Doing so could prevent users from logging on to the domain or their computers, and it could require you to restore your entire system.

# Security Key

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM

**Description**
The SECURITY key contains security information used by the system and network.

The information in the SECURITY key is not viewable by users of Windows XP Professional, and should not be edited directly in Windows Server 2003. All the data in this key is in binary form.

**Change Method**
To change configurations that are specified by information in this key, use the tools designed for configuring Group Policy, Security Policy, and Active Directory, and other tools designed for managing computers and users.

### Caution

- Do not modify or add entries in the SECURITY key. Doing so could prevent users from logging on to the domain or their computers, and it could require you to restore your entire system.

# HKLM\SOFTWARE

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM

**Description**
The SOFTWARE key stores program variables that apply to all users of the computer. The system stores some of its variables in the subkeys in SOFTWARE. In addition, the SOFTWARE subkey contains subkeys representing the vendors, including Microsoft, who produce the software running on the system.

**See Also**
**Concepts**
SOFTWARE Subtree

# SOFTWARE\Microsoft

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE

**Description**
The Microsoft subkey stores configuration data for Microsoft programs running on the computer. The subkeys in the Microsoft subkey represent each of the programs, and they store settings that affect only that program.

The Microsoft subkey in HKEY_LOCAL_MACHINE stores entries that apply to all users of the computer. The Microsoft subkey in HKEY_CURRENT_USER stores entries that apply only to the current user of the computer.

**See Also**
**Concepts**
Microsoft Subkey

# Microsoft\Command Processor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
The Command Processor subkey stores user preferences for the command processor (Cmd.exe).

**Change Method**
You can change the values of the entries in this subkey by using Command Processor (Cmd.exe), but only for the duration of that Cmd.exe's execution. For all other changes, you must edit the registry directly.

**Activation Method**
If you make changes to the value of the entries in this subkey by editing the registry directly, you must restart Cmd.exe to make the changes effective.

## Notes

- Entries in the Command Processor subkey can also appear in HKLM. If both appear, in most cases the values in HKCU take precedence over the values in HKLM. However, the HKLM **Autorun** entry executes before the HKCU **Autorun** entry. Command-line settings entered in Cmd.exe take precedence over registry settings.

- For more information about Command Processor, see Windows Server 2003 Help or Windows XP Professional Help.

**See Also**
**Concepts**
Command Processor Subkey

# Command Processor\AutoRun

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *command* | (None) |

**Description**
Contains commands that are run each time you start Command Processor (Cmd.exe).

**Change Method**
You can change the value of this entry by using Cmd.exe and typing **CMD /D**, but only for the duration of that Cmd.exe's execution. For all other changes, you must edit the registry directly.

**Activation Method**
To make the value of this entry effective, you must restart Cmd.exe.

### Note

- **AutoRun** can appear in HKLM and HKCU. If both appear in the registry, the system first runs the value of the entry in HKLM, and then it runs the value in HKCU.

### Tip

- For more information about the AutoRun feature, at the command prompt, type **CMD /?**.

**See Also**
**Concepts**
AutoRun Entry

# Command Processor\CompletionChar

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CompletionChar**
HKLM\SOFTWARE\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0x1F \| 0x20–0xFF | 0x40 (*Completion disabled*) |

**Description**
Specifies a character that activates the file-name completion feature in the command processor (Cmd.exe).

To specify a character, enter the hexadecimal value of an ASCII control character. For example, 0x4 represents CTRL+D and 0x6 represents CTRL+F. To disable the file-name completion feature, set the value of this entry to 0x0 or to a value greater than or equal to 0x20.

| Value | Meaning |
|---|---|
| 0x0 | Disables completion. |
| 0x1–0x1F | Corresponding ASCII control character activates completion. |
| 0x20 or greater | Disables completion. |

**Change Method**
To change the completion character in Windows Server 2003, use the registry editor Regedit.exe. You can also change the value of this entry by using Cmd.exe, but only for the duration of that Cmd.exe's execution.

**Activation Method**
If you make changes to the value of this entry by editing the registry directly, you must restart Cmd.exe to make the changes effective.

### Notes

- **CompletionChar** can appear in HKLM and HKCU. If both appear in the registry, then the value of the entry in HKCU takes precedence over the value in HKLM. The command-line parameters take precedence over the registry settings while using Cmd.exe.
- Assigning the values 0x0, 0xD, or 0x20 to this entry disables file name completion rather than assigning a completion character.
- If you use the console Paste function to enter text into a CMD window, you might trigger completion if the characters you paste contain completion characters.

### Tip

- For more information about the file name completion feature, at the command prompt, type: **CMD /?**
- The datatype of this entry can be either REG_DWORD or REG_SZ.

### Tip

- To enable or disable file name completion and directory name completion for one use of Cmd.exe, at the command prompt, type **CMD /F:ON** (to enable) or **CMD /F:OFF** (to disable). This command sets the completion character to CTRL+F (0x6).

- For more information about the file-name completion feature, at a command prompt, type **CMD /?**

**See Also**
**Concepts**
PathCompletionChar Entry
CompletionChar Entry

# Command Processor\DefaultColor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0xFE | 0x0 |

**Description**
Specifies a default background color and text color for the window in Command Processor (Cmd.exe). The value consists of two hexadecimal digits. The first digit specifies the background color; the second digit specifies the text color. The hexadecimal values correspond to the following colors:

| Hexadecimal value | Color |
|---|---|
| 0 | Black |
| 1 | Blue |
| 2 | Green |
| 3 | Aqua |
| 4 | Red |
| 5 | Purple |
| 6 | Yellow |
| 7 | White |
| 8 | Gray |
| 9 | Light Blue |
| A | Light Green |
| B | Light Aqua |
| C | Light Red |
| D | Light Purple |
| E | Light Yellow |
| F | Bright White |

This entry is used only when its value is valid and not 0x0, and when the user has not specified the window color by using the COLOR or /T commands. Values are not valid if the background color and the text color are identical, such as 0x55. If the value of this entry is not valid or is 0x0, and the user has not entered a command to change the color, then the command processor uses the colors specified for the console window in which the command processor runs.

**Activation Method**
If you make changes to the value of this entry by editing the registry directly, then you must restart Cmd.exe to make the changes effective.

### Notes

- **DefaultColor** can appear in HKLM and HKCU. If both appear in the registry, the value of the entry in HKCU takes

precedence over the value in HKLM.

- The datatype of this entry can be either REG_DWORD or REG_SZ.

**See Also**
**Concepts**
DefaultColor Entry
ScreenColors

# Command Processor\DelayedExpansion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the command processor supports delayed expansion of environment variables. If the value of this entry is 1, then the command processor interprets an exclamation point (**!**) as an environment variable expands only when used.

By default, the command processor expands variables when it reads a line of text. But you can direct the command processor to expand a variable only when it is used. As a result, you can include variables in compound conditional statements and prevent them from being set before they are tested.

| Value | Meaning |
|---|---|
| 0 | Delayed expansion is not supported. The command processor expands environment variables when it reads them. It does not support exclamation points as delayed variables. |
| 1 | Delayed expansion is supported. The system expands environment variables surrounded by exclamation points (such as !VAR!) only when they are used. |

**Change Method**
You can change the value of this entry by using Command Processor (Cmd.exe) and typing **cmd /v:on**, but only for the duration of that Cmd.exe's execution. For all other changes, you must use the registry editor Regedit.exe.

**Activation Method**
If you make changes to the value of this entry by using Regedit.exe, then you must restart Cmd.exe to make the changes effective.

## Notes

- The **DelayedExpansion** entry can appear in HKEY_LOCAL_MACHINE and in HKEY_CURRENT_USER. If both appear in the registry, then the value of the entry in HKEY_CURRENT_USER takes precedence over the value in HKEY_LOCAL_MACHINE.
- Windows Server 2003 does not add this entry to the registry. You can add it by using the registry editor Regedit.exe. Even when this entry appears in the registry, the setting of the command line parameter **/V** takes precedence over this value.
- The datatype of this entry can be either REG_DWORD or REG_SZ.

## Tip

- For more details, start the Command Processor (Cmd.exe), type either **help set** or **cmd /?**, and read the entry on the **/V** command.

**See Also**
**Concepts**
DelayedExpansion Entry

# Command ProcessorEnableExtensions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the extensions to Command Processor (Cmd.exe), such as chdir and setlocal, are enabled. Because the extensions might be incompatible with a command-script language, Windows Server 2003 lets you disable the extensions. This entry affects all extensions. You cannot use it to enable or disable extensions selectively. You can, however, disable extensions for a particular invocation of Cmd.exe by using the **/E:OFF** switch.

| Value | Meaning |
|---|---|
| 0 | Disabled |
| 1 | Enabled |

**Change Method**
You can change the value of this entry by using Cmd.exe and typing **cmd /e:off**, but only for the duration of that Cmd.exe's execution. For all other changes, you must edit the registry directly.

**Activation Method**
If you make changes to the value of this entry by editing the registry directly, you must restart Cmd.exe to make the changes effective.

### Notes

- **EnableExtensions** can appear in HKLM and HKCU. If both appear in the registry, then the value of the entry in HKCU takes precedence over the value in HKLM.

- The datatype of this entry can be either REG_DWORD or REG_SZ.

**See Also**
**Concepts**
EnableExtensions Entry

# Command Processor\PathCompletionChar

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Command Processor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0 \| 0x1–0x1F \| 0x20–0xFF | 0x40 (*Completion disabled*) |

**Description**
Specifies a character that activates the directory name completion in the command processor (Cmd.exe).

To specify a character, enter the hexadecimal value of an ASCII control character. For example, 0x4 represents CTRL+D and 0x6 represents CTRL+F. To disable the directory name completion, set the value of this entry to 0x0 or to a value greater than or equal to 0x20.

| Value | Meaning |
|---|---|
| 0x0 | Disables completion. |
| 0x1–0x1F | Corresponding ASCII control character activates completion. |
| 0x20 or greater | Disables completion. |

**Change Method**
To change the completion character in Windows Server 2003, use the registry editor Regedit.exe. You can also change the value of this entry by using Cmd.exe, but only for the duration of that Cmd.exe's execution.

**Activation Method**
If you make changes to the value of this entry by editing the registry directly, you must restart Cmd.exe to make the changes effective.

### Note

- **PathCompletionChar** can appear in HKLM and HKCU. If both appear in the registry, then the value of the entry in HKCU takes precedence over the value in HKLM.

### Tip

- To enable or disable directory name completion for one use of Cmd.exe, at the command prompt, type **CMD /F:ON** (to enable) or **CMD /F:OFF** (to disable). This command sets the completion character to CTRL+D (0x4).

- For more information about the path completion feature, at the command prompt, type **CMD /?**

# Microsoft\Driver Signing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
The Driver Signing subkey in HKLM stores entries for the driver signing feature. The entries in this subkey apply to all users of the computer.

Microsoft digitally signs driver files to affirm that the driver software has been tested with Windows and has not been altered since it was tested.

### Note

- The entries in this subkey apply to all users of the computer. The entries in the Driver Signing Subkey subkey in HKCU apply only to the current user.

### Tip

- For more information about driver signing, see Windows Server 2003 Help or Windows XP Professional Help.

**See Also**
**Concepts**
Driver Signing Subkey

# Driver Signing\Policy

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Driver Signing

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | 00 \| 01 \| 02 | 01 |

**Description**
Specifies how the system responds when a user tries to install device driver files that are not digitally signed.

| Value | Meaning |
|---|---|
| 00 | Ignore. The installation proceeds, even if it includes unsigned files. |
| 01 | Warn. The system notifies the user that files are not digitally signed, and it prompts the user to decide whether to stop the installation or to proceed with it and permit unsigned files to be installed. |
| 02 | Block. The system will not install unsigned files. As a result, the installation stops, and none of the files in the driver package are installed. |

This entry applies to all users of the computer. However, if a stricter setting is configured for the current user (in Policy Entry in HKCU) or a user Group Policy setting establishes a stricter setting (in **BehaviorOnFailedVerify**), then this value is ignored for the current user.

This entry stores the option selected in the **File signature verification** section of the **Driver Signing Options** dialog box when the **Apply setting as system default** box is selected. If the box is not selected, then the selection applies only to the current user, and it is stored in the value of Policy Entry in HKCU\SOFTWARE\Microsoft\Driver Signing.

**Change Method**
To change the value of this entry, use System in Control Panel. Click the **Hardware** tab, click **Driver Signing**, select an option in the **File signature verification** section, and then click the **Apply setting as a system default** box.

### Note

- This entry applies to all users of the computer. The **Policy** entry also can appear in HKCU for a particular user.

**Concepts**
Policy Entry

# DrWatson

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
The DrWatson subkey stores configuration settings for Dr. Watson for Windows (drwtsn32.exe), the application error debugger. These entries specify how Dr. Watson for Windows notifies the user of an application error, and how its log file and crash dump file are configured.

Dr. Watson for Windows installs with Windows Server 2003. The registry adds these entries in this subkey the first time Dr. Watson for Windows starts on the system.

**Change Method**
To change the values of the entries in this subkey, use Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

# AppendToLogFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Dr. Watson for Windows overwrites the existing log file with new data or appends new data to the end of the existing log file. By default, the log file is named Drwtsn32.log and is stored in the system root directory.

| Value | Meaning |
|---|---|
| 0 | Do not append. Dr. Watson for Windows overwrites the existing log file each time it records data about an application error. |
| 1 | Append. Dr. Watson for Windows appends new data to the end of the existing log file. |

**Change Method**
To change the value of this entry, use the **Append to Existing Log File** option in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**Tip**

- For a detailed description of the log file of Dr. Watson for Windows, start Drwtsn32.exe, click **Help**, and then double-click **Log File Description**.

# CrashDumpFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File path & name* | %windrive%\Documents and Settings\All Users\Application Data\Microsoft\Dr Watson\user.dmp |

**Description**
Specifies the location of the crash dump file for Dr. Watson for Windows. The crash dump file is a binary file that is created when a program stops abnormally. The crash dump file can be interpreted by the Windows Debugger.

All users must have permission to read and write to the crash dump file. By default, the crash dump file is named user.dmp and resides in the root of the system directory.

This entry is used only when the value of CreateCrashDump is 1.

**Change Method**
To change the value of this entry, enter a file name in the **Crash Dump** text box in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**See Also**
**Concepts**
CreateCrashDump

# CreateCrashDump

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Dr. Watson for Windows creates a binary crash dump file when a program stops abnormally. The crash dump file can be interpreted by the Windows Debugger.

If the value of this entry is 1, then the location of the crash dump file must appear in the value of the CrashDumpFile entry. By default, the crash dump file is named user.dmp and is in the system root directory.

**Change Method**
To change the value of this entry, use the **Create Crash Dump File** option in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**Concepts**
CrashDumpFile

# DumpAllThreads

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies which application threads are included in the log file that Dr. Watson for Windows creates when an application error occurs. By default, the log file is named Drwtsn32.log and is in the system root directory.

| Value | Meaning |
|---|---|
| 0 | Error thread only. The log file includes data only for the thread that caused the application error. |
| 1 | All threads. The log file includes data for all threads that run in the process in which the application error occurred. |

**Change Method**
To change the value of this entry, use the **Dump All Thread Contexts** option in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**Tip**

- For a detailed description of the log file of Dr. Watson for Windows, start Drwtsn32.exe, click **Help**, and then double-click **Log File Description**.

# DumpSymbols

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether Dr. Watson for Windows includes the symbol table for each application module in its log file. The symbol table consists of the name and memory address of each symbol. By default, because it can be very large, the symbol table is not included in the log file.

| Value | Meaning |
|---|---|
| 0 | Omit symbol table |
| 1 | Include symbol table |

**Change Method**
To change the value of this entry, use the **Dump Symbol Table** option in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**Tip**

- For a detailed description of the log file of Dr. Watson for Windows, start Drwtsn32.exe, click **Help**, and then double-click **Log File Description**.

# Instructions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0x1F4 (*0–500*) | 0xA (*10*) |

**Description**
Specifies how many instructions preceding and following the faulty instruction are included in the instruction disassembly portion of Drwtsn32.log, the log file for Dr. Watson for Windows.

The instruction disassembly includes:

- The function that was being executed when the error occurred;
- The memory address, raw machine instruction, and decoded machine instruction for each adjacent instruction; and
- A complete analysis of the faulty instruction.

**Change Method**
To change the value of this entry, enter a number in the **Number of Instructions** text box in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**Tip**

- To see an example of the instruction disassembly portion of the Dr. Watson for Windows log file, start Drwtsn32.exe, click **Help**, double-click **Log File Description**, and then scroll through the file.
- For a detailed description of the Dr. Watson for Windows log file, start Drwtsn32.exe, click **Help**, and then double-click **Log File Description**.

# LogFilePath Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Path name* | %windrive%\Documents and Settings\All Users\Application Data\Microsoft\Dr Watson |

**Description**
Specifies the location of Drwtsn32.log, the log file for Dr. Watson for Windows.

The log file contains diagnostic data about application errors that occur. All users must have permission to read and write to the log file.

**Change Method**
To change the value of this entry, enter a path in the **Log File Path** box in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**Tip**

- For a detailed description of the log file of Dr. Watson for Windows, start Drwtsn32.exe, click **Help**, and then double-click **Log File Description**.

# MaximumCrashes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0xA |

**Description**
Specifies how many errors Dr. Watson for Windows maintains at any given time in its application error viewer and in the Event Viewer application log. When the number of recorded errors reaches the value of this entry, Dr. Watson operates normally and adds new errors to its log and crash dump file, but it does not add any new errors to its application log viewer or to the Event Viewer application log until it is reset.

The user is not notified that the number of crashes has reached the maximum.

To reset Dr. Watson for Windows, run Drwtsn32.exe. You can either click **Clear** or increase the value in the **Number of Errors to Save** box. When you click **Clear**, you delete all errors from the application error viewer in Dr. Watson for Windows, and you delete all events from the Event Viewer application log, even those not generated by Dr. Watson for Windows. However, records of the application errors remain in the Drwtsn32.log and in the crash dump file, user.dmp, if one has been selected.

**Change Method**
To change the value of this entry, enter a number in the **Number of Errors to Save** box in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

**Tip**

- The number of application errors Dr. Watson for Windows has analyzed since it was last reset is stored in the value of the NumberOfCrashes entry.

# NumberOfCrashes

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–*Value of the* MaximumCrashes*entry* | (None) |

**Description**
Counts the number of application errors Dr. Watson for Windows is maintaining in its application error viewer and in the Event Viewer application log. When this value reaches the value of MaximumCrashes**,** Dr. Watson for Windows operates normally and adds new errors to its log and crash dump file, but it does not add any new errors to its application log viewer or to the Event Viewer application log until it is reset.

The user is not notified that the number of crashes has reached the maximum.

To reset Dr. Watson for Windows, run Drwtsn32.exe. You can either click **Clear** or increase the value in the **Number of Errors to Save** box. When you click **Clear**, you delete all errors from the application error viewer in Dr. Watson for Windows, and you delete all events from the Event Viewer application log, even those not generated by Dr. Watson for Windows. However, records of the application errors remain in the Drwtsn32.log and in the crash dump file, user.dmp, if one has been selected.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

### Caution

- Do not change the value of this entry. Dr. Watson for Windows uses this entry to maintain an accurate count of application errors.

# SoundNotification

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether Dr. Watson for Windows generates a sound when it detects an application error. If the value of this entry is 1, then you can enter the name of a wave file (.wav) in the value of the WaveFile entry. Otherwise, Dr. Watson generates two standard beeps.

This entry is used only when the computer is equipped with a sound card.

| Value | Meaning |
|---|---|
| 0 | No sound |
| 1 | Beeps or plays a specified wave file when an application error is detected |

**Change Method**
To change the value of this entry, use the **Sound Notification** option in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

# VisualNotification

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether Dr. Watson for Windows displays a message box when it detects an application error.

While the message box is displayed, no new messages or windows can be displayed, but background processes are not affected. If the buttons on the message box are not clicked within five minutes, the message box is removed.

**Change Method**
To change the value of this entry, use the **Visual Notification** option in Dr. Watson for Windows. To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

# WaveFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\DrWatson

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *File name* | (None) |

**Description**
Specifies the file containing the sound that Dr. Watson for Windows plays when it detects an application error.

This entry is used only when the computer has a sound card and the value of the SoundNotification entry is 1.

**Change Method**
To change the value of this entry, use the **Wave File** option in Dr. Watson for Windows. (If the computer does not have a sound card, this option is disabled.) To start Dr. Watson for Windows, from the **Start** menu, click **Run**, and then type **drwtsn32**.

**Activation Method**
This entry appears in the registry when you run Dr. Watson for Windows or when it runs automatically.

# Fax Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\

**Description**
The Fax sub key stores configuration data for the Fax Service. This sub key and its contents appear only when you install the Fax Service.

**Change Method**
You must restart the Fax Service to make changes to entries in this subkey effective.

# LastUniqueLineId

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
| --- | --- | --- |
| REG_DWORD | | |

**Description**
Identifies fax devices. This entry is used and maintained automatically by the Fax Service.

...

### Caution

- Do not modify this entry.

# CfgWzdrDevice

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the Fax Configuration wizard has configured the Fax service. This entry is used by the Fax Configuration Wizard.

| Value | Meaning |
|---|---|
| 0 | The Fax service has not yet been configured by the Fax Configuration Wizard. |
| 1 | The Fax service has been configured by the Fax Configuration Wizard. |

**Change Method**
This entry is set by the Fax Configuration Wizard when it configures the Fax service.

# DisableRoutingExtensionConfiguration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies whether the Fax Configuration Wizard displays the **Routing Options** page during configuration of the Fax service.

| Value | Meaning |
|---|---|
| 0 | The **Routing Options** page of the Fax Configuration Wizard is displayed. |
| 1 | The **Routing Options** page of the Fax Configuration Wizard is not displayed. |

The **Routing Options** page allows the user to specify the printer to which the Fax service sends faxes for printing and the folder to which it saves additional copies of incoming faxes. (Saved copies of incoming faxes are also available from the Inbox archive of the Fax console.)

**Change Method**
You can change this entry only by editing the registry.

**Tip**

- If you have a custom method for routing configuration, consider hiding the standard method so that users cannot select it.

# Inbound Profile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
| --- | --- | --- |
| REG_SZ | | |

**Description**
Obsolete. This entry is no longer used by the Fax service, but it might continue to appear in some registries.

# ManualAnswerDevice

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Specifies the ID of the fax device that is set to manual answer mode. Only one device at a time can be set to manual answer mode. If the value of this entry is zero, then no devices are configured for manual answer mode.

If a fax device is configured for manual answer mode, then Fax Monitor displays an alert when the telephone line of the fax device is ringing, and gives the user the option of answering the call with Fax Monitor to receive a fax transmission.

**Change Method**
To configure a fax device for manual answer mode, click the **Start** menu, point to **Settings**, and then select **Printers and Faxes**. Right-click the name of the fax device, and then select **Properties**. Click the **Devices** tab, and then click **Properties** under the name of the fax-capable hardware (usually a modem). In the new window that opens (its title is the same as the name of the fax-capable hardware), on the **Receive** tab, click **Manual** under **Answer Mode**.

You can also change this entry by using the Fax application programming interface (API).

**Activation Method**
Changes made to this entry through **Printers and Faxes**, or through the Fax API, are effective immediately.

# MaxLineCloseTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 300 |

**Description**
Specifies the time, in seconds, that the Fax Service waits between attempts to turn on a fax device that is turned off.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must restart the Fax Service for changes to this entry to take effect.

# NextJobNumber

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 1 |

**Description**

Specifies the next job number for the Fax Service. This entry is maintained automatically by the service.

**Caution**

Do not modify this entry.

# RecipientsLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Specifies the maximum number of recipients of a single fax broadcast. If the value of this entry is zero, or if this entry is absent from the registry, the Fax Service imposes no limit.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must restart the Fax Service for changes to this entry to take effect.

# QueueDirectory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | %ALLUSERSPROFILE%\Application Data\Microsoft\Windows NT\MSFax\Queue |

**Description**
Specifies the path of the folder in which the Fax Service stores queued faxes. This entry does not exist in the registry by default. You must add this entry if you want to change the default location of the fax queue.

**Change Method**
You can add or change this entry only by editing the registry.

**Activation Method**
You must restart the Fax Service for changes to this entry to take effect.

**Tip**

- You only need this entry if you want to change the default location of the fax queue.

# QueueState

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | bit mask | 0 |

**Description**
Specifies incoming and outgoing actions to prohibit on the fax queue of the Fax Service. This entry is a bit mask of the values shown in the following table.

| Value | Meaning |
|---|---|
| 1 | Fax Service does not receive new incoming faxes. |
| 2 | Fax Service does not accept new outgoing fax jobs. |
| 4 | Fax Service does not send outgoing faxes. |

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager from the **Computer Management** console.

To change the value of this entry by using the Computer Management console, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **General** tab. This entry corresponds to the three options on the **General** tab that you can clear or check:

- **Disable submission of new outgoing faxes**
- **Disable transmission of outgoing faxes**
- **Disable reception of new faxes**

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

# Branding

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether or not the pages of outgoing fax transmissions have a banner. The banner includes the date and time of transmission, the transmitting subscriber identification (TSID), the current page number, and the telephone number of the recipient's fax device. The banner is prepended to all pages of outgoing fax transmissions.

| Value | Meaning |
|---|---|
| 0 | The system does not add a banner to outgoing fax transmissions. |
| 1 | The system adds a banner to all pages of outgoing fax transmissions. |

**Change Method**
To change the value of this entry, click on the **Start** menu, point to **Settings**, and then select **Printers and Faxes**. Right-click the name of the fax device, and then select **Properties**. Click the **Devices** tab, and then click **Properties** under the name of the fax-capable hardware (usually a modem). In the new window that opens (its title is the same as the name of the fax-capable hardware), select or clear the **Include banner** check box.

This entry can also be changed by using the Fax application programming interface (API).

**Activation Method**
Changes made to this entry though **Printers and Faxes** or through the Fax API are effective immediately.

# ActivityLogging

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

The ActivityLogging subkey stores settings for activity logging by the Fax service.

# DBFile

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\ActivityLogging

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | C:\Documents and Settings\All Users\Application Data\Microsoft\Windows NT\MSFax\ActivityLog |

**Description**
Specifies the location in the file system where the Fax Service creates and maintains files that log incoming and outgoing fax activity. The Fax Service only logs activity if the values in the registry entries LogIncoming and LogOutgoingspecify that the service keeps logs.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, click the **Activity Logging** tab, and then type a file path and name into the **Activity log folder location** box. Click **OK**.

**Activation Method**
Changes made through **Fax Service Manager** or **Computer Management** are effective immediately.

### Note

- You can configure the Fax Service to create and maintain logs of incoming and outgoing fax jobs. Incoming activity is logged to a single file (InboxLOG.txt) that contains status, call time, file name, and other fax-specific information. Outgoing activity is logged to a single file (OutboxLOG.txt) that contains fax-specific information that, in addition to the type of information found in the incoming activity log, includes job IDs, submission time, and fax header contents.

# LogAgeLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\ActivityLogging

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Specifies the time, in months, that the Fax Service retains activity logs. If the value of this entry is zero, the Fax Service uses a default age limit of one month.

The value of this entry only affects retention of entries in activity logs if the value of the registry entry LogLimitCriteria specifies age as the criteria. In addition, the values of the registry entries LogIncoming and LogOutgoing must specify that the Fax Service keep activity logs.

When the oldest entry in an activity log reaches the age specified by this entry, the Fax Service takes the action specified by the registry entry LogLimitReachedAction.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax service for changes to this entry to take effect.

### Note

- You can configure the Fax Service to create and maintain logs of incoming and outgoing fax jobs.
    - **Incoming activity** is logged to a single file that contains status, call time, file name, and other fax-specific information.
    - **Outgoing activity** is logged to a single file that contains fax-specific information that, in addition to the type of information found in the incoming activity log, includes job IDs, submission time, and fax header contents.

# LogIncoming

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\ActivityLogging

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 1 |

**Description**
Specifies whether the Fax Service logs incoming fax activity. The log is kept in a single file and contains status, call time, file name, and other fax-specific information for each log entry.

| Value | Meaning |
|---|---|
| 0 | The Fax Service does not log incoming fax activity. |
| 1 | The Fax Service logs incoming fax activity. |

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager from the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, click the **Activity Logging** tab, and then clear or check **Log incoming fax activity**.

**Activation Method**
Changes made through **Fax Service Manager** or **Computer Management** are effective immediately.

### Note

- Outgoing fax activity is logged to a single file that contains fax-specific information. In addition to the type of information found in the incoming activity log, the file includes information the Fax Service used to create the fax, like job IDs, submission time, and banner contents.

LogOutgoing

# LogLimitCriteria

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\ActivityLogging

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 0 |

**Description**
Specifies the criteria that the Fax Service uses to limit its activity logs.

| Value | Meaning |
|---|---|
| 0 | The Fax Service does not limit its activity logs. This is the default configuration. |
| 1 | The Fax Service limits its activity logs by file size. |
| 2 | The Fax Service limits its activity logs by age. |

The size and age by which the Fax service limits its activity logs are specified, respectively, by the registry entries LogSizeLimit and LogAgeLimit. When an activity log reaches a limit, the Fax Service performs an action on the log as specified by the registry entry LogLimitReachedAction.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax Service to make changes to this entry effective.

**See Also**
**Concepts**
LogSizeLimit
LogAgeLimit
LogLimitReachedAction
LogIncoming
LogOutgoing

# LogLimitReachedAction

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\ActivityLogging

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Specifies the action that the Fax Service performs on its activity logs when a log reaches a limit.

| Value | Meaning |
|---|---|
| 0 | The Fax Service copies the activity log to a new file. Then the service erases the original log file, creates a replacement file, and continues logging activity. |
| 1 | The Fax Service deletes the log file. Then the service creates a replacement file and continues logging activity. |

The registry entry LogLimitCriteria specifies the type of limit that the Fax Service imposes on its activity logs. The registry entries LogSizeLimit and LogAgeLimit set the limits on size and age, respectively, for activity logs kept by the Fax Service.

**Change Method**
You can change this value only by editing the registry.

**Activation Method**
You must stop and restart the Fax Service to make changes to this registry entry effective.

### Notes

- Incoming fax activity is logged to a single file named InboxLOG.txt.
- Outgoing activity is logged a single file named OutboxLOG.txt.
- When the Fax Service is configured to copy a log that has reached its limit to a new file, it names the new file for the current date by using the format *4-digit-year-2-digit-month-2-digit-day*.txt. For examle, on April 02, 2002, a newly copied log file would be named 2002-04-02.txt.

# LogOutgoing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\ActivityLogging

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 1 |

**Description**
Specifies whether the Fax Service logs outgoing fax activity. The log is kept in a single file and contains job IDs, submission time, banner contents, status, call time, file name, and other fax-specific information for each log entry.

| Value | Meaning |
|---|---|
| 0 | The Fax Service does not log incoming fax activity. |
| 1 | The Fax Service logs incoming fax activity. |

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, click the **Activity Logging** tab, and then clear or check **Log outgoing fax activity**.

**Activation Method**
Changes made through **Fax Service Manager** or **Computer Management** are effective immediately.

### Note

- Incoming fax activity is logged to a single file that contains status, call time, file name, and other fax-specific information for each log entry. Because incoming faxes are not scheduled or created by the local Fax service, the incoming activity log does not contain job IDs, submission time, or other information used to create the fax.

# LogSizeLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\ActivityLogging

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Specifies the maximum size, in megabytes, of activity logs kept by the Fax Service. If the value of this entry is zero, the Fax Service uses a default size limit of 50MB. When an activity log reaches the maximum size specified by this entry, the Fax Service takes the action specified by the registry entry LogLimitReachedAction.

The value of this entry only affects the size of activity logs if the value of the registry entry LogLimitCriteria specifies size as the criteria. In addition, the values of the registry entries LogIncoming and LogOutgoing must specify that the Fax service keep activity logs.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax Service for changes to this entry to take effect.

### Note

- You can configure the Fax Service to create and maintain logs of incoming and outgoing fax jobs.
    - Incoming activity is logged to a single file that contains status, call time, file name, and other fax-specific information.
    - Outgoing activity is logged to a single file that contains fax-specific information that, in addition to the type of information found in the incoming activity log, includes job IDs, submission time, and fax header contents.

# Device Providers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\

**Description**
The Device Providers subkey contains the list of registered fax service providers (FSPs) for the Fax Service.

# {2172FD8F-11F6-11D3-90BF-006094EB630B}

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Device Providers

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The {2172FD8F-11F6-11D3-90BF-006094EB630B} subkey stores configuration information about the Microsoft Fax Service Provider (FSP) for the Fax Service.

### Notes

- The Microsoft Fax Service Provider (FSP) is identified by the globally unique identifier 2172FD8F-11F6-11D3-90BF-006094EB630B. The configuration data that the Fax Service uses for the Microsoft FSP is identified by the globally unique identifier F10A5326-0261-4715-B367-2970427BBD99.

- A globally unique identifier (GUID) is a 128-bit value that uniquely identifies objects such as OLE servers, interfaces, manager entry-point vectors, and client objects. GUIDs are used in cross-process communication, such as remote procedure calling (RPC) and OLE.

- A fax service provider is a dynamic-link library (DLL) that provides an application programming interface (API) that the Fax Service uses to interact with one or more fax devices. Microsoft supplies a fax service provider that supports the fax protocol specified by the T.30 specification of the International Telecommunications Union for standard fax modems. Third parties can also supply fax service providers to support other fax-capable devices.

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 \| 2 | 2 |

**Description**
Specifies whether or not the Microsoft Fax Service Provider writes logs of fax jobs. Logs are written to the location in the file system that is specified by the registry entry LoggingFolder. They are named for the fax jobs for which they provide transmission and reception detail.

A log consists of the conversation between the Microsoft Fax Service Provider and the fax device.

| Value | Meaning |
|---|---|
| 0 | The Fax Service does not keep a log. |
| 1 | The Fax Service logs all jobs. |
| 2 | The Fax Service logs all failed jobs. |

**Note**

- A fax service provider is a dynamic-link library (DLL) that provides an application programming interface (API) that the Fax Service uses to interact with one or more fax devices. Microsoft supplies a fax service provider that supports the fax protocol specified by the T.30 specification of the International Telecommunications Union for standard fax modems. Third parties can also supply fax service providers to support other fax-capable devices.

# LoggingFolder

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Device Providers\{2172FD8F-11F6-11D3-90BF-006094EB630B}

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | *path and file name* | %windir%\system32\logfiles\fax |

**Description**
Specifies the location in the file system where the Microsoft Fax Service Provider writes logs generated during transmission and reception of fax jobs. Which logs are written is specified by the registry entry LoggingEnabled, which can also specify that no logs are written.

In the folder specified by this entry, the Microsoft Fax Service Provider creates two subfolders, Outgoing and Incoming. Log files in the Outgoing folder are named FSPS*number*.log, where *number* is the number of the corresponding fax job. Similarly, log files in the Incoming folder are named FSPR*number*.log. Log files consist of the conversation between the Microsoft Fax Service Provider and the fax device that sent or received the fax job.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax Service to make changes effective.

### Note

HKLM\SOFTWARE\Microsoft\Fax\Device Providers\{2172FD8F-11F6-11D3-90BF-006094EB630B}

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 3 |

**Description**
Specifies the maximum number of times, before terminating the connection, that the Microsoft Fax Service Provider retransmits a page that a receiving fax device has failed to receive. The receiving fax device communicates with the sending fax device to request that pages be resent.

Before disconnecting, the Microsoft Fax Service Provider tries decreasing the transmission speed when the number of retransmission attempts exceeds the value of registry entry RetriesBeforeDropSpeed.

**Change Method**
You can change this entry only by editing the registry.

### Note

- A fax service provider is a dynamic-link library (DLL) that provides an application programming interface (API) that the Fax Service uses to interact with one or more fax devices. Microsoft supplies a fax service provider that supports the fax protocol for standard modems, as described by the T.30 specification of the International Telecommunications Union. Third parties can also supply fax service providers to support other fax-capable devices.

HKLM\SOFTWARE\Microsoft\Fax\Devices*device-ID*

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The {F10A5326-0261-4715-B367-2970427BBD99} subkey stores configuration data for the Microsoft Fax Service Provider for the device specified by *device-ID* in the registry path.

### Notes

- The Microsoft Fax Service Provider (FSP) is identified by the globally unique identifier 2172FD8F-11F6-11D3-90BF-006094EB630B. The configuration data that the Fax Service uses for this FSP is identified by the globally unique identifier F10A5326-0261-4715-B367-2970427BBD99.

- A globally unique identifier (GUID) is a 128-bit value that uniquely identifies objects such as OLE servers, interfaces, manager entry-point vectors, and client objects. GUIDs are used in cross-process communication, such as remote procedure calling (RPC) and OLE.

# {F10A5326-0261-4715-B367-2970427BBD99}\CSID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Devices*device-ID*\{F10A5326-0261-4715-B367-2970427BBD99}

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies the Called Subscriber ID (CSID) that is assigned to the fax device specified by *device-ID* in the registry path.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, expand **Services and Applications**, then expand **Fax**, then expand **Devices and Providers**, then expand **Devices**, and then click the name of the fax device for which you want to set the CSID. From the **Action** menu, click **Properties**, and then click the **General** tab. Next, check **Receive faxes** if it is not already checked, and then type the CSID in the **Called Subscriber ID (CSID)** box. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

### Note

- When receiving a fax transmission, the Fax Service sends the CSID to the sender to identify the receiver. A CSID usually consists of the telephone number of the receiving fax device and a name. The CSID is limited to 20 characters.

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Devices*device-ID*\{F10A5326-0261-4715-B367-2970427BBD99}

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 2 |

**Description**
Specifies whether the fax device, that is specified by *device-ID* in the registry path, is enabled to automatically answer calls and receive faxes and whether the device is enabled to send faxes. This entry stores the values in the following table as a bit mask.

This entry also specifies whether the device is a virtual device and not available through the Telephony Application Programming Interface (TAPI).

| Value | Meaning |
|---|---|
| 1 | The fax device is enabled to automatically answer calls and receive faxes. |
| 2 | The fax device is enabled to send faxes. |
| 4 | The fax device is a virtual device and is not available to TAPI. |

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, expand **Services and Applications**, then expand **Fax**, then expand **Devices and Providers**, then expand **Devices**, and then click the name of the fax device for which you want to set the CSID. From the **Action** menu, click **Properties**, and then click the **General** tab. Next, check **Receive faxes** if it is not already checked, and then select either **Automatic Answer** or **Manual Answer**. Click **OK**.

Only the Fax Configuration Wizard sets the value that specifies a virtual device. You cannot do this by using the user interface.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

HKLM\SOFTWARE\Microsoft\Fax\Devices*device-ID*\{F10A5326-0261-4715-B367-2970427BBD99}

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores the globally unique identifier (GUID) that identifies the fax service provider associated with the fax device specified by *device-ID* in the registry path.

A globally unique identifier (GUID) is a 128-bit value that uniquely identifies objects such as OLE servers, interfaces, manager entry-point vectors, and client objects. GUIDs are used in cross-process communication, such as remote procedure calling (RPC) and OLE.

**Change Method**
This entry is configured automatically when a fax device is installed in the system and should not be changed.

### Notes

The Microsoft Fax Service Provider (FSP) is identified by the GUID 2172FD8F-11F6-11D3-90BF-006094EB630B. The configuration data that the Fax service uses for this FSP is identified by the globally unique identifier F10A5326-0261-4715-B367-2970427BBD99.

A fax service provider is a dynamic-link library (DLL) that provide an application programming interface (API) that the Fax Service uses to interact with one or more fax devices. Microsoft supplies a fax service provider that supports the fax protocol specified by the T.30 specification of the International Telecommunications Union (ITU) for standard fax modems. Third parties can also supply fax service providers to support other fax-capable devices.

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Devices*device-ID*\{F10A5326-0261-4715-B367-2970427BBD99}

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Stores a unique ID number that is used internally by the Telephony Application Programming Interface (TAPI) to identify the fax device specified by *device-ID* in the registry path.

**Change Method**
This entry is maintained automatically by the Fax service and should not be changed.

### Caution

- Do not delete this entry from the registry or change its value. Doing so can cause the Fax Service to fail.

# {F10A5326-0261-4715-B367-2970427BBD99}\TSID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Devices*device-ID*\{F10A5326-0261-4715-B367-2970427BBD99}

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies the Transmitting Subscriber ID (TSID) that is assigned to the fax device specified by *device-ID* in the registry path. When sending a fax, the Fax Service sends the TSID to the receiver to identify the sender. A TSID usually consists of the telephone number of the sending fax device and a name. The TSID is limited to 20 characters.

The Fax Service sends the TSID, depending on the value of registry entry **UseDeviceTsid**. The receiving fax device might use the TSID in a variety of ways; fax machines often display the TSID when receiving a fax and also might print it on the top of each received page. The Fax Service can also include the TSID in a banner, which it prepends to each transmitted page, when the registry entry Branding is set to 1.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003.

You can view and change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, expand **Services and Applications**, then expand **Fax**, then expand **Devices and Providers**, then expand **Devices**, and then click the name of the fax device for which you want to set the CSID. From the **Action** menu, click **Properties**, and then click the **General** tab. Next, check **Send faxes** if it is not already checked, and then type the CSID in the **Transmitting Subscriber ID (TSID)** box. Click **OK**.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Inbox** tab. Under **Archive folder**, check **Archive all incoming faxes to this folder** if it is not already checked. Next, type the path for the folder in the **Archive all incoming faxes to this folder** box, or click **Browse...** and browse to the folder. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

### Note

- Before the Fax Service puts an incoming fax in the inbox folder, the Fax Service stores it in the incoming folder. The incoming folder is a repository for all incoming faxes from devices local and remote. The Fax Service only moves a fax from the incoming folder to the inbox folder when it has been received and routed in accordance with the policy specified by the fax administrator. If a fax reception is terminated while in progress, but a portion of the fax is successfully received, the fax is assigned the status of "partially received," and is moved to the inbox.

# Inbox\HighWatermark

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Inbox

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 120 |

**Description**
Specifies a size threshhold, in megabytes, for the inbox folder of the Fax Service. When the combined size of the contents of the inbox folder reach the size specified by this entry, the Fax Service enters a warning event into the Windows event log if the registry entry Inbox\SizeQuotaWarn specifies that the service do so. The inbox folder is the folder in which the Fax Service stores faxes that have been received and routed successfully.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Inbox** tab. Under **Archive rules**, check or clear **Generate warning in the Event Log,** if it is not already checked. Next, change the number in the **Size quota high watermark** box by selecting the number and typing a new number, or by clicking the arrow buttons next to the number. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

## Notes

- This entry specifies the higher of two threshholds for the inbox folder. The other threshhold is specified by the registry entry Inbox\LowWatermark.
- Checking or clearing **Generate warning in the Event Log** changes the value of the registry entry Inbox\SizeQuotaWarn.
- Before the Fax Service puts an incoming fax in the inbox folder, the Fax Service stores it in the incoming folder. The incoming folder is a repository for all incoming faxes from devices local and remote. The Fax Service only moves a fax from the incoming folder to the inbox folder when it has been received and routed in accordance with the policy specified by the fax administrator. If a fax reception is terminated while in progress, but a portion of the fax is successfully received, the fax is assigned the status of "partially received," and is moved to the inbox.

# Logging Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

The Logging subkey stores the configuration for logs that the Fax Service keeps.

# event-type

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Logging

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The *event-type* subkey stores configuration data for event logs that are kept by the Fax Service. The four types of *event-type* subkeys listed in the following table categorize the type of event that the Fax Service logs.

| Value | Meaning |
|---|---|
| 1 | Initialization and termination of fax transmissions |
| 2 | Outgoing fax transmissions |
| 3 | Incoming fax transmissions |
| 4 | General fax-related activity |

**Note**

- The *event-type* subkey is a placeholder in the Logging Subkey subkey. It represents the subkeys, which have a specific number as their name; "*event-type*" does not actually appear in the registry.

**Concepts**
ActivityLogging

# Level

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Logging*event-type*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 - 3 | 2 |

**Description**
Specifies a level for entries that the Fax Service makes in the Windows event log. The Fax Service logs the greatest number of events when this entry is equal to 3, and the lowest number when this entry is equal to 1. When this entry is equal to zero, no events are logged.

The Fax Service categorizes the entries that it makes in the Windows event log into four types. This entry specifies the logging level for the category that is specified by the number *event-type* in the registry path.

**Change Method**
This entry and its value are created when the Microsoft Fax Service Provider is configured. You can change the value later by using Fax Service Manager, which is part of the Fax service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Event Reports** tab. For each type of event—**General**, **Incoming**, **Outgoing**, or **Initialization or shutdown**—for which you want to change the logging level, move the slider to the left to reduce the logging level, or to the right to increase the logging level. Click **OK**.

**Activation Method**
Changes that you make by using **Fax Service Manager** or **Computer Management** are effective immediately.

### Notes

- For more information about the event categories that the Fax Service uses, see the event-type subkey.
- This entry pertains to entries that the Fax Service creates about itself in the Windows event log. The Fax Service also maintains activity logs that record information about the faxes that it has sent and received. Activity logs are configured by the registry entries in the ActivityLogging subkey.

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The Outbound Routing subkey stores the configuration for the routing of outbound faxes by the Fax Service.

# Outbound Routing\Groups

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing

**Description**
The *Groups* subkey stores information for the Fax Service about routing for outgoing faxes. This subkey contains other subkeys that are named for groups of fax-capable devices that are registered with the Fax Service.

**See Also**
**Concepts**
group-name

# group-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\Groups

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

The *group-name* subkeys have names that match the names of routing groups for outgoing faxes in the Fax Service. Routing groups are groups of fax-capable devices as defined by an administrator, and together with routing rules, an administrator uses them to control the routing of outgoing faxes.

# group-name\Devices

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\Groups*group-name*

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | | |

**Description**
Stores a list of the devices in the outbound routing group of the Fax Service. Each group of four bytes in the binary value of this entry can identify a single device, and does so when a device is present in the system.

**Change Method**
This entry is automatically maintained by the Fax Service, and you should not change it by editing the registry. To manage devices that are used by the Fax Service, make changes by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003 (but not on Windows XP) To start Fax Service Manager, from the **Start** menu, point to **Accessories**, point to **Communications**, point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

# Rules

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\

| Data type | Range | Default value |
|---|---|---|
| NULL | | |

**Description**
The Rules subkey stores routing rules for the Fax Service. Each subkey in the Rules subkey stores the configuration for a single routing rule for outgoing faxes. The names of these subkeys have the format *country code*:*area code*.

**See Also**
**Concepts**
CountryCode:AreaCode

# CountryCode:AreaCode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\Rules

| Data type | Range | Default value |
|---|---|---|
| NULL | | |

**Description**
The *CountryCode:AreaCode* subkey stores the configuration of a routing rule for the Fax Service. Each subkey of this type stores the configuration for a single routing rule for outgoing faxes.

In the names of these types of subkeys, *CountryCode* is the telephone dialling code for a country or region and *AreaCode* is the telephone dialing code for a city or area within the specified country or region.

**Change Method**
You can add routing rules—and, thus, subkeys of this type—by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To add a routing rule, in Fax Service Manager, expand **Outgoing Routing** and click **Rules**. From the **Action** menu, point to **New**, and then click **Rule...**. In **Add New Rule** dialog box, type a number in the **Country/region code** box, or click **Select...** to select a code from a list. Next, under **Area code**, select **Specific** and type an area code in the **Specific** box, or select **All areas**. Under **Target device**, select **Device** and then, in the **Device** list, click the name of a device; or select **Routing group** and then, in the **Routing group** list, click the name of a routing group. Click **OK**.

To delete a routing rule, in Fax Service Manager, expand **Outgoing Routing** and click **Rules**. In the results pane, click the rule that you want to delete, and on the **Action** menu, click **Delete**.

**Activation Method**
Changes that you make by using **Fax Service Manager** or **Computer Management** are effective immediately.

# CountryCode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\Rules*CountryCode:AreaCode*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Specifies the area code to which the Fax Service applies the routing rule that is named in the registry path by *CountryCode:AreaCode*. If the telephone number for an outgoing fax matches the area code and country code of a routing rule, the Fax Service sends the fax by using a fax device that the routing rule specifies.

If this entry is equal to zero, the routing rule applies to faxes with telephone numbers for any country or region. The Fax Service automatically creates such a routing rule when the service is installed, and routing rules added subsequently by an administrator have precedence when the Fax Service routes an outgoing fax.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change this entry, in Fax Service Manager, expand **Outgoing Routing** and click **Rules**. In the results pane, click the rule that you want to delete, and on the **Action** menu, click **Properties**. Under **Dialed number**, type a country or region code into the **Country/region code** box or click **Select** to select the code from a list. If you select the code from the list, click **OK** in the **Select Country or Region** dialog box. Click **OK** in the properties sheet for the routing rule.

**Activation Method**
Changes that you make by using **Fax Service Manager** or **Computer Management** are effective immediately.

# DeviceID Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\Rules*CountryCode:AreaCode*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies the fax device by which the Fax Service sends a fax for which the routing rule, named in the registry path by *CountryCode:AreaCode*, applies. If the telephone number for an outgoing fax matches the area code and country code of a routing rule, the Fax Service sends the fax according to the matching routing rule.

Routing rules can specify sending a fax by either a specific device or a group of devices. This registry entry only appears in the registry when the associated routing rule is configured to route faxes to a single fax device. When a routing rule specifies a routing group, this entry is replaced by the registry entry GroupName.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change this entry, in Fax Service Manager, expand **Outgoing Routing** and click **Rules**. In the results pane, click the rule that you want to delete, and on the **Action** menu, click **Properties**. Under **Target device**, select **Device** to route faxes to a single device or select **Routing group** to route faxes to a group of devices. To specify the device, in the **Device** list, click the name of a device. To specify a group, in the **Routing group** list, click the name of a routing group. Click **OK** in the properties sheet for the routing rule.

**Activation Method**
Changes that you make by using **Fax Service Manager** or **Computer Management** are effective immediately.

**Tip**

- You must create a routing group before you can specify it in a routing rule.

# GroupName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\Rules*CountryCode:AreaCode*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | <All devices> |

**Description**
Specifies the routing group by which the Fax Service sends a fax for which the routing rule, named in the registry path by *CountryCode:AreaCode*, applies. If the telephone number for an outgoing fax matches the area code and country code of a routing rule, the Fax Service sends the fax according to the matching routing rule.

Routing rules can specify sending a fax by either a specific device or a group of devices. This registry entry only appears in the registry when the associated routing rule is configured to route faxes to a routing group. When a routing rule specifies a single fax device, this entry is replaced by the registry entry GroupName.

When this entry is "<All devices>", the default value, the Fax Service sends a fax that matches the associated rule by using any fax device installed on the system. If the routing rule specifies a particular routing group, this entry contains the name of the routing group as it appears in Fax Service Manager.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change this entry, in Fax Service Manager, expand **Outgoing Routing** and click **Rules**. In the results pane, click the rule that you want to delete, and on the **Action** menu, click **Properties**. Under **Target device**, select **Device** to route faxes to a single device or select **Routing group** to route faxes to a group of devices. To specify the device, in the **Device** list, click the name of a device. To specify a group, in the **Routing group** list, click the name of a routing group. Click **OK** in the properties sheet for the routing rule.

**Activation Method**
Changes that you make by using **Fax Service Manager** or **Computer Management** are effective immediately.

**Tip**

- You must create a routing group before you can specify it in a routing rule.

# UseGroup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Outbound Routing\Rules*CountryCode:AreaCode*

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 1 |

**Description**
Specifies how the Fax Service selects a fax device when it sends a fax for which the routing rule, named in the registry path by *CountryCode:AreaCode*, applies. A routing rule can specify either a single specific fax device, or it can specify a routing group, a group of fax devices, from which the Fax Service selects a device by which to transmit the outgoing fax.

| Value | Meaning |
|---|---|
| 0 | The routing rule specifies a single fax device. |
| 1 | The routing rule specifies a routing group. |

When an administrator creates a routing rule, the default selection method for devices is by routing group.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change this entry, in Fax Service Manager, expand **Outgoing Routing** and click **Rules**. In the results pane, click the rule that you want to delete, and on the **Action** menu, click **Properties**. Under **Target device**, select **Routing group**.

To specify a routing group (the name of which is stored in the registry entry GroupName, in the **Routing group** list, click the name of a routing group.

To finish, click **OK**.

**Activation Method**
Changes that you make by using **Fax Service Manager** or **Computer Management** are effective immediately.

### Notes

- If the telephone number for an outgoing fax matches the area code and country code of a routing rule, the Fax Service sends the fax according to the matching routing rule.
- The default routing group, called "<All devices>", is a group that the Fax Service creates automatically that includes all fax devices installed on the system.

# Receipts

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

The Receipts subkey stores the configuration information for receipts that the Fax Service generates for delivered faxes.

**Note**

- You can configure the Fax service to create delivery receipts either as alerts on the computer that runs the Fax Service in your enterprise, or as e-mail that it sends through an SMTP server.

# From Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Receipts

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies the e-mail address from which the Fax Service sends messages to senders of faxes to report success or failure in the delivery of a fax.

The Fax Service uses Simple Mail Transfer Protocol (SMTP) to send the messages. The Fax Service uses the string stored by this entry as the "From" address when it connects to the server specified by the registry entry Server Entry, and does so on the Internet Protocol (IP) port specified by the registry entry Port.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry, in Fax Service Manager, click **Fax**. From the **Action** menu, click **Properties**, and then click the **Receipts** tab. Under **SMTP e-mail**, check **Enable SMTP e-mail receipts delivery**, if it is not already checked. Next, in the **From e-mail address** box, type the e-mail address from which you want the Fax service to send receipts. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

### Note

- The delivery notification feature of the Fax Service provides users with information about the success or failure of their sent faxes. If delivery notification is enabled by an administrator, a user sending a fax with the Send Fax Wizard can choose to receive a delivery receipt for the sent fax, in accordance with enabled delivery notification methods. Having a delivery receipt means that a user does not need to track the progress of an outgoing fax from Fax Console.

| REG_BINARY | | |

**Description**
Specifies the password that the Fax Service uses to authenticate itself to the Simple Mail Transfer Protocol (SMTP) service when it sends notification of delivery by e-mail.

Authentication also requires a user name, specified by the registry entry User. The type of authentication is specified by the registry entry SMTPAuth.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service onWindows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry in Fax Service Manager, click **Fax**. From the **Action** menu, click **Properties**, and then click the **Receipts** tab. Under **SMTP e-mail**, check **Enable SMTP e-mail receipts delivery**, if it is not already checked. Next, click **Authentication**. In the **Authentication** window, select **Basic authentication** or **Integrated Windows Authentication**. Then click **Credentials**. Enter the user name and password when you are prompted to do so, and then click **OK**.

When you are done configuring authentication, click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

## Notes

- The delivery notification feature of the Fax Service provides users with information about the success or failure of their sent faxes. If delivery notification is enabled by an administrator, a user sending a fax with the Send Fax Wizard can choose to receive a delivery receipt for the sent fax, in accordance with the enabled delivery notification methods. Having a delivery receipt means that a user does not need to track the progress of an outgoing fax from Fax Console.

- Previously known as Windows NT Challenge/Response (NT/CR) or NT LAN Manager (NTLM), Integrated Windows Authentication is a secure authentication method that does not transmit user names or passwords. Instead, it relies on a cryptographic exchange with the server. Integrated Windows Authentication can use either the Kerberos V5 authentication protocol or its own challenge/response protocol.

- **Basic authentication** sends a user name and password over the network to the server as unencrypted plain text.

# Port

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Receipts

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 25 |

**Description**
Specifies the number of the port to which the Fax Service connects when it sends a message to report success or failure in the delivery of a fax.

The Fax Service sends the message by e-mail by using Simple Mail Transfer Protocol (SMTP). The Fax Service connects to the Internet Protocol (IP) port specified by this entry on the server specified by the registry entry Server Entry.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Standard Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry, in Fax Service Manager, click **Fax**. From the **Action** menu, click **Properties**, and then click the **Receipts** tab. Under **SMTP e-mail**, check **Enable SMTP e-mail receipts delivery** if it is not already checked. Next, delete the number in the **Port** box and type the correct number for the SMTP port for the SMTP service running on the mail server. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

## Notes

- The delivery notification feature of the Fax Service provides users with information about the success or failure of their sent faxes. If delivery notification is enabled by an administrator, a user sending a fax with Send Fax wizard can choose to receive a delivery receipt for the fax being sent, in accordance with the delivery notification methods enabled. Having a delivery receipt means that a user does not need to track the progress of an outgoing fax from Fax Console.

- Port 25 for SMTP services on the Internet is one of the "well-known" port number assignments made by the Internet Assigned Numbers Authority.

# SMTPAuth

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Receipts

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Specifies the type of authentication that the Fax Service uses when it connects to the SMTP service on a server to send fax delivery notification. To send the message in e-mail, the Fax Service transmits the message by connecting to a server (specified by the registry entry Server Entry) that has SMTP service.

| Value | Meaning |
|---|---|
| 0 | **Anonymous access**. The Fax service does not authenticate itself, because the SMTP service allows anonymous connections. |
| 1 | **Basic authentication**.The Fax Service authenticates itself by sending a user name and password in unencrypted plain text over the network. |
| 2 | **Integrated Windows Authentication**.The Fax Service authenticates itself by using Integrated Windows Authentication. |

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry, in Fax Service Manager, click **Fax**. From the **Action** menu, click **Properties**, and then click the **Receipts** tab. Under **SMTP e-mail**, check **Enable SMTP e-mail receipts delivery** if it is not already checked. Next, click **Authentication**. In the **Authentication** window, select **Anonymous access**, **Basic authentication**, or **Integrated Windows Authentication**.

If you select **Basic authentication** or **Integrated Windows Authentication**, you must also supply a user name and password for the Fax Service to use for authentication. To do so, click **Credentials...**, and enter a user name and password when prompted. Click **OK**.

When you are done configuring authentication, click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

### Notes

- The delivery notification feature of the Fax Service provides users with information about the success or failure of their sent faxes. If delivery notification is enabled by an administrator, a user sending a fax with Send Fax wizard can choose to receive a delivery receipt for the fax being sent, in accordance with the delivery notification methods enabled. # Receipts\Type

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Receipts

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 4 |

**Description**
Specifies the types of receipts that the Fax Service delivers to the senders of faxes. The value of this entry is a bit-wise combination of the values shown in the following table.

| Value | Meaning |
|---|---|
| 1 | The Fax Service notifies the sender in e-mail by using Simple Mail Transport Protocol (SMTP). |
| 2 | This value is not used. |
| 4 | The Fax Service notifies the sender by using **net send** to create a message window on the sender's computer. |

An administrator can configure the Fax Service to use either, both, or none of these notification methods.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry, in Fax Service Manager, click **Fax**. From the **Action** menu, click **Properties**, and then click the **Receipts** tab. To configure the Fax Service to create pop-up messages in the sender's login session, under **Message Box**, check **Enable message boxes as receipts**. Then, clear the check box to prevent the Fax Service from sending such messages. To configure the Fax Service to send delivery receipts by e-mail, under **SMTP e-mail**, check **Enable SMTP e-mail receipts delivery**, and then clear the check box to prevent the Fax Service from sending such e-mail.

When you finish setting the receipts configuration, click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

### Notes

- Note that, if you check **Enable SMTP e-mail receipts delivery**, you must also type an e-mail address in the **From e-mail address** box, the name of a server in the **Server address** box, and a port number in the **Port** box.

- The delivery notification feature of the Fax Service provides users with information about the success or failure of their sent faxes. If delivery notification is enabled by an administrator, a user sending a fax with Send Fax wizard can choose to receive a delivery receipt for the fax being sent, in accordance with the delivery notification methods enabled. Having a delivery receipt means that a user does not need to track the progress of an outgoing fax from Fax Console.

# UseForMsRoute

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Receipts

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 0 |

**Description**
Specifies whether the e-mail configuration that the Fax Service uses for sending delivery receipts is also used as the e-mail configuration for routing incoming faxes. The Fax Service applies this method of routing incoming faxes, seen in Fax Service Manager as **Route through e-mail**, according to routing rules established by the administrator.

To route an incoming fax through e-mail, the Fax Service connects to the server specified by the registry entry Server Entry on the port specified by the registry entry Port, and sends the fax in an e-mail message from the address specified in the registry entry From Entry.

| Value | Meaning |
|---|---|
| 0 | The Fax Service does not use the e-mail configuration for delivery receipts as the configuration for the **Route through e-mail** routing method. |
| 1 | The Fax Service routes incoming faxes, according to routing rules established by the administrator, through e-mail, by using the e-mail configuration for sending delivery receipts. |

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry, in Fax Service Manager, click **Fax**. From the **Action** menu, click **Properties**, and then click the **Receipts** tab. Under **SMTP e-mail**, check or clear **Use these SMTP settings for the Route Through E-Mail incoming routing method**. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

## Notes

- If you check **Use these SMTP settings for the Route Through E-Mail incoming routing method**, you must also type an e-mail address in the **From e-mail address** box, the name of a server in the **Server address** box, and a port number in the **Port** box.

- The delivery notification feature of the Fax Service provides users with information about the success or failure of their sent faxes. If delivery notification is enabled by an administrator, a user sending a fax with Send Fax wizard can choose to receive a delivery receipt for the fax being sent, in accordance with the enabled delivery notification methods. Having a delivery receipt means that a user does not need to track the progress of an outgoing fax from Fax Console.

# Routing Extensions

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

The Routing Extensions subkey stores configuration information about routing extensions for the Fax Service.

# ExtensionName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Routing Extensions

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The *ExtensionName* subkeys store configuration information for routing extensions to the Fax Service. A routing extension provides the Fax Service with routing functions for incoming faxes.

The Microsoft Routing Extension is installed automatically when you add the Fax Service component to the operating system, and its configuration is stored in a subkey with the same name. (The name "ExtensionName" does not actually appear in the registry; *ExtensionName* is a placeholder for a type of registry subkey.) Other routing extensions might also be installed on a system.

# ExtensionName\FriendlyName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Routing Extensions*ExtensionName*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | Microsoft Routing Extension |

**Description**
Specifies the name of the routing extension named in the registry path by *ExtensionName*. Fax Service Manager displays the string stored by this entry in **Incoming Routing** to identify for each routing method the extension that provides the method.

### Notes

- A routing extension provides the Fax Service with routing functions for incoming faxes.
- The Microsoft Routing Extension is installed automatically when you add the Fax Service component to the operating system. Other routing extensions might also be installed on a system.

# ExtensionName\ImageName

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Routing Extensions*ExtensionName*

| Data type | Range | Default value |
|---|---|---|
| REG_EXPAND_SZ | | %SystemRoot%\system32\faxroute.dll |

**Description**
Specifies the file name and path of the dynamic-link library (DLL) that provides the routing extension named in the registry path by *ExtensionName*. When the routing extension is the Microsoft Routing Extension, this entry has the default value **%SystemRoot%\system32\faxroute.dll**. For other routing extensions, this entry will have a different value.

**Change Method**
This entry is configured automatically when the routing extension is registered with the Fax Service. The extension is registered automatically during installation of the Fax component on the operating system. Do not change this entry.

### Notes

- A routing extension provides the Fax Service with routing functions for incoming faxes.
- The Microsoft Routing Extension is installed automatically when you add the Fax Service component to the operating system. Other routing extensions might also be installed on a system.

# Routing Methods

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Routing Extensions*ExtensionName*

**Description**
The Routing Methods subkey stores configuration information for the routing methods available to the Fax Service. The routing extension that is identified in the registry path by *ExtensionName* provides the routing methods.

The Microsoft Routing Extension provides the Fax Service with three routing methods. These are identified by the names Email, Folder, and Printing, which appear by name as subkeys in this subkey.

### Notes

- A routing extension provides the Fax Service with routing functions for incoming faxes.
- The Microsoft Routing Extension is installed automatically when you add the Fax Service component to the operating system. Other routing extensions might also be installed on a system.

HKLM\SOFTWARE\Microsoft\Fax

**Description**
The Security subkey stores security information for the Fax Service.

# Descriptor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Security

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | | |

**Description**
Stores the security descriptor for the Fax Service. This entry is configured automatically when the Fax Service registers a routing extension.

### Notes

- A security descriptor is a structure and associated data that contains the security information for a securable object. A security descriptor identifies the owner and primary group of an object. It can also contain a discretionary access-control list (DACL) that controls access to the object, and a system access-control list (SACL) that controls the logging of attempts to access the object.

- A routing extension provides the Fax Service with routing methods for incoming faxes.

- The Microsoft Routing Extension is installed automatically when you add the Fax Service component to the operating system. Other routing extensions might also be installed on a system.

### Caution

- Do not change this entry. Changing this entry will cause the Fax Service to fail.

# SentItems

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

The SentItems subkey stores the configuration for the folder in which the Fax Service stores outgoing faxes.

# SentItems\AgeLimit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\SentItems

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 60 |

**Description**
Specifies the time, in days, that the Fax Service allows a sent fax to remain in the Sent Items folder. (The location of the Sent Items folder is specified by the registry entry SentItems\Folder.) If a resent fax is in the Sent Items folder longer than this time, the Fax Service automatically deletes it. If the value of this entry is zero, there is no time limit, and the Fax Service does not delete faxes from the Sent Items folder.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Sent Items** tab. Under **Archive rules**, check **Automatically delete faxes older than** if it is not already checked. Next, change the number in the **days** box by selecting the number and typing a new number or by clicking the arrow buttons next to the number. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

# SentItems\Folder

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\SentItems

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | C:\Documents and Settings\All Users\Application Data\Microsoft\Windows NT\MSFax\SentItems |

**Description**
Specifies the location of the Sent Items folder of the Fax Service. The Fax Service stores a sent fax in the Sent Items folder when the fax has been sent successfully.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Sent Items** tab. Under **Archive rules**, check or clear **Generate warning in the Event Log**, if it is not already checked. Next, change the number in the **Size quota low watermark** box by selecting the number and typing a new number or by clicking the arrow buttons next to the number. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

Folder Entry

# HighWatermark Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\SentItems

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 100 |

**Description**
Specifies a size threshhold, in megabytes, for the Sent Items folder of the Fax Service. When the combined size of the contents of the Sent Items folder reach the size specified by this entry, the Fax Service enters a warning event into the Windows event log if the registry entry SizeQuotaWarn Entry specifies that the service do so. The Sent Items folder is the folder in which the Fax Service stores faxes that have been sent successfully.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Sent Items** tab. Under **Archive rules**, check **Generate warning in the Event Log** if it is not already checked. Next, change the number in the **Size quota high watermark** box by selecting the number and typing a new number, or by clicking the arrow buttons next to the number. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

## Notes

- This entry specifies the higher of two threshholds for the Sent Items folder. The other threshhold is specified by the registry entry LowWatermark Entry.
- Checking or clearing **Generate warning in the Event Log** changes the value of the registry entry SizeQuotaWarn Entry.

# LowWatermark Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\SentItems

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 95 |

**Description**
Specifies a size threshhold, in megabytes, for the Sent Items folder of the Fax Service. When the combined size of the contents of the Sent Items folder reach the size specified by this entry, the Fax Service enters a warning event into the Windows event log if the registry entry SizeQuotaWarn Entry specifies that the service do so. The Sent Items folder is the folder in which the Fax Service stores faxes that have been sent successfully.

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Sent Items** tab. Under **Archive rules**, check **Generate warning in the Event Log**, if it is not already checked. Next, change the number in the **Size quota low watermark** box by selecting the number and typing a new number, or by clicking the arrow buttons next to the number. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

## Notes

- This entry specifies the lower of two threshholds for the inbox folder. The other threshhold is specified by the registry entry HighWatermark Entry.
- Checking or clearing **Generate warning in the Event Log** changes the value of the registry entry SizeQuotaWarn Entry.

# SizeQuotaWarn Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\SentItems

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the Fax Service enters a warning event into the Windows event log when the contents of the Fax Service Sent Items folder reach a combined size equal to or greater than one of two size threshholds (specified by LowWatermark Entry and HighWatermark Entry). The Sent Items folder is the folder in which the Fax Service stores faxes that have been sent successfully.

| Value | Meaning |
|---|---|
| 0 | The Fax Service does not create warning events in the Windows event log regarding the size of the Sent Items folder. |
| 1 | The Fax Service creates a warning event in the Windows event log when the contents of the Sent Items folder reach a combined size equal to or greater than Inbox\LowWatermark or Inbox\HighWatermark). |

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, and then click the **Sent Items** tab. Under **Archive rules**, check or clear **Generate warning in the Event Log**. Click **OK**.

**Activation Method**
Changes made to this entry through **Computer Management** or **Fax Service Manager** are effective immediately.

# SentItems\Use

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\SentItems

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether the Fax Service archives outgoing faxes.

| Value | Meaning |
|---|---|
| 0 | The Fax Service does not archive outgoing faxes. |
| 1 | The Fax Service archives outgoing faxes. |

Archived outgoing faxes are stored in the location specified by the registry entry Folder Entry (in the same subkey as this entry).

**Change Method**
You can change this entry by using Fax Service Manager, which is part of the Fax Service on Windows Server 2003, but not on Windows XP. To start Fax Service Manager, click the **Start** menu, point to **Accessories**, then point to **Communications**, then point to **Fax**, and then select **Fax Service Manager**. You can also access Fax Service Manager in the **Computer Management** console.

To change the value of this entry by using Computer Management, open Computer Management. In the console tree, click **Services and Applications**, and then click **Fax**. From the **Action** menu, click **Properties**, click the **Sent Items** tab, and check **Archive all outgoing faxes to this folder**, if it is not already checked. Next, type a valid folder path in the **Archive all incoming faxes to this folder** box, or click **Browse** to browse the file system for the folder. Click **OK**.

**Activation Method**
Changes that you make by using **Fax Service Manager** or **Computer Management** are effective immediately.

# Fax\Setup Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

**Description**
The Setup subkey stores information about the Fax Service, such as the version number of the service and which components are installed on the system.

# Installed

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 1 |

**Description**
Specifies whether the Fax Service component is installed on the operating system.

| Value | Meaning |
|---|---|
| 0 | The Fax Service is not installed. |
| 1 | The Fax Service is installed. |

This entry is set automatically when the Fax Service component is installed or removed from the operating system.

**Change Method**
Do not change this entry.

### Caution

- This entry is maintained automatically by the Fax Service setup program. Do not change it.

# InstalledComponents Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Indicates, to the Fax Service, which Fax Service modules are installed on the operating system. If a bit in the value of this entry is 1, the Fax Service behaves as if the corresponding module, as shown in the following table, is absent.

| Value | Meaning |
|---|---|
| 1 | Fax Service (Fxssvc.exe) |
| 2 | Fax Console (Fxsclnt.exe) |
| 4 | Fax Service Manager (Fxsadmin.dll) |
| 8 | Send wizard (Fxssend.exe) |
| 16 | Configuration wizard (Fxscfgwz.dll) |
| 32 | Cover page editor (Fxscover.exe) |
| 64 | Client Help (Fxsclnt.hlp) |
| 128 | Client context help (Fxsclnt.chm) |
| 256 | Fax Service Manager Help (Fxsadmin.hlp) |
| 512 | Fax Service Manager context help (Fxsadmin.chm) |
| 1024 | Cover page editor help (Fxscover.chm) |
| 2048 | Fax Monitor (Fxsst.dll) |
| 4096 | Fax printer driver (Fxsui.dll) |

This entry does not exist by default, and its absence indicates to the Fax Service that all modules are installed.

**Activation Method**
You must stop and restart the Fax Service to make changes to this entry effective.

### Note

- This entry was invented for testing purposes. There is no reason for an administrator to add this entry to the registry.

### Caution

- If you create this entry and set any of the bits of its value equal to 1, you might prevent the Fax Service from working successfully.

# W2K_Inbox

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores the location in the file system of the Inbox folder of Personal Fax for Windows. This entry is created automatically by the Fax Service setup program when the Fax component is installed as an upgrade.

### Note

- When you upgrade from an operating system running Personal Fax for Windows (for example, Windows 2000) to Windows Server 2003, the Windows Server 2003 Fax service replaces Personal Fax for Windows as your fax application, and keeps your previous fax configuration settings.

# W2K_SentItems

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores the location in the file system of the Sent Items folder of Personal Fax for Windows. This entry is created automatically by the Fax Service setup program when the Fax component is installed as an upgrade.

### Note

- When you upgrade from an operating system running Personal Fax for Windows (for example, Windows 2000) to Windows Server 2003, the Windows Server 2003 Fax Service replaces Personal Fax for Windows as your fax application, and keeps your previous fax configuration settings.

# ProductBuild

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Identifies the build number of the Fax Service that is currently installed on the operating system.

**Change Method**
Do not change this entry.

### Caution

- This entry is set automatically when the Fax Service component is installed on the operating system, and you should not change it.

# ServerCoverPageDir

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | Microsoft\Windows NT\MSFax\Common Coverpages |

**Description**
Specifies the location in the file system, relative to %ALLUSERSPROFILE%\Application Data, where the Fax Service stores cover page templates that are available to all users. This entry is configured automatically when the Fax Service component is installed on the operating system.

### Note

- Users can send faxes with one of the cover pages stored in the location specified by this entry, or they can use their own cover pages if the administrator enables personal cover pages in Fax Service Manager.

# Original Setup Data

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

**Description**
The Original Setup Data subkey stores configuration information for the Fax service to use to configure newly discovered fax devices.

# Original Setup Data\CSID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup\Original Setup Data

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | Fax |

**Description**
Specifies the default Called Subscriber ID (CSID) for new fax devices that the Fax service registers.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax service to make changes to this entry effective.

### Note

- When receiving a fax transmission, the Fax service sends the CSID to the sender to identify the receiver. A CSID usually consists of the telephone number of the receiving fax device and a name. The CSID is limited to 20 characters.

Original Setup Data\TSID

# Original Setup Data\Flags

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup\Original Setup Data

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 2 |

**Description**
Specifies whether a fax device, by default, is enabled to automatically answer calls and receive faxes, and whether the device is enabled to send faxes. The Fax Service configures this default for each newly discovered fax device when it registers the fax device.

This entry stores its configuration information as bit-masked values. The following table explains the possible values.

| Value | Meaning |
|---|---|
| 1 | The fax device is enabled to automatically answer calls and receive faxes. |
| 2 | The fax device is enabled to send faxes. |
| 3 | The fax device is enabled both to send and to receive faxes. |

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax Service to make changes to this entry effective.

**Tip**

- If you are deploying many systems on which you want a different default number of rings, you can change the value of this entry during unattended installation of the operating system. For more information about unattended installations, see "Planning and Designing Unattended Installations" in the *Windows Resource Kit Deployment Planning Guide*.

# Original Setup Data\Rings

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup\Original Setup Data

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | 2 |

**Description**
Specifies the default number of times that an incoming call is allowed to ring before the fax device answers. The Fax service configures this default for each newly discovered fax device when it registers the fax device.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax service to make changes to this entry effective.

### Note

- A fax device only answers calls if it is configured to do so by the device-specific registry entry {F10A5326-0261-4715-B367-2970427BBD99}\Flags.

**See Also**
**Concepts**

# Original Setup Data\TSID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup\Original Setup Data

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | Fax |

**Description**
Specifies the default transmitting subscriber identification (TSID) for every new fax device installed on the system.

**Change Method**
You can change this entry only by editing the registry.

**Activation Method**
You must stop and restart the Fax service to make changes to this entry effective.

### Note

- The Fax service sends the TSID when making fax transmissions, depending on the value of registry entry **UseDeviceTsid**. The receiving fax device might use the TSID in a variety of ways; fax machines often display the TSID when receiving a fax and also might print it on the top of each received page. The local Fax service can also include the TSID in a banner, which is prepended to each transmitted page, when the value of registry entry Branding is set to 1.

# ServiceStartup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

The ServiceStartup subkey stores information for the Fax Service about the startup state of the service.

# RPCReady

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\Setup\ServiceStartup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | | |

**Description**
Specifies to the Fax Service that the Fax Service is ready for remote procedure call (RPC) connections.

**Caution**

- This registry entry is maintained automatically by the Fax Service. Do not modify it.

# TAPIDevices

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The TAPIDevices subkey stores information for the Fax Service about Telephony Application Programming Interface (TAPI) devices installed on the system.

# TAPIDevices\DeviceID

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The *DeviceId* subkey stores configuration information for the Fax Service about the Telephony Application Programming Interface (TAPI) device specified by the name of this type of subkey. The Fax Service automatically maintains a *DeviceId* subkey for each TAPI device that it registers.

**Caution**

- Do not attempt to remove a device by deleting registry subkeys like this subkey. If you need to remove a fax device or prevent the Fax Service from using a device, then use Fax Service Manager to delete the device or create routing rules that exclude it from use. For more information about adding and removing fax devices and about routing rules, see Fax Service Manager Help.

# {Guid}

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | | |

**Description**
Stores configuration information for the Fax service about a routing extension for a single fax device. The routing extension iis identified by the globally unique identifier (GUID) in the name of this entry, and the fax device is identified in the registry path by *DeviceId*. For example, the name of the folder for the Store In Folder routing method or the name of the printer for the Print routing method.

The values of this type of entry, which are specified by the GUID in their name and *DeviceID* in their path, are encrypted.

**Change Method**
These types of registry entries, which are specified by the GUID in their name and *DeviceID* in their path, are created and maintained automatically by the Fax service. Do not change them.

# Modem Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**
The Modem subkey stores configuration information for the modem specified by *DeviceId* in the registry path. The Fax Service creates the entries in this subkey during the first fax transmission that it makes with the specified device.

The Fax Service creates most of the entries in this subkey by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.

**Note**

- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

# AnswerCommand

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies commands that the Fax service sends to the specified modem to configure it for adaptive answer and to answer a call. The modem is specified by *DeviceId* in the registry path.

### Notes

- The Fax Service creates entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.

- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

# EnableV17Recv

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | "1" |

**Description**
Specifies the command that the Fax Service sends to the modem to disable use of the communication protocol V.17 during reception of a fax.

| Value | Meaning |
|---|---|
| "0" | The Fax Service cannot use V.17 for reception of faxes. |
| "1" | The Fax Service can use V.17 for reception of faxes. |

Note that the numeric values shown in the preceding table are stored as strings by this entry.

**Notes**

- V.17 is a protocol established by the International Telecommunications Union (ITU) for fax communications. The Fax Service also supports ITU fax protocols V.29 and V.27.

- The Fax Service creates entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.

- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

# HighestSendSpeed

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | "0" |

**Description**
Specifies, in bits per second, the highest over-the-wire speed that the Fax Service uses for sending a fax with the modem specified by *DeviceId* in the registry path. A value of "0" for this entry indicates the highest available speed.

### Notes

- This entry stores numeric values as string values.
- The T.30 protocol engine uses this setting when creating the DIS frame.
- The Fax service creates entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.
- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

# ModemId

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies the string for which the Microsoft Fax Service Provider (FSP) searches in the response from a modem. The FSP attempts to elicit the response from a modem by sending it the command specified in the ModemIdCmd entry. The modem is identified in the registry path by *DeviceId*. If the string is absent, the FSP reinstalls the modem in the operating system.

This entry is not always present in the registry. When it is absent, the FSP does not query the modem for identification.

### Notes

- This entry can by used to check the version of the firmware of the modem.
- The Fax Service creates most of the other entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.
- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.
- A fax service provider is a dynamic-link library (DLL) that provides an application programming interface (API) that the Fax Service uses to interact with one or more fax devices. Microsoft supplies a fax service provider that supports the fax protocol specified by the T.30 specification of the International Telecommunications Union (ITU) for standard fax modems. Third parties can also supply fax service providers to support other fax-capable devices.

# ModemIdCmd

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies the command that the Microsoft Fax Service Provider (FSP) sends to a modem to request identification from the modem. The modem is identified in the registry path by *DeviceId*. If the FSP searches the response from the modem for the string specified by the ModemId entry, and if the string is absent, the FSP reinstalls the modem in the operating system.

This entry is not always present in the registry. When it is absent, the FSP does not query the modem for identification.

### Notes

- This entry can by used to check the version of the firmware of the modem.
- The Fax Service creates most of the other entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.
- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

# ModemSendSpeeds

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Stores the sending capabilities of the modem specified by *DeviceId* in the registry path.

| Value | Meaning |
|---|---|
| 0 | V.27 (2400 bps) |
| 1 | V.29 (7200/9600 bps) |
| 2 | V.27 (2400/4800 bps) |
| 4 | V.33 (12000/14400 bps) |
| 8 | V.17 (7200/9600/12000/14400 bps) |

The Microsoft Fax Service Provider (FSP) determines the value of this entry when it detects and installs the modem to the operating system. The FSP sets the fifth bit (8) to 0 if the registry entry **EnableV17Send** specifies that the modem should not use the V.17 protocol to transmit faxes.

# PreAnswerCommand

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies the modem command string that the Fax Service sends to the modem just before sending the answer command. By default, this entry stores an empty string.

This entry is created automatically by the Fax Service when it sends a fax for the first time using the modem identified in the registry path by *DeviceId*.

### Notes

- The Fax Service creates entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.

- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

# PreDialCommand

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | |

**Description**
Specifies the modem command string that the Fax Service sends to the modem just before sending the dial command. By default, this entry stores an empty string.

Before sending the modem command specified by this entry, if there is a command specified, then the Fax Service sends the setup command, specified by the registry entry **SetupCommand**, and the modem class command, specified by the registry entry **FixModemClass**.

This entry is created automatically by the Fax Service when it sends a fax for the first time using the modem identified in the registry path by *DeviceId*.

### Notes

- The Fax Service creates entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.

- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

# ResetCommand

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Fax\TAPIDevices*DeviceId*\Modem

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | | AT&FS0=0E0V1Q0 |

**Description**
Specifies the modem command string that the Fax Service sends to the modem before commencing each transmission and before answering each incoming call, unless the modem is in auto-answer mode. This reset command instructs the modem to load its factory default settings, disable auto-answer, turn off command echo, use words (rather than numbers) for results messages, and turn on results messaging. If the value of this entry is null, then the Fax Service does not send a reset command.

This entry is created automatically by the Fax Service when it sends a fax for the first time using the modem identified in the registry path by *DeviceId*.

### Notes

- The Fax Service creates entries in the subkey Fax\TAPIDevices*DeviceId*\Modem by copying the values of identically named entries in the part of the registry that stores settings for Unimodem 5. Unimodem 5 acquires some of these settings from the setup information (.inf) file for the modem when Windows installs the modem driver.

- Unimodem 5 is a Telephony Service Provider that provides an abstraction for modem devices such that applications can operate transparently across a wide variety of types and makes of modems. In addition, modem installation is greatly simplified since Unimodem 5 is aware of the operating characteristics of these modems, and their drivers are already available in the operating system.

- If the reset command fails, Unimodem 5 sends the command string **AT&FS0=0E0**. If this replacement command fails, Unimodem 5 sends the command string **AT&FE0**. If all of these reset commands fail, modem initialization fails.

# Internet Explorer Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Media

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Internet Explorer

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Autoplay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Internet Explorer\media

**Description**
Stores configuration data for the policy setting **Configure Media Explorer Bar**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# MSMQ

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
The MSMQ subkey stores configuration data for Message Queuing (also known as MSMQ). This subkey and its contents appear only if you have installed the Message Queuing service.

Message Queuing is a store-and-forward service that enables applications to communicate across heterogeneous networks and operating systems, even when the networks and applications are running at different times. Message Queuing stores messages in queues and forwards them when the destination networks and applications come online. The entries in this subkey apply to all users of the computer.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# Parameters

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ

**Description**
The Parameters subkey stores configuration options for Message Queuing (also known as MSMQ).

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# AckTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*milliseconds*) | (Message Queuing calculates a value for this entry dynamically.) |

**Description**

Specifies how long Message Queuing (also known as MSMQ) waits for internal message acknowledgment of a network session before deciding that the session should be closed.

By default, Message Queuing calculates an optimal acknowledgment timeout based on the quality of the communication line. However, you can override the result of the calculation by adding this entry to the registry and setting it to a different value.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Adding this entry to the registry prevents the system from using an optimal value calculated for each line. If you set the value of this entry too low, then sessions can be disconnected before any messages are delivered.

# CertInfoCacheSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*certificates*) | 0x35 (53) |

**Description**
Specifies the maximum number of certificates stored in the certificate cache, which stores information about certificates found in incoming messages. This cache helps Message Queuing (also known as MSMQ) authenticate incoming messages more quickly.

If the cache is full (that is, if the number of certificates equals the value of the **CertInfoCacheSize** entry) when the next certificate arrives, then Message Queuing deletes half of the certificates in the cache. The oldest certificates are deleted first.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Entries in the certificate cache are not subject to an expiration time. Certificates are deleted from the cache only when the cache is full.

# MsmqIpPingPort

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*port number*) | 0xDC7 (3527) |

**Description**
Specifies the User Datagram Protocol (UDP) port that Message Queuing (also known as MSMQ) uses to ping servers. Message Queuing uses an internal ping algorithm to quickly determine the availability and configuration of a server.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- This entry is used only when the value of UsePing is 1.

### Caution

- This value must be the same on all computers in the enterprise. Using different UPD ports can significantly increase the time it takes for Message Queuing to establish network connections.

# MsmqIpPort

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*port number*) | 0x709 (1801) |

**Description**

Specifies the TCP port that Message Queuing (also known as MSMQ) uses to connect queue managers.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Caution

- Do not change the value of this entry. Changing this value can prevent Message Queuing computers from exchanging messages.

# PerThreadDSServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Enables applications to work with a different directory service server for each thread.

The default value allows all threads to work with the same directory service server, and if one thread changes the directory service, then it affects the others. In Windows Server 2003, some operations might require access to a specific directory service server. Enabling this mode guarantees that the directory service activity of the other threads will not change the server. This is relevant only in Message Queuing (also known as MSMQ) mixed mode, when some of the servers in the site are running MSMQ 1.0 and some are running Message Queuing.

| Value | Meaning |
|---|---|
| 0 | All threads access the same directory service server. |
| 1 | All threads can access a different directory service server. |

# QmPbKeyCacheSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *keys* | 0x35 (53 keys) |

**Description**
Specifies the maximum number of keys that can be stored in the queue manager (QM) public encryption key cache. This cache stores public encryption keys recently used in replication and notification messages.

If the cache is full (that is, if the number of keys is equal to the value of this entry) when the next key arrives, then Message Queuing (also known as MSMQ) deletes half of the keys in the cache. The oldest keys are deleted first.

All replication and notification messages are digitally signed by the Message Queuing Information Store (MQIS) that generated the message. The Message Queuing computers that receive the message validate its signature by using the public key of the sending MQIS. Storing recently used keys in a cache reduces the time it takes to verify the signature.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- Entries in the public encryption key cache are not subject to an expiration time. These entries are deleted only when the cache is full.

# QMThreadNo

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0x10 *threads* | Windows Server 2003: *(Number of processors x 5) + 3* Windows XP Professional: *Number of processors x 3* |

**Description**
Specifies the number of threads created in the Message Queuing (also known as MSMQ) process (Mqsvc.exe) to handle messages.

Increasing the value of this entry can improve the performance of Message Queuing, but too many threads can overload the processor.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# RemoteQMMachine

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Computer name* | *Computer name* |

**Description**
Specifies the name of the supporting server computer for the local Message Queuing (also known as MSMQ) dependent client. The supporting server routes messages to the client, transmits queries and responses, and updates the client's view of the enterprise.

**Change Method**
To change the value of this entry, in Control Panel, double-click **MS Message Queue**, and then click the **MSMQ Client** tab.

### Note

- This entry is used only when it appears in the registry of a Message Queuing client that is dependent on a parent server, and it appears there by default.

# RMFlushInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *milliseconds* | 0x1B7740 (1,800,000 millseconds = 30 minutes) |

**Description**
Specifies how often Message Queuing (also known as MSMQ) takes a checkpoint of Resource Manager transactions. The checkpoint saves the current transactions and exactly-once-delivery state of Message Queuing.

The value of this entry is used when no checkpoints have been taken in the Resource Manager as a result of other events, such as when its log file is more than half full. It guarantees that a checkpoint is performed no less frequently than the time specified.

If this value is too large, it might prolong the time it takes to recover files to their last checkpoint. However, if the value is too small, frequent checkpoints can degrade Message Queuing performance.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with logging, transactions, and the exactly-once delivery mechanism.

# RpcCancelTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *minutes* | 0x5 |

**Description**
Specifies how long a Message Queuing (also known as MSMQ) client waits after submitting a request before it notifies the user that the Message Queuing Information Store (MQIS) server has not responded. This entry appears only in the registries of Message Queuing client computers.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- This entry is used only when it appears in the registry of a Message Queuing client computer.

# CryptReceiveKeyCacheSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*keys*) | 0x7F (*127*) |

**Description**
Specifies the maximum number of symmetric encryption keys found in incoming messages that can be stored in the cryptographic key cache on the receiving server.

If the cache is full (that is, if the number of incoming keys is equal to the value of the **CryptReceiveKeyCacheSize** entry) when the next certificate arrives, then Message Queuing (also known as MSMQ) deletes half of the certificates in the cache. The oldest certificates are deleted first.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Incoming keys in the cryptographic key cache are not subject to an expiration time. Incoming keys are deleted from the cache only when the cache is full.

CryptSendKeyCacheSize

# CryptSendKeyCacheSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*keys*) | 0x35 (*53*) |

**Description**
Specifies the maximum number of outgoing symmetric encryption keys that can be stored in the cryptographic key cache on the sending server.

If the cache is full (that is, if the number of outgoing keys is equal to the value of the **CryptReceiveKeyCacheSize** entry) when the next key arrives, then Message Queuing (also known as MSMQ) deletes half of the keys in the cache. The oldest keys are deleted first.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Incoming keys in the cryptographic key cache are not subject to expiration. Incoming keys are deleted from the cache only when the cache is full.

**Concepts**
CryptReceiveKeyCacheSize

# DeferredInit

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**
Defers the contact between Message Queuing (also known as MSMQ) and the MQIS server that would otherwise occur automatically at startup.

| Value | Meaning |
|---|---|
| 0 | Automatic. Message Queuing contacts the MQIS server automatically when the service starts. |
| 1 | Deferred. Message Queuing does not contact the MQIS server automatically when the service starts. Instead, it contacts the MQIS when the first Message Queuing program requires access to the MQIS. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- The deferred setting can cause a brief delay while Message Queuing connects to the MQIS server. This delay might cause the first program that requires the MQIS server to appear momentarily unresponsive.

# DSAdsRefreshIPSitesIntervalSecs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*seconds*) | 0xE10 (*3,600 seconds = 1 hour*) |

**Description**

Specifies the minimum interval between successive updates of the IP subnets data for the site. Message Queuing (also known as MSMQ) servers use information from these updates to find the IP addresses of computer sites.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# DSAdsRefreshNT4SitesIntervalSecs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*seconds*) | 0x5460 (*21,600 seconds = 6 hours*) |

**Description**
Specifies the minimum interval between successive updates of the list of primary site controllers running Windows NT 4.0. Message Queuing (also known as MSMQ) uses information from these updates to determine whether it needs to support clients using previous versions of the operating system.

### Note

- This entry is used only when Windows Server 2003 or Windows 2000 Message Queuing servers are supporting Windows NT 4.0 clients.

# DSCliSearchAdsForServersIntervalSecs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*seconds*) | 0x708 (*1,800 seconds = 30 minutes*) |

**Description**
Specifies the minimum interval between successive searches through Active Directory for Message Queuing (also known as MSMQ) servers. Message Queuing searches the Active Directory when it cannot connect to known Message Queuing servers.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Caution

- Do not change the value of this entry. Changing it can prevent Message Queuing from locating known servers in the Active Directory.

# DSSecurityCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *Security descriptor* | (None. The security descriptor of the computer is copied from the MQIS.) |

**Description**

Stores the security descriptor of the local Message Queuing (also known as MSMQ) computer. The security descriptor of the computer determines, among other things, which users or groups of users have permission to create queues on the computer. The value of this registry entry is used if an offline user attempts to create a private queue when a queue request is processed.

The security descriptor is saved in the registry to allow private queues to be created while the computer is not connected to the network.

**Caution**

- Do not change the value of this entry. If you do, then the online operation of Message Queuing might be inconsistent with the offline operation.

# IdleAckDelay Entry

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*milliseconds*) | 500 |

**Description**

Sets the maximum idle delay time between receiving a message and sending an acknowledgment to the source.

Idle time is the time during which no messages are sent on the session. It ensures that computers creating a session for a limited time only will get all acknowledgments possible during the session. This prevents unnecessary resending due to lost acknowledgments.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# This Topic Is No Longer Available

We're sorry—the topic that you requested is no longer available. Use the search box below to find related information.

# LastPrivateQueueId

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | 0x0–0xFFFFFFFF | 0xA (*10*) |

**Description**
Records the serial number of the last private queue created. Message Queuing (also known as MSMQ) updates this entry any time a private queue is created.

### Caution

- Do not change the value of this entry. Doing so could cause Message Queuing to generate the same identifier for a private queue and damage both the queue and the message service.

# LogDataCreated

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether log files are missing.

When Message Queuing (also known as MSMQ) runs for the first time, it creates local log files and sets the value of this entry to 1. Later, Message Queuing uses this entry to determine whether log files are missing. If they are, then Message Queuing does not start, and an appropriate event is generated.

| Value | Meaning |
|---|---|
| 0 | Local log files are not created on the computer. |
| 1 | Local log files are created on the computer. |

# LogMgrBuffers

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*buffers*) | 0x190 (*400*) |

**Description**

Specifies how many buffers the Log Manager allocates for each new log file.

This entry is used to optimize Log Manager performance.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with logging, transactions, and the exactly-once delivery mechanism.

# LogMgrChkptInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*milliseconds*) | 0x2710 (*10 seconds*) |

**Description**
Specifies how often the Log Manager performs an internal checkpoint on the log. This entry is used to optimize Log Manager performance.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with logging, transactions, and the exactly-once delivery mechanism.

# LogMgrFileSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*bytes*) | 0x600000 (*6 MB*) |

**Description**

Specifies the size of the Log Manager file. The size of this file affects the maintenance of the Log Manager file and the performance of Message Queuing (also known as MSMQ). Message Queuing performs checkpoints, in which it saves the current log entries, when the log file occupies more than half of the space allocated for it. If the value of this entry is too small, then Message Queuing takes checkpoints frequently, diminishing overall performance. If the file is too large, then it consumes unnecessary disk space.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with logging and with the operation of Message Queuing.

# LogMgrFlushInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *milliseconds* | 0x32 (50) |

**Description**

Specifies how often the Log Manager flushes the log file.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Caution

- Do not change the value of this entry. An inappropriate value can interfere with logging, transactions, and the exactly-once delivery mechanism.

# LogMgrProbeInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *milliseconds* | 0x64 (100) |

**Description**
Specifies how often the Log Manager considers writing an empty record to the log file buffer. Empty records are written to fill the log file buffers so that the buffer contents are written to disk.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with logging, transactions, and the exactly-once delivery mechanism.

# LogMgrTimerInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *milliseconds* | 0xA (10) |

**Description**

Specifies how often the Log Manager considers performing a flush or internal checkpoint (*pulse interval*).

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with logging, transactions, and the exactly-once delivery mechanism.

# StoreAckTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *milliseconds* | (Not in registry) |

**Description**
Specifies how long Message Queuing (also known as MSMQ) waits for internal message acknowledgement of persistent messages on a network session before deciding that the session should be closed.

By default, Message Queuing calculates an optimal acknowledgment timeout based on the quality of the communication line. However, you can add this entry to the registry and then set it to a different value to override the result of the calculation.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Adding this entry to the registry prevents the system from using an optimal value calculated for each line. If you set the value of this entry too low, then sessions can be disconnected before any messages are delivered.

# StoreMqLogPath

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Path and directory name* | *Installation path*\MSMQ\Storage |

**Description**
Specifies the directory where Message Queuing (also known as MSMQ) stores the transaction log file, also known as the QM log. Message Queuing stores the current state of active transactions and incoming transacted messages in the transaction log file.

**Change Method**
To view or change the value of this entry, in Control Panel, double-click **Message Queuing**. The directory where the transaction log and all checkpoint files are stored appears in the **Transaction Logger Folder** box.

### Note

- Message Queuing stores all checkpoint files in the same directory as transaction log file (QM Log). If you use **Message Queuing** in Control Panel to change the value in the **Transaction Logger Folder** box, then Message Queuing moves all checkpoint files and the transaction log to the new location.

# SysQueuePriority

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x7FFF (32,767) |

**Description**

Specifies the base priority of messages destined for system queues.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Caution

- Do not reduce the value of this entry. Permitting lower-priority messages to be sent to queues might delay messages with higher priority, including system messages.

# TCPNoDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Disables nagling. Nagling is a TCP feature that combines several small packets into a single, larger packet for more efficient transmission.

By default, Message Queuing (also known as MSMQ) enables nagling on the TCP sockets it uses. This improves overall performance, but it might briefly delay transmission of smaller packets. If the delay is undesirable or unacceptable, then you can add this entry to the registry to disable nagling.

| Value | Meaning |
|---|---|
| 0 | Nagling is enabled. |
| 1 | Nagling is disabled. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# TransactionMode

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | DefaultCommit \| (blank) | DefaultCommit |

**Description**
Specifies whether Message Queuing (also known as MSMQ) uses the default-abort mode or the default-commit mode to process transactions.

When the value of this entry is blank, the service uses the default-abort mode. When the value of this entry contains DefaultCommit, the service uses the default-commit mode.

# UsePing

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 1 |

**Description**
Specifies whether Message Queuing (also known as MSMQ) uses an internal ping algorithm to determine the availability and configuration of a server. Using a ping, the service can find this information quickly.

| Value | Meaning |
|---|---|
| 0 | Message Queuing does not use the ping algorithm. |
| 1 | Message Queuing does use the ping algorithm. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
MsmqIpPingPort

# UserCacheSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *entries* | 0xFD (253 entries) |

**Description**

Specifies the maximum number of entries that can be stored in the user account information cache. This cache stores information about users who recently sent messages to the computer.

When Message Queuing (also known as MSMQ) receives a message, it uses user account information to verify that the sending user has permission to send messages to the particular queue. Storing user account information in the cache reduces the time it takes to verify user permissions.

If the cache is full (that is, if the number of entries is equal to the value of **UserCacheSize**) when the next entry arrives, then Message Queuing deletes half of the entries in the cache. The oldest entries are deleted first.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# WriteMsgTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 10 |

**Description**
Determines how long write-request messages are active. When the value of this entry expires, the write-request message is deleted.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- This entry is used only when it appears in the registry of a Message Queuing MQIS server.

# XactDeadLetterAlways

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | 0 |

**Description**

Specifies whether messages that are timed-out or undeliverable are placed in the XactDeadLetter queue.

In MSMQ 1.0, transactional messages messages that were timed-out or undeliverable were placed in the XactDeadLetter queue by default. In Windows Server 2003, the messages are placed in the XactDeadLetter queue only if the MSMQ_DEADLETTER property is selected.

Setting the value of this entry to 1 forces the local Message Queuing service to revert to MSMQ 1.0 behavior. Use this entry when the change in default behavior might break the existing application.

| Value | Meaning |
|---|---|
| 0 | Messages are placed in the XactDead Letter queue only if the message property (MSMQ_DEADLETTER) was set on the message. |
| 1 | Messages are placed in the XactDeadLetter queue. |

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# XactDelayReceiveNack

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFE *seconds* | (None) |

**Description**

Specifies an additional delay for timing out non-received transactional messages sent from this computer.

Message Queuing (also known as MSMQ) will wait an additional amount of time, equal to the value of the **XactDelayReceiveNack** entry, after the Time-To-Be-Received (TTBR) has expired and before placing the message in the XactDeadLetterQueue. The purpose of this delay is to allow positive receive acknowledgments (sent shortly before the TTBR expires) to reach the sender. If this value is not explicitly set in the registry, then the value of **XactDelayReceiveNack** will be automatically set to the smallest of the Time-To-Be-Received and Time-To-Reach-Queue properties of the message.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# MaxMessageSize

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *bytes* | 0x400000 (4 MB) |

**Description**
Specifies the maximum size of the message file. Because messages must fit in the file, the value of this entry also limits the size of messages that Message Queuing (also known as MSMQ) sends and receives.

When Message Queuing starts, it restores all persistent messages in message files. If it finds a message file larger than the value of this entry, then it might not operate correctly. Also, if it encounters messages larger than this value, then it blocks all further transports from the sending computer. To restore communication, you must set the value of this entry greater than or equal to the size of the message that exceeded this value, and then restart Message Queuing.

If you increase this value, you might be able to transmit larger messages between applications on the same computer. However, because this entry affects both incoming and outgoing messages, in order to send a larger message to other computers running Message Queuing, you must increase this value on all participating systems. If any system has a lower value, it might block transports from computers sending larger messages.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
Message Queuing checks this entry only at startup. If you change the value of this entry, you must restart Message Queuing to make the change effective.

### Note

- This entry affects Message Queuing only. It does not change characteristics of the network or network programs that might limit the size of messages.

### Caution

- Do not change the value of this entry. Increasing this value might prevent you from sending messages larger than 4 MB. Decreasing this value might block transports between Message Queuing computers.

# MaxUnackedPacket

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF*Messages* | 0x40 (64 Messages) |

**Description**

Specifies the maximum size of the message queue to each network session. The value of this entry limits the number and size of messages that can be stored between internal acknowledgments from the receiving server. If the queue fills before an acknowledgment is received, additional messages are discarded.

If the queue is too small, messages might be lost. But because messages in the queue are released again when a session fails, a large queue can flood the system with duplicate messages.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SeqIDAtLastRestore

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | (None) |

**Description**

Records the value of the last assigned sequence ID at the time of the last restore in the registry.

This entry is used to distinguish between restored messages and those messages sent after the restore. This entry is necessary to guarantee the exactly-once-delivery of transactional messages when the backup/restore utility is used. Do not edit this value.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SeqMaxAckDelay

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFE *seconds* | 0xA (10 seconds) |

**Description**

Defines the length of delay in sending acknowledgements for transacted messages.

Message Queuing (also known as MSMQ) sends an order acknowledgment for the delivered, transacted messages. The value of this entry defines the delay in sending these messages. The receiving computer never sends an order acknowledgment more frequently than once per the number of seconds specified in the value of this entry.

This entry provides for batching of messages, which saves unnecessary traffic. Too large a value might cause resending of the messages because the sending computer might think the packets did not arrive. Too small a value might cause more order-acknowledgment packets to be sent.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# SeqResend10Time

Updated: November 6, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 0x5460 (21,600 seconds = 6 hours) |

**Description**

Determines how often outgoing, transacted messages are resent because they are unacknowledged.

The value of this entry specifies the interval between resends for the tenth and subsequent resend attempts. If the sender still does not receive an acknowledgement from the intended recipient, the message is resent at the rate specified by this value until it times out.

The interval between earlier resends is determined by the values of the following entries: SeqResend13TimeSeqResend46Time, SeqResend79Time.

| **Note** |
|---|
| Windows does not add this entry to the registry. You can add it by editing the registry or by using a program that edits the registry. |

| **Caution** |
|---|
| Do not change the value of this entry. An inappropriate value can interfere with message delivery. |

# SeqResend13Time

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 0x1E (30) |

**Description**

Specifies how often outgoing, transacted messages are resent because they are unacknowledged.

The value of this entry specifies the interval between resends for the first three times the message is resent. If, after the third resend, the sender still does not receive an acknowledgement from the intended recipient, then the message is resent at intervals determined by the values of the following entries: SeqResend46Time, SeqResend79Time, **SeqResend10Time**.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with message delivery.

# SeqResend46Time

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 0x12C (300 seconds = 5 minutes) |

**Description**

Specifies how often outgoing, transacted messages are resent because they are unacknowledged.

The value of this entry specifies the interval between resends for the fourth, fifth, and sixth times the message is resent. If, after the sixth resend, the sender still does not receive an acknowledgment from the intended recipient, then the interval between acknowledgments is determined by the values of the following entries: SeqResend79Time, **SeqResend10Time**. The interval between the first three resends is determined by the value of SeqResend13Time.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with message delivery.

# SeqResend79Time

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 0x708 (1800 seconds = 30 minutes) |

**Description**

Specifies how often outgoing, transacted messages are resent because they are unacknowledged.

The value of this entry specifies the interval between resends for the seventh, eighth, and ninth times the message is resent. If, after the ninth resend, the sender still does not receive an acknowledgment from the intended recipient, then the interval between acknowledgments is determined by the value of **SeqResend10Time**.

The interval between earlier resends is determined by the values of the following entries: SeqResend13Time, SeqResend46Time.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Caution**

- Do not change the value of this entry. An inappropriate value can interfere with message delivery.

# CryptKeyExpirationTime

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF (*milliseconds*) | 0x927C0 (*600,000 milliseconds = 10 minutes*) |

**Description**
Specifies how long outgoing symmetric keys remain in the cryptographic key cache. When the time specified by this value expires, the key is deleted from the cache of the source server, and symmetric keys used for encrypting messages are renewed.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**See Also**
**Concepts**
CryptSendKeyCacheSize

# CertificationAuthorities

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The CertificationAuthorities subkey contains X509-V3 certificates from external certification authorities (CAs). These subkeys are created by Microsoft Crypto API 2.0. Message Queuing (also known as MSMQ) uses the certificates to generate digital signatures that uniquely identify the message sender. The certificate and the digital signature are sent with each authenticated message.

**Change Method**
To enable or disable certificates, in Control Panel, double-click **MS Message Queue**, click the **Security** tab, and then click the **Certification Authorities** button.

### Note

- The entries in the subkeys in CertificationAuthorities store actual certification authority (CA) certificates, not just pointers to entries in another location.

### Caution

- Do not change the value of entries in this subkey by editing the registry. Changing these values can disable the security features of Message Queuing.

# ClusteredQMs

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The ClusteredQMs subkey stores entire registry sections of Message Queuing (also knowns as MSMQ) services running as cluster resources.

For every clustered Message Queuing resource, there is a subkey in the ClusteredQMs subkey that holds all the entries of this Message Queuing resource.

**Note**

- Only edit the entries in this subkey that are on the node currently hosting the resource, and only when the resource is online.

# MachineCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The MachineCache subkey of the MSMQ\Parameters subkey stores configuration data that associates the local Message Queuing Information Store (MQIS) client computer with other computers in the enterprise managed by Message Queuing (also known as MSMQ).

# CurrentMQISServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Computer name* | *Computer name* |

**Description**
Stores the computer name of the MQIS server currently selected by Message Queuing (also known as MSMQ) on this computer. The MQIS client uses the server specified for MQIS queries.

### Note

- This entry is used only when it appears in the registry of a Message Queuing MQIS client, and is updated each time the system starts.

**See Also**
**Concepts**
StaticMQISServer

# EnterpriseId

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *Identifier* | (None) |

**Description**
Stores a globally unique identifier (GUID) that uniquely identifies the enterprise in which the computer is installed. The value of this entry must be the same in all Message Queuing (also known as MSMQ) computers in the enterprise.

**Caution**

- Do not change the value of this entry. If you change it, Message Queuing responds as though you removed the computer from the enterprise, and the computer will not be able to access any MQIS server or to establish any network connections.

# ForcedDSServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Computer Names* | (None) |

**Description**
Stores the MQIS server name, which Message Queuing (also known as MSMQ) uses when its querying of the directory service for the MQIS servers list either fails or returns no results.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- **ForcedDSServer** is the name of the Message Queuing directory service server used for the join domain. The value of this entry will not override a server name if one is found by the Message Queuing service.

# MachineJournalQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFE *bytes* \| 0xFFFFFFFF | 0xFFFFFFFF |

**Description**

Limits the amount of data that is stored in the journal file on the computer.

| Value | Meaning |
|---|---|
| 0x0–0xFFFFFFFE *bytes* | Journal file size limit |
| 0xFFFFFFFF | No limit on the size of the journal file |

**Change Method**

To change the value of this entry, use Message Queuing Explorer.

# MachineQuota

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFE *kilobytes* \| 0xFFFFFFFF | 0xFFFFFFFF |

**Description**
Limits the total amount of data that is stored in message files on the computer. The sum of bytes in all message files on the computer cannot exceed the value of this entry.

| Value | Meaning |
|---|---|
| 0x0–0xFFFFFFFE kilobytes | Total message file size limit. |
| 0xFFFFFFFF | There is no limit on the message file size. |

**Change Method**
To change the value of this entry, use Message Queuing Explorer.

# MasterId

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | *Globally unique identifier (GUID)* | (None) |

**Description**
Stores a globally unique identifier (GUID) that uniquely identifies the computer to other MQIS servers in the enterprise.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- This entry is used only when it appears in the registry of a Message Queuing MQIS server. It appears by default only on Windows 4.0 computers.

### Caution

- Do not change the value of this entry. If you change it, other MQIS servers will not recognize the computer.

# QMId

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_BINARY | *Globally unique identifier (GUID)* | (None) |

**Description**
Stores the globally unique identifier (GUID) that uniquely identifies the computer in the enterprise. The GUID is generated when Message Queuing (also known as MSMQ) is installed.

### Caution

- Do not change the value of this entry. Message Queuing stores this GUID when Message Queuing is set up. Changing the value of this entry might cause Message Queuing to misidentify the computer.

# StaticMQISServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Computer name* | (None) |

**Description**

Specifies the server that Message Queuing (also known as MSMQ) uses for this client.

By default, this entry does not appear in the registry, and Message Queuing selects a current server randomly from the list of available backup site controller (BSC) and primary site controller (PSC) servers at the site. By adding this entry to the registry, you direct Message Queuing to use only the server specified by this value. The value of this entry replaces the values of the MQISServer and CurrentMQISServer entries, so that this server is the only one known to the client.

A static server is recommended when one server is clearly preferable to others, such as specifying a local server when other servers are remote and rely on slow network connections.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- This entry is used only when it appears in the registry of a Message Queuing MQIS client.

# MQISServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\MachineCache

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Computer names* | (None) |

**Description**
Stores a list of the Message Queuing (also known as MSMQ) servers in the current site.

For computers with Message Queuing belonging to a Windows 2000 site, this list contains all Windows 2000 domain controllers running Message Queuing, as well as all Windows 2000 servers running Message Queuing with Routing. For computers with Message Queuing belonging to Windows NT 4.0 MSMQ Enterprise, this list contains the primary site controller (PSC) and all backup site controllers (BSCs) at the local site. Message Queuing compiles the list at intervals specified by the value of the **DSListRefresh** entry, and it stores the list in the value of this entry. The Message Queuing client selects a server from this list.

### Note

- This entry is used only when it appears in the registry of a Message Queuing client.

**See Also**
**Concepts**
StaticMQISServer

# Migration

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The Migration subkey stores entries that determine how Message Queuing (also known as MSMQ) data is propagated to clients running previous versions of the operating system. Entries in the Migration subkey are used only when there are MSMQ 1.0 servers running Windows NT 4.0 and earlier. They are not used when all servers are running Windows Server 2003 or Windows 2000.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# HelloInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Migration

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 0x4B0 (1,200 seconds = 20 minutes) |

**Description**
Specifies how often a Message Queuing (also known as MSMQ) server sends *hello* messages to each client.

*Hello* messages are Layer Two Tunneling Protocol (L2TP) control messages sent at regular intervals to prevent an active, but silent, connection from being mistaken for an idle line. They are also known as *keep-alive* messages.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- Entries in the Migration subkey are used only when there are MSMQ 1.0 servers that are running Windows NT 4.0 and earlier. They are not used when all servers are running Windows Server 2003 or Windows 2000.

**Tip**

- The length of the replication interval is a multiple of the length of the hello-message interval. The multiplier that determines the length of the replication interval is stored in the value of TimesHelloForReplicationInterval.

**See Also**
**Concepts**
TimesHelloForReplicationInterval

# PurgeBuffer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Migration

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x400 (1,024) |

**Description**
Specifies the number of recently deleted objects that cannot yet be permanently erased.

When objects are deleted, they remain in Active Directory until they are erased permanently. Message Queuing (also known as MSMQ) creates a buffer zone of recently deleted objects that cannot be erased. If an object is deleted accidentally, then you can retrieve it if it is still in the buffer zone. The value of this entry determines the number of recently deleted objects in the buffer zone.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Entries in the Migration subkey are used only when there are MSMQ 1.0 servers running Windows NT 4.0 and earlier. They are not used when all servers are running Windows Server 2003 or Windows 2000.

# ReplMsgTimeout

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Migration

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF *seconds* | 0x4B0 (1,200 seconds = 20 minutes) |

**Description**

Specifies how long replication messages can remain in Active Directory before they are deleted.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Note**

- Entries in the Migration subkey are used only when there are MSMQ 1.0 servers running Windows NT 4.0 and earlier. They are not used when all servers are running Windows Server 2003 or Windows 2000.

# ReplThreads

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Migration

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0x4 |

**Description**
Specifies the number of threads that Message Queuing (also known as MSMQ) allocates for answering replication and sync messages from servers running Windows NT 4.0.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Entries in the Migration subkey are used only when there are MSMQ 1.0 servers running Windows NT 4.0 and earlier. They are not used when all servers are running Windows Server 2003 or Windows 2000.

# TimesHelloForReplicationInterval

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Migration

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | 0xFFFFFFFF |

**Description**
Specifies how often Message Queuing (also known as MSMQ) sends replication messages.

The interval between replication messages is based on the length of the interval between *hello* messages, as determined by the value of HelloInterval. The replication interval is expressed as the number of hello-message intervals. The value of this entry specifies the number of *hello* message intervals that must elapse between replication messages.

For example, if the value of **HelloInterval** is 60 seconds, and the value of **TimesHelloForReplicationInterval** is 60, then the interval between replication messages is one hour (60 × 60 seconds).

*Hello* messages are Layer Two Tunneling Protocol (L2TP) control messages sent at regular intervals to prevent an active, but silent, connection from being mistaken for an idle line. They are also known as *keep-alive* messages.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

### Note

- Entries in the Migration subkey are used only when there are MSMQ 1.0 servers running Windows NT 4.0 and earlier. They are not used when all servers are running Windows Server 2003 or Windows 2000.

**See Also**
**Concepts**
HelloInterval

# OCMsetup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The OCMsetup subkey stores information about the installation and configuration of Message Queuing (also known as MSMQ) when it is set up using the Optional Components Manager setup.

**Caution**

- These values are stored by Message Queuing for internal use. Do not add or change any entries or values in this subkey.

# Directory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\OCMsetup

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Path and directory name* | (None) |

**Description**
Stores the location of the directory where Message Queuing (also known as MSMQ) is installed.

**Caution**

- Do not change the value of this entry. Changing the value can prevent the Setup program from successfully installing, upgrading, or uninstalling Message Queuing.

# InstalledComponents

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\OCMsetup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | (None) |

**Description**

Records the Message Queuing (also known as MSMQ) components that were installed on this computer.

**Caution**

- Do not change the value of this entry. Changing the value can prevent the Setup program from successfully installing, upgrading, or uninstalling Message Queuing.

# ShortcutCount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\OCMsetup

| Data type | Range | Default value |
|---|---|---|
| | 0x0–0xFFFFFFFF | (None) |

**Description**

Records the number of shortcuts installed by Optional Components Manager (OCM) Setup.

**Caution**

- Do not change the value of this entry. Changing the value can prevent the Setup program from successfully installing, upgrading, or uninstalling Message Queuing (also known as MSMQ).

# ShortcutDirectory

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\OCMsetup

| Data type | Range | Default value |
|---|---|---|
| | *Path and directory name* | (None) |

**Description**

Records the location of the directory where Message Queuing (also known as MSMQ) shortcuts are installed

**Caution**

- Do not change the value of this entry. Changing the value can prevent the Setup program from successfully installing, upgrading, or uninstalling Message Queuing.

# OnHold Queues

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
This subkey contains a list of outgoing queues that are currently paused.

# Parameters\Security

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The Security subkey contains subkeys that contain information about the computer account and about whether server authentication is used (secured communication between client and server).

### Note

- The entries in the subkeys in the HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\CertificationAuthorities subkeys store actual certification authority (CA) certificates, not just pointers to entries in another location.

### Caution

- Do not change the values of entries in this subkey by editing the registry. Changing these values can disable the security features of Message Queuing.

# ServerCertDigest

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Security

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x0–0xFFFFFFFF | (None) |

**Description**
Specifies which server certificate is used if the certificate store contains several certificates. Message Queuing (also known as MSMQ) will use only the certificate whose hash (digest) matches this value.

The value of this entry is set when the user registers a server certificate through Control Panel. The **ServerCertDigest** entry is used only on a Message Queuing server that runs on a Windows Server 2003 domain controller.

This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

# ServerCertStore

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Security

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *string* | (None) |

**Description**

Specifies the name of the machine certificate store where the server certificate for the local server is stored.

This entry is used only on a Message Queuing (also known as MSMQ) server that runs on a Windows Server 2003 domain controller. The server certificate is used for the Secured Communication feature, where Message Queuing clients can verify that they query an authentic Message Queuing server.

The value of this entry is set when the user registers a server certificate through Control Panel. The value is read by Message Queuing the first time a client wants to authenticate the server.

# ServersCache

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The ServersCache subkey of the MSMQ\Parameters subkey stores information pertaining to Message Queuing (also known as MSMQ) about each site in the enterprise. ServersCache contains a separate entry for each site in the enterprise. The entry is the name of the site, and its value consists of a list of all the MQIS servers in the site. These values are updated at an interval specified by the value of the **DSListRefresh** entry.

Each of the entries in the ServersCache subkey represents a site and stores the computer names and supported protocols of all Message Queuing servers at the site. These entries have the following format:

| Entry name | Data type | Value |
|---|---|---|
| Site name | REG_SZ | 01 \| 10 \| 11 *NumberComputer name*[,*NumberComputer name*...] |

Each computer name follows a number (01, 10, or 11), which indicates the communication protocols that each server supports. If the site includes multiple servers, the entries must be separated by commas.

- A value of 1 in the lower (right) digit indicates that the server supports the IPX protocol.
- A value of 1 in the higher (left) digit indicates that the server supports the IP protocol.

For example, the following entry indicates that, at the Central site, three computers are running Message Queuing: \\ServerOne supports both IP and IPX, \\ServerTwo supports only IP, and \\ServerThree supports only IPX:

| Entry name | Data type | Value |
|---|---|---|
| **Central** | REG_SZ | 11ServerOne,10ServerTwo,01ServerThree |

# Setup

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters

**Description**
The Setup subkey stores entries that contain information about the operating system installed, the name of the computer, name of the local domain, and the name of the local organizational unit (OU).

**Note**

- The entries in the subkeys in CertificationAuthorities store actual certification authority (CA) certificates, not just pointers to entries in another location.

# JoinStatus

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0x1–0x4 | (None) |

**Description**
Implements transactional semantics for the join process, so that if a computer stops abnormally, the join process continues after Windows Server 2003 restarts.

Message Queuing (also known as MSMQ) adds this entry to the registry when Message Queuing detects that a computer joined a domain.

| Value | Meaning |
|---|---|
| 1 | MSMQ_JOIN_STATUS_START_JOINING |
| 2 | MSMQ_JOIN_STATUS_JOINED_SUCCESSFULLY |
| 3 | MSMQ_JOIN_STATUS_FAIL_TO_JOIN |
| 4 | MSMQ_JOIN_STATUS_UNKNOWN |

**Note**

- This entry appears by default only on computers installed in workgroup mode. For all other computers, it must be added by using the registry editor Regedit.exe.

# MachineDN

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* | (None) |

**Description**
Describes the local computer in the Active Directory.

The value of this entry is the distinguished name of the computer object and is used when the computer moves between domains to check if the Message Queuing (also known as MSMQ) configuration object is still in its old place. This entry is updated on every restart.

# MachineDomain

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSMQ\Parameters\Setup

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *String* | (None) |

**Description**

Enables the user to check if the computer has moved between domains.

The value of the **MachineDomain** entry is the NetBIOS name of the domain that owns the computer object. This entry is not erased when you move your computer from a domain to a workgroup.

# MSSQLServer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# Client Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSSQLServer

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# ConnectTo

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\MSSQLServer\Client

| Data type | Range | Default value |
|---|---|---|
| NULL | | |

**Description**
The ConnectTo subkey stores connection information for Windows-based clients that connect to instances of the Microsoft SQL Server database engine. Registry entries in this subkey are of data type REG_SZ, and their values specify the Net-Library to use for connecting to the instance, as well as any network-specific parameters.

The connection information stored in this subkey is read by the OLE DB Provider for SQL Server, the SQL Server ODBC driver, or the SQL Server DB-Library dynamic-link library (DLL).

**Change Method**
You should not modify entries in this subkey by using the registry editor. Use the SQL Server Client Network Utility to configure server name and connection information. See SQL Server Client Network Utility Help for further instructions.

### Notes

- The ConnectTo subkey is used by the OLE DB Provider for SQL Server, the SQL Server ODBC Driver, and the SQL Server DB-Library DLL. Entries in this subkey identify which Net-Library these data access application programming interface (API) components call.

- Net-Libraries are SQL Server components that shield the data access API components from the details of using different Interprocess Communication (IPC) methods to communicate with an instancess of the SQL Server database engine.

### Caution

- Improperly updating the ConnectTo subkey might prevent applications from successfully connecting to an instance of the SQL Server database engine.

# BlockExeAttachments

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\Software\Microsoft\Outlook Express

**Description**
Stores configuration data for the policy setting **Configure Outlook Express**.

**Change Method**
To change the value of this entry, use the Group Policy Object Editor (Gpedit.msc). The corresponding policy is located in \Windows Components\Internet Explorer.

# Outlook Express_DepKit

HKLM\SOFTWARE\Microsoft\PCHealth\ErrorReporting\

**Description**
This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# PswdSync

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
The PswdSync subkey stores configuration data for the Password Synchronization Service. The Password Synchronization Service lets users use a single password for computers that are running Windows Server 2003 and UNIX. It ensures that any password changes made in Windows Server 2003 are communicated to the UNIX system, in encrypted text. It also ensures that all passwords conform to the security standards implemented on the system by notification packages, such as Passfilt.dll.

The PswdSync subkey contains two subkeys, Domains Subkey and NotifyChange. The Domains subkey contains *UNIX-system-name* subkeys, each of which represents a UNIX system and stores data that applies to only to that system. The NotifyChange subkey is used internally by the Password Synchronization Service to detect and implement configuration changes while the service is running. Do not delete or change it.

The PswdSync subkey can also contain entries. The entries in PswdSync apply to all UNIX systems. These entries can also appear in the PswdSync\Domains*UNIX-system-name* subkeys, where they apply only to the UNIX systems. If the same entry appears in the PswdSync subkey and in a *UNIX-system-name* subkey, then the value in the *UNIX-system-name* subkey takes precedence over the value in PswdSync when configuring that UNIX system.

**Change Method**
To change the value of the entries in this subkey, use the Password Synchronization wizard in Services for UNIX Administrator. Do not edit the registry.

### Note

- The Pswdsync subkey appears in the registry when you configure the Password Synchronization Service by using the Password Synchronization wizard in Services for UNIX Administrator.

# Domains Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\PswdSync

**Description**
The Domains subkey stores configuration data for the UNIX systems that are associated with the Windows Server 2003 Password Synchronization Service. The Password Synchronization Service lets users use a single password for computers that are running Windows Server 2003 and UNIX.

The Domains subkey contains UNIX-system-name, each of which represents a UNIX system and stores data that applies only to that UNIX system.

**Change Method**
To change the value of the entries in this subkey, use the Password Synchronization wizard in Services for UNIX Administrator. Do not edit the registry.

### Note

- This subkey appears in the registry when you use the Password Synchronization wizard in Services for UNIX Administrator to configure a UNIX system.

# UNIX-system-name

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\PswdSync\Domains

**Description**
The *UNIX-system-name* subkey is named for a particular UNIX system associated with this Windows Server 2003, and it contains entries that apply only to that UNIX system. There is a *UNIX-system-name* subkey for each UNIX system associated with this Windows Server 2003.

The entries listed in *UNIX-system-name* can appear in any *UNIX-system-name* subkey. Some of the entries can also appear in the PswdSync subkey. However, when they appear in PswdSync, their values apply to all UNIX systems. When the same entry appears in PswdSync and in a *UNIX-system-name subkey*, the value in the *UNIX-system-name* subkey takes precedence over the value in the PswdSync subkey when configuring the named UNIX system.

**Change Method**
To change the value of entries in this subkey, use the Password Synchronization wizard in Services for UNIX Administrator. Do not edit the registry.

### Notes

- This subkey appears in the registry when you use the Password Synchronization wizard to configure a UNIX system.
- The *UNIX-system-name* subkey is a variable representing the subkeys in the Domains subkeys. It does not actually appear in the registry. This variable subkey displays the entries that can appear in any of the subkeys within the Domains Subkey subkey. The entries that actually appear in the registry depend upon the configuration of the UNIX system.

# LoginAccount

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\PswdSync\Domains*UNIX-system-name*

| Data type | Range | Default value |
|---|---|---|
| REG_SZ | *Account-name* | root |

**Description**
Stores the account name used when using Rlogin to log on to a remote UNIX computer to synchronize passwords. Rlogin sends passwords in clear text.

This entry appears in the registry only when the system is running Services for Unix 1.0 and the **Unsecure using Rlogin** password propagation method is selected—that is, when the value of **PropagateMethod** is 0. Services for Unix 2.0 and Services for Unix 3.0 do not use this entry.

**Change Method**
To change the value of this entry, use the Password Synchronization Administrator. Do not edit the registry.

### Note

- This entry does not appear in the registry unless you install Services for Unix 1.0.

# SystemMonitor

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

| Data type | Range | Default value |
|---|---|---|
| NULL (subkey) | | |

**Description**

This subkey contains documentation for registry elements that are listed in the table of contents under this subkey.

# DisplaySingleLogSampleValue

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\SystemMonitor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | (None) |

**Description**
Specifies that System Monitor display only the average value of each group of data points. When System Monitor needs to display more than 100 data points, it groups the values into 100-point data buffers. System Monitor then calculates the minimum, average, and maximum value of each group and displays them as a vertical line. If this entry is present in the registry and its value is 1, System Monitor instead displays only the average value for each group of data points.

System Monitor ignores this entry when its data source is real-time data; it uses this entry when the data source is an SQL database or one or more log files.

**Change Method**
This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must stop and restart System Monitor for changes to take effect.

# DisplayThousandsSeparator

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\SystemMonitor

| Data type | Range | Default value |
|---|---|---|
| REG_DWORD | 0 \| 1 | (None) |

**Description**
Specifies whether System Monitor groups the digits of the values that it displays. For example, 50000000 with digits grouping is displayed as 50,000,000. If this entry exists in the registry and its value is 1, then System Monitor uses digit grouping. If this entry is absent from the registry or its value is zero, then System Monitor does not use digit grouping.

| Value | Meaning |
|---|---|
| 0 | System Montor does not group digits. |
| 1 | System Monitor uses digit grouping. |

**Change Method**
This entry does not exist in the registry by default. You can add it by using the registry editor Regedit.exe.

**Activation Method**
You must stop and restart System Monitor for changes to take effect.

# Microsoft\Windows Subkey

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft

**Description**
The Windows subkey stores configuration data for the programs running on the Win32 subsystem. The subkeys of the Windows subkey represent versions of the Win32 subsystem, such as CurrentVersion. Each version subkey contains subkeys representing programs that run on that version of the subsystem.

The Windows subkey in HKEY_LOCAL_MACHINE stores entries that apply to all users of the computer. There is also a SOFTWARE\Microsoft\Windows subkey in HKEY_CURRENT_USER that stores entries that apply only to the current user of the computer.

# Windows\CurrentVersion

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows

**Description**
The CurrentVersion subkey stores configuration data for programs running on the Win32 subsystem. The subkeys of CurrentVersion represent programs that run on the current version of the Win32 subsystem, and they store configuration data for those programs that apply to all users of the computer.

# CurrentVersion\Explorer

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion

**Description**
The Explorer subkey stores configuration data for Windows Explorer and for the Windows interface.

# Explorer\Shell Folders

Updated: March 28, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer

**Description**
Windows Server 2003 does not use this subkey. The subkey remains in the registry to support programs designed for Windows NT 4.0 or earlier.

### Note

- Paths to the Windows Explorer folders are stored in the Explorer\User Shell Folders subkey. For more information about shell folders, see the Software Development Kit (SDK) information in the MSDN Library link on the Web Resources page.

### Caution

- Do not delete this subkey or its entries from the registry, and do not change the values in the entries. These changes can cause serious, unexpected results.
